1. Industry response to the draft SOL Exceedance definition indicated numerous significant concerns. Given this response, the SDT concluded that creating a definition of SOL Exceedance which adequately reflects reliable operating principles could create an unnecessary compliance burden if action is not taken to substantially modify the existing TOP and IRO standards. Therefore, the SDT maintained system performance criteria through FAC-011-4 Requirement R6, similar to the approach within the currently effective FAC standards, rather than through an SOL Exceedance definition. Do you agree with the performance criteria in Requirement R6?

Laura Nelson - IDACORP - Idaho Power Company - 1

Answer	No
Document Name	

Comment

Requirement R6.3 does not address SOL violations, but only checks against instability, cascading, or uncontrolled separation, even though this criteria is being used to evaluate performance on additional single or multiple contingency events (R5.2) for use in OPA and Real-time assessments. This suggests that SOL violations would be allowed for these contingencies.

The language presented in the R6 is unclear and can lead to different interpretations. The language in R6 needs further clarification.

The drafting team needs to clarify that both actual pre-Contingency state and anticipated pre-Contingency state referred in R6.1 are referring to a TPL equivalent of P0 (system normal) state of the transmission system.

The drafting team should consider rephrasing the language in R6.2.1. Drafting team proposing not to allow usage of Emergency Ratings for contingency events irrespective of presence of operating plan is in complete variation of the planning standard requirements that allows usage of emergency ratings for contingencies described in R5.1.1.

The real time pre-Contingency state could be much different than the anticipated pre-Contingency state and the operating plan proposed for the anticipated pre-Contingency state may not be adequate during the real time pre-Contingency state. Under these conditions, not allowing the operators to use the Emergency ratings is very much disadvantageous and opposite to the intent of PRC-023 where the operator should be allowed to have flexibility to operate the system under Contingency conditions.

PacifiCorp recommends rephrasing 6.2.1 requirement as below

“Flow through Facilities are within applicable Emergency Ratings. Flow through a Facility must not be above the Facility’s highest available Rating, following an N-1 contingency.”

The MRO NSRF supports the efforts of the SDT to clarify for the industry what is considered SOL exceedance in the context of the IRO and TOP Standards. We appreciate the SDT listening to the concerns raised by industry regarding the previously proposed SOL Exceedance definition and we agree with the SDT's approach to abandon that potential change. We also agree with the SDT's concept that the Reliability Coordinator's SOL Methodology must address the system performance criteria to ensure consistent identification of SOLs. However, what is still not broadly understood is if each Facility must have an associated thermal-based SOL dependent on current system topology. In Requirement R3 it addresses establishment of a voltage-based SOL at each bus, but there isn’t a similar requirement for thermal ratings. Is it the expectation of the SDT that each Facility has a thermal-based SOL or can a subset (Flowgates?) be used to manage power flow on the system? This needs to be clearly stated in a requirement so that everyone is planning and operating the BES from the same understanding. Additionally, it’s not clear if exceeding the Normal Rating or normal System Voltage Limit is considered a SOL exceedance if you have a higher Emergency Rating or emergency System Voltage Limit for a specified time duration. It could be interpreted to say there isn’t SOL exceedance until you’re over the highest value of the Emergency Rating. This understanding translates to compliance expectations in the IRO and TOP Standards for when you must implement your Operating Plan. If we’re relying on the SOL whitepaper to clarify, then some entities may choose not to follow it saying it’s not mandatory and we’ll continue to have disagreement and confusion in the industry.

In order to support this project, the MRO NSRF needs to understand all the compliance expectations for SOL exceedances, including those associated with the IRO/TOP standards. Is every indication where the FAC-011 R6 performance criteria is exceeded considered a violation of FAC-014 R6 and/or an inadequate real time Operating Plan? Are current operating protocols, which are agreed upon by the Transmission Operator and Reliability Coordinator and allow for temporary exceedances while control actions (such as LMP binding) are being implemented, now going to be prohibited and considered violations? As the proposed performance criteria (for post-contingent thermal and voltage exceedances) does not include any time threshold (in analogy with Tv for IROLs) does that imply the Transmission Operator and Reliability Coordinator would NOT be given any timeframe (such as 30 minutes) to correct an exceedance (particularly post-contingent thermal or voltage exceedances), before it becomes a reportable event and a potential compliance issue? Will the performance criteria be identical independently of the system state (i.e. if the system is in N-1 as opposed to N-4, or even more severe, topology conditions)? Is the Transmission Operator expected to perform a timing analysis to determine if ramp rates, start-up times and location and amount of load shedding are adequate every time it operates above the Normal Rating but below Emergency Rating to verify its Operating Plan will eliminate exceedance within the timeframe of the Emergency Rating? Would the proposed performance criteria not allow for any regional differences even in cases where a Reliability Coordinator is not registered as a Transmission Operator, but has critically important mitigating control actions under its responsibilities? We do not want to unintentionally approve a standard that creates overly burdensome compliance demonstration expectations for the industry, while the SER project is actively seeking ways to streamline and reduce these burdens. Since the SDT cannot answer all these questions, then we request NERC staff to draft a CMEP Practice Guide to inform the industry of the compliance expectations for SOLs as applied in the FAC, IRO and TOP standards.

Will entities be forced to create separation between the highest Emergency, Emergency, and Normal ratings if they are currently the same? An example is a conductor limited transmission line with a 10-minute time constant where all three ratings are identical. Does an entity have to de-rate the line by increments of sag temperature or percentage to create time between ratings or be in violation of the FAC-011-4 timing requirements. Short time frames of under 30 minutes could also lead to a violation of FAC-011-4 R6.5. Short time frames under 30 minutes aren't sufficient time for a system operator to consider "all" other available system adjustments before implementing load shedding.[A1]

To further explain, we believe the proposed performance criteria in FAC-011-4 Requirement R6 seems to capture the essence of SOL exceedance. However, we are concerned the proposed language creates a significant reliability/compliance burden for Transmission Operators and Reliability Coordinators as follows:

1. R6.2 - The language mandates evaluation of all contingencies listed in R5.1.1 of FAC-011-4 as part of the Real Time Assessment (RTA) and the Operational Planning Analysis (OPA) without exception. When coupled with R6.2.3, this language pulls in dynamic analysis of all of these contingencies for both the RTA and OPA. This is an infeasible expectation for the Transmission Operator and Reliability Coordinator to include in their RTAs and OPAs, since R5.1.1 contains no caveats to limit the list of applicable single contingencies.
2. R6.2.1 - The flows on a transmission element may exceed the applied Emergency Rating during the dynamic time period, but there is likely no risk to the system. Although the first phrase "applicable Emergency Ratings" might seem to provide the flexibility, this means an entity must know the *"applicable Emergency Rating"* for a particular dynamic loading and time period for each piece of equipment and each piece of equipment would need to be monitored in a dynamics analysis. It may be that the SDT does not intend to pull in dynamics in 6.2.2 but it is a logical reading of the standard.
3. R6.2.3 - As noted above, although this is the desired result, it is infeasible to perform dynamic analyses of all R5.1.1 contingencies as part of either an RTA or an OPA. In fact, it is an extremely expensive proposition to perform any real time dynamic simulations due to the complexities of maintaining an accurate dynamic model that incorporates traditional transmission equipment let alone the myriad of user written or proprietary dynamic models in use today for FACTs devices and variable generation.
4. R6.3 and R6.4 contain the same problems as noted above. It is infeasible to run dynamic simulations as part of the RTA and it is very complex to do so for the OPA. At least in this case, R5.2 and R5.3 allow the Reliability Coordinator to provide a very limited list of contingencies. Still, even with a limited list, the language of R6 and its sub-parts does not limit the scope of what a Transmission Operator would be required to run under FAC-014-3 (see R2 of that standard). Rather, FAC-011-4 R6 language implies that a Transmission Operator would be required to evaluate all of the contingencies identified by a Reliability Coordinator, not just those that apply to the Transmission Operator's footprint. Note that FAC-014-3 R2 limits the Transmission Operator to identifying SOLs to its footprint, but it does not limit the contingencies a Transmission Operator would need to consider.
5. R6.5 - The standard incorrectly eliminates planned load shedding from consideration when a RAS or UVLS programs may have specifically established the need to take such action to maintain system stability for the particular contingencies under consideration.

We offer the following proposed improvements to address the comments above:

- R6.1.1, R6.1.2, R6.2.1 and R6.2.2 could be improved by clarifying that these sub-requirements are only describing steady-state conditions. Each requirement could have the following leading statement added: *"Under steady-state analysis:"*.

- In addition, R6.2.1 and R6.2.2 would also benefit from adding the word *"Anticipated"* ahead of the terms *"Flow"* and *"Voltages"* in these requirements, respectively, to make it clear that these are potential system flows and voltages, not real time flows and voltages, being evaluated.

Regarding the scope of dynamic simulations, the best location to make modifications is likely the R5 and R5.1 language, not R6. Proposed modifications are as follows:

- R5 - Strike *"and performing the Operational Planning Analysis (OPAs) and Real-time Assessments (RTAs) for the area under study"* since this language is redundant to the R6 performance criteria language that will require these contingencies to be evaluated as part of the RTA and OPA. With this removed, R5 is tailored to only describe what contingency events need to be examined for the identification of SOLs.

R5.1 - Remove the language regarding *"determining stability limits and performing OPAs and RTAs"* and add *"for use in determining steady state SOLs",* since the SOL methodology should require examination of all of the single contingencies listed under R5.1.1 using steady-state analysis. The contingencies to examine for dynamics will be a very small list (hopefully) and can be adequately addressed by modifications to

R5.3.

- R5.2 - Remove *"for use in performing Operational Planning Analysis and Real-time Assessments"* since, again, this is adequately covered by R6, and add in language as follows *"for use in determining steady state SOLs"*.

R5.3 - Strike the word *"additional"* from the existing R5.3 language and add the following to the end of the requirement: *"where the identified single Contingency events involving the loss of a generator, transmission circuit, transformer, shunt device, or single pole block in a monopolar or bipolar high voltage direct current system must simulate either: (a) Normal Clearing of a single phase to ground or three phase Fault (whichever is more severe) or (b) tripping without a Fault condition"*.

- Regarding the Transmission Operator performing a certain set of contingencies, the R6.2, R6.3 and R6.4 language could all be modified to state: *"The evaluation of applicable potential single Contingencies …"* (for R6.2) and *"The evaluation of the applicable potential Contingencies …"* (for R6.3 and R6.4).

R6.5 could be improved by clarifying that RAS and UVLS actions should be implemented in the stability analysis, as applicable. The SDT should also recognize that underfrequency load shedding (UFLS) may be a necessary part of system stabilization once a RAS operates if that RAS is creating a planned islanded system. As such, UFLS may also be a warranted load shedding component when performing stability analysis. R6.5 language could be modified by adding *"planned load shedding, other than Remedial Action Scheme (RAS) or UVLS action, is acceptable …"* and then adding a new sentence that reads, *"The use of UFLS programs should only be simulated when incorporated as part of the system design to maintain stability (e.g., RAS)."*

NRECA agrees that it is not necessary to create a definition of SOL Exceedance, but still believes the new FAC-011-04 R6 requirement creates undue compliance burden by prescribing an excessive number of sub-requirements. The structure of R6 is confusing. Many of the sub- requirements that are not standalone with references to other requirements in the proposed standard.

The use of the undefined term 'instability' could lead to inconsistent results and result in additional compliance burdens that add little to no reliability benefit. As used in FAC-011 R6, instability is not limited to the BES or wide area but instead, as currently worded, applies to ANY instability that has ANY impact to any element or facility. R6.1.3 and 6.2.3 should be limited to the interconnection or at the very least the wide-area to prevent misunderstanding.

Terry Harbour - Berkshire Hathaway Energy - MidAmerican Energy Co. - 1

Answer	No
Document Name	

Comment

MidAmerican Energy Company (MEC) understands and supports the SDT's efforts to come up with the broad industry consensus with regard to definition of SOL and associated definition of SOL Exceedance.

MidAmerican supports the SDT's proposal to create a definition of SOL exceedance, **as long as that definition would NOT cause unintended consequences in terms of setting unrealistic expectations or imposing additional and undesirable administrative compliance burden on numerous entities**. In this effort, the SDT should carefully assess repercussions on reliability and efficient market operations

We certainly appreciate the SDT's rational approach of not proceeding with the proposed definition of SOL exceedance having in mind significant number of negative comments which were received in October, 2017, primarily from MISO and SPP Regions.

Unfortunately, instead of patient continuation of efforts to adjust and improve proposed definition of SOL exceedance, the NERC Standard Drafting Team decided to take, in our view, **inappropriate approach of incorporating that controversial and arguable (although somewhat modified) definition of SOL Exceedance as a performance criteria in Requirement 6 of FAC-011-4 Standard. We consider this pathway as potentially worse and more risky in comparison with coming up with definition of SOL Exceedance. The reason for such a characterization is that by substituting definition of SOL Exceedance via embedding it as a performance criteria into FAC-011-4, the SDT would expose a number of TOPs and RCs to risk of directly violating FAC-011-4 (Requirement 6) and associated penalties, if (non-agreed upon in terms of definition) exceedances of system operating limits occur either in RTA or OPA**.

Furthermore, we believe that addressing a fundamental concept of SOL Exceedance definition needs to be done within the framework of IRO and TOP standards, where it inherently and logically belongs. We do not agree with an approach of moving that cornerstone of reliable operations from IRO/TOP set of standards to the FAC set of standards. In other words, we believe that the present context of defining what constitutes SOL exceedance **and reacting to it by initiating Operating Plan (per IRO-008-2-R2 and TOP-001-4-R14) is far better** than directly exposing large number of entities to the risk of non-compliance without appropriate considerations related to physical constraints that need to be overcome during implementation of Operating

Plans, in a timely manner.

Fundamental principles and complexities of real power systems do not allow for ignoring the time dimension that always exist when implementing corrective control actions when temporary exceedances of SOL occur, especially in RTA. That was, unfortunately, overlooked in proposed versions of FAC-011-4 and FAC-014-3.

The role of SOL exceedance definition (or performance criteria within FAC-0114-R6), in our opinion, should be to clearly and unambiguously formulate critical operational borderlines of reliable operations, while **respecting existing limitations of existing transmission infrastructure and human resources that operate that infrastructure**.

Our quite specific reasons for NOT agreeing with the proposed Requirement 6 of FAC-011-4 are:

1. **Requirements 6.1.1; 6.1.2 and 6.2.1** use the phrase "*when System adjustments to return the flow/voltage within its Normal Rating/Voltage Limits could be executed and completed within the specified time duration of those Emergency Ratings/Voltage Limits".*

We would like to show our appreciation to the SDT for their reasonable approach of listening to the industry's comments and gradually improving the definition of SOL exceedance. In this particular case we are pleased that the SDT now considers exceedance of Emergency (rather than Normal) limits as a reportable event.

However, there is a problem with using the phrase "*could be executed and completed within the specified time duration of those Emergency Ratings/Voltage Limits" as* clearly pointed out by Mr. Terry Volkmann. We completely agree with his comment: "*This implies that in order to use the range between normal and emergency rating for an anticipated contingency, a timing analysis needs to be performed before the contingency occurs to determine if ramp rates, start-up times and location and amount of load shedding are adequate…. TOP (in MISO and SPP reliability footprints) cannot perform such analyses, because the RC/market operator has all the data and tools to do the analysis….* ***This analysis is best served as an internal control not a compliance obligation*****.** " MEC agrees with Mr. Volkmann that above mentioned quoted phrase shall be eliminated from the draft of the standard.

The implementation risk and compliance risk associated with this language is substantial and very concerning. Based on the language, TOP is expected to perform and document a timing analysis to determine if the adjustments could be executed within the specified time duration of Emergency Ratings each and every time when TOP performs RTA and find its facilities operating between Normal and Emergency Rating (either in real-time or on a contingency basis). It should be noted that such a timing analysis in real-time is difficult and requires significant time and resources. If such timing analysis cannot be performed (or is not performed due to lack of time or other reasons, or simply not logged/recorded) that may trigger non-compliance, concerning FAC-011 R6 in conjunction with FAC-014 R6

The second problem is that it is necessary to differentiate between flow exceedances and voltage exceedances in terms of risk to the equipment and the time tolerance.

We recommend the following definition:

- ***Actual steady state flow on a BES Facility is greater than the Facility's highest Emergency Rating for any time period.***

- ***Actual steady state flow on a BES Facility is above the Normal Rating but below the next Emergency Rating for longer than the time frame of the next Emergency Rating.***

- ***Actual steady state voltage on a BES Facility is greater than the emergency high voltage limit for time frame identified by the TOP.***

- ***Actual steady state voltage on a BES Facility is less than the defined emergency low voltage limit for time frame identified by the TOP.***

Alternatively, our comments can be formulated in the following red-line (highlighted in yellow changes):

1\.

   i.

      a. *Steady state Flow through Facilities are within Normal Ratings; however, Emergency Ratings may be used only when System adjustments to return the flow within its Normal Rating can be executed and completed within the specified time duration of those Emergency Ratings*.

      b. *Steady state Voltages are within normal System Voltage Limits; however, emergency System Voltage Limits may be used only when System adjustments to return the voltage within its normal System Voltage Limits can be executed and completed within the specified time duration of those emergency System Voltage Limits*.

1. **Requirements 6.1.3 and 6.2.3** refer to preventing instability, cascading or uncontrolled separation.

- We find it inappropriate that **the proposed definition does not recognize time-frame associated with exceedances of established stability limits**. If not recognized, this can lead to hundreds of meaningless (nuisance) exceedances (for sake of an example, such as those that last less than 1 minute and have magnitude of less than 1%). More importantly, it should be noticed that even present definition of the IROL violation has associated Tv time threshold (or 30 minutes) before it becomes a compliance issue. Proposed formulation of 6.1.3 and 6.2.3 should include the time threshold (in analogy with Tv) so that RCs/TOPs would be given specified time frame to correct exceedance, before it becomes compliance issue.

We recommend the following definition:

- ***Any established stability limit (non-IROL) or limit that may cause cascading outages or uncontrolled separation shall not be exceeded***

for longer than the 30 minutes, or defined by Operating Plan.

Alternatively, our comments can be formulated in the following red-line (highlighted in yellow changes):

1.
    i.
        a. *Any established stability limit (non-IROL) is mitigated within the time-frame specified in (and in accordance with) the RC's SOL methodology and Operating Plan, or with RC's approved post-contingency action plan.*
        b. *System-wide Instability, Cascading or uncontrolled separation do not occur.*

2.
    i.
        a. *Any established stability limit (non-IROL) is mitigated within the time-frame specified in (and in accordance with) the RC's SOL methodology and Operating Plan, or with RC's approved post-contingency action plan.*
        b. *System-wide Instability, Cascading or uncontrolled separation do not occur*.

1. **Requirement 6.2.1** is of particular importance and probably the single, most frequent concern in present industry's practice. MidAmerican Energy Company appreciates SDT's reasonable approach of listening to the industry's comments and gradually improving the definition of SOL exceedance/performance criteria. However, we would like to draw the SDT's attention to the following issues with their present formulation of the Requirement 6.2.1, which states that:

"*provided that System adjustments could be executed and completed within the specified time duration of those Emergency Ratings*. ***Flow through a Facility must not be above the Facility's highest Emergency Rating*.**"

We would like to point out several issues with regard to this formulation:

- First, **the proposed definition does not recognize time-frame associated with exceedances of the Facility's highest Emergency Rating**. If not recognized, this can lead to hundreds of meaningless (nuisance) exceedances (for sake of an example, such as those that last less than 1 minute and have magnitude of less than 1%). Others exceedances may last several minutes(5-30 minutes, just for sake of example) due to time constraints associated with operators' response to these exceedances and physical reality/timing of corrective control actions that need to be implemented. More importantly, it should be noticed that even present definition of the IROL violation has associated Tv time threshold (or 30 minutes) before it becomes a compliance issue. Proposed formulation of 6.2.1 should include the time threshold (in analogy with Tv) so that RCs/TOPs would be given specified time frame to correct exceedance, before it becomes compliance issue.

- Second, regarding the phrase "*Flow through a Facility must not be above the Facility's highest Emergency Rating*", the SDT's formulation appears to be based on the Project 2014 NERC White paper.
Paper (from May 2014) was stating that "Post-contingency flow in this range is not acceptable **unless Operating Plan address reliability**

impact so that it has localized impact". Subsequent version of the NERC White Paper (revision of January 2015) introduced statement that "Post-contingency flow in this range is not acceptable" . **This revision, with a major impact, was never presented to the industry, never approved by the Industry and, in our opinion, was step in the wrong direction. The most recently published revision adds clarity and improved formulations, but still departs from the original concept and ignores time dimension that is necessary to implement corrective control actions, especially for inevitable short term exceedances in RTA, on a contingency basis.**

- Third, the SDT's proposed definition of the post-Contingency flow SOL exceedance **fails to recognize the important difference between actual, pre-contingency SOL exceedance and calculated, post-contingency RISK of SOL exceedance**. This attempt to include both of them under the single, generic term "performance criteria/SOL exceedance" may easily cause an incorrect expectation that TOP/RC's control actions response to these two types of exceedances should be similar, in terms of timing, logging and recording.

- Fourth, **it is perfectly clear and understandable that both of these types of exceedances require and should trigger implementation of a control action from Operating Plan, but they should be treated *differently in terms of urgency and severity of mitigating control actions*, as they have different repercussions on system reliability**.

- Fifth, there is a problem with using the phrase "*could be executed and completed within the specified time duration of those Emergency Ratings" as* clearly pointed out by Mr. Terry Volkmann. We completely agree with his comment: "*This implies that in order to use the range between normal and emergency rating for an anticipated contingency, a timing analysis needs to be performed before the contingency occurs to determine if ramp rates, start-up times and location and amount of load shedding are adequate…. TOP (in MISO and SPP reliability footprints) cannot perform such analyses, because the RC/market operator has all the data and tools to do the analysis….* ***This analysis is best served as an internal control not a compliance obligation***. " MEC agrees with Mr. Volkmann that this phrase shall be eliminated from the draft of the standard.

The implementation risk and compliance risk associated with this language is substantial and very concerning. Based on the language, TOP is expected to perform and document a timing analysis to determine if the adjustments could be executed within the specified time duration of Emergency Ratings each and every time when TOP performs RTA and find its facilities operating between Normal and Emergency Rating (either in real-time or on a contingency basis)? It should be noted that such a timing analysis in real-time is difficult and requires significant time and resources. If such timing analysis cannot be performed (or is not performed due to lack of time or other reasons, or simply not logged/recorded) that may trigger non-compliance, concerning FAC-011 R6 in conjunction with FAC-014 R6.

• Sixth, regarding the **language in FAC-011-4 (R6.2.1)** "*Flow through a Facility must not be above the Facility's highest Emergency Rating"*, let's consider the following scenario. TOP operates in REAL-TIME with one scheduled outage (N-1 topology). Then a fault occurs (single event such as bus fault or similar) and takes out of service two (or more) facilities, thus bringing the system in real-time into N-3 topology condition. Now, RTCA starts showing overloading for next single contingency (N-4).

The concern is if the language in the draft of the standard assumes that **the performance criteria are identical, independently of the system state** (i.e. if the system is in N-1 as opposed to N-3, or even more severe, topology conditions). We certainly understand that in OPA such a scheduled outage would not be approved if it causes SOL exceedances. However, what will be applicable performance criteria if that event happens in real-time due to single event? Of course TOP will implement its Operating Plan to correct the exceedance, but due to significantly deteriorated topology (for which the system was never designed) it may take longer time period to eliminate exceedance on a contingency basis. Or, analysis may show that only firm load shedding may eliminate the exceedance.

The issue is that if the same performance criteria are applicable independently of topology conditions, in order to avoid performance criteria violation (on a contingency basis) the only viable option might be pre-contingent firm load shedding to correct contingency based (not real-time) exceedance.

We recommend the following definition for 6.2.1:

- ***Projected post-Contingent loading on a BES Facility is greater than the highest Emergency Rating for longer than 30 minutes with NO agreed upon Post Contingency Action Plan that would mitigate the condition if the Contingency were to occur.***

Alternatively, our comments can be formulated in the following red-line (highlighted in yellow changes):

1.

   i. *The evaluation of potential single Contingencies listed in Part 5.1.1 for system intact and N-1 operating conditions, against the actual pre-Contingency state (Real-time monitoring and Real-time Assessments) and anticipated pre-Contingency state (Operational Planning Analysis) demonstrates the following:*

      a. *Flow through Facilities are within applicable Emergency Ratings, provided that System adjustments can be executed and completed within the specified time duration of those Emergency Ratings. Post-Contingency flow in this range that is not mitigated within the time-frame specified in (and in accordance with) the RC's SOL methodology, or without RC's approved post-contingency action plan, constitutes reportable exceedance to RC. The Operating Plan developed and mutually agreed to by TOP and RC is required to address potential impacts and post-contingent mitigating strategies, including but not limited to load shedding, while normal congestion relief control actions are being implemented, to ensure potential impact is localized. Flow through a Facility must not be above the Facility's highest Emergency Rating.*

      b. *Voltages are within emergency System Voltage Limits. Post-Contingency voltage outside of the emergency System Voltage Limits that is not mitigated within the time-frame specified in (and in accordance with) the RC's SOL methodology, or without RC's approved post-contingency action plan, constitutes reportable exceedance to RC. The Operating Plan developed and mutually agreed to by TOP and RC is required to address potential impacts and post-contingent mitigating strategies, including but not limited to load shedding, while normal control actions for eliminating System voltage exceedance are being implemented, to ensure potential impact is localized.*.

Rationale for using Post-contingency action plan concept

- The main difference between our proposed definition and the SDT's proposed definition is the **concept of post-contingent action plan**. *The Post-contingency action plan is the RC's/TOP's agreed upon control action to be used* ***while the normal congestion management processes are attempting to return the projected post contingent flow within longer-term rating.*** It is very important to note that the Post-contingency action plans are **NOT** a vehicle to justify continual operation where the projected post contingent flow is above Facility's highest Emergency Rating.

- **In contrast to this, we believe that the Post-contingency action plan developed by TOP and RC is required to address potential impacts and post-contingent mitigating strategies, including but not limited to load shedding or generator tripping, while normal congestion management actions are being implemented, to ensure potential impact is localized and to prevent equipment damage**.

- Therefore, we would NOT consider SOL exceedance to exist anytime the Projected post-contingency flow is above Facility's highest Emergency Rating, but only for those situations when the Projected post-contingency flow is above the Facility's highest Emergency Rating (Rate C) for longer than 30 minutes **WITHOUT associated post-contingency action plan**.

- We recognize that there may be situations in the system when normal congestion management is not effective or has been exhausted, and the projected post-contingent loading on a facility remains greater than the highest available emergency rating. In this situation, load shedding may be the sole remaining option to address the projected post-contingency loading. The TOP and RC may decide to operate in this manner and not implement load-shedding pre-contingency if the impacts would be localized. In this case the SOL exceedance would be reportable, even though a post-contingent action plan exists, since normal congestion management is no longer taking place.

- The SDT's concept insists on the concept "highest Emergency Rating". Our definition is based on the concept of "post-contingency action plan". We do recognize that issuing a new Short Term Emergency rating would be an alternative for the TOP to pursue rather than agreeing with its RC on a post-contingency action plan. **The huge practical obstacle to issuing higher emergency rating (or "Load Shed Rating**") that the Industry always faced is that each TOP would have to **get manufacturers' confirmations for using shorter term Emergency Ratings (such as 10-minute ratings) for every single piece of equipment** (breakers, switches, wave traps, CTs conductors, all pieces on transformers etc). Majority of manufacturers would not be even able nor willing to provide such a data. Therefore, **for practical reasons, it is almost impossible to get such a short-term ratings based on manufacturers' data and technical facilities justifications**. Consequently, as opposed to being "pushed/forced" to using technically unjustified short-term emergency/load shedding ratings, each TOP and RC might need to define criteria within their Operating Plan for using post-contingent action plans. These criteria might be based, for sake of example, on Relay Loadability Limits of transmission facilities.

1. **Requirements 6.3 and 6.4**:

Our comments can be formulated in the following red-line (highlighted in yellow changes):

1.

   i. *The evaluation of the potential Contingencies identified in Part 5.2 (which are not mitigated within the time-frame specified in, and in accordance with, the RC's SOL methodology) against the actual pre-Contingency state (Real-time monitoring and Real-time Assessments) and anticipated pre-Contingency state (Operational Planning Analysis) demonstrates that instability, Cascading, or uncontrolled separation does not occur.*

The evaluation of the potential Contingencies identified in Part 5.3, (which are not mitigated within the time-frame specified in, and in accordance with, the RC's SOL methodology) demonstrates that instability does not occur.

Comment	
ReliabilityFirst votes in the negative for the following two reasons. 1. For requirement R6 part 6.5, ReliabilityFirst believes not being permitted to plan to drop load prior to taking all other actions seems is not technically correct. Here are a few real life scenarios that ReliabilityFirst is aware of: there are Remedial Action Schemes that drop non-firm load for first contingency events. There is another Remedial Action Scheme that drops 1/3 of the total station load for a breaker failure event.	

RF recommends the following changes to Part 6.5 for consideration: "In determining the System's response to any Contingency identified in Parts 5.1 through 5.3, planned load shedding [non-firm load] is acceptable [and planned shedding of firm load is acceptable] only after all other available System adjustments have been made [or where pre-approved by state regulators, and the shedding of load with Remedial Action Schemes.]

2. For Requirement R6 parts 6.1.1, 6.1.2, and 6.2.1, these three statement assume that the ONLY way that flows, voltages can be controlled within a specified time duration is with system adjustments. There are times when it is known that voltages or flows will change without the operator making any system adjustments. The operator could know that the 2nd shift at a factory ends in 5 minutes, and that there is no 3rd shift.

RF recommends the following changes to Part 6.1.1, 6.1.2 and 6.2.1 for consideration:
6.1.1 - Flow through Facilities are within Normal Ratings; however, Emergency Ratings may be used [when flows can be returned to within Normal Ratings within the specified time duration of those Emergency Ratings.]
6.1.2 - Voltages are within normal System Voltage Limits; however, emergency System Voltage Limits may be used [when voltage can be returned to within its normal System Voltage Limits within the specified time duration of those emergency System Voltage Limits.]
6.2.1 - Flow through Facilities are within applicable Emergency Ratings, [provided that flows can be returned to within Normal Ratings System within the specified time duration of those Emergency Ratings]. Flow through a Facility must not be above the Facility's highest Emergency Rating.

R6 uses the term "performance criteria". This is the same term used in R6 in FAC-014-3 (see NIPSCO comments for question 4). Using the same term in two different standards with different context is confusing. For FAC-011-4 R6 NIPSCO suggests eliminating the phrase "Bulk Electric System performance criteria" and just placing a ":" after the word "following".

Comment

CenterPoint Energy Houston Electric, LLC ("CenterPoint Energy)" does not agree with the performance criteria in FAC-011-4 Requirement R6 and believes that the language is ambiguous and unnecessary. In particular, the use of the term "instability" in Requirements R6.1.3 and R6.2.3 without any qualifiers may broaden the scope of the language, which could lead to inconsistent results. CenterPoint Energy recommends that the SDT revise the language in Requirements R6.1.3 and R6.2.3 to clarify that instability that adversely impacts the reliability of the BES is what is intended.

AZPS does not have an issue with the performance criteria set forth in FAC-011-4 R6. However, the use of performance criteria could still result in ambiguity regarding what qualifies as a "SOL Exceedance." For this reason, AZPS recommends that the SDT reconsider use of a defined term for "SOL Exceedance." Additionally, if there is intent to continue to use the term "SOL exceedance" within the body of reliability standards, then both

industry and the ERO Enterprise would benefit from the clarity that would result from a definition of the term.

Comment	

NV Energy supports the SDT's proposal to create a definition of SOL exceedance, **as long as that definition would NOT cause unintended consequences in terms of setting unrealistic expectations or imposing additional and undesirable administrative compliance burden on numerous entities**. In this effort, the SDT should carefully assess repercussions on reliability and efficient market operations

NV Energy believe the SDT took an **inappropriate approach of incorporating that controversial and arguable (although somewhat modified) definition of SOL Exceedance as a performance criteria in Requirement 6 of FAC-011-4 Standard. We consider this pathway as potentially worse and more risky in comparison with coming up with definition of SOL Exceedance. The reason for such a characterization is that by substituting definition of SOL Exceedance via embedding it as a performance criteria into FAC-011-4, the SDT would expose a number of TOPs and RCs to risk of directly violating FAC-011-4 (Requirement 6) and associated penalties, if (non-agreed upon in terms of definition) exceedances of system operating limits occur either in RTA or OPA**.

Furthermore, we believe that addressing a fundamental concept of SOL Exceedance definition needs to be done within the framework of IRO and TOP standards, where it inherently and logically belongs. We do not agree with an approach of moving that cornerstone of reliable operations from IRO/TOP set of standards to the FAC set of standards. In other words, we believe that the present context of defining what constitutes SOL exceedance **and reacting to it by initiating Operating Plan (per IRO-008-2-R2 and TOP-001-4-R14) is far better** than directly exposing large number of entities to the risk of non-compliance without appropriate considerations related to physical constraints that need to be overcome during implementation of Operating Plans, in a timely manner.

Fundamental principles and complexities of real power systems do not allow for ignoring the time dimension that always exist when implementing corrective control actions when temporary exceedances of SOL occur, especially in RTA. That was, unfortunately, overlooked in proposed versions of FAC-011-4 and FAC-014-3.

The role of SOL exceedance definition (or performance criteria within FAC-0114-R6), in our opinion, should be to clearly and unambiguously formulate critical operational borderlines of reliable operations, while **respecting existing limitations of existing transmission infrastructure and human resources that operate that infrastructure**.

We appreciate that the SDT listened to the industry's comments and gradually improved the definition of SOL exceedance. In particular, we are pleased that the SDT now considers exceedance of Emergency (rather than Normal) limits as a reportable event.

However, there is a problem with using the phrase "*could be executed and completed within the specified time duration of those Emergency Ratings/Voltage Limits*". We agree with previous commenting of: "*This implies that in order to use the range between normal and emergency rating for an anticipated contingency, a timing analysis needs to be performed before the contingency occurs to determine if ramp rates, start-up times and location and amount of load shedding are adequate….* ***This analysis seems to be better served as an internal control not a compliance obligation.***'

The implementation risk and compliance risk associated with this language is substantial and very concerning. Based on the language, TOP is expected to perform and document a timing analysis to determine if the adjustments could be executed within the specified time duration

of Emergency Ratings each and every time when TOP performs RTA and find its facilities operating between Normal and Emergency Rating (either in real-time or on a contingency basis). It should be noted that such a timing analysis in real-time is difficult and requires significant time and resources. If such timing analysis cannot be performed (or is not performed due to lack of time or other reasons, or simply not logged/recorded) that may trigger non-compliance, concerning FAC-011 R6 in conjunction with FAC-014 R6

The second problem is that it is necessary to differentiate between flow exceedances and voltage exceedances in terms of risk to the equipment and the time tolerance.

We share the industry recommendation of the following definition:

- ***Actual steady state flow on a BES Facility is greater than the Facility's highest Emergency Rating for any time period.***
- ***Actual steady state flow on a BES Facility is above the Normal Rating but below the next Emergency Rating for longer than the time frame of the next Emergency Rating.***
- ***Actual steady state voltage on a BES Facility is greater than the emergency high voltage limit for time frame identified by the TOP.***
- ***Actual steady state voltage on a BES Facility is less than the defined emergency low voltage limit for time frame identified by the TOP.***

1. **Requirements 6.1.3 and 6.2.3** refer to preventing instability, cascading or uncontrolled separation.

- We find it inappropriate that **the proposed definition does not recognize time-frame associated with exceedances of established stability limits**. If not recognized, this can lead to hundreds of meaningless (nuisance) exceedances (for sake of an example, such as those that last less than 1 minute and have magnitude of less than 1%). More importantly, it should be noticed that even present definition of the IROL violation has associated Tv time threshold (or 30 minutes) before it becomes a compliance issue. Proposed formulation of 6.1.3 and 6.2.3 should include the time threshold (in analogy with Tv) so that RCs/TOPs would be given specified time frame to correct exceedance, before it becomes compliance issue.

We recommend the industry discussed following definition:

- ***Any established stability limit (non-IROL) or limit that may cause cascading outages or uncontrolled separation shall not be exceeded for longer than the 30 minutes, or defined by Operating Plan.***
-

1. **Requirement 6.2.1** is of particular importance and probably the single, most frequent concern in present industry's practice. MidAmerican Energy Company appreciates SDT's reasonable approach of listening to the industry's comments and gradually improving the definition of SOL exceedance/performance criteria. However, we would like to draw the SDT's attention to the following issues with their present formulation of the Requirement 6.2.1, which states that:

"*provided that System adjustments could be executed and completed within the specified time duration of those Emergency Ratings*. ***Flow through a Facility must not be above the Facility's highest Emergency Rating*.**"

We would like to point out several issues with regard to this formulation:

- First, **the proposed definition does not recognize time-frame associated with exceedances of the Facility's highest Emergency Rating**. If not recognized, this can lead to hundreds of meaningless (nuisance) exceedances (for sake of an example, such as those that last less than 1 minute and have magnitude of less than 1%). Others exceedances may last several minutes(5-30 minutes, just for sake of example) due to time constraints associated with operators' response to these exceedances and physical reality/timing of corrective control actions that need to be implemented. More importantly, it should be noticed that even present definition of the IROL violation has associated Tv time threshold (or 30 minutes) before it becomes a compliance issue. Proposed formulation of 6.2.1 should include the time threshold (in analogy with Tv) so that RCs/TOPs would be given specified time frame to correct exceedance, before it becomes compliance issue.

- Second, regarding the phrase "*Flow through a Facility must not be above the Facility's highest Emergency Rating*", the SDT's formulation appears to be based on the Project 2014 NERC White Paper. Paper (from May 2014) was stating that "Post-contingency flow in this range is not acceptable **unless Operating Plan address reliability impact so that it has localized impact**". Subsequent version of the NERC White Paper (revision of January 2015) introduced statement that "Post-contingency flow in this range is not acceptable" . **This revision, with a major impact, was never presented to the industry, never approved by the Industry and, in our opinion, was step in the wrong direction. The most recently published revision adds clarity and improved formulations, but still departs from the original concept and ignores time dimension that is necessary to implement corrective control actions, especially for inevitable short term exceedances in RTA, on a contingency basis.**

- Third, the SDT's proposed definition of the post-Contingency flow SOL exceedance **fails to recognize the important difference between actual, pre-contingency SOL exceedance and calculated, post-contingency RISK of SOL exceedance**. This attempt to include both of them under the single, generic term "performance criteria/SOL exceedance" may easily cause an incorrect expectation that TOP/RC's control actions response to these two types of exceedances should be similar, in terms of timing, logging and recording.

Fourth, **it is perfectly clear and understandable that both of these types of exceedances require and should trigger implementation of a control action from Operating Plan, but they should be treated *differently in terms of urgency and severity of mitigating control actions*, as they have different repercussions on system reliability**.

- **The implementation risk and compliance risk associated with this language is substantial and very concerning. Based on the language, TOP is expected to perform and document a timing analysis to determine if the adjustments could be executed within the specified time duration of Emergency Ratings each and every time when TOP performs RTA and find its facilities operating between Normal and Emergency Rating (either in real-time or on a contingency basis)**? It should be noted that such a timing analysis in real-time is difficult and requires significant time and resources. If such timing analysis cannot be performed (or is not performed due to lack of time or other reasons, or simply not logged/recorded) that may trigger non-compliance, concerning FAC-011 R6 in conjunction with FAC-014 R6.

• Fifth, regarding the **language in FAC-011-4 (R6.2.1)** "*Flow through a Facility must not be above the Facility's highest Emergency Rating"*, let's consider the following scenario. TOP operates in REAL-TIME with one scheduled outage (N-1 topology). Then a fault occurs (single event such as bus fault or similar) and takes out of service two (or more) facilities, thus bringing the system in real-time into N-3 topology condition. Now, RTCA starts showing overloading for next single contingency (N-4).

The concern is if the language in the draft of the standard assumes that **the performance criteria are identical, independently of the system state** (i.e. if the system is in N-1 as opposed to N-3, or even more severe, topology conditions). We certainly understand that in OPA such a scheduled outage would not be approved if it causes SOL exceedances. However, what will be applicable performance criteria if that event happens in real-time due to single event? Of course TOP will implement its Operating Plan to correct the exceedance, but due to significantly deteriorated topology (for which the system was never designed) it may take longer time period to eliminate exceedance on a contingency basis. Or, analysis may show that only firm load shedding may eliminate the exceedance.

The issue is that if the same performance criteria are applicable independently of topology conditions, in order to avoid performance criteria violation (on a contingency basis) the only viable option might be pre-contingent firm load shedding to correct contingency based (not real-time) exceedance

We recommend the following industry discussed definition for 6.2.1:

- ***Projected post-Contingent loading on a BES Facility is greater than the highest Emergency Rating for longer than 30 minutes with NO agreed upon Post Contingency Action Plan that would mitigate the condition if the Contingency were to occur.***

We believe there is need for using a Post-contingency action plan concept

- The main difference between our proposed definition and the SDT's proposed definition is the **concept of post-contingent action plan**. *The Post-contingency action plan is the RC's/TOP's agreed upon control action to be used* ***while the normal congestion management processes are attempting to return the projected post contingent flow within longer-term rating****.* It is very important to note that the Post-contingency action plans are **NOT** a vehicle to justify continual operation where the projected post contingent flow is above Facility's highest Emergency Rating.

In contrast to this, we believe that the Post-contingency action plan developed by TOP and RC is required to address potential impacts and post-contingent mitigating strategies, including but not limited to load shedding or generator tripping, while normal congestion management actions are being implemented, to ensure potential impact is localized and to prevent equipment damage.

- Therefore, we would NOT consider SOL exceedance to exist anytime the Projected post-contingency flow is above Facility's highest Emergency Rating, but only for those situations when the Projected post-contingency flow is above the Facility's highest Emergency Rating (Rate C) for longer than 30 minutes **WITHOUT associated post-contingency action plan**.

- We recognize that there may be situations in the system when normal congestion management is not effective or has been exhausted, and the projected post-contingent loading on a facility remains greater than the highest available emergency rating. In this situation, load shedding may be the sole remaining option to address the projected post-contingency loading. The TOP and RC may decide to operate in this manner and not implement load-shedding pre-contingency if the impacts would be localized. In this case the SOL exceedance would be reportable, even though a post-contingent action plan exists, since normal congestion management is no longer taking place.

- The SDT's concept insists on the concept "highest Emergency Rating". Our definition is based on the concept of "post-contingency action plan". We do recognize that issuing a new Short Term Emergency rating would be an alternative for the TOP to pursue rather than agreeing with its RC on a post-contingency action plan. **The huge practical obstacle to issuing higher emergency rating (or "Load Shed Rating**") that the Industry always faced is that each TOP would have to **get manufacturers' confirmations for using shorter term Emergency Ratings (such as 10-minute ratings) for every single piece of equipment** (breakers, switches, wave traps, CTs conductors, all pieces on transformers etc). Majority of manufacturers would not be even able nor willing to provide such a data. Therefore, **for practical reasons, it is almost impossible to get such a short-term ratings based on manufacturers' data and technical facilities justifications**. Consequently, as opposed to being "pushed/forced" to using technically unjustified short-term emergency/load shedding ratings, each TOP and RC might need to define criteria within their Operating Plan for using post-contingent action plans. These criteria might be based, for sake of example, on Relay Loadability Limits of transmission facilities.

We believe the SOL exceedance definition did create an unnecessary compliance burden. However, the approach the SDT took does not reduce the compliance burden by moving the SOL Exceedance definition to a requirement. Requirement R6 is overly complicated and confusing. It has 11 sub-parts and references other requirements four separate times. Compliance standards should be clear and should be able to stand alone without the need to cross reference other requirements.

Comment

Duke Energy requests further clarification on the use of “pre-Contingency state” in R6.2. Was it the drafting team’s intent that an RC should anticipate a “pre-Contingency state”? Was this a typographical error? Should “post-Contingency state” be used instead?

Duke Energy is unclear on the expectations for R6.4. Is it the drafting team intent that with the use of the term “demonstrates” in R6.4, that entities are required to do stability studies in Real-time? The drafted language appears to be more suitable for Planning Coordinators and Transmission Planners, not for Operators of the BES in Real-time. We suggest the drafting team consider the following language for R6.4:

“The evaluation of the potential Contingencies identified in Part 5.3 demonstrates that the system will be operated within stability limits.”

Should other Time Horizons be considered for R6 as well, (Same Day)?

General Observation

The companies believe reliability and establishing compliance thresholds are better served by keeping performance criteria within the performance Standards, e.g. TOP and IRO Standards, and keeping Standards that establish a methodology free from such performance criteria.

Like the SDT’s statement in Question 3, the companies agree that to address the issue, revisions would likely need to be made within a TOP or IRO standard and the Project 2015-09 SAR does not specifically authorize the SDT to modify those standards.

Suggestion: Add Flexibility

The companies recognize each Registered Entities' system is unique in design, complexity, footprint, and Facilities. To address the differences between systems across the BES, the companies suggest FAC-011-4 R6 language provide flexibility to accomplish the reliability outcomes offered in the proposed revisions by leveraging entities' FAC-008 Facility Rating Methodology and applicable internal documents to guide:

- When Normal and Emergency Ratings/Voltage limits are used under pre or post-contingent conditions, and
- The allowable time duration for the applicable condition.

Suggestion: Remove Prescriptive Language

Also, the companies suggest removing prescriptive language to provide entities more flexibility executing Requirement 6. Replacing the NERC Glossary Terms, "Normal Ratings" and "Emergency Ratings" with the words "applicable ratings" or "applicable voltage limits" will provide the suggested flexibility without compromising BES reliability.

Comment

Although the current FAC standards include performance criteria, MISO believes that they should reside in IRO and TOP standards. The FAC standard should focus on defining acceptable Operating Limit methodologies. With respect to the proposed performance criteria, MISO has the following concerns:

- Revised standard and SOL exceedance definition appears to imply that exceeding the System Operating Limit (SOL) is not allowed. This makes SOLs more restrictive in management than IROLs, for which there is an allowance to exceed the rating as long as the load is reduced to below the rating prior to exceeding the Tv of the facility. There is no Tv allowance for SOLs, as the definition is currently written.

In particular, the performance criteria as written fail to allow time for the RC or TOP to respond to an event, and readjust the system without immediately putting them in violation of the performance criteria. For example, RTA will show all elements within their emergency ratings per the criteria, but then a contingency occurs and the next RTA shows one or more elements above the highest emergency rating.

- Transmission system could be underutilized, if the SOL Exceedance definition is implemented as currently written.
- Planning standards recognize exceedances of operating limits will occur, and require a plan to mitigate those exceedances. This definition does not allow for the same to occur in Operations

- R6.5 appears to disallow load shedding that may have been specifically designed as part of a RAS or UFLS scheme.

Finally, any change to SOL exceedance in the IRO and TOP standards need to be clear that exceeding a non-IROL SOL, particularly post contingency, is not a violation of any operating standard or criteria.

Do not agree with 6.5, too restrictive. Should be allowed to apply non-consequential load loss.

The language mandates evaluation of all contingencies listed in R5.1.1 of FAC-011-4 as part of the Real Time Assessment (RTA) and the Operational Planning Analysis (OPA) without exception.

R6.2.1 - The flows on transmission element may exceed the applied Emergency Rating during the dynamic time period but there is likely no risk to the system. Although the first phrase "applicable Emergency Ratings" might seem to provide the flexibility, this means an entity must know the "applicable Emergency Rating" for a particular dynamic loading and time period for each piece of equipment and each piece of equipment would need to be monitored in a dynamics analysis

R6.2.3, this language pulls in dynamic analysis of all of these contingencies for both the RTA and OPA

6.3. The evaluation of the potential Contingencies identified in Part 5.2 against the actual pre -Contingency state (Real-ti monitoring and Real Assessments) and anticipated pre -Contingency state (Ope or uncontrolled separation does not occur.

6.4. The evaluation of the potential Contingencies identified in Part 5.3 demonstrates that instability does not occur.

R6.3 and R6.4 contain the same problems. It is infeasible to run dynamic simulations as part of the RTA and it is very complex to do so for the OPA. At least in this case, R5.2 and R5.3 allow the RC to provide a very limited list of contingencies.

6.5. In determining the System’s response to any Contingency identified in Parts 5.1 through 5.3, planned load shedding is acceptable only after all other available System adjustments have been made.

R6.5 - The standard incorrectly eliminates planned load shedding from consideration when RAS or UVLS programs may have specifically established to take such action to maintain system stability for the particular contingencies under consideration.

Comment

American Transmission Company LLC (ATC) supports the efforts of the SDT to clarify for the industry what is considered SOL exceedance in the context of the IRO and TOP Standards. We appreciate the SDT listening to the concerns raised by industry regarding the previously proposed SOL Exceedance definition and we agree with the SDT's approach to abandon that potential change. We believe the proposed performance criteria in FAC-011-4 Requirement R6 seems to capture the essence of SOL exceedance. We do agree with the SDT's concept that the Reliability Coordinator's (RC) SOL Methodology must address the system performance criteria to ensure consistent identification of SOLs.

However, ATC is concerned the proposed language creates a significant reliability/compliance burden for RCs and Transmission Operators (TOP) as follows:

- R6.2 - The language mandates evaluation of all contingencies listed in R5.1.1 of FAC-011-4 as part of the Real Time Assessment (RTA) and the Operational Planning Analysis (OPA) without exception. When coupled with R6.2.3, this language pulls in dynamic analysis of all of these contingencies for both the RTA and OPA. This is an infeasible expectation for the RC and TOP to include in their RTAs and OPAs, since R5.1.1 contains no caveats to limit the list of applicable single contingencies.

- R6.2.1 - The flows on a transmission element may exceed the applied Emergency Rating during the dynamic time period, but there is likely no risk to the system. Although the first phrase "applicable Emergency Ratings" might seem to provide the flexibility, this means an entity must know the *"applicable Emergency Rating"* for a particular dynamic loading and time period for each piece of equipment and each piece of equipment would need to be monitored in a dynamics analysis. It may be that the SDT does not intend to pull in dynamics in 6.2.2 but it is a logical reading of the standard.
- R6.2.3 - As noted above, although this is the desired result, it is infeasible to perform dynamic analyses of all R5.1.1 contingencies as part of either an RTA or an OPA. In fact, it is an extremely expensive proposition to perform any real time dynamic simulations due to the complexities of maintaining an accurate dynamic model that incorporates traditional transmission equipment let alone the myriad of user written or proprietary dynamic models in use today for FACTs devices and variable generation.
- R6.3 and R6.4 contain the same problems as noted above. It is infeasible to run dynamic simulations as part of the RTA and it is very complex to do so for the OPA. At least in this case, R5.2 and R5.3 allow the RC to provide a very limited list of contingencies. Still, even with a limited list, the language of R6 and its sub-parts does not limit the scope of what a TOP would be required to run under FAC-014-3 (see R2 of that standard). Rather, FAC-011-4 R6 language implies that a TOP would be required to evaluate all of the contingencies identified by an RC, not just those that apply to the TOP's footprint. Note that FAC-014-3 R2 limits the TOP to identifying SOLs to its footprint, but it does not limit the contingencies a TOP would need to consider.
- R6.5 - The standard incorrectly eliminates planned load shedding from consideration when a RAS or UVLS programs may have specifically established the need to take such action to maintain system stability for the particular contingencies under consideration.

ATC offers the following proposed improvements to address the comments above:

- R6.1.1, R6.1.2, R6.2.1 and R6.2.2 could be improved by clarifying that these sub-requirements are only describing steady-state conditions. Each requirement could have the following leading statement added: *"Under steady-state analysis:"*.

- In addition, R6.2.1 and R6.2.2 would also benefit from adding the word *"Anticipated"* ahead of the terms *"Flow"* and *"Voltages"* in these requirements, respectively, to make it clear that these are potential system flows and voltages, not real time flows and voltages, being evaluated.

Regarding the scope of dynamic simulations, the best location to make modifications is likely the R5 and R5.1 language, not R6. Proposed modifications are as follows:

- R5 - Strike *"and performing the Operational Planning Analysis (OPAs) and Real-time Assessments (RTAs) for the area under study"* since this language is redundant to the R6 performance criteria language that will require these contingencies to be evaluated as part of the RTA and OPA. With this removed, R5 is tailored to only describe what contingency events need to be examined for the identification of SOLs.

- R5.1 - Remove the language regarding *"determining stability limits and performing OPAs and RTAs"* and add *"for use in determining steady state SOLs",* since the SOL methodology should require examination of all of the single contingencies listed under R5.1.1 using steady-state analysis. The contingencies to examine for dynamics will be a very small list (hopefully) and can be adequately addressed by modifications to R5.3.should require examination of all of the single contingencies listed under R5.1.1 using steady-state analysis. The contingencies to examine for dynamics will be a very small list (hopefully) and can be adequately addressed by modifications to R5.3.
- R5.2 - Remove *"for use in performing Operational Planning Analysis and Real-time Assessments"* since, again, this is adequately covered by R6, and add in language as follows *"for use in determining steady state SOLs"*.

- R5.3 - Strike the word *"additional"* from the existing R5.3 language and add the following to the end of the requirement: *"where the identified single Contingency events involving the loss of a generator, transmission circuit, transformer, shunt device, or single pole block in a monopolar or bipolar high voltage direct current system must simulate either: (a) Normal Clearing of a single phase to ground or three phase Fault (whichever is more severe) or (b) tripping without a Fault condition"*.

- Regarding the TOP performing a certain set of contingencies, the R6.2, R6.3 and R6.4 language could all be modified to state: *"The evaluation of applicable potential single Contingencies …"* (for R6.2) and *"The evaluation of the applicable potential Contingencies …"* (for R6.3 and R6.4).

- R6.5 could be improved by clarifying that RAS and UVLS actions should be implemented in the stability analysis, as applicable. The SDT should also recognize that underfrequency load shedding (UFLS) may be a necessary part of system stabilization once a RAS operates if that RAS is creating a planned islanded system. As such, UFLS may also be a warranted load shedding component when performing stability analysis. R6.5 language could be modified by adding *"planned load shedding, other than Remedial Action Scheme (RAS) or UVLS action, is acceptable …"* and then adding a new sentence that reads, *"The use of UFLS programs should only be simulated when incorporated as part of the system design to maintain stability (e.g., RAS)."*

The criteria given are not clear as written such that they appear to occur in the Real-time horizon and apply to real-time operations rather than in the Operations Horizon as stated. As a consequence, the criteria do not seem to meet a methodology requirement but an operating one. Specifically, the identification of real-time monitoring and assessment as a demonstration is inappropriate for a FAC methodology requirement and belongs in TOP and IRO standards relating to operations. We believe there should not be an operating requirement in FAC-011 and in our opinion this is a poor practice and should be shelved. The Standard "families" set certain expectations and should be respected because to do otherwise will create risks of inconsistency. If the TOP and IRO standards need amending, then amend them!

SRP is concerned the language in 6.5 may be too limiting, specifically the phrase “only after **all** other available System adjustments”. SRP suggests either adjusting the language to state “after other reasonable System adjustments have been made”, or to state “while other system adjustments are being made”. It may be necessary to respond first with load shed while other system adjustments are being made, then returning the load. The language should allow entities to use all available tools and determine the best process for maintaining stability of the system.

Also, SRP recommends retaining some of the language in FAC-011-3 R2.3 and R2.4 explicitly identifying acceptable post-Contingency actions. Consideration of post-Contingency actions is appropriate in an SOL methodology because the available actions delineate the “specified System configuration". Furthermore, including the language in the standard and as a result in the RC's SOL Methodology, helps ensure the performance criteria in the Operations Horizon is not more limiting than the performance criteria used in the Near-term or Long-term Planning Horizons.

ITC agrees with MEC and believes that addressing the fundamental concept of defining SOL Exceedance needs to be done within the framework of IRO and TOP standards, where it inherently and logically belongs. We do not agree with the approach of moving that cornerstone of reliable operations from IRO/TOP set of standards to the FAC set of standards. In other words, we believe that the present context of defining what constitutes SOL exceedance and reacting to it by initiating an Operating Plan (per IRO-008-2-R2 and TOP-001-4-R14) is far better than directly exposing large number of entities to the risk of non-compliance without appropriate considerations related to physical constraints that need to be overcome during implementation of Operating Plans, in a timely manner.

The FAC standards should facilitate the creation of SOL's, not define operating criteria. SOL's should; (1) at a minimum be equal to Facility thermal or voltage limits and (2) consider system stability (voltage or transient) limits that may require limits more restrictive than Facility thermal or voltage limits.

The FAC standards should in no way infer that dynamic analysis needs to be performed as part of RTAs. Requirement R6 of FAC-011-4 as currently written could be inferred to require real time dynamic analysis. Specifically, it is unclear if requirements R6.1.3, R6.2.3, R6.3 and R6.4 require that RTA's include dynamic analysis to determine if Instability would occur or if operating to the pre-identified SOL's would provide this determination.

ITC agrees with MEC that the phrase "could be executed and completed within the specified time duration" throughout requirement R6. This could be interpreted as requiring a timing analysis before the contingency occurs to determine if ramp rates, start-up times and location and amount of load shedding are adequate. The implementation risk and compliance risk associated with this language is substantial and very concerning. Based on the language, TOP is expected to perform and document a timing analysis to determine if the adjustments could be executed within the specified time duration of Emergency Ratings each and every time when TOP performs RTA and find its facilities operating between Normal and Emergency Rating (either in real-time or on a contingency basis). It should be noted that such a timing analysis in real-time is difficult and requires significant time and resources.

Instability, as used throughout the existing standards is an undefined term which leaves room for broad interpretation. This term should be removed or defined to clarify that single unit instability would not constitute "instability" as it is used in these proposed standards.

Texas RE has concerns with the performance criteria specified in FAC-011-4 Requirement R6. As an initial matter, until FAC-014-3 Requirement R6 is read, it isn’t understood that the performance criteria in FAC-011-4 R6 is referring to SOL exceedances.

That said, Texas RE is concerned that the way the performance criteria is written, and that an SOL exceedance would not occur until the highest Emergency Rating is exceeded. Therefore, the RC and TOP may not develop an Operating Plan for exceedances of the Normal Rating identified through the OPA (TOP-002-4 and IRO-008-2), and would not be required take action to return flow to Normal Ratings when Real-time flows exceed the Normal Rating (TOP-001-4), since there is no exceedance occurring in the Parts 6.1 and 6.2 scenarios:

- FAC-011-4 Part 6.1 - Operating Plans should be created anytime the anticipated pre -Contin demonstrates flow above the normal Rating or voltage outside of the normal System Voltage Limits. Additionally, Operating Plans should be initiated when the actual pre -Contingency state normal Rating.
- FAC-011-4 Part 6.2 should still require entities to create an Operating Plan that is available to System Operators if evaluation of potential single Contingencies listed in Part 5.1.1 against the anticipated pre -Contingency state (ow above normal Ratings. There is no way to know if System adjustments could be executed within time duration of Emergency Ratings without creating an Operating Plan to address the issue, and identifying a time-frame in which the Operating Plan could be executed. Since FAC-014-3 R6 states determination of SOL exceedances during the OPA is required to be in accordance with RC SOL Methodology, this language would not require a the creation of an Operating Plan to mitigate an exceedance of the normal Rating that is identified during the OPA.
- Real-time flows may legitimately exceed Normal Ratings as a result of conditions unanticipated by OPA, initiating the use of Emergency Ratings and their associated time limits in order to return flows to below Normal Ratings without an Operating Plan. This is the intended purpose of Emergency Ratings. It is unrealistic to assume that all operating conditions are captured by OPA, as OPA is based on preconceived contingent states.
- The same does not hold true for “anticipated pre-Contingency states” based on OPA. An anticipated pre-Contingency overload beyond the Normal Rating indicated by OPA is a base case overload which requires mitigating actions or an Operating Plan before the condition which would cause the overload occurs. Using Emergency Ratings and their associated time limits for this situation is not their intended purpose.

RCs and TOPs should be prepared when flow is outside of Normal Ratings. In order to maintain reliability, Texas RE recommends immediate action through the use of an Operating Plan to mitigate any flows or voltages outside the Normal ratings or System Voltage Limits.

Comment

Southern California Edison (SCE) believes that the NERC Standard Drafting Team approach of defining SOL Exceedance through a performance criteria in Requirement 6 of FAC-011-4 is inappropriate. If the Standards Drafting Team decides to include the undefined term “SOL Exceedance” within the performance criteria of FAC-011-4, the SDT effectively exposes a number of TOPs and RCs to the risk of violating FAC-011-4 (Requirement 6) if/when exceedances of system operating limits occur either in RTA or OPA. SCE believes that NERC should mitigate the regulatory uncertainty of using the undefined terminology within the performance criteria of FAC-011-4, and create a standard definition of SOL Exceedance. SCE is particularly sensitive to this issue due to Peak RC ceasing operations in 2019.

Additionally, SCE believes NERC should create a definition for “SOL Exceedance” by using existing framework of IRO and TOP standards. SCE believes that the present context of defining what constitutes SOL exceedance and reacting to it by initiating Operating Plan (per IRO-008-2-R2 and TOP-001-4-R14) is far better than directly exposing large number of entities to the risk of non-compliance without appropriate considerations related to physical constraints that need to be overcome during implementation of Operating Plans, in a timely manner.

Finally, SCE supports the examples presented by MidAmerican and the MRO NSRF that demonstrate the unintended consequences of using the undefined term “SOL Exceedance” within FAC-011-4 Requirement R6.

Comment

We are in general agreement over the proposed changes as they essentially maintain the system performance criteria, similar to the approach in the currently effective FAC standards. Our main comments are:

- **The proposed standards should require the Reliability Coordinator's (RC) methodology to establish stability limits when those limits also impact other RC Areas, and that the criteria for the selection of contingency events is defined and applied consistently in all the RC areas, in order to ensure that all IROLs within a defined scope are detected and properly studied.**

- **Throughout the standard development process for the revisions of the IRO/TOP standards the IESO continued to comment on our serious concern over the proposed retirement of Requirement R4 of TOP-004-2 without having it reinstated in TOP-001-3 or having some of the requirements in TOP-001-3 revised to addressing the reliability need for confirming or reestablishing valid SOLs/IROLs in an unknown or unstudied state. We recognized that by virtue of the proposed definition of Operational Planning Analysis (OPA) and Real-time Assessment (RTA), as well as the new requirement for TOPs to update their OPA results through the performance of a RTA every 30 minutes, that the entities will always be assessing the reliability of the BES. However, this falls short of requiring an entity to determine new/revised limits to begin with. Without knowing the boundaries, performing real-time analysis every 30 minutes does not give the entity an indication if current operations (power flow or voltage levels) exceed the limits that are valid and applicable for the present conditions. These conditions pose unacceptable risks of instability since the operator does not know whether the next contingency will result in system instability.**

We recognize that this issue is not within the scope of this project, but is directly related through the methodology that will be used to determine operating limits for these unknown states. In order to better coordinate the development of standards, we recommend that the scope of future NERC projects should better identify relationships between families of standards at the onset, and encourage potential revisions to related requirements.

We support the FAC revisions.

We have the following comments:

Subrequirements R7.1 andR 7.2

We agree with comments submitted by the NPCC RSC in regards to requirements 7.1 and 7.2. The subrequirements R7.1 and R7.2 require the identification of SOL that are IROL and the criteria for identifying SOL violations that are IROL. We do not understand the difference and our compliance department do not see how the evidence of those two subrequirements would be distinct.

Requirement R5.1

We have a minor comment regarding the addition in R5.1 of "Specify the" makes the use in 5.1.1 of "any" more ambiguous than it is in the current version. Consider that R5 now requires

a) identify in its SOL methodology…

b) Specify the following single contingency event…

c) Loss of "any" of the following.

Before it clearly "included" the following "list" of single contingency events. It would be better for the language to clearly state in 5.1.1. "Loss of each of the following" or return to language that clearly mandates the inclusion of the loss of all the listed elements.

Requirement 9

Also, the last sentence of the Rationale for Requirement R9 for FAC-011-4 should be modified as follows.   "(…) mandates provision of the SOL Methodology to non-adjacent RCs [or to adjacent RCs in another Interconnection] that have specifically requested (…)"

Numbering typos exist in Measure Nos. M7, M8, and M9. Requirement Nos. R7, R8, and R9 should be referenced accordingly.

Revised language in Requirement R1 is not included in the Violation Security Levels table. Specifically, the term “documented” was added to Requirement R1. ERCOT suggests including the term in the Violation Severity Levels table order to be consistent.

Similarly, the revised language in Requirement R2 is not included in the Violation Security Levels table. Specifically, “the applicable” was replaced with “which” and “are” in Requirement R2. ERCOT suggests including the same revisions in the Violation Severity Levels table.

In requirement R9, “and any changes to the SOL Methodology prior to the effective date of the SOL Methodology” was deleted. ERCOT suggests aligning the Violation Severity Levels table to align with this revision and the specific language of the applicable requirements. For Part 9.1, there is no distinction between “new or revised” in the wording of the requirement, but it is explicitly stated in the Violation Severity Levels table.

ERCOT suggests capitalizing “methodology” in Requirement R9, Part 9.2.

Requirement R2 specifically states that the RC “shall include in its SOL Methodology the method for Transmission Operators to determine which owner-provided Facility Ratings are to be used in operations”. This requirement needs to be bounded such that the RC is not specifying in its methodology how a Transmission Operator and thus a Transmission Owner is required to rate its transmission facilities, up to and including the use of real time ratings. This would determine the amount of risk a Transmission Owner is subject to for its facilities. The standard should only specify the end objective and not the process to achieve that objective.

Requirement R8 is redundant with IRO-010-2 R1. SOLs are inputs to OPA and RTAs. As such, R1 of IRO-010-2 already requires the RC to maintain a documented specification of the data necessary for it to perform its Operational Planning Analyses, Real-time monitoring and Real-time Assessments. This requirement included requirements for periodicity of providing the data. As such, R8 of proposed FAC-011-4 is redundant and should be deleted from the proposed standard.

FMPA is concerned that Project 2015-09 does not consider the work done by the MEITF (Methods for Establishing IROLs Task Force). There are defined terms used in R6 that the MEITF has proposed changes to, and that have been endorsed by the NERC PC and OC. FMPA asks that the implementation plan be changed so that FAC-011-4 would only be effective once the new definitions proposed by the MEITF become effective

ATC does have other comments on FAC-011-4:

- Requirement R3 addresses the establishment of a voltage-based SOL at each bus. No similar requirement is given for thermal ratings. It is unclear if the SDT expects each Facility to have a thermal-based SOL. Alternatively, can TOPs and RCs use multi-element or proxy flowgates to manage power flow on the system? The expectation regarding thermal related SOLs needs to be clearly stated in any requirement such that entities can fulfill the requirements and all entities are operating the BES from the same understanding.

- R3.3 should be improved by clarifying what undervoltage load shedding (UVLS) systems are in view (i.e. owned by the Transmission Owner, the Distribution Provider, end-use customer). It would seem that R3.3 should not be limited by UVLS relay settings implemented by a distribution utility or an end-use customer. A suggested edit is to clarify these are BES systems as follows: *"in-service BES relay settings for undervoltage load shedding…"*.

- Similar to comments provided in question #1 related to R6.5, Requirement R4.7 should be modified to remove the restriction on using UVLS Programs when setting stability limits. It is generally accurate to state that UFLS should not be relied upon to maintain stability, although the SDT needs to recognize that UFLS may be a necessary component to maintain stability of a portion of a system deliberately islanded by a Remedial Action Scheme. As such, R4.7 should be modified to read, *"State that the use of underfrequency load shedding (UFLS) programs are not allowed in the establishment of stability limits except in specific, documented circumstances (e.g., Remedial Action Schemes)."*

Comment

We offer the following specific comments:

Sub-Requirement R4.1.3:

It is not clear what is meant by “unit” stability. We suggest reverting back to using the current term “angular” stability as it is a term well understood by the industry.

Sub-Requirement R4.3:

A main concern is the lack of criteria to define contingencies for the establishment of IROLs. Today, some RCs respect single contingencies, while other respect double contingencies. Given the impact on the Interconnection, it is crucial that criteria for the selection of contingency events is defined and applied consistently in all the RC areas, in order to ensure that all IROLs within a defined scope are detected and properly studied. We recommend that the following wording is added to Sub-Requirement R4.3 to establish SOLs that impact on the Interconnection:

“Describe how the Reliability Coordinator establishes stability limits when there is an impact to more than one Transmission Operator in its Reliability Coordinator Area or other Reliability Coordinator Areas in accordance with its SOL Methodology.”

Sub-Requirements R5.2 and R5.3

Sub-Requirements R5.2 and R5.3 require the RC to identify any additional single or multiple Contingency events. We believe that specifying, at a minimum, which contingencies must be respected (similar to Sub-Requirement R5.1.1. for single Contingencies) would improve reliability. In particular, to the extent there is an alignment in respecting the same set of contingencies and performance criteria for IROLs.

Furthermore, the loss of small or radial portions of the system should be acceptable provided the performance requirements are not violated for the remaining bulk power system.

Sub-Requirement R6.2.2

Sub-Requirement R6.2.2 should include the same wording as sub-requirement 6.1.2:

“Voltages are within normal System Voltage Limits; however, emergency

System Voltage Limits may be used when System adjustments to return

the voltage within its normal System Voltage Limits could be executed

and completed within the specified time duration of those emergency System Voltage Limits.”

Sub-Requirements R6.3 and R6.4

For consistency purposes, we recommend that Sub-Requirements R6.3 and R6.4 also require to demonstrate that flow through Facilities are within Normal Ratings, similar to Sub-Requirements 6.1.1 and 6.2.1:

“Flow through Facilities are within Normal Ratings; however, Emergency

Ratings may be used when System adjustments to return the flow within its Normal Rating could be executed and completed within the specified time duration of those Emergency Ratings.”

Sub-Requirements R7.1 and 7.2

Sub-requirements R7.1 and R7.2 require to describe how to identify IROLs, and to identify the criteria for IROLs which is basically the same thing. We recommend merging these sub-requirements into one:

7.1. A description of the criteria to identify the subset of SOLs that qualify as Interconnection Reliability Operating Limits (IROLs) and for developing any associated IROL Tv.

R3

Sub-Requirement 3.5 combines two requirements, (1) require a method for determining… and (2) require common use.   Sub-Requirement 3.5 should be re-written as “require a method for determining…” as shown below.

We assume that 3.6 and 3.7 intend to “address coordination” within the “method for determining” the limit. As such, that consideration should be rolled into the requirement for “a method for determining..”

Since System Voltage Limits are SOLs, it is unnecessary to explicitly require the operation within the restrictions of System Voltage Limits. Also it is inappropriate to place any system operation requirement (Require the use…) within an operating parameter development methodology. There are already requirements for the system to always be studied and operated within the SOL restrictions of the local reliability entity as well as the SOL of adjacent reliability entities. All requirements for “require the use of common” should be deleted.

3.5 Provide the method for determining the common System Voltage Limits in coordination with adjacent Reliability Coordinators and Transmission Operators.

R4

What is the point of R4.2? If R5 requires that all stability analysis to evaluate the contingencies listed in “5.1. Specify the following single Contingency events for use in determining stability limits and performing OPAs and RTAs.” How can one violate 5 without also violating 4.2? Is this not double jeopardy? The identical requirements are applied to both general SOL stability analysis and OPA/RTA stability analysis.   R4.2 is a requirement to comply with R5.1.

Sub requirements 5.3 and 5. 4 are double jeopardy and should be deleted. How can there be any contingencies used “determining the stability limits to be used in operations” that are not completely identical to the contingencies used in “determining stability limits and performing OPAs and RTAs.” It is impossible to violate 5.3 or 5.4 without simultaneously violating 5.2

We suggest the SDT Re-write 4.2 determining the stability limits to be used in operations as follows and eliminate R5 its entirety.

4.2 Specify the following single Contingency events for use in determining stability limits

4.2.1. Loss of any of the following either by single phase to ground or three phase Fault (whichever is more severe) with Normal Clearing, or without a Fault:

• generator;

• transmission circuit;

• transformer;

• shunt device; or

• Single pole block, with Normal Clearing, in a monopole or bipolar high voltage direct current system.

4.2.2. Identify any additional single or multiple Contingency events or types of Contingency events for use in performing Operational Planning Analysis and Real -time Assessments.

R5

What is the point of R5.2? If 5.2 requires that all stability analysis to evaluate the contingencies listed in “5.1. Specify the following single Contingency events for use in determining stability limits and performing OPAs and RTAs.” How can one violate 5.1 without also violating 4.2? Is this not double jeopardy? The identical requirements are applied to both general SOL stability analysis and OPA/RTA stability analysis.   R4.2 is a requirement to comply with R5.1.

Sub requirements 5.3 and 5. 4 are double jeopardy and should be deleted.   It is impossible to violate 5.3 or 5.4 without simultaneously violating 5.2

Re-write 4.2 as follows and eliminate R5 its entirety.

4.2 Specify the following single Contingency events for use in determining stability limits

4.2.1. Loss of any of the following either by single phase to ground or three phase Fault (whichever is more severe) with Normal Clearing, or without a Fault:

• generator;

• transmission circuit;

• transformer;

• shunt device; or

• Single pole block, with Normal Clearing, in a monopole or bipolar high voltage direct current system.

4.2.2. Identify any additional single or multiple Contingency events or types of Contingency events for use in performing Operational Planning Analysis and Real -time Assessments.

Comment	
R5.1.1 includes all generators and all shunt devices. There is minimal benefit to attempting to study the impact of the unavailability of every shunt device on the transmission system. Defining some criteria on which shunt devices will be studied would be ideal, to avoid creating an unnecessarily burdensome requirement for studies being performed. RCs should specify their criteria for including these, recognizing the size and potential impact of individual elements, the design of system protection, and the needs of their area.

Recommendation: Replace “Instability” with “System instability”

Proposed FAC-011-4. The companies suggest replacing “instability” with “System instability” to provide context and boundaries to the proposed Requirements.

The companies recognize the word “instability” is used without a modifier in the NERC Reliability Standards and Glossary Terms but equally so, it is used with a modifier to provide a boundary to the word. For example:

- Glossary Term: ULVS Shedding Program, “…leading to voltage instability, voltage collapse…”
- Glossary Term: Adverse Reliability Impact, “…an event that results in frequency-related instability…”
- TPL-001-4 R6, “…system instability…voltage instability…”
- PRC-012-2 R4.1.3, “…angular instability, voltage instability…”
- PRC-024-2 R1, “…instability in power conversion…”

Significant Administrative Burden. The effect of using “instability” without a modifier will require entities to report every single instance of “instability” developed from a significant number of contingency events identified during the annual Planning Assessments, including unit instability under TPL-001-4.

Recommendation 1

Replace “instability” with “System instability” throughout the proposed FAC-011-4 revision. “System instability” is already used in TPL-001-4. Replacing the term provides an effective parameter to reporting by requiring reporting of coordinated instances of instability that necessitate a Correction Action

Plan and, in turn, relieve entities of a time-consuming and overly-burdensome reporting requirement.

Recommendation 2

Requirements 6.1.3 and 6.2.3

The companies suggest 30-minute time thresholds, Tv, be added to the proposed revisions to FAC-011-4 R6.1.3 and R6.2.3. This provides RCs / TOPs a time certain threshold to correct exceedance for determinations of compliance.

R6.1.3 and R6.2.3 refer to preventing instability, cascading or uncontrolled separation.

- The present definition of IROL Violation has a Tv time threshold (< 30 minutes) before it becomes a compliance issue.
- The proposed language does not recognize time-frames associated with exceedances of established stability limits.
- Effect: Without a time-frame, it is conceivable a system could experience a significant number of exceedances that possibly last less than 1-minute with a magnitude less than 1%. In such a case, to report would be an onerous compliance burden.

To mitigate potentially over burdensome reporting of a significant number of *di minimis* exceedances, the companies recommend establishing a parameter by requiring reporting of only coordinated instances of instability that necessitate a Correction Action Plan.

Comment

The SPP Standards Review Group (SSRG) recommends that the drafting team consider IROLs in Phase 2 of this project. As discussed at the September 2018 Planning Committee (PC) Meeting, although this project includes IROLs, the drafting team's feedback to the PC was to focus on only the SOL for this commenting period (Phase I). During Phase II, the drafting team will put more focus on the IROL. This is a reasonable suggestion given that all relevant materials pertaining to the IROL were approved at that most recent meeting and couldn't be implemented in the Phase I comment period.

Kevin Salsbury - Berkshire Hathaway - NV Energy - 5

Answer	
Document Name	

Comment
NV Energy understands and supports the SDT's efforts to come up with the broad industry consensus with regard to definition of SOL and associated definition of SOL Exceedance. However, we believe that addressing a fundamental concept of SOL Exceedance definition needs to be done within the framework of IRO and TOP standards, where it inherently and logically belongs. Due to reasons that we outlined in response to the question 1 (see above) we find it inappropriate to incorporate the definition of SOL Exceedance as a performance criteria in Requirement 6 of FAC-011-4 Standard and significantly worse and more risky in comparison with coming up with definition of SOL Exceedance**.** NV Energy shares the industry concern that the proposed changes to Standards FAC-011-4 and FAC-014-3 would cause the following unintended consequences and repercussion: • If approved, new versions of the NERC Standards FAC-011-4 and FAC-014-3 **would expose a large number of TOPs and RC to the SIGNIFICANTLY increased compliance risk (direct violation of the FAC-014 R6 in conjunction with FAC-011-4 R6) unless enormous resources and efforts are added within each TOP's/RC's organization.** • **If the interpretation is correct that TOP/RC would not violate FAC standards in case of exceeding performance criteria as long as they implement their Operating Plan (per TOP-001 R14), our above mentioned concern transforms into another concern about huge administrative, compliance related, burden. Namely, TOP/RC would have to have** (as evidence of compliance), logging and recording documentation that it implemented its Operating Plan in response **to each and every instance when projected post-contingent flow on RTCA exceeds highest emergency rating, even for short time period (such as several minutes).** • Therefore, due to the absence of time-frame considerations for exceedances of projected post-contingent flows or voltages, the new versions of the NERC Standards FAC-011-4 and FAC-014-3 would cause frequent SOL exceedances (and therefore frequent violations of the new FAC-011 performance criteria) and prohibitively costly and time consuming administrative burden. • **This definition may decrease reliability as opposed to the SDT's intention of increasing reliability, because of the overwhelming pressure on transmission operators and reliability coordinators to record and communicate frequent SOL exceedances as opposed of being focused on monitoring and implementing control actions to maintain system reliability in real-time.** • We believe the definition would **delay implementation of the Operating Plan in real-time** due to logging and documentation requirements, as this functionality is not a built-in feature of many SCADA systems in use today. • We believe that another unintended outcome would be operation **in an unnecessarily conservative state, as TOP would have to operate with higher reliability margin from the highest emergency rating, to ensure that following a forced outage or other system disturbance, that the next execution of real-time contingency analysis would not show any facility beyond its highest emergency thermal rating or emergency voltage rating**

- **The proposed standards would significantly constrain the business in the industry** as conservative limits would **not allow for many of scheduled outages to proceed** without risk of SOL exceedance/performance criteria violation.

We re-iterate our ***recommendation that SDT re-considers adoption of the performance criteria/SOL exceedance per above mentioned suggestions.*** We believe that these modifications would provide the following benefits:

- They are *more realistic in recognizing reality of existing transmission infrastructure and human resources allocated to operate such an infrastructure*
- *They would provide for significantly less administrative burden* on numerous Industry's entities related to providing evidences of compliance.
- They would provide *comparably reliable operation* of power systems.
- They are *based on physical limitations of various components of transmission facilities*.
- They would *prevent potentially huge increase of cost* of market operations.
- They provide *more clarity and avoid ambiguity and interpretation issues*.

Comment	

We believe R1 should be the only requirement in FAC-011-4. The SDT can accomplish their goal by having Requirement R1 that requires an entity to cover the performance criteria within a newly created appendix. There are 9 requirements and approximately 34 sub-parts in FAC-0011 that increases compliance risk without commensurate benefits to reliability.

Kelsi Rigby - APS - Arizona Public Service Co. - 5	
Answer	
Document Name	Proposed text for FAC-011-4 R5, R6, and R7.docx
Comment	

a. Stability Limit should be capitalized as it is a defined term

b. The wording of FAC-011-4 R5 implies that stability studies are required for OPAs and RTAs. This would be a new requirement and does not correspond with the SDT's intent. We suggest the edits to R5 shown in the attached WORD document to clarify that stability studies are not needed for OPAs and RTAs, but, rather, stability limits derived by other studies need to be respected in OPAs and RTAs.

c. Please clarify the need for the word "potential" in R6 as the word is not used in other places, such as the TPL standards, where single contingencies are also referred to without the word "potential." We suggest the following language to R6 and R7.

d. The word "potential" is not used elsewhere to modify contingencies, which are, by their nature, "potential." For example, in the TPL standards, single contingencies are referred to without the word "potential." For this reason, AZPS recommends that the SDT clarify the need for inclusion of the word "potential" in R6. If such need is not identified, AZPS suggests the following language to R6 and R7. Further, AZPS notes that performance criteria is established in Requirement 6.1 as well as in FAC-014, requirement R6. For this reason, its inclusion in Requirement R6.3 appears redundant. AZPS recommends deletion as set forth below. Finally, AZPS recommends consistency when referring to the operation of the BES within SOLs. For this reason, AZPS recommends replacing "violating" with "exceeding" in Requirement R7.

e. The wording of FAC-011-4 R6.1.3 and R6.2.3 seems to imply that dynamic studies are required for OPAs and RTAs. This would be a new requirement and does not correspond with the SDT's intent. AZPS also suggests adding the word "widespread" under R6.1.3 and R6.2.3 to exclude local area instability or instability of a small generator. We suggest the following edits to R6 to clarify that dynamic studies are not needed for OPAs and RTAs, but, rather, stability limits derived by other studies need to be respected in OPAs and RTAs.

f. As written, FAC-011-4 R6.1.1 and R6.2.1 leaves the burden of proof on the TOP to be able to demonstrate that the operating actions can be taken within the appropriate time of the Facility Rating which is a very difficult and extensive task.

g. Regarding R6.2.1, if RTCA shows that emergency ratings are exceeded, there should be a recognized time frame in which to correct the problem prior to it becoming a compliance issue. As written, the proposed definition does not recognize a time-frame associated with exceedances of the facility's highest emergency rating. If not recognized, this could lead to a large volume of inconsequential exceedances such as those less than one minute and have magnitude of less than one percent.

h. AZPS suggests R6.1, R6.2, and R6.3 be broken into two separate sub-requirements: one related to Real-time monitoring and Real-time Assessment, and one related to Operational Planning Analysis.

Response

Laurie Williams - PNM Resources - Public Service Company of New Mexico - 1

Answer	
Document Name	

Comment

This standard in its current form allows a single entity the ability to dictate operating and effectively planning criteria. PNM believes that the development of the SOL methodology should be a joint effort including RCs, TOPs, and PAs.

PNM believes R2 gives the RC that ability to dictate how an entity uses its own Facility Ratings effectively modifying FAC-008. PNM agrees the requirement does not specifically change, limit, or modify Facility Rating determined by the equipment owner; however, there is no point for an entity to establish a Facility rating that can't be used when operating the system. PNM recommend removal of R2 and revision of FAC-008-3 to address any concerns regarding the coordination of Facility Ratings.

PNM questions the reliability basis of R3.3. PNM believes that there may be reasons to have the UVLS setting higher than the limits for certain critical contingencies. FERC order No. 818 specifies not using UVLS for N-1; however, this requirement doesn't have that qualifier. If the SDT feels this concept should be included in the standard that requirement should move under R4.6 and shall clearly specify that it is only applicable to single contingencies.

The construct of the current active version, FAC-011-3, makes for a lengthy RSAW response with respect to Requirements that lump all SOL types (thermal, voltage, stability) into a single Requirement. The SDT efforts to split these types up into their individual areas, should make for a much more consistent, focused & streamlined RSAW, appreciated by both the Applicable Functional Entity, and their incoming audit teams alike.

For the SDT's consideration

In all areas (Standard, Rationale, Mapping, etc.)

- R3.1 "Reliability Coordinators" should be either "Reliability Coordinator" or "Reliability Coordinator's"; (Note: Given that R3 is talking about the RC SOL Methodology, one could argue that the full reference to the RC SOL Methodology again in R3.1 is duplicative, and could be replaced with "Methodology");
- R5: Repetitive language around determining stability limits and performing OPA & RTA could be remedied for greater clarity by splitting into one requirement focused on stability limits and one requirement focused on OPA & RTA. Otherwise, to stick to the same structure you have for

R5.1, R5.2 & R5.3 could be merged into one sub-requirement.

- R8: Inconsistency between Standard language. “Reliability Coordinator.” vs “Reliability Coordinator(s).”
- M7, M8, M9: Incorrect references to M6, M7 & M8 respectively.

The rationale document for FAC-011-4 has the following typos:

- R3.1 “specificall” should be “specifically”
- R6.1.1 “normal rating” should be capitalized “Normal Rating”
- R8 Rationale discusses R7, when it’s referring to R8.

BPA believes Requirement 3.5 should be modified for clarity: change “provide” to “define.” ”*Require the use of common System Voltage Limits between the Transmission Operator and its Reliability Coordinator and “define” the method for determining the common System Voltage Limits to be used in Operations.”*

BPA believes that in Requirement 4.1.3, the term should remain “angular stability” as this is industry standard. “Unit stability” is not a defined term and is not as understood as angular stability.

BPA recommends consolidating requirements 5.2 and 5.3 and requirements 6.3 and 6.4 to make it so an RC may specify additional single or multiple Contingency events or types of Contingency events for use in determining stability limits and performing OPAs and RTAs. BPA does not support the RC being allowed to specify two additional lists (as allowed by 5.2 and 5.3 when not consolidated) of single or multiple Contingency events or types of Contingency events because BPA believes this could complicate the RC’s SOL Methodology without benefiting reliability. If there is a reliability benefit, BPA would like to request the SDT include that in the White Paper.

BPA proposed edits:

5.2. Identify any additional single or multiple Contingency events or types of Contingency events for use in determining stability limits and performing OPAs and RTAs.

Delete 5.3

6.3. The evaluation of the potential Contingencies identified in Part 5.2 against the actual pre -
Assessments) and anticipated pre Contingency state (Ope or uncontrolled
separation does not occur.

Delete 6.4

Comment	

MidAmerican Energy Company (MEC) understands and supports the SDT's efforts to come up with the broad industry consensus with regard to definition of SOL and associated definition of SOL Exceedance. However, we believe that addressing a fundamental concept of SOL Exceedance definition needs to be done within the framework of IRO and TOP standards, where it inherently and logically belongs. Due to reasons that we outlined in response to the question 1 (see above) we find it inappropriate to incorporate the definition of SOL Exceedance as a performance criteria in Requirement 6 of FAC-011-4 Standard and significantly worse and more risky in comparison with coming up with definition of SOL Exceedance**.**

MidAmerican believes that the proposed changes to Standards FAC-011-4 and FAC-014-3 would cause the following unintended consequences and repercussion:

- If approved, new versions of the NERC Standards FAC-011-4 and FAC-014-3 would expose a large number of TOPs and RC to significant increased compliance risk (direct violation of the FAC-014 R6 in conjunction with FAC-011-4 R6) unless enormous resources and efforts are added within each TOP's/RC's organization.
- If the interpretation is correct that a TOP/RC would not violate FAC standards in case of exceeding performance criteria as long as they implement their Operating Plan (per TOP-001 R14), our above mentioned concern transforms into another concern about huge administrative, compliance related, burden. Namely, TOP/RC would have to have (as evidence of compliance), logging and recording documentation that it implemented its Operating Plan in response to each and every instance when projected post-contingent flow on RTCA exceeds highest emergency rating, even for short time period (such as several minutes).
- Therefore, due to the absence of time-frame considerations for exceedances of projected post-contingent flows or voltages, the new versions of the NERC Standards FAC-011-4 and FAC-014-3 would cause frequent SOL exceedances (and therefore frequent violations of the new FAC-011 performance criteria) and prohibitively costly and time consuming administrative burden.
- This definition may decrease reliability as opposed to the SDT's intention of increasing reliability, because of the overwhelming pressure on transmission operators and reliability coordinators to record and communicate frequent SOL exceedances as opposed of being focused on monitoring and implementing control actions to maintain system reliability in real-time.
- The definition would delay implementation of the Operating Plan in real-time due to logging and documentation requirements, as this functionality is not a built-in feature of many SCADA systems in use today.
- Another unintended outcome would be operation in an unnecessarily conservative state, as TOP would have to operate with higher reliability margin from the highest emergency rating, to ensure that following a forced outage or other system disturbance, that the next execution of real-time contingency analysis would not show any facility beyond its highest emergency thermal rating or emergency voltage rating
- The proposed standards would significantly constrain the business in the industry as conservative limits would not allow for many of scheduled outages to proceed without risk of SOL exceedance/performance criteria violation.

The SDT should reconsider adoption of the performance criteria/SOL exceedance per above mentioned suggestions, which are in accordance with current definition of SOL exceedance that is in effect in MISO Reliability footprint. These modifications would provide the following benefits:

- They are *more realistic in recognizing reality of existing transmission infrastructure and human resources allocated to operate such an infrastructure*
- *They would provide for significantly less administrative burden* on numerous Industry's entities related to providing evidences of compliance.
- They would provide *comparably reliable operation* of power systems.
- They are *based on physical limitations of various components of transmission facilities*.
- They would *prevent potentially huge increase of cost* of market operations.
- They provide *more clarity and avoid ambiguity and interpretation issues*.

Leonard Kula - Independent Electricity System Operator - 2

Answer	
Document Name	

Comment

We offer the following specific comments:

Sub-Requirement R4.1.3:

It is not clear what is meant by "unit" stability. We suggest reverting back to using the current term "angular" stability as it is a term well understood by the industry.

Sub-Requirement R4.3:

A main concern is the lack of criteria to define contingencies for the establishment of IROLs. Today, some RCs respect single contingencies, while other respect double contingencies. Given the impact on the Interconnection, it is crucial that criteria for the selection of contingency events is defined and applied consistently in all the RC areas, in order to ensure that all IROLs within a defined scope are detected and properly studied. We recommend that the following wording is added to Sub-Requirement R4.3 to establish SOLs that impact on the Interconnection:

"Describe how the Reliability Coordinator establishes stability limits when there is an impact to more than one Transmission Operator in its Reliability Coordinator Area or other Reliability Coordinator Areas in accordance with its SOL Methodology."

Sub-Requirements R5.2 and R5.3

Sub-Requirements R5.2 and R5.3 require the RC to identify any additional single or multiple Contingency events. We believe that specifying, at a minimum, which contingencies must be respected (similar to Sub-Requirement R5.1.1. for single Contingencies) would improve reliability. In particular, to the extent there is an alignment in respecting the same set of contingencies and performance criteria for IROLs.

Furthermore, the loss of small or radial portions of the system should be acceptable provided the performance requirements are not violated for the remaining bulk power system.

Sub-Requirement R6.2.2

Sub-Requirement R6.2.2 should include the same wording as sub-requirement 6.1.2:

"Voltages are within normal System Voltage Limits; however, emergency

System Voltage Limits may be used when System adjustments to return

the voltage within its normal System Voltage Limits could be executed

and completed within the specified time duration of those emergency System Voltage Limits."

Sub-Requirements R6.3 and R6.4

For consistency purposes, we recommend that Sub-Requirements R6.3 and R6.4 also require to demonstrate that flow through Facilities are within Normal Ratings, similar to Sub-Requirements 6.1.1 and 6.2.1:

"Flow through Facilities are within Normal Ratings; however, Emergency

Ratings may be used when System adjustments to return the flow within its Normal Rating could be executed and completed within the specified time duration of those Emergency Ratings."

Sub-Requirements R7.1 and 7.2

Sub-requirements R7.1 and R7.2 require to describe how to identify IROLs, and to identify the criteria for IROLs which is basically the same thing. We recommend merging these sub-requirements into one:

7.1. A description of the criteria to identify the subset of SOLs that qualify as Interconnection Reliability Operating Limits (IROLs) and for developing any associated IROL Tv.

1. R 4.1.3: why SDT used “unit stability” instead of “angular”? We believe it is better to match the language in PRC-26 R1.
2. R.4.7: We would recommend revising the requirement R4.7 to state that the use of UFLS and UVLS is not allowed in the establishment of stability limits for the single contingencies identified in R5.1.1.

Dana Klem - MRO - 1,2,3,4,5,6 - MRO, Group Name MRO NSRF

Answer	
Document Name	

Comment

The MRO NSRF does have other comments on FAC-011-4:

- R3.3 should be improved by clarifying what undervoltage load shedding (UVLS) systems are in view (i.e. owned by the Transmission Owner, the Distribution Provider, end-use customer). It would seem that R3.3 should not be limited by UVLS relay settings implemented by a distribution utility or an end-use customer. A suggested edit is to clarify these are BES systems as follows: *"in-service BES relay settings for undervoltage load shedding…"*.
- Similar to comments provided in question #1 related to R6.5, Requirement R4.7 should be modified to remove the restriction on using UVLS Programs when setting stability limits. It is generally accurate to state that UFLS should not be relied upon to maintain stability, although the SDT needs to recognize that UFLS may be a necessary component to maintain stability of a portion of a system deliberately islanded by a Remedial Action Scheme. As such, R4.7 should be modified to read, *"State that the use of underfrequency load shedding (UFLS) programs are not allowed in the establishment of stability limits except in specific, documented circumstances (e.g., Remedial Action Schemes)."*

We also support the recently developed SAR, submitted as a result of phase 1 of the Standards Efficiency Review project, to retire many non-essential or redundant requirements. To reduce the need for a similar effort in the future, the MRO NSRF requests the SDT to consider if Requirement R8 is sufficiently covered with the IRO-010-2 Requirements. In accordance with IRO-010-2 R1 the Reliability Coordinator can specify any information it needs to support its Operational Planning Analyses, Real-time monitoring, and Real-time Assessments. The primary purpose of these activities is to identify SOL exceedances. Therefore, it’s essential that the Reliability Coordinator would include in its data specifications SOLs from all Transmission Operators, which should remove the need for R8. If kept, there may be overlapping compliance obligations with two requirements for the same activity.

Kayleigh Wilkerson - Lincoln Electric System - 5, Group Name Lincoln Electric System

Answer	
Document Name	

Comment	
R3.1 introduces ambiguity and potential inconsistency by allowing the Reliability Coordinator to decide whether to require that a BES bus/station have an associated System Voltage Limit without also requiring any sort of technical rationale or criteria. If the intent of R3.1 is to address a specific issue, LES recommends the drafting team clarify their intent within the requirement. R3.2 is confusing and unnecessary with an in-place definition of System Voltage Limit. As written, R3.2 appears to provide two different methods for an entity to determine voltage limits. R3.3 should state: "Require that **the upper (or higher)** System Voltage Limits…" for improved clarity. R3.4 should be removed in consideration that the definition of System Voltage Limit already requires a "minimum steady-state voltage limit". Combining the language from the definition and R3.4 would essentially read "Identify the lowest allowable minimum steady-state voltage limit…" LES is concerned that R2 does not provide adequate assurance that the RC will respect the Facility Ratings established by the TO or the TO's FAC-008 methodology. As written, the language is vague and appears to allow the RC to determine the Facility Ratings that a TO must use. Also, based on the NERC definition of Facility Rating, there is a potential conflict between System Voltage Limits and Facility Ratings as both could utilize voltage ratings. These conflicts between FAC-011-4 and FAC-008-3 and the definition of Facility Rating need addressed.

With respect to R5.4, requiring Reliability Coordinators to identify Contingency events to use in determining stability limits for the Near Term Planning Horizon (FAC-015-1 R4) which also includes 5-year horizon is added burden to both Reliability Coordinators and the Planning Coordinators/Transmission Planners without added benefit. The drafting team should consider limiting this requirement to 0-1 year period which would be the most concerning for the Reliability Coordinators.

It is not clear what other additional single contingency events are there that are not already included in R5.1.1. Some guidance/criteria in selecting/identifying multiple contingency events (R5.2) for use in OPAs & Real-time Assessments would not only be helpful but ensure that the set of contingencies that meet basic minimum criteria are being evaluated.

Comment	

Just a general comment on the use of the term "owner -provided Facility Ratings -011, FAC-014, and FAC-015. I believe this reference is referring to the FAC-008 Facility Ratings that TOs and GOs are required to determine and make available to various reliability entities. This may or may not be true. If it is true, any ambiguity could be eliminated by changing the reference to "Transmission Owner and Generator Owner provided Facility Ratings determined in accordance with FAC-008."

Please at least address the issue in the response to this comment especially if there is a different owner provided facility rating that these standards are referring to. Thanks.

3. The SDT acknowledges that requirement R6 could alternatively be located within a TOP or IRO standard; however, the Project 2015-09 SAR does not specifically authorize the SDT to modify those standards. The SDT is seeking feedback specific to the content of the requirement not where it should reside. Proposed Requirement R6 was created to correspond with FAC-011-4 Requirement R6 in lieu of creating a definition for SOL Exceedance. Do you agree with Requirement R6?

However, we have the same comment as with Question 1: **Throughout the standard development process for the revisions of the IRO/TOP standards the IESO continued to comment on our serious concern over the proposed retirement of Requirement R4 of TOP-004-2 without having it reinstated in TOP-001-3 or having some of the requirements in TOP-001-3 revised to addressing the reliability need for confirming or reestablishing valid SOLs/IROLs in an unknown or unstudied state.** **We recognize that this issue is not within the scope of this project, but is directly related through the methodology that will be used to determine operating limits for these unknown states. In order to better coordinate the development of standards, we recommend that the scope of future NERC projects should better identify relationships between families of standards at the onset, and encourage potential revisions to related requirements.**

Thomas Foltz - AEP - 5	
Answer	No
Document Name	
Comment	

While AEP supports, in general, the proposed revisions to FAC-011, we believe additional clarity is needed within 6.1.3 to make it clear these obligations are only in reference to known stability limits and do *not* require TOP-provided, dynamic, real-time stability studies. While there are entities that do perform such real-time stability studies, this requirement should not impose that sort of analysis on *all* TOPs. AEP has chosen to vote negative on this revised standard driven by the current lack of clarity in this regard.

The MRO NSRF is not clear if the question is addressing FAC-014-3 R6, but we believe it is. Although we understand the SDT's intent of placing R6 in FAC-014-3, it's inappropriate to place an operating requirement within the FAC family of standards and doing so is contrary to the improvements being made to the NERC Reliability Standards via various forums, including the Standards Efficiency Review project. More importantly, we believe that the existing relevant IRO and TOP standards adequately cover what FAC-014-3 R6 intends to implement. For example, TOP-001-4 requires an RTA to be performed by the Transmission Operator in requirement R13. The Transmission Operator is required to examine both the pre-Contingency and post-Contingency states based on the definition of Real Time Assessment. By creating FAC-011-3 R5 and R6, the SDT has adequately covered what Contingencies need to be evaluated to identify or monitor SOLs as part of RTAs and OPAs. Similarly, we believe the language of IRO-008-2 R1 and R4 as well as TOP-001-4 R10 and TOP-002-4 R1 adequately address the SDT's concern and language of proposed FAC-014-3 R6.

Additional, patient efforts by the SDT to develop a flexible definition of SOL exceedance is a superior approach versus a FAC-011 and FAC-014 performance requirement. The language of IRO-008-2 R1 and R4 as well as TOP-001-4 R10, R13 and R14 and TOP-002-4 R1 would be sufficient and would adequately address the SDT's concerns and industry's needs. MidAmerican shares the MRO NSRF position regarding FAC-014-3 R6 that *"it's inappropriate to place an operating requirement within the FAC family of standards and doing so is contrary to the improvements being made to the NERC Reliability Standards via various forums*". General principles and good utility practice within the industry is to align and coordinate definition of SOL and SOL exceedance/performance criteria between RC and TOP's within the RC's reliability footprint,. Consequently, all arguments presented in answering Questions 1 and 2 would apply and be of a significant concern to the TOPs.

The SPP Standards Review Group (SSRG) supports the previous draft of FAC-011-4 and proposes the definition of SOL Exceedance should be retained. Removal of the SOL Exceedance definition and expanding FAC-011-4 Requirement R6 has resulted in FAC-011-4 becoming convoluted and confusing to interpret. The previous draft of FAC-011-4 in conjunction with the SOL Exceedance definition is less ambiguous and, therefore, produces a more desirable end result.

We acknowledge the drafting team's question regarding the substance of R6 for FAC-014-3. We do not have any specific concerns regarding the language used. While we understand that the drafting team is not soliciting comment on where a requirement should reside, we would be remiss not to comment that this requirement is indeed out of place as proposed. The proposed R6 is a Real-time performance requirement surrounded by other requirements pertaining to methodology, and not the execution of said methodology. We understand that the SAR does not allow for an alternative approach at this time, but believe that this may need to be revisited at a later date.

SAR Scope Issue

The companies believe the proposed revisions to FAC-014-3 R6 are, for all intents and purposes, incorporated into TOP-001 and TOP-002, and, as such, creates a potential conflict with Requirements in TOP-001 and TOP-002.

If that is the case, the proposed FAC-011-3 R6 revisions create a challenge to the SDT by basically requiring revision to TOP-001 and TOP-002 and, as such, the revisions fall outside the scope of the SAR.

Observation: SOL Exceedance Glossary Term

The companies would note, and we are confident the SDT is aware, TOP-001 and TOP-002 could be strengthened by a SOL Exceedance Glossary Term and the proposed R6 revisions do not eliminate the need for a SOL Exceedance Glossary Term.

See comments to question 1. Because the SDT is not authorized to make changes to the TOP or IROs is not sufficient reason to place requirements in standards to which they don't belong. The performance criteria should rightly be debated and crafted in the context of system operations by a SDT with appropriate focus and expertise.

Comment	
However, we have the same comment as with Question 1: Throughout the standard development process for the revisions of the IRO/TOP standards the IESO continued to comment on our serious concern over the proposed retirement of Requirement R4 of TOP-004-2 without having it reinstated in TOP-001-3 or having some of the requirements in TOP-001-3 revised to addressing the reliability need for confirming or reestablishing valid SOLs/IROLs in an unknown or unstudied state. We recognize that this issue is not within the scope of this project, but is directly related through the methodology that will be used to determine operating limits for these unknown states. In order to better coordinate the development of standards, we recommend that the scope of future NERC projects should better identify relationships between families of standards at the onset, and encourage potential revisions to related requirements.

ATC is not clear if the question is addressing FAC-014-3 R6, but we believe it is given that the previous question asked for any further comments on FAC-011-4 and the next question asks for any further comments on FAC-014-3. Although we understand the SDT's intent of placing R6 in FAC-014-3, it is inappropriate to place an operating requirement within the FAC family of standards and doing so is contrary to the improvements being made to the NERC Reliability Standards via various forums, including the Standards Efficiency Review project. More importantly, we believe that the existing relevant IRO and TOP standards adequately cover what FAC-014-3 R6 intends to implement. For example, TOP-001-4 requires an RTA to be performed by the TOP in requirement R13. The TOP is required to examine both the pre-Contingency and post-Contingency states based on the definition of Real Time Assessment. By creating FAC-011-3 R5 and R6, the SDT has adequately covered what Contingencies need to be evaluated to identify or monitor SOLs as part of RTAs and OPAs. Similarly, we believe the language of IRO-008-2 R1 and R4 as well as TOP-001-4 R10 and TOP-002-4 R1 adequately address the SDT's concern and language of proposed FAC-014-3 R6.

The criteria given are not clear as written such that they appear to occur in the Real-time horizon and apply to real-time operations rather than in the Operations Horizon as stated. As a consequence, the criteria do not seem to meet a methodology requirement but an operating one. Specifically, the identification of real-time monitoring and assessment as a demonstration is inappropriate for a FAC methodology requirement and belongs in TOP and IRO standards relating to operations. We believe there should not be an operating requirement in FAC-011 and in our opinion is a poor practice and should be shelved. The Standard "families" set certain expectations and should be respected because to do otherwise will create risks of inconsistency. If the TOP and IRO standards need amending, then amend them!

Without the option of modifying TOP and IRO standards to accommodate a SOL Exceedence definition, it is reasonable to add the performance criteria to FAC-011-4 R6. However, the language in R6 is unclear. While it is clear in 6.1 that we may exceed the Normal Rating without a contingency if we return to Normal within the Emergency Rating time duration, it is not clear in 6.2 that the system response (or anticipated system response) to a single contingency must be within Emergency Ratings. Similarly for 6.3, it is not clear that the criteria is for the system response to the contingency.

IRC Standards Review Committee understands that the current Standards Authorization Request (SAR) doesn't provide the authority to revise the TPL, MOD, etc. standards that have a potential affiliation with FAC-015. Notwithstanding, the SRC recommends that the drafting team consider that FAC-015 data requirements are redundant with other families of standards and, therefore, provide no additional reliability benefit but add additional compliance burden to responsible entities. For example, MOD-32-1 and TPL-001-4 Requirements both require data provisions that overlap with FAC-015.

Since the SDT for this Project recognized that there might be a better placement of the Project Requirements, yet apparently felt that a process to consider addressing Standards other than those in the Project's SAR was not available, NERC should consider a process to allow expediting revised SARs that would enable the SDT to address Standards that were not contemplated in the original SAR, while the Project is ongoing.

The IRC would also like to note that the Standard Efficiency Review Project has made similar observations with respect to consolidation of or better coordination of standards. We would suggest that the SDT work with NERC Staff to follow the approach and principles of the SER team to ensure those efficiencies are realized on this project.

SCE shares the opinion of the MRO NSRF regarding FAC-014-3 R6. Specifically, SCE "agrees with the proposed SOL definition. However, as stated in our (MRO NSRF's) response to question 1, we need additional clarification on the SOL expectation of the SDT." Additionally, SCE believes "it's inappropriate to place an operating requirement within the FAC family of standards and doing so is contrary to the improvements being made to the NERC Reliability Standards via various forums." Finally, SCE believes it is good industry practice to align and coordinate definition of SOL and SOL exceedance/performance criteria between RC and TOP's within the RC's reliability footprint.

Regarding R6: The requirement does not provide sufficient clarity with regard to how SOL methodology is incorporated into RTA and real-time monitoring. For example is the expectation that the methodology be implemented in both RTA and real-time monitoring, or can the real-time monitoring schemes be used to incorporate some aspects of the methodology where the RTA tool lacks capability.

ITC agrees with MRO NSRF that in order to reduce the need for a future Standards Efficiency Review effort, ITC requests the SDT to consider if Requirement R3 is unnecessary and sufficiently covered with the IRO-010-2 Requirements. In accordance with IRO-010-2 R1 the Reliability Coordinator can specify any information it needs to support its Operational Planning Analyses, Real-time monitoring, and Real-time Assessments. The primary purpose of these activities is to identify SOL exceedances. Therefore, it’s essential that the Reliability Coordinator would include in its data specifications SOLs from all Transmission Operators. Once the data specification is sent to the Transmission Operators in accordance with IRO-010-2 R2, the Transmission Operators must provide its SOLs to the Reliability Coordinator to meet the obligations of IRO-010-2 R3. This should remove the need for the proposed FAC-014-3 Requirement R3. If kept, there may be overlapping compliance obligations with two requirements for the same activity.

R5 – This should require providing SOL information to Transmission Planners, not just Planning Coordinators, because there is no requirement for Planning Coordinators to provide this information to Transmission Planners. In addition, in FAC-015-1, Transmission Planners are required to coordinate with the SOLs established by the Reliability Coordinators and Transmission Operators. As such, the Transmission Planners should receive SOL information directly from the Reliability Coordinators and Transmission Operators, rather than second hand information from Planning Coordinators. If the SDT decides to proceed with FAC-015-1 as a standard, FAC-014-3 Part 5.1 and Part 5.2 should be reworded to *“Each Planning Coordinator and each Transmission Planner within . . . “*

Requirement R4:

Similar to our comment on Sub-Requirement 4.3 (FAC-011-4) in Question 2, a main concern is the lack of criteria to define contingencies for the establishment of IROLs. Today, some RCs respect single contingencies, while other respect double contingencies. Given the impact on the Interconnection, it is crucial that criteria for the selection of contingency events is defined and applied consistently in all the RC areas, in order to ensure that all IROLs within a defined scope are detected and properly studied. We recommend that the following wording is added to Requirement R4 to establish SOLs that impact on the Interconnection:

"Each Reliability Coordinator shall establish stability limits to be used in operations when the limit impacts more than one Transmission Operator in its Reliability Coordinator Area or other Reliability Coordinator Areas in accordance with its SOL Methodology."

Sub-Requirement R5.2.5

A description of the associated system conditions is normally included in the RC's methodology as part of Requirement R4.4 in FAC-011-4. The sub-requirement R5.2.5 can be removed as it is redundant with Requirement R4.4 in FAC-011-4.

Comment

MISO believes that the TPL-001-4 covers SOLs and IROLs in the long-term planning horizon. Therefore MISO agrees that the Planning Coordinator should not be the applicable entity that establishes and communicates SOLs and IROLs. The requirement for the RC to provide the PC the SOL and IROLs should reside in FAC-015-1, not FAC-014.

R5 – Share results of Operations assessments with Planning: Operations uses real time assessment to identify operating limits. This information has value for Operations assessment, however the value of identifying and sharing these limits with the Planning Coordinator is anticipated to have minimal value to planning assessments. This is in part due to the variability of the scenarios studied in Operations, and how closely those will align to scenarios studied in the Planning Horizon.

Cowlitz PUD agrees that the establishment of SOLs and IROLs should be consistent for both operational and planning aspects of the BES. Having a single source for SOL Methodology from the Reliability Coordinator, implementation of the SOL Methodology by the Transmission Operator, and requiring the Planning Coordinator and Transmission Planner to coordinate the Planning Assessments with SOLs and IROLs provided by the Reliability Coordinator will improve Reliability. However, Cowlitz PUD cautions that IROLs should be carefully identified such that local isolated limitations remain as SOLs.

The companies suggest FAC-014 would be strengthened if it better aligned or explicitly addressed the following precepts:

The RC is in the best position to establish guidelines or criteria for determining System voltage limit.

The companies recognize each entities' system is unique in design, complexity, footprint, and Facilities, as is the RC's. To address the differences between systems across the BES, the companies suggest BES reliability will be strengthened by considering the uniqueness of these systems and letting the RC set guidelines or criteria for determining System voltage limits.

The TOP is in the best position to determine limits and avoid conflicts with Facility Ratings.

The revised proposed Glossary Term, while establishing boundaries, may create circumstances that add complexity to determining Facility Ratings, System Voltage Limits, and stability limits. Generally, adding complexity to Standards adds opportunity for undesired results in operating the BES.

To simplify the determination of System Voltage Limits and stability limits, the companies suggest that the TOP determine these values to ensure they do not conflict with Facility Ratings.

The SPP Standards Review Group (SSRG) recommends that the drafting team consider IROLs in Phase II of this project. As discussed at the September 2018 Planning Committee (PC) Meeting, although this project includes IROLs, the drafting team's feedback to the PC was to focus on only the SOL for this commenting period (Phase I). During Phase II, the drafting team will put more focus on the IROL. This is a reasonable suggestion given that all relevant materials pertaining to the IROL were approved at that most recent meeting and couldn't be implemented in the Phase I comment period.

The sub-Requirements of R5.2 are a list of specific criteria with the exception of the newly added 5.2.5. Sub-part 5.2.5 is unnecessary and is too general of a statement and could include a variety of system conditions. It is unclear what the SDT is trying to accomplish with 5.2.5. Further in Requirement R6, OPAs and RTAs are listed as acronyms and have not been previously defined in the standard. This issue should also be addressed.

In R6 what is the definition of “performance criteria”? NIPSCO believes that “performance criteria” is used in R3 in the establishment of SOLs. It is not something separate from that process. R3 states that the TOP supplies SOLs to the RC according to the RC’s SOL Methodology. R6 implies that "performance criteria" is in addition to what is used to establish SOLs. NIPSCO believes that "performance criteria specified in the Reliability Coordinator's SOL Methodology" should be replaced with "SOLs established as part of R3".

Dana Klem - MRO - 1,2,3,4,5,6 - MRO, Group Name MRO NSRF

Answer	
Document Name	

Comment

To reduce the need for a future Standards Efficiency Review effort, the MRO NSRF requests the SDT to consider if Requirement R3 is unnecessary and sufficiently covered with the IRO-010-2 Requirements. In accordance with IRO-010-2 R1 the Reliability Coordinator can specify any information it needs to support its Operational Planning Analyses, Real-time monitoring, and Real-time Assessments. The primary purpose of these activities is to identify SOL exceedances. Therefore, it's essential that the Reliability Coordinator would include in its data specifications SOLs from all Transmission Operators. Once the data specification is sent to the Transmission Operators in accordance with IRO-010-2 R2, the Transmission Operators must provide its SOLs to the Reliability Coordinator to meet the obligations of IRO-010-2 R3. This should remove the need for the proposed FAC-014-3 Requirement R3. If kept, there may be overlapping compliance obligations with two requirements for the same activity.

If the SDT decides to proceed with FAC-015-1; then R1, R2, and R3 obligate each Planning Coordinator and each Transmission Planner to use Facility Ratings that are equally limiting or more limiting than those used by the Reliability Coordinator in its Operations Planning Horizon SOLs. Therefore, FAC-014-3 Part 5.1 and Part 5.2 should be reworded to *"Each Planning Coordinator and each Transmission Planner within . . . "*

R5 – should require providing SOL information to Transmission Planners, not just Planning Coordinators, and not rely on Planning Coordinators to provide them to applicable Transmission Planners, especially since there is not a requirement for Planning Coordinators to do so. However, in FAC-015-1 Transmission Planners are required to coordinate with the Reliability Coordinators and Transmission Operators SOLs. Our preference is for the Transmission Planners to get the SOL information directly from the Reliability Coordinators and Transmission Operators, rather than second hand information from Planning Coordinators.

Thomas Foltz - AEP - 5

Answer	
Document Name	

Comment

AEP believes much of the proposed changes would be beneficial and provide clarity, but would like to provide feedback on some key areas:

While AEP has no objections to the proposed changes to R6, and while acknowledging that no changes were proposed to R2, we still would like to again express our concern how the lack clarity in FAC-011 R6.1.3 potentially impacts these requirements in FAC-014. Once again, clarity is needed in FAC-011 to make it clear these obligations are only in reference to known stability limits and do *not* require TOP-provided, dynamic, real-time stability studies as part of OPAs, RTAs, and Real-time Monitoring. AEP has chosen to vote negative on this revised standard driven by the current lack of clarity in this regard.

The text “in accordance with” is subjective, and could be interpreted inconsistently across RE footprints as well as within RE footprints. For example, would the language from FAC-015-1 “equally limiting or more limiting than” be considered “in accordance with?”

AEP does not object to R1 as proposed, we believe that Transmission Operators should be afforded opportunity to provide input into the process, even if not specifically designated within the standard.

5. The original posting of FAC-015-1 included six requirements. Industry comments to this original version indicated significant concerns. In response to these concerns, the SDT attempted to streamline and clarify the intended interactions between relevant functional entities and to consolidate the standard into fewer requirements. To achieve this the SDT:

- **Consolidated Requirements R1 – R5 in the original posting into three (R1 – R3) requirements,**
- **Clarified the roles of the Planning Coordinator and Transmission Planner in Requirements R1 – R3, and**
- **Clarified that Facility Ratings are "owner-provided" in Requirement R1.**

The SDT acknowledges that some of the requirements in FAC-015-1 could alternatively be located within other standards such as TPL, MOD, etc.; however, the Project 2015-09 SAR does not currently authorize the SDT to modify those standards. The SDT is seeking feedback specific to the content of the requirement not where it should reside. Do you support the revised FAC-015-1? Please provide any other comments regarding FAC-015-1.

Sandra Shaffer - Berkshire Hathaway - PacifiCorp - 6	
Answer	No
Document Name	
Comment	
FAC-015-1 R4 should more specifically state that each Planning Coordinator and Transmission Planner shall communicate any instability, Cascading or uncontrolled separation identified in either its Operational Planning Analysis or a Transfer Capability assessment in the Operations Horizon to each impacted Reliability Coordinator, Transmission Operator, Transmission Owner and Generation Owner. The current draft wording may be interpreted as requiring the Planning Coordinator and Transmission Planner to coordinate with the Reliability Coordinator for results of 5-year planning assessment, which is not only burdensome to TP/PC but also non-beneficial to the RC where RC focus is on 0-1 year horizon. As an additional comment, any new requirements put on a Near-Term Transmission Planning Horizon assessment or Transfer Capability assessment in the Planning Horizon would more appropriately reside in the respective Standards for those assessments, TPL-001 and MOD-001, not the new FAC-015-1.

Comment	

The MRO NSRF understands the SDT isn't requesting industry input on the location of the requirements. However, to reduce the need for a future Standards Efficiency Review effort, the MRO NSRF requests the SDT to consider if the proposed FAC-015-1 altogether is needed or if its purpose can be fulfilled with existing standards and/or compliance monitoring processes as described below.

The Data Reporting Requirements in Attachment 1 of MOD-032-1 contains a tabular listing of *"information that is required to effectively model the interconnected transmission system for the Near-Term Transmission Planning Horizon and Long-Term Transmission Planning Horizon"*. It's also stated in the paragraph above the table *"A Planning Coordinator may specify additional information that includes specific information required for each item in the table below"*. Item 4c in the table is *ratings (normal and emergency)**. The asterisk refers to a note that states *"(Items marked with an asterisk indicate data that vary with system operating state or conditions. Those items may have different data provided for different modeling scenarios)*. It appears these statements along with Requirement R1 of TPL-001-4 establish a compliance expectation for models to *"represent projected System conditions"*, which should include the most limiting Facility Ratings applicable to the modeling scenario. Additionally, if Planning Coordinators, Transmission Planners, Transmission Operators and Reliability Coordinators are not all using the same set of Facility Ratings provided by the Transmission Owner in accordance with FAC-008 R8, then that inaccuracy can be addressed via compliance monitoring for FAC-014, TPL-001 and various IRO/TOP requirements. During its webinar regarding Project 2015-09, the SDT indicated that it would be a very rare occurrence where a Reliability Coordinator would have a more limiting rating than those already provided by Transmission Owners and available to Planning Coordinators and Transmission Planners. Therefore, where is the reliability gap that necessitates creation of Requirement R1 in FAC-015-1?

In a similar manner, if the compliance expectation in Requirements R5 and R6 of TPL-001-4 is for the Transmission Planner and Planning Coordinator to demonstrate a technically sound rationale for voltage and stability criteria applicable to the modeling scenario, then where is the reliability gap that necessitates creation of Requirements R2 and R3 in FAC-015-1?

To ensure relevant entities are considering the information described in FAC-015-1 Requirement R4, it could be added as sub-requirement in FAC-011-4 Requirement R4. To ensure those entities can get the information, it could be requested from the Planning Coordinator and Transmission Planner in accordance with TPL-001-4 Requirement R8. Therefore, is there a need for Requirement R4 in FAC-015-1?

Another consideration in lieu of the new FAC-015-1 standard is to develop compliance guidance, which can improve the industry's understanding of the importance and value in a consistent approach to aligning planning and operational limits.

However, If the SDT decides to proceed with FAC-015, then the MRO NSRF provides the following suggestions for improvement.

Since the FAC-015-1 R1, R2, and R3 obligate each Planning Coordinator and each Transmission Planner to develop SOLs that are equally limiting or more limiting than the Operations Planning Horizon SOLs, then FAC-014-3 Part 5.1 and Part 5.2 should be reworded to *"Each Planning Coordinator and each Transmission Planner within . . . "*

The FAC-015-1 title does not match its stated purpose. We suggest "Coordination of System Planning Criteria and Methodologies with Reliability Coordinator SOL Methodology. The stated purpose of FAC-015-1 is to ensure that Facility Ratings, voltage limits, and stability criteria are coordinated with the Reliability Coordinator's SOL methodology, but R4 is calls for providing selected Planning Assessment and Transfer Capability assessment results to Reliability Coordinators and Transmission Operators. We agree with obligating Planning Coordinators and Transmission Planners to communicate selected assessment results information with Reliability Coordinators and Transmission Operators, but propose that the obligations be added to the respective FAC-013 and TPL-001 standards, not FAC-015-1.

We believe that purpose of FAC-015 would be better fulfilled if it required Planning Coordinators and Transmission Planners to provide their planning horizon Facility Ratings, voltage limits, stability criteria, and methodologies (i.e. TPL-001-4 R5 and R6) to their applicable Reliability Coordinators. This would allow Reliability Coordinators to know what criteria and methodologies Planning Coordinators and Transmission Planners are using in Planning Assessments and better understand how their SOL Methodology might be adjusted to achieve better coordination with the planning horizon criteria and methodologies.

R1, R2, and R3 – We are skeptical that requiring Planning Coordinator and Transmission Planner system planning criteria and methodologies to be equally limiting or more limiting than Facility Ratings, voltage limits, and stability criteria derived from the Reliability Coordinator SOL methodologies is an appropriate coordination strategy.

R4 – The requirement calls for the communication of CEII information from Planning Assessments and Transfer Capability assessment to impacted Transmission Owners and Generator Owners. This obligation should not be included until it is verified that compliance with the FERC Standards of Conduct can be guaranteed.

Consider the following ideas for sub-parts of a requirement to communicate selected Planning Assessment and Transfer Capability assessment results.

R4.1 – The MRO NSRF agrees with including the type of identified instability but suggest revising the list of examples to match those listed in FAC-011-4 Part 4.1 *". . . (e.g. steady state voltage instability, transient overvoltage or undervoltage instability, unacceptable tie-line phase angle instability, generating unit loss of synchronism, unacceptable generating unit phase angle damping).* Steady state voltage instability criteria can be a percentage of margin from the expected voltage collapse point in a P-V analysis. The term *"voltage collapse"* incorrectly implies that all Planning Coordinators and Transmission Planners choose the voltage collapse point in a P-V analysis as their voltage stability limit. FAC-011-4 changed *"angular stability"* to *"unit stability"*. *"Transient voltage dip criteria violation"* is not a type of instability. If *"transient voltage dip criteria"* is to be retained, then it should be included in R4.2, as an example of an *"associated stability criteria"* for voltage instability. *"Angular instability"* is a very broad type of instability. Consider providing the Planning Coordinator and Transmission Planner with more understanding of what types of specific angular instability by mentioning some specific sub-elements of the category like those suggested above.

R4.2 – Consider adding some stability criteria examples for the benefit of Planning Coordinators and Transmission Planners, such as steady state P-V curve criteria, steady state high and low voltage protective relay trip levels, transient voltage dip criteria, transient overvoltage spike criteria, transient high and low voltage protective relay trip levels, generating unit loss of synchronism criteria, generating unit phase angle damping criteria.

R4.3 – The MRO NSRF requests the SDT consider the following suggestions for clarification:

1.

   - Asociated Contingencies and Facilities are two different items and should be two separate sub-sections.

   - The Contingencies used in Planning Assessments and Transfer Capability assessments include contingencies beyond the Contingencies used in Operational Planning Analysis.

   - *"Facilities critical to . . ."* does not have a clear meaning and uses the 'loaded' wording of *"critical to"*. Consider wording like, *"The Elements that exceed the system performance criteria"*.

   R4.4 – No suggested wording change. However after Planning Coordinators and Transmission Planners describe the studied System conditions, it should explained that the System conditions, which will be used for Operational Planning Analysis, may be considerably different from the studies System conditions (e.g. different known outages, different load forecasts, interchange with economic transfers, different generation resource dispatches), so the reliability impacts identified in the Operations Planning Horizon may be very different from those based on the Near-Term Planning Horizon System conditions.

   R4.5 – The automatic controls and expected system operator actions that are expected to address potential instability, Cascading, or uncontrolled separation in the Operations Planning Horizon should be split into two sub-bullets or be split into two separate sub-sections.

   - A sub-section for automatic control actions could say, "Automatic controls expected to address potential instability, Cascading, or uncontrolled separation available in the Operations Planning Horizon, such as Remedial Action Schemes (RASs), undervoltage load shedding (UVLS), underfrequency load shedding (UFLS).

- A sub-section for system operator actions could say, “Operating Procedures expected to address potential instability, Cascading, or uncontrolled.

R4.6 – We suggest that the wording be modified slightly to something like “Any Corrective Action Plans intended to mitigate or reduce identified instability, Cascading or uncontrolled separation.

LES recommends the following changes to the bulleted list in FAC-015-1 R1.

- Bullet #1: Recommend removing the first bullet since it is not an exception to the RC’s SOL Methodology.
- Bullet #2: Recommend revising the second bullet as follows to be more general and not associated with variations in ambient temperature assumptions only: “Facility Ratings differences are due to variations in **seasonal assumptions such as in** ambient temperature assumptions”.

Additionally, the reference to “Near-Term Transmission Planning Horizon” in R1-R3 should only refer to the Planning Assessment with the Near-Term removed. For example, in R1 the required PC/TP process would likely not specify different Facility Ratings between the Near-Term versus Long-Term planning horizons. Use of the phrase “Near-Term Transmission Planning Horizon” in R4 seems appropriate.

The use of the undefined term 'instability' in R4.4 could lead to inconsistent results and result in additional compliance burdens that add little to no reliability benefit. As used in FAC-011 R6, instability is not limited to the BES or wide area but instead, as currently worded, applies to ANY instability that has ANY impact to any element or facility. R4.4 should be limited to the interconnection or at the very least the wide-area to prevent misunderstanding.

MEC supports the MRO NSRF recommendation to SDT "to consider if the proposed FAC-015-0 altogether is needed". The general feeling within numerous industry's entities is that there is a risk of "over-regulation" as numerous additional requirements within various families of NERC Standards attempt to regulate aspects of the industry in a "micro-managing" manner. That leads to duplication and difficulties regarding interpretation of requirements.

FAC-015-1 R4.1 should be limited to TPL-001-4 P1-P7 events. Regarding FAC-015-1 R4.5, TPL-001-4 requires that studies are run with RAS, and if no instability is found, then no additional stability studies are run to determine if RAS was needed to maintain the stability. Also, when a RAS is established, the reason for establishing the RAS (i.e., to address instability or thermal problems) is known. FAC-015-1 R4.5 as written would require additional studies in order to determine whether the RAS is needed to maintain stability, and there is no justification for this additional work because the information would not provide any value. Further, TPL-001-4 P1-P7 events do not permit the use of Under Voltage Load Shedding and Under Frequency Load Shedding to address instability, cascading, or uncontrolled separation, which is referenced in FAC-015-1 R4.5. For this reason, AZPS recommends that those actions not be included in FAC-015-1 R4.5.

Each requirement of FAC-015-1 appears to already be included in existing standards, or should be incorporated into existing standards as opposed to creating a new standard. The content of FAC-015-1 R1 should be included in MOD-032. The content of FAC-015-1 R2 and R3 should be included in TPL-001. The Planning Assessment requirements referenced in FAC-015-1 R4 should be incorporated into TPL-001-4, and the Transfer Capability Assessment requirements referenced in FAC-015-1 R4 should be incorporated into FAC-013-3 R5. AZPS urges a change in SAR scope or a new SAR to review all of the affiliated requirements and determine whether there is overlap or potential concern with creating a new standard.

The SPP Standards Review Group (SSRG) understands that the current Standards Authorization Request (SAR) doesn't provide the authority to revise the TPL, MOD, etc. standards that have a potential affiliation with FAC-015. Notwithstanding, the SSRG recommends that the drafting team consider that FAC-015 data requirements are redundant with other families of standards and, therefore, provide no additional reliability benefit but add additional compliance risk to responsible entities. For example, MOD-32-1 and TPL-001-4 Requirements both require data provisions that overlap with FAC-015.

Additionally, the SSRG recommends coordinated efforts with the Standards Efficiency Review (SER) Team to see if those particular standards can be modified in the Phase II of the SER without having to revise the current SAR. The SSRG understands that Phase II of the SER is dedicated to Requirements that could be combined and/or modified. From our perspective, this coordinated effort will provide value and efficiencies to both projects by identifying and removing redundancy issues.

Finally, the SSRG, while recognizing the IROL is not a part of the current comment period, suggests that during Phase II of the project the drafting team re-evaluate the use of references to Planning Assessments of the Near -Term T instability, Cascading, or uncontrolled separation." The SSRG is concerned that the drafting team may have inadvertently omitted how this reference includes TPL-001-4 Table 1 Extreme Events, as well as Planning Events. The SSRG recommends that the drafting team either clarify that the proposed replacement language for IROLs in associated Reliability Standards, as well as FAC-015-1, is only referring to TPL-001-4 Table 1 Planning Events, or, explicitly direct the planning entities to document those Extreme Events that cause instances of instability, Cascading, or uncontrolled separation if they are not specifically identified in Planning Assessments.

Comment

Duke Energy is unclear on the expectations listed in the sub-bullets for R1. Can a PC or TP use a less limiting Facility Rating with the justification of one of the sub-bullets, or do all sub-bullets need to be satisfied in order to use a less limiting Facility Rating? The use of the word “or” in the 3rd bullet adds tp the confusion. If the intent is that only one sub-bullet must be satisfied, we suggest the following:

“The process may allow the use of less limiting Facility Ratings due to one of the following:”

Also, the second sub-bullet is not clear on where the ambient temperature assumptions are coming from. Would this be referencing a difference between Planning and Operations?

Requirement 1

The intent of Requirement 1 stated in the Rationale for FAC-015-1 “is not to change, limit, or modify Facility Ratings determined by the equipment owner per FAC-008. The intent is to utilize those owner-provided Facility Ratings such that the System is planned to support the reliable operation of that System.” Requiring the Planning Coordinator to change ratings to what is provided to the Reliability Coordinator is contrary to established NERC criteria.

The requirement as written would require planning to use different ratings than what is provided for the purposes of planning under MOD-032-1 and FAC-008-3 which is contrary to the stated purpose of the standard. As the Transmission Owners are already obligated to provide planning and operating ratings under FAC-008-3 and MOD-032-1, the burden of establishing a technical justification for potentially different ratings used in planning and operations should be placed upon Functional Entities who own facilities (such as Transmission or Generation).

Requirement 2

The rationale provided for Requirement #2 has strong ties to NERC TPL-001. The intent of this requirement is to try and ensure that Planning is fulfilling its role to determine potential reliability deficiencies of the future planned system and to develop Corrective Action Plans to resolve the reliability concerns. This requirement is viewed as a supplement of TPL-001-4 R5.

The voltage requirements stated in TPL-001-4 R5 essentially state that Planning TPL assessments need to have criteria (and document that criteria) for:

- Acceptable system steady state voltage limits
- Post-contingency voltage deviations
- Transient voltage response

o For this criteria at minimum the criteria need to specific a low voltage level and maximum length of time that the transient voltages may remain below that level.

The idea to implement R2 would be to state our requirements as exactly what is put forward in the RC SOL methodology. In reviewing the criteria for the RC SOL methodology, the above criteria for the TPL standard are all achieved with the exception of post-contingency voltage deviation.

Our recommendation would be that FAC-011-4 R4 list include criteria for post-contingency voltage deviation.

Requirement 3

While the rationale provided for Requirement #3 attempts to have ties to NERC TPL-001, no specific requirement of the TPL standard is identified (like there is in FAC-015-1 R2's rationale).

Requirement 4

The rationale for R4 does not provide justification for the inclusion of Transfer Capability Assessments to be included in this requirement. NERC should clarify as to how referencing to FAC-013 plays a role in the requested communication in FAC-015 R4. Further, if the Transfer Capability Assessment respects known SOLS (R1.2) there would be no reporting in FAC-015 regarding Transfers. Further FAC-015 R4.6 requires discussion of corrective action plans which are not required as part of the Assessment of Transfer Capability.

It seems that their argument for rationalizing this standard is circular to existing standards. For example, the rationale states, "the details required by Requirement R4 will supplement the severe system conditions identified in Requirements R4 Parts 4.4 and 45 of the TPL-001-4". The TPL standard requires that entities evaluate the events that may produce the more severe system impacts. It is unclear about how reporting this information per the FAC-015 standard will improve the TPL assessments. It is also unclear how this information in the near-term planning horizon will benefit the entities to which this information is provided. Instead, when violations are observed in the Planning Horizon, corrective Action Plans should be developed which

resolve the violation.

While we appreciate the constraints the SAR places on the SDT, FMPA cannot support FAC-015-1. FMPA still questions if R1-R3 of the proposed FAC-015-1 is even necessary. From the previous comment period: “We question what the value of R1-R3 is and if the requirements are even needed. R1-R3 are really dealing with TPL-001-4 and there shouldn’t be three additional requirements in FAC-015-1 to deal with the uncommon occurrence of a PC using less limiting Facility Ratings, System steady-state voltage limits, or stability performance criteria. It certainly shouldn’t require a technical justification, it should only require coordination”

Comment	

The FAC-015-1 title does not match its stated purpose. We suggest “Coordination of System Planning Criteria and Methodologies with Reliability Coordinator SOL Methodology.

The stated purpose of FAC-015-1 is to ensure that Facility Ratings, voltage limits, and stability criteria are coordinated with RC SOL Methodology, but R4 is calls for providing selected Planning Assessment and Transfer Capability assessment results to RCs and TOPs. We agree with obligating PCs and TPs to communicate selected assessment results information with RCs and TOPs, but propose that the obligations be added to the respective FAC-013 and TPL-001 standards, not FAC-015-1.

We believe that purpose of FAC-015 would be better fulfilled if it required PCs and TPs to provide their planning horizon Facility Ratings, voltage limits, stability criteria, and methodologies (i.e. TPL-001-4 R5 and R6) to their applicable RCs. This would allow RCs to know what criteria and methodologies PCs and TPs are using in Planning Assessments and better understand how their SOL Methodology might be adjusted to achieve better coordination with the planning horizon criteria and methodologies.

R1, R2, and R3 – We are skeptical that requiring PC and TP system planning criteria and methodologies to be equally limiting or more limiting than Facility Ratings, voltage limits, and stability criteria derived from RC SOL Methodologies is an appropriate coordination strategy.

In addition, for R2 and R3, note that edits are needed to these requirements if they will be retained. Specifically, the "stability performance" and "System steady-state voltage" language in each of the sub-bullets of R2 and R3 are reversed (i.e. "stability performance" should appear in R3 and "System stead-state voltage" should appear in R2).

R4 – The requirement calls for the communication of CEII information from Planning Assessments and Transfer Capability assessment to impacted Transmission Owners and Generator Owners. This obligation should not be included until it is verified that compliance with the FERC Standards of Conduct can be guaranteed.

Consider the following ideas for sub-parts of a requirement to communicate selected Planning Assessment and Transfer Capability assessment results.

4.1 We agree with including the type of identified instability but suggest revising the list of examples to match those listed in FAC-011-4 Part 4.1 “. . . (e.g. steady state voltage instability, transient voltage response instability, unit instability, System damping). Steady state voltage instability criteria can be a percentage of margin from the expected voltage collapse point in a P-V analysis. The term “voltage collapse” incorrectly implies that all PCs and TPs choose the voltage collapse point in a P-V analysis as their voltage stability limit. FAC-011-4 changed “angular stability” to “unit stability”. “Transient voltage dip criteria violation” is not a type of instability, but rather a reference to a type of criteria, which should be cited in Part 4.2.

4.2 Consider adding some stability criteria examples for the benefit of PCs and TPS, such as steady state P-V curve criteria, steady state high and low voltage protective relay trip levels, transient voltage dip criteria, transient overvoltage spike criteria, transient high and low voltage protective relay trip levels, generating unit loss of synchronism criteria, generating unit phase angle damping criteria.

4.3 Consider the following suggestions:

- Associated Contingencies and Associated Facilities are two different items and should be split into two separate sub-sections.

- The Contingencies used in Planning Assessments and Transfer Capability assessments include contingencies beyond the Contingencies used in Operational Planning Analysis.

- “Facilities critical to . . .” does not have a clear meaning and uses the ‘loaded’ wording of “critical to”. Consider wording like, “The Elements that exceed the system performance criteria”.

4.4 No suggested wording change. However after PCs and TPs describe the studied System conditions, it should explained that the System conditions, which will be used for Operational Planning Analysis, may be considerably different from the studies System conditions (e.g. different known outages, different load forecasts, interchange with economic transfers, different generation resource dispatches), so the reliability impacts identified in the

Operations Planning Horizon may be very different from those based on the Near-Term Planning Horizon System conditions.

4.5 The automatic controls and expected system operator actions that are expected to address potential instability, Cascading, or uncontrolled separation in the Operations Planning Horizon should be split into two sub-bullets or be split into two separate sub-sections.

- A sub-section for automatic control actions could say, “Automatic controls expected to address potential instability, Cascading, or uncontrolled separation available in the Operations Planning Horizon, such as Remedial Action Schemes (RASs), undervoltage load shedding (UVLS), underfrequency load shedding (UFLS).

- A sub-section for system operator actions could say, “Operating Procedures expected to address potential instability, Cascading, or uncontrolled.

4.6 We suggest that the wording be modified slightly to something like “Any Corrective Action Plans intended to mitigate or reduce identified instability, Cascading or uncontrolled separation.

Comment

We agree that transmission owner-provided Facility (thermal) Ratings should be used in R1 and that the ratings of existing facilities should be coordinated between RC, PC, and TP entities to ensure system model accuracy. Thermal ratings of future facilities planned for the near-term planning horizon would not be coordinated with the RC as these facilities do not exist in the operating horizon.

As proposed, the use of System Voltage Limits described in R2 and stability performance criteria described in R3 would not require coordination between entities, but would be based on the RC methodology and not on local TO planning criteria, which has been filed with FERC and the States. The use of more stringent limits set by the RC would provide the means to unilaterally drive the planning assessment results developed by the PC and TP and could force significant future system expansion above existing planned levels. In our opinion, the language in R2 and R3 needs to be changed to require a more collaborative use of PC and TP existing planning criteria with the RC methodology.

SRP agrees with the clarification of “owner-provided” Facility Ratings and restructuring of the requirements. However, SRP has concerns with the language found in R1, R2 and R3. In each of these requirements, the Transmission Planner or Planning Coordinator may use less limiting criteria, limits or ratings if they provide technical rationale to affected Transmission Planners, Planning Coordinators or Reliability Coordinators. SRP is concerned because there is no requirement for the affected entities to agree with the technical rationale. In addition, technical rationale is not a NERC defined term so SRP is concerned with what will be considered technical rationale and what will not. What happens if there is a disagreement between the Transmission Planner and the affected entity as to the technical rationale that was used?

ITC agrees with MEC and the MRO NSRF recommendations to SDT “to consider if the proposed FAC-015-0 altogether is needed”. The general feeling within numerous industry’s entities is that there is a risk of “over-regulation” as numerous additional requirements within various families of NERC Standards attempt to regulate aspects of the industry in a “micro-managing” manner. That leads to duplication and difficulties regarding interpretation of requirements.

The Data Reporting Requirements in Attachment 1 of MOD-032-1 contains a tabular listing of *“information that is required to effectively model the interconnected transmission system for the Near-Term Transmission Planning Horizon and Long-Term Transmission Planning Horizon”*. It’s also stated in the paragraph above the table *“A Planning Coordinator may specify additional information that includes specific information required for each item in the table below”*. Item 4c in the table is *ratings (normal and emergency)**. The asterisk refers to a note that states *“(Items marked with an asterisk indicate data that vary with system operating state or conditions. Those items may have different data provided for different modeling scenarios)*. It appears these statements along with Requirement R1 of TPL-001-4 establish a compliance expectation for models to *“represent projected System conditions”*, which should include the most limiting Facility Ratings applicable to the modeling scenario. Additionally, if Planning Coordinators, Transmission Planners, Transmission Operators and Reliability Coordinators are not all using the same set of Facility Ratings provided by the Transmission Owner in accordance with FAC-008 R8, then that inaccuracy can be addressed via compliance monitoring for FAC-014, TPL-001 and various IRO/TOP requirements. During its webinar regarding Project 2015-09, the SDT indicated that it would be a very rare occurrence where a Reliability Coordinator would have a more limiting rating than those already provided by Transmission Owners and available to Planning Coordinators and Transmission Planners. Therefore, where is the reliability gap that necessitates creation of Requirement R1 in FAC-015-1?

In a similar manner, if the compliance expectation in Requirements R5 and R6 of TPL-001-4 is for the Transmission Planner and Planning Coordinator to demonstrate a technically sound rationale for voltage and stability criteria applicable to the modeling scenario, then where is the reliability gap that necessitates creation of Requirements R2 and R3 in FAC-015-1?

R1, R2, and R3 – We are skeptical that requiring Planning Coordinators and Transmission Planners system planning criteria and methodologies to be equally limiting or more limiting than Facility Ratings, voltage limits, and stability criteria derived from the Reliability Coordinator SOL methodologies is an appropriate coordination strategy. They also require a documentation burden that may ultimately be eliminated in a later NERC Standards Efficiency Review.

Requirement 4 should not be included in a FAC standard. The TPL standard already provides a provision for anyone with a reliability need to obtain the TPL Assessment. Any of these entities must request the TPL Assessment from the PC or TP and identify the reliability need. They must also demonstrate that they can maintain that the communication of CEII information is not outside the bounds of the FERC Standards of Conduct. R4 provides far too much of an open ended list of information on the transmission system and does not guarantee the required confidentiality.

Finally, ITC, while recognizing the IROL is not a part of the current comment period, suggests that during Phase II of the project the drafting team re-evaluate the use of references to Planning Assessments of the Near Term Transmission Planning Horizon that show results of “instances of instability, Cascading, or uncontrolled separation.” ITC is concerned that the drafting team may have inadvertently omitted how this reference includes TPL-001-4 Table 1 Extreme Events, as well as Planning Events. ITC recommends that the drafting team either clarify that the proposed replacement language for IROLs in associated Reliability Standards, as well as FAC-015-1, is only referring to TPL-001-4 Table 1 Planning Events. If it were to explicitly have the planning entities include and document those Extreme Events that cause instances of instability, Cascading, or uncontrolled separation if they are not specifically identified in Planning Assessments, this list would most likely be extremely long and cause issues for planning entities in their completion of all associated studies.

Texas RE is concerned with the use of a technical rationale to use less limiting Facility Ratings (R1), less limiting System Voltage Limits (R2), and less limited stability performance criteria (R3). There is nothing that states what should go into the technical rationale, who should determine whether or not the technical rational provides a valid reason for not using the most limiting factor, and what shall occur if the technical rationale is not valid. As written, an entity could put any reason whatsoever for not using the most limiting factor and have no consequence if it is not a valid reason.

Texas RE strongly recommends there be some sort of criteria for a technical rationale, it go through an approval process, and, if not approved, it be sent back to the entity who submitted the technical rationale. At the very least, the technical rationale should explain how reliability is or is not impacted.

Texas RE has the following additional comments regarding Requirement R1:

- PCs and TPs should request facility owners to provide ratings based on the ambient temperature assumptions in the Planning Assessments, and for each ambient temperature assumption in the Planning Assessment, the PCs and TPs should not be able to use a rating which is less limiting than the corresponding owner-provided Facility Rating.

- Higher Facility Ratings for a planned upgrade or addition should only be allowed to be utilized in studies the year the upgrade or addition is expected to be in service and for following years. Facility Rating increases that are only proposed as part of a Corrective Action Plan should not be used in the analysis performed to determine if the System meets performance requirements in Table 1 of TPL-001-4, but may be used to address deficiencies identified as part of the analysis.

IRC Standards Review Committee understands that the current Standards Authorization Request (SAR) doesn’t provide the authority to revise the TPL, MOD, etc. standards that have a potential affiliation with FAC-015. Notwithstanding, the SRC recommends that the drafting team consider that FAC-015 data requirements are redundant with other families of standards and, therefore, provide no additional reliability benefit but add additional compliance burden to responsible entities. For example, MOD-32-1 and TPL-001-4 Requirements both require data provisions that overlap with FAC-015.

Since the SDT for this Project recognized that there might be a better placement of the Project Requirements, yet apparently felt that a process to consider addressing Standards other than those in the Project’s SAR was not available, NERC should consider a process to allow expediting revised SARs that would enable the SDT to address Standards that were not contemplated in the original SAR, while the Project is ongoing.

The IRC would also like to note that the Standard Efficiency Review Project has made similar observations with respect to consolidation of or better coordination of standards. We would suggest that the SDT work with NERC Staff to follow the approach and principles of the SER team to ensure those efficiencies are realized on this project.

FAC-015 creates a sort of double jeopardy for the Transmission Planner by placing the requirement of establishing a process on top of the requirements set out in FAC-001, FAC-007, FAC-011, FAC-014, MOD-032 and MOD-033 to establish and communicate the limits and should not be applicable to entities that already have the requirement to produce and use this data in analysis required by other NERC Reliability Requirements such at TPL-001.

The purpose of the FAC-015 standard is to ensure the Facility Ratings, steady-state voltage limits, and stability criteria used in the Planning Assessments are coordinated with the RC’s SOL Methodology. **Requirement R4 in FAC-015-1 requires Transmission Planner to communicate its Stability Assessment results to the impacted Reliability Coordinator, Transmission Operator, Transmission Owner, and Generation Owner. We agree that Transmission Planner should communicate their Stability Assessment results to impacted entities, but we believe that this requirement belongs to TPL-001 standard and should not be a part of FAC-015 standard.**

GTC is in agreement with the SDT's proposed FAC-015-1. The coordination of limits between planning and operations is an improvement over the current construct of having separate SOL methodologies for the planning and operations horizons. GTC is in agreement that some requirements in FAC-015-1 could alternatively be located within other standards such as TPL, MOD, etc. but recognizes the limits of the Project 2015-09 SAR.

We believe it would be acceptable for the PC to use the RC's SOL methodology or develop their own methodology that does not conflict with the RC's approach. Once this standard is approved in final form, FAC-008 should be checked for interoperability and conformity with FAC-015 such that all ratings are covered(i.e., thermal, voltage, stability).

Measures M1, M2 and M3 must be revised to include the Transmission Planner. Also we support NYISO's comment in regards to R1 and the conditions for using less limiting Facility Ratings. We support the first clause ("The Facility has higher Facility Ratings as a result…"). Allowing for less restrictive Facility Ratings because of differences in temperature seems inappropriate. If a different temperature is used by a planner, they should obtain the Facility Rating for that temperature. As for the possibility of submitting technical	

rationales to other entities, the requirement does not require buy-in by the receiving entities. Since the objective of this requirement is to align planning and operations, we respectfully submit that the Facility Ratings should be consistent in planning and operating models. Where there is disagreement, the more conservative value should be retained. This follows the approach in other standards where, in disagreement, the more conservative option is retained (for example, IRO-014).

The same comment applies to R2 and R3 - that is, we consider that the receiving entity, in particular when it is the RC, should be able to enforce the use of the more conservative assumption. However, for those two requirements we note that a "planned upgrade, addition, or Corrective Action Plans" (like in R1) are not explicitly included as reasons to modify the limits. They should be included like in R1.

We reiterate that the most conservative rating, limit should be used. However, we agree that facility upgrades or additions do not need to be referred to the RC for its confirmation.

The VSL for R4, with its concern with the number of missing characteristics, does not make sense. If a PC or TP were to incorrectly communicate an instability - but only incorrect in one characteristic - this would be a lower VSL, but it could, if that error was important, make the communication useless and put the system at risk. The VSL should be severe, unless the error without consequence from an operational point of view. That is, if the RC was able to take correct actions as a consequence, then the error is without consequence. If the RC's actions were incorrect as a consequence of the error, then it should be Severe.

6. Discussions within the SDT indicated concerns with eliminating some of the components of the approved SOL definition. While the industry feedback was largely supportive of the draft SOL definition provided in the informal posting, the SDT modified the proposed definition to incorporate some of the concepts in the approved version. The SDT believes that the revised definition posted for ballot represents an improvement over the definition provided in the informal posting. Reference the SOL rationale document for more information. Do you agree with the proposed SOL definition?

SRP generally agrees with the proposed definition. However, when read separately from the technical rationale, the phrase "specified System configuration" is ambiguous and does not add clarity to the definition. SRP recommends adjusting the proposed definition to more completely explain the relationship between limits and specified System configurations.

While the proposed definition is indeed a vast improvement over the existing, ambiguity is introduced when specifying "facility ratings" if the current definition of IROL (which relies on the definition of SOL) is kept. The singular of facility implies one facility but in practice, IROLs are often established a combination flows not specific to one facility but aggregations of facilities. These IROL MW flow limits may not trigger voltage or stability concerns. The definition should be modified to reflect this concept either by replacing "facility" with "facility(ies)" or by adding a dependent clause such as "facility ratings, either individually or taken in combinations, system voltage…"

NIPSCO believes that the start of the definition should read “SOL is the most limiting of”, as all limits should not be considered a System Operating Limit. We believe only the most limiting of the limits on a facility should be considered a System Operating Limit. If “all” ratings need to be monitored this would present a problem for many software platforms as there is no way to insert more than 3 or 4 ratings into a facility record.

Comment

“Monitoring and assessing” implies the process that is gone through to develop and use an SOL. This definition should focus on what an SOL is, not the process by which SOLs are found or how SOLs are used.

BPA suggested definition:

All Facility Ratings, System Voltage Limits, and stability limits, applicable to specified System configurations, to ensure reliable operation of the Bulk Electric System in both the pre - and post- Contingency operating states.

The MRO NSRF agrees with the proposed SOL definition. However, as stated in our response to question 1, we need additional clarification on the SOL expectation of the SDT. Is it your intent that each Facility has a thermal-based SOL or can a subset (Flowgates) be used to manage power flow on the system? This needs to be clearly stated in a requirement so that everyone is planning and operating the BES from the same understanding. Additionally, it's not clear if Normal Ratings and normal System Voltage Limits are considered SOLs, if you have higher Emergency Ratings or emergency System Voltage Limits for the Facilities. It could be interpreted to say Normal Ratings and normal System Voltage Limits aren't SOLs if you have higher Emergency Ratings and emergency System Voltage Limits. This understanding translates to compliance expectations in the IRO and TOP Standards for exceedances and when you must implement your Operating Plan. If we're relying on the SOL whitepaper to clarify, then some entities may choose not to follow it saying it's not mandatory. Since the SDT may not be able to answer compliance questions, we request NERC staff to draft a CMEP Practice Guide to inform the industry of the compliance expectations for SOLs as applied in the FAC, IRO and TOP standards.

7. With the retirement of FAC-010, and the elimination of Planning-based SOLs and IROLs, do you agree with the changes to CIP-014, FAC-003, FAC-013, PRC-002, PRC-023 and PRC-026?

Ginette Lacasse - Seattle City Light - 1,3,4,5,6 - WECC, Group Name Seattle City Light Ballot Body

Answer	No
Document Name	

Comment

On behalf of our City Light SME: There is confusion about why the terms "SOL" and "IROL" need to be removed from some of these standards. In FAC-003, for example, shouldn't any element identified as part of a currently effective IROL be considered under the applicability section, not just things identified in the Planning Assessment?

Response

Sandra Shaffer - Berkshire Hathaway - PacifiCorp - 6

Answer	No
Document Name	

Comment

FAC-003-5 should be revised to align with the comments to FAC-015-1 in #5 above. Any requirements associated with a Near-Term Planning Assessment should align with the specific requirements in the approved TPL-001 Standard either the Operations Horizon or to a specific requirement within the TPL-001 Standard – R3.5 and R4.2.

Comments specifically for CIP-014-3: Applicability 4.1.1.3 should simply be removed. The proposed wording change causes confusion with the actual CIP-014 assessment, the whole purpose of which is to identify those Transmission substations that if rendered inoperable or damaged as a result of a physical attach could result in instability, Cascading or uncontrolled separation. The new proposed 4.1.1.3 would either create a circular argument or could inadvertently be interpreted to expand the scopes of TPL-001 and MOD-001. Any revisions to the requirements of the assessments in TPL-001 and MOD-001 should be made in those Standards, not through CIP-014.

Comment
While AEP has no objections to the proposed changes to CIP-014, FAC-013, PRC-002, PRC-023 and PRC-026, we do have concerns regarding 4.2.2, Transmission Facilities, within FAC-003. We believe additional text is needed here to ensure no lines are unintentionally excluded by a) the timing of their being identified as part of an IROL and b) the timing of any facilities identified, which could lead to instability, Cascading, or uncontrolled separation within associated planning assessments. AEP recommends that this section be clarified in the following manner… *"Each overhead transmission line operated below 200kV, identified by the Planning Coordinator or Transmission Planner, per its Planning Assessment of the Near-Term Transmission Planning Horizon or its Transfer Capability Assessment (Planning Coordinator only) as a Facility that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation* ***<u>or overhead transmission line operated below 200kV that have been established as part of an IROL by the Reliability Coordinator per IRO-014-3 R1.</u>****"* AEP has chosen to vote negative on the proposed revisions to FAC-003, driven by the concerns expressed in this response.

Comment
FAC-003-5 should have an implementation period once a study identifies a new Facility below 200 kV (Applicability Section) that could lead to instability, Cascading or uncontrolled separation. An entity needs the time to get that new Facility into it's vegetation plan and meet the clearences. The way the **current FAC-003-4 and proposed Standard FAC-003-5** is written an entity is out of compliance once the new studied Facility is identified if it does not meet clearences and the entity would then need to self report. NPPD recommends an implementation period of up to 24 months to allow for the newly identified facility to be incorporated into it's vegetation plan and for clearences to be met. For the other Standards NPPD supports the comments submitted by the MRO NSRF.

Dana Klem - MRO - 1,2,3,4,5,6 - MRO, Group Name MRO NSRF	
Answer	No
Document Name	

Comment	
The MRO NSRF supports the effort of the SDT to eliminate planning-based SOLs and IROLs, but to ensure clarity of expectations the revisions to these standards need to directly map to the applicable TPL-001-4 contingency results that indicate unacceptable instances of instability, Cascading, or uncontrolled separation. As currently proposed, every instance of instability or tripping of multiple elements could be considered in scope for IROLs. Additionally, the SDT should consider that requirements to perform transfer capability studies were determined by the Standards Efficiency Review project to be for commercial purposes and proposed for retirement in the phase 1 SAR. Even though we realize the changes to CIP-002-6 are not in scope for this question and the modifications to the standard were given to the CIP SDT, the 2015-09 SDT is the one who understands the concept of IROLs. Therefore, we would appreciate the SDT passing the following concerns to the CIP SDT. The changes to CIP-002-6 criterion 2.6 and 2.9 do not add clarity. Unfortunately, the proposed changes to criterion 2.9 would bring in most SPS/RAS in the country because these systems are typically designed to avoid instability or a cascading outage scenario. Similarly, the proposed changes to criterion 2.6 substantially expands the scope of analysis. The current CIP-002-5.1 criterion 2.6 language is very clear and narrow because it limits the evaluation to those Facilities that have been shown to impact a large area of the system (i.e. what it means to be an IROL). With the proposed changes, many more Facilities will need to be evaluated for instability, but the end result will still be very few Facilities on the list (and those that make it on the list probably have an SPS/RAS to mitigate the concern). This appears to be an unneeded expansion of the criterion whereas the current language is precise. The SDT should keep in mind that IROLs will still exist under the proposed FAC standard revisions for the operating horizon and, therefore, no change is needed to R2.6 or R2.9. We are not opposed to removing the Planning Coordinator in PRC-002 as an applicable functional entity and having the Reliability Coordinator as the only applicable regional function entity. However, we propose that the Time Horizon of all the Requirements be changed from “Long-term Planning” to “Operations Planning”, to be consistent with the direct and indirect applicability of the Requirements to the Reliability Coordinator.

We agree with changes to reflect the elimination of Planning-based SOLs and IROLs for CIP-014, FAC-003, FAC-013, PRC-002, and PRC-023.

However, we do not agree with the change to the PRC-026 standard. The Planning Coordinator requires the Reliability Coordinator to provide those SOLS that are based on angular stability in order to assess Criteria 1 and 2 of Requirement R1. We suggest revising Requirement R1 to require the Reliability Coordinator provide the Planning Coordinator with those SOLs that are based on angular stability.

BPA recommends that CIP-014, FAC-003, FAC-015, PRC-023 and any other standards that reference "instability, uncontrolled separation, or Cascading" with the intent of replacing the term IROL be modified to include the qualifying phrase "*that adversely impact the reliability of either the interconnection or other Reliability Coordinator Area(s)*." This change aligns with the current NERC definitions for IROL and IROL Tv.

NERC definitions:

Interconnection Reliability Operating Limit (IROL): A System Operating Limit that, if violated, could lead to instability, uncontrolled separation, or Cascading outages *that adversely impact the reliability of the* Bulk Electric System.

Interconnection Reliability Operating Limit Tv (IROL Tv): The maximum time that an Interconnection Reliability Operating Limit can be violated before the risk to the *interconnection or other Reliability Coordinator Area(s)* becomes greater than acceptable. Each Interconnection Reliability Operating Limit's Tv shall be less than or equal to 30 minutes.

BPA believes that the two NERC definitions work in conjunction to define when IROLs should be declared. The IROL definition identifies the BES, while the IROL Tv definition identifies an IROL Tv is used to protect the interconnection as a whole or other RC areas.

Comment	

Replacement of IROLs with vague unbounded terminology of “instability, uncontrolled separation, and cascading" isn't appropriate and is inferior to the current IROL approach. If IROLs aren't maintained, at a minimum, instability should be quantified with terms such as wide-area or a MW threshold such as the loss of 1,000 MW. The benefit of IROLs is the understanding of an impact threshold clearly understood and outlined in current IROL methodologies.

Vague terminology in zero defect standards results in unnecessary violations, interpretations, and compliance guidance.

Comment	

CenterPoint Energy supports the elimination of Planning-based SOLs and IROLs; however, CenterPoint Energy does not agree with the changes to the standards listed above. By not incorporating language such as "that adversely impact the reliability of the BES" or some equivalent limiting phrasing into the proposed language used to replace IROL in these standards, the SDT may have expanded the scope of the applicability or requirement. Not all instances of instability rise to the level of adversely impacting the reliability of the BES, and these should not be considered in scope for the standards above.

Comment	

The proposed responsibility shift in Requirement R5 from Responsible Entity (Planning Coordinator, where presently applicable) to Reliability Coordinator is outside of the scope of Project 2015-09 set forth by the SAR and does not align with the Long-term Planning Time Horizon of PRC-002, as the RC is responsible for real-time operating reliability of its area.

Additionally, Santee Cooper has concerns over shifting the responsibilities of Requirement R5 from the Responsibility Entity (Planning Coordinator) to the Reliability Coordinator at this stage in the existing PRC-002-2 implementation plan.

- The initial implementation deadline for Requirement R5 has past. Capital expenditure decisions have already been made based on the initial identification by the Responsible Entity of BES Elements for which DDR data is required per the prescriptive requirements of the standard.
- Changing the evaluator and spreading the minimum DDR coverage requirement over the Reliability Coordinator's historical simultaneous peak

System Demand vs. the Responsible Entity could potentially change the results of the evaluation, and could potentially require additional equipment from an entity that is unbudgeted at this point.

Furthermore, there is a gap in the Implementation Plan for Project 2015-09 with regard to PRC-002-3.

- In the elements listed that shall remain applicable to the Implementation of PRC-002-3 R2, R3, R4, R6, R7, R8, R9, R10, R11, the Implementation Plan for Project 2015-09 does not address compliance requirements for a re-evaluated list from Requirement R1 or R5. The original PRC-002-2 gives entities three (3) years to be 100 percent compliant with a re-evaluated list from R1 or R5, allowing entities time to budget, design and commission any additional equipment that may be needed to comply. This omission creates a gap in the Implementation Plan, as R1 and R5 include mandatory re-evaluation at least once every five (5) years.

Multiple references to PRC-002-2 within the text of the draft standard have not been redlined, and should be replaced with PRC-002-3.

Multiple references to PRC-023-4 within the text of the draft standard have not been redlined, and should be replaced with PRC-023-5.

Multiple references to PRC-026-1 within the text of the draft standard have not been redlined, and should be replaced with PRC-026-2.

With the elimination of Planning –based SOLs and IROLs, the Standards drafting team has attempted to come up with alternate means of identification of facilities to fill the void, such as under Applicability Criterion 4.1.1.3 in CIP-014-3. The concern is that the use of terms like “instances of instability,” “Cascading,” and “uncontrolled separation” in place of IROL definition, is very vaguely defined in existing NERC standards and is highly subjective to individual entity’s interpretation and application methodology. Further, there are no thresholds suggested that can be applied to derive these facilities from Near Term Transmission Planning Assessments. Such a list of facilities could vary considerably even between the Planning Coordinator’s Assessment and the Transmission Planner’s Assessment. Use of such vaguely defined criteria will subject entities to undue burden of evaluating lot more facilities under all of the above standards (CIP-014, FAC-003, FAC-013, PRC-002, PRC-023 and PRC-026) with increased risk of additional cost to be incurred. Suggest the standard drafting team come up with more specific methodology in place of IROL or delete this Criterion in CIP-014-3 and other applicable standards.

AZPS requests clarification on what contingencies are included in:

- “Facilities that if lost or degraded” in CIP-014 and FAC-003;
- “Planning Assessments that identify instances of instability, Cascading, or uncontrolled separation” in B2 of Attachment B in PRC-023; and
- “Elements associated with angular instability identified in Planning Assessments.”

AZPS suggests the following changes to FAC-013-3:

- Remove R3
- Remove “Reserved for future use” in R1.2 and update numbering accordingly

Additionally, Planning Assessments, completed through TPL-001-4, include multiple categories of contingencies (P0-P7) and Extreme Events as detailed in Table 1 of TPL-001-4. Extreme Events referenced in TPL-001-4 should be excluded from those addressed through CIP-014, FAC-003, FAC-013, PRC-023 and PRC-026. To fail to do so could result in double-counting of contingencies. Further, to fail to do so could result in local impact contingencies being considered as a result of other contingency evaluations. For example, evaluation of Extreme Events under CIP-014 can bring in low impact substations despite the fact that the instability identified would only have a very small impact that is confined to a local area. Such identified local instability does not and should not result in required hardening under CIP-014. For this reason, only Planning Events from Table 1 of TPL-001-4 should be included. AZPS is further concerned that studies that have previously been completed would need to be restudied in accordance with the new standard in order to satisfy the 12 month timeline in the implementation plan even if the timeline prescribed in the existing requirement has a longer timeframe. For example, CIP-014-2 R1 requires studies every 30 calendar months. AZPS does not support doing an additional study for CIP-014-2 R1 before the 30 month deadline that we will have already created a scheduled for in order to be compliant with the new standard before the 12 month implementation date.

The changes for PRC-002 seems unrelated to the proposed FAC changes.

The proposed changes for CIP-014, PRC-023, and FAC-003 the replacement language is too broad. The Planning Assessment looks at extreme events which have low probability of occurring and for which corrective actions are not required. It doesn’t seem reasonable that extreme events which result in instability, Cascading, or uncontrolled separation are now pulled into scope for CIP-014, PRC-023, and FAC-003 when CAP are not required by the TPL-001.

The proposed change to FAC-013 R1.3 seems unrelated to the proposed FAC change.

Kevin Salsbury - Berkshire Hathaway - NV Energy - 5

Answer	No
Document Name	

Comment

NV Energy believes there is inconsistency with the language used in the CIP-002-6 Draft of the impact of instability, Cascading, or uncontrolled separation. NV Energy would request that the SDT include "Wide Area Impacts" to the language revisions in CIP-014, FAC-003, and PRC-023:

CIP-014 Applicability 4.1.1.3 should read:

4.1.1.3 *Transmission Facilities at a single station or substation location that are identified by the Planning Coordinator or Transmission Planner, per its Planning Assessment of the Near r Only), as Facilities that if lost or degraded are expected to result instances of **Wide Area impacts** such as instability, Cascading, or uncontrolled separation.*

FAC-003-5 Applicability 4.2.2 and 4.3.1.2 should read:

4.2.2. *Each overhead transmission line, operated below 200kV, identified by the Planning Coordinator or Transmission Planner, per its Planning Assessment of the Near ly), as Facilities that if lost or degraded are expected to result in instances of **Wide Area impacts** such as instability, Cascading, or uncontrolled separation.*

4.3.1.2. *Operated below 200kV and are identified by the Planning Coordinator or Transmission Planner, per its Planning Assessment of the Near Transmission Planning Horizon or its Transfer Capability Assessment (Planning Coordinator only), as Facilities that if lost or degraded are expected to result in instances of **Wide Area impacts** such as instability, Cascading, or uncontrolled separation; or …*

PRC-023-5 Attachment B (Criterion 2) should read:

B2. *The circuit is selected by the Planning Coordinator based on Planning Assessments that identify instances of **Wide Area impacts** such as instability, Cascading, or uncontrolled separation.*

Comments: An administrative revision to PRC-023-5 is recommended to carry forward the approved implementation timing language from the PRC-023-3 Implementation Plan and the Errata to the Implementation Plan for the Revised Definition of “Remedial Action Scheme” (which included the PRC-023-4 revision). This non-substantive change to bring the current standard under revision into line with the currently approved version (and implementation notes) is necessary to avoid possible future errata revisions. A suggested revision is to include a footnote for the relevant sections in Section 4.2 Circuits (Sections 4.2.1.2, 4.2.1.3, 4.2.1.5, and 4.2.1.6) as follows:

4.2.1.2 Transmission lines operated at 100 kV to 200 kV selected by the Planning Coordinator in accordance with Requirement R6. *1*

4.2.1.3 Transmission lines operated below 100 kV that are part of the BES and selected by the Planning Coordinator in accordance with Requirement R6.*1*

4.2.1.5 Transformers with low voltage terminals connected at 100 kV to 200 kV selected by the Planning Coordinator in accordance with Requirement R6. *1*

4.2.1.6 Transformers with low voltage terminals connected below 100 kV that are part of the BES and selected by the Planning Coordinator in accordance with Requirement R6. *1*

Footnote 1 suggested language:

1. Circuits identified by the Planning Coordinator in accordance with Requirement R6 shall be compliant the later of the first day of the first calendar quarter 39 months following notification by the Planning Coordinator of a circuit’s inclusion on a list of circuits per application of Attachment B, or the first day of the first calendar year in which any criterion in Attachment B applies, unless the Planning Coordinator removes the circuit from the list before the applicable effective date.

Comment	
For CIP-014, FAC-003, PRC-023, and PRC-026, I think there needs to be a revison to every proposed redline change, that states "per its Planning Assessment of the Near-Term Transmission Planning Horizon or its Transfer Capability Assessment as Facilities that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation." To those proposed change statements, I believe we need to add at the end of each one in all the referenced above Standards, the simple phrase ", or other Study." I believe this is needed because the TPL Assessments or Transfer Capability Assessments in themselves, don't necessarily require the type of extreme contingencies to be studied that would cause instability, Cascading, or uncontrolled separation. Hence to demonstrate the impact of these type of extreme contingencies (such as was done for the CIP-014 analysis), studies other than the Annual TPL Assessment or Transfer Capabilty Assessments might need to be completed.

Comment	
Duke Energy has concerns with the language proposed as a replacement to the IROL language in these standards. The language, *"per its Planning Assessment of the Near -Term) as Facilities that if lost to only Transmission Planning or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation,"* is too broad as written, and appears to bring TPL-001-4 Extreme Events into scope and other single & multiple contingency events well beyond the scope of the original single contingencies specified in R2 of FAC-010/011 and specified in R5.1.1 of the proposed FAC-011-4 to identify SOL's and IROl's. We believe more limiting language is appropriate. CIP-014- Duke Energy feels that the draft language is too broad (see above). FAC-003- As stated above, we have concerns with the appearance of an expansion of scope. This would be in conflict with the original intent of the standard which did not include such events. We believe more limiting language is appropriate. Also, there appears to be inconsistent use of Planning Coordinator or Transmission Planner (as used in the Applicability section), and Categories 1A-4B which references the Planning Coordinator only. Was it the drafting team's intent that only the Planning Coordinator apply to those Categories? PRC-002- Duke Energy does not support the change from Responsible Entity to Reliability Coordinator in R5. This would be a significant departure from current industry practices since the RC does not currently have assess operation in the Long Term Planning Horizon. This would prompt the need for Reliability Coordinators to revise current processes, and include steps to reach out to entities in its RC Area for this information. We fail to see the reliability benefit of transferring historically planning related activities to the Reliability Coordinator. PRC-023- Duke Energy feels that the draft language is too broad (see above). We believe more limiting language is appropriate. PRC-026- Duke Energy feels that the draft language is too broad (see above). We believe more limiting language is appropriate. Also, there appears to be a grammatical error in R1. Consider removing the "a" before "limiting the output of a generator".

Comment

FAC-013-3

The companies recommend keeping FAC-013-3 R1.3 without revision and preserve the words "planning practices."

The proposed R1.3 revisions, replacing "planning practices" with the NERC Glossary term, "Planning Assessments," effectively assigns TPL assessment criteria and requirements to FAC-013. Such an outcome is inconsistent with the FAC-013 purpose to "…reliably transfer energy in the Near-Term Transmission Planning Horizon."

Also, by effectively assigning TPL assessment criteria and requirements to FAC-013, assessments are duplicated and establish similar compliance obligations over multiple Standards.

Furthermore, by having similar compliance obligations over multiple Standards creates a compliance conundrum when either Standards yield a similar issue of noncompliance.

CIP-014 FAC-003 PRC-002 PRC-023 and PRC-026

The companies support the proposed revisions.

The proposed redline changes in CIP-014 and FAC-003 limit the application of facility identification that may result in instances of instability, Cascading or uncontrolled separation to only Planning Coordinator's Planning Assessments of the near-term Planning Horizon and transfer assessments. This proposed change might be read to reduce the potential sources of information / analysis which entities use to today to make such identifications. The FAC-013 and PRC-002 changes are acceptable. With regard to PRC-023, the changes made to Criterion B2 have made it very unclear. The language "is selected by" infers that there is some sort of optional or judgement, but there is no indication of what that should be based on. Additionally, referring to Planning Assessment is too vague. Planning Assessments include consideration of extreme events, but these seem inappropriate for consideration in PRC-023. If the decision is made to keep B2 similar to what has been drafted, please change "Planning Assessments" to "assessments", as this would allow for consideration of any available inputs. Proposed language is shown below. Similarly, for PRC-026, R1 criterion 2 is too restrictive by using the term "Planning Assessments". This should be changed to "technical assessment" as shown below. Also in PRC-026, page numbers should be added to the Guidelines and Technical Basis section.	

PRC-023 Criterion B2 further modification in bold below:

*The circuit is selected **identified** by the Planning Coordinator based on assessments **of P0 – P7 Planning Events** that identify instances of instability, Cascading, or uncontrolled separation.*

Additional revision for PRC-026, R1 criterion 2 in bold below:

*Elements associated with angular instability identified in **technical assessments including but not limited to** Planning Assessments.*

MISO agrees with retiring FAC-010.

With regard to PRC-026_R1, the first sub-bullet appears to either have a grammatical error or it should be revised for clarity. “Generator(s) where an angular stability constraint exists that is addressed by a limiting the output of a generator or RAS…”. Suggestion is to remove the words “…addressed by a…”.

The Standard Drafting Team needs to address whether the proposed redlines in Projects 2016-02 and 2015-09 are meant to clarify existing practices for identifying BES assets, or are intended to modify current approaches, specifically with regard to identifying generation resources under CIP-002. The proposed redline changes in CIP-002 and CIP-014 limit the application of facility identification that may result in instances of instability, Cascading or uncontrolled separation to only Planning Coordinator's Planning Assessments of the near-term Planning Horizon and transfer assessments. This proposed change might be read to reduce the potential sources of information / analysis which entities use to today to make such identifications. Lastly, the Project 2016-02 Standard Drafting Team must coordinate with the Project 2015-09 Standard Drafting Team since these redlines appear not only for modifications to CIP-002 but also to CIP-014, and the requisite and primary technical expertise to understand IROLs is in the Project 2015-09 SDT.

It is our understanding that 'Planning Assessment' in the proposed change from referring to IROLs to "…, per its Planning Assessment of the Near [illegible]	

expected to result in instances of instability, Cascading, or uncontrolled separation" refers to studies performed for the Near -Term T Planning Horizon per NERC Reliability Standard TPL-001-4. The term Planning Assessment is in the NERC 'Glossary of Terms Used in NERC Reliability Standards' defined as "Documented evaluation of future Transmission System performance and Corrective Action Plans to remedy identified deficiencies." To reduce the risk of continued inconsistency, we propose to add "technical analyses such as its" to the text replacing the previous reference to IROLs as well as a minor editorial change to the reference to Transfer Capability assessment in all applicable NERC Reliability Standards listed in Project 2015-09 as well as, if approved, to NERC Reliability Standard CIP-006-2. Hence, we proposed the text replacing the reference to IROLs to read "…, per technical analyses such as its Planning Assessment of the Near -Term Transmission Planning Coordinator's Transfer Capability assessment, as Facilities, that, if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation."

We agree with changes to reflect the elimination of Planning-based SOLs and IROLs for CIP-014, FAC-003, FAC-013, PRC-002, and PRC-023.

However, we do not agree with the change to the PRC-026 standard. The Planning Coordinator requires the Reliability Coordinator to provide those SOLS that are based on angular stability in order to assess Criteria 1 and 2 of Requirement R1. We suggest revising Requirement R1 to require the Reliability Coordinator provide the Planning Coordinator with those SOLs that are based on angular stability.

CIP-014:

The SDT proposed the following language for CIP-014-3 Applicability 4.1.1.3:

Transmission Facilities at a single station or substation location that are identified by the Planning Coordinator or Transmission Planner, per its Planning Assessment of the Near-Term Transmission Planning Horizon or its Transfer Capability Assessment (Planning Coordinator only) as Facilities that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation.

ERCOT proposes that “instability” be changed to “system instability.”

ERCOT believes the use of the term “instability” is too broad and could be interpreted to include localized instability events that do not have a widespread impact. This suggestion is consistent with the concern noted in the NERC Methods for Establishing IROLs Task Force (MEITF) report at p. vii:

Specifically, the PRR acknowledged that the use of the word “instability” in the IROL definition is particularly problematic as this term can be interpreted to include any and every instance of instability that spans the entire spectrum of consequences and severity of impact—ranging from one extreme where instability results in the loss of a single small unit to the other extreme where instability results in widespread outage of a major portion of an RC area or beyond. The PRR contended that localized, contained instances of instability that affect a small amount of load have little to no impact on the reliability of the BES and do not warrant IROL establishment.

The MEITF report defines the term “system instability” as:

The inability of the Bulk Power System,* for a given initial operating condition, to regain a state of operating equilibrium after being subjected to a Disturbance.

*Refers to the remaining portion of the interconnected Bulk Power System, with the exception of the Elements disconnected as a result of the Disturbance.

ERCOT agrees that not all instances of instability warrant IROL establishment. For this reason, and to remain consistent with the MEITF report, ERCOT recommends that the proposed language for CIP-014-3 Applicability 4.1.1.3 be modified to include “system instability” rather than “instability.”

ERCOT notes there are other instances in various Requirements where the use of “system instability” may be more appropriate than “instability.”

FAC-003: None

FAC-013: None

FAC-015:

It appears there may be a copy/paste typo. ERCOT suggests using “steady-state voltage,” instead of “stability.”

PRC-002: None

PRC-023: None

PRC-026:

ERCOT is concerned that the phrase, “Elements associated with angular instability identified in Planning Assessments” in R2, Criteria No. 2 creates ambiguity and an unintended expansion in the scope of PRC-026.

ERCOT suggests deleting the current draft Criteria 1 & 2 and replacing them with the following in order to more closely align with the intent of both PRC-026 and Project 2015-09:

1. Generator(s) where an angular stability constraint exists that is addressed by limiting the output of the generator or by a Remedial Action Scheme (RAS), and those Elements terminating at the Transmission station associated with the generator(s). 2. Elements that are monitored in order to enforce an existing angular stability constraint.

CIP-014-3: Per the CIP-014 Guidance, ITC believes the CIP-014 Applicability 4.1.1.1 to 4.1.1.4 should mirror the CIP-002-5.1a Attachment 1 criterion 2.4-2.7. The proposed changes for CIP-014 Applicability 4.1.1.3 do match the proposed (Project 2016-02 Modifications to CIP Standards) changes for CIP-002-5.1a Attachment 1 criterion 2.6. However, ITC believes any discussion pertaining to CIP-014 Applicability is better suited for “Project 2016-02 Modifications to CIP Standards. In addition, ITC remains concern that the originating changes from FAC Reliability standards diminish the need for a process to ensure the RC/PC/TO entities are including for evaluation facilities and assets to support the intent of the NERC CIP standards. ”

PRC-002-3: Changes made do not affect ITC’s current PRC-002 process.

Pamela Hunter - Southern Company - Southern Company Services, Inc. - 1,3,5,6 - SERC, Group Name Southern Company	
Answer	No
Document Name	

Comment

Regarding 4.1.1.3 in the Functional Entities section of CIP-014-3, Southern believes that the verbiage ***“would adversely affect reliability of the Bulk Electric System”*** should be added to the proposed wording to ensure that the changes are more in line with the current definition of an IROL (see below):

4.1.1.3 Transmission Facilities at a single station or substation location that are identified by the Planning Coordinator or Transmission Planner, per its Planning Assessment of the Near Only) as Facilities that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation ***would adversely affect reliability of the Bulk Electric System***.

Regarding 4.2.2 in the Functional Entities section of FAC-003-5, Southern believes that the verbiage ***“would adversely affect reliability of the Bulk Electric System”*** should be added to the proposed wording to ensure that the changes are more in line with the current definition of an IROL.

4.2.2. Each overhead transmission line operated below 200kV, identified by the Planning Coordinator or Transmission Planner, per its Planning Assessment of the Near-Term Transmission Planning Horizon or its Transfer Capability Assessment (Planning Coordinator only) as a Facility that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation ***would adversely affect reliability of the Bulk Electric System.***

Regarding B2 in the Criteria section of PRC-023-5, Southern believes that the verbiage “***would adversely affect reliability of the Bulk Electric***

System” should be added to the proposed wording to ensure that the changes are more in line with the current definition of an IROL (see below):

B2. The circuit is selected by the Planning Coordinator based on Planning Assessments that identify instances of instability, Cascading, or uncontrolled separation that ***would adversely affect reliability of the Bulk Electric System***.

Regarding PRC-002-3, Southern does not believe that the Responsible Entity (under Functional Entities 4.1) should be changed.

Southern Company’s main concern with the proposed changes is not the substitution of the IROL term with the three outcomes – instability, Cascading, or uncontrolled separation – our main concern is the prescriptive nature of naming Planning Coordinator studies which is beyond existing IROL methodologies, and the use of the unbounded term “instability”. For example, compliance with present TPL-001-4 standard for Planning (P) events (and proposed TPL-001-5) requires that any future instability, Cascading, or uncontrolled separation circumstances to be identified and mitigated as per the Corrective Action Plan. While instability, Cascading, or uncontrolled separation do not have to be mitigated for Extreme Events in TPL-001-4/(future 5), as the name implies, Extreme Events are rare events.

Southern Company, like many other companies, has an IROL methodology that is largely based in RC and PC stability input. This methodology identifies SOLs and any subset of the identified SOLs that should be elevated to IROLs. As such, we suggest that references to specific compliance-based studies such as TPL-001 and FAC-013 be removed and allow the use of in-place proven study methodologies to determine and communicate scenarios that are realistic potential instances of instability, Cascading, or uncontrolled separation. (reference CIP-014, FAC-003, PRC-023 and PRC-026).

Looking at FAC-003-5 as an example:

The application of the text "Facility that if lost or degraded are expected to result in instances of instability Cascading, or uncontrolled separation", while used to identify those lines (under 200 kV) that are applicable to FAC-003-5, appears too discretionary. Is the intent to identify those elements that if lost/degraded and in combination with a contingency is expected to result in instances of ....?

CIP-014:

- The applicability section 4.1.1.3 in CIP-014-3 specifies that if instances of instability, Cascading or uncontrolled separation occurred due to the loss of a facility in the Near-term planning assessment, it would be applicable to the CIP-014 analysis.
- The term "instances of instability" is not clear and needs to be defined clearly to eliminate confusion of what qualifies a facility to be assessed in CIP-014.

FAC-003:

- Violation Severity Levels (Table 1) (pgs. 13-16)
- Since R2 was removed from the table on pg. 14, there is no documentation of the severity levels for lines above 200 kV that are not "identified by the Planning Coordinator, per its Planning Assessment of the Near-Term Transmission Planning Horizon or its Transfer Capability Assessment (Planning Coordinator only) as Facilities that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation"
- FAC-003 1.4 Additional Compliance Information (pg. 10)
  - There appears to be a typo regarding the footnote that is referenced:
    - "Periodic Data Submittal: The applicable Transmission Owner and applicable Generator Owner will submit a quarterly report to its Regional Entity, or the Regional Entity's designee, identifying all Sustained Outages of applicable lines operated within their Rating and all Rated Electrical Operating Conditions as determined by the applicable Transmission Owner or applicable Generator Owner to have been caused by vegetation, except as excluded in footnote 2, and including as a minimum the

following:”

- Should this be changed to “footnote 4”? This typo has been in FAC-003-3 & FAC-003-4 versions.
- This change will ensure we are not required to submit tree related outages that are “beyond our control”.

The modifications to the standards are not consistent.

We note three key differences:

1. In PRC-002-2, the PC function is removed leaving the RC function, whereas in the other standards (e.g. CIP-014-3), the RC function is removed, leaving the PC function. We disagree with this change.

When PRC-002-2 was being developed, the Drafting Team was aware that different Functional Entities across the continent would be the appropriate parties to be responsible for the Standard’s requirements. This was presented to industry in the Request for Comments posted November 1, 2013 through December 16, 2013. The Responsible Entity was defined in Section 4 of the Introduction in PRC-002-2 accordingly. Nothing in section R5 supposes that the SOL are planning SOL; the PC can obtain the relevant SOL for their determination per requirement R5 of FAC-014-3.

2. In the CIP-013 and FAC-003, the Near Term Transmission Planning Horizon of the Planning Assessment is specified, whereas it is not specified in for the two PRC standards. The two PRC standards should use the same approach. In particular, issues in the long-term horizon of the Planning Assessment should not be relevant to the application of the PRC-023 and PRC-026 standards.

3. In PRC-023, the text “that identify instances of instability, Cascading, or uncontrolled separation” is different than the text “Facilities that if lost or

degraded are expected to result in instances of instability, Cascading, or uncontrolled separation" used in the other standards. The use of different text implies differences that are hard to interpret. We support that the same text should be used in these different standards.

Also, we point out a minor typo in PRC-026-2 :

R1 – (…)

Criteria:

1. Generator(s) where an angular stability constraint exists that is addressed by [a] limiting the output of a generator (…)

GTC agrees with the modifications to the standards impacted by the retirement of FAC-010. Further GTC notes the following:

- The removal of the Planning Coordinator as an entity responsible for Requirement 5 in PRC-002 represents a material change to the Applicability section of the standard. GTC agrees with this change and the SDT's rationale that "placing responsibility solely on the Reliability Coordinator adds clarity and consistency for the task of identifying the BES Elements for which dynamic Disturbance recording (DDR) data is Required."
- The proposed modification to FAC-013 is an improvement to this standard.
- The streamlined language in the proposal for FAC-003 is a much needed improvement.
- The other modifications represent an appropriate replacement for the planning SOL/IROLs.

- We believe the proposed language FAC-003, 4.2.2 should be revised for clarity. The proposed R 4.2.2 identifies a line to which the standard is applicable, "Each overhead transmission line operated below 200kV, identified by the Planning Coordinator or Transmission Planner, per its Planning Assessment of the Near-Term Transmission Planning Horizon or its Transfer Capability Assessment (Planning Coordinator only) as a Facility that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation."

Based on recent planning assessments and studies related to transfer capability, the PC would not ever add such facilities. If a loss of a single line (whether or not below 200kV) would result in cascading, that would result in the utility failing to comply with TPL-001. Since a PC would have to be compliant with TPL-001-4, the PC would ensure such a sub-200kV line would never be added to the system, resulting in a null set for such lines, rendering 4.2.2 meaningless.

- We also recommend adding the language: "that adversely impact the reliability of the Bulk Electric system" following references to "uncontrolled separation." This addition would bring the language in alignment with the Glossary of terms definition of IROL.

We agree with the changes as they are applied consistently throughout the standards. However, if the SDT changes the approach as stated in the previous comments, these areas will need to be revisited. In terms of FAC-003-5 and CIP-014-3, there may be an un-intended consequence of potentially pulling in facilities below 200 kV for compliance with both standards. The language is also not consistent in the FAC-003-5 applicability section, and the Sustained Outage categories beginning on page 10. Thank you for the opportunity to comment.

The SPP Standards Review Group (SSRG) recommends that the drafting team consider IROLs in Phase 2 of this Project 2015-09. As discussed at the September 2018 Planning Committee (PC) Meeting, although this project includes IROLs, the drafting team's feedback to the PC was to focus on only the SOL for this commenting period (Phase I). During Phase II, the drafting team will put more focus on the IROL. This is a reasonable suggestion given that all relevant materials pertaining to the IROL were approved at that most recent meeting and couldn't be implemented in the Phase I comment period.

Texas RE appreciates the SDT reviewing the standards to identify those impacted by the retirement of FAC-010. Regarding the Implementation Plan, under General Considerations, it states that for PRC-002-3, PRC-023-4, and PRC-005-3, the elements of the prior implementations plans shall remain applicable and are incorporated herein by reference. Texas RE's understanding is that although the effective date of the new proposed versions of these standards is "the first day of the first calendar quarter that is twelve calendar months after the effective date of the applicable governmental authority's order approving the standards", the prior versions of the implementation plans indicated in the general considerations section remains in place. If this is the case, it may be more clear to list out those exact dates that remain in place for the prior versions of the standards. Texas RE also recommends including a question about the implementation plan on each comment form going forward to encourage stakeholders to review the implementation plans.

There were 68 sets of responses, including comments from approximately 183 different people from approximately 117 companies representing 10 of the Industry Segments as shown in the table on the following pages.

All comments submitted can be reviewed in their original format on the project page.

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process. If you feel there has been an error or omission, you can contact the Vice President of Engineering and Standards, Howard Gugel (via email) or at (404) 446-9693.

Questions

1. Industry response to the draft SOL Exceedance definition indicated numerous significant concerns. Given this response, the SDT concluded that creating a definition of SOL Exceedance which adequately reflects reliable operating principles could create an unnecessary compliance burden if action is not taken to substantially modify the existing TOP and IRO standards. Therefore, the SDT maintained system performance criteria through FAC-011-4 Requirement R6, similar to the approach within the currently effective FAC standards, rather than through an SOL Exceedance definition. Do you agree with the performance criteria in Requirement R6?

2. If you have any other comments regarding FAC-011-4 that you haven't already provided, please provide them here.

3. The SDT acknowledges that requirement R6 could alternatively be located within a TOP or IRO standard; however, the Project 2015-09 SAR does not specifically authorize the SDT to modify those standards. The SDT is seeking feedback specific to the content of the requirement not where it should reside. Proposed Requirement R6 was created to correspond with FAC-011-4 Requirement R6 in lieu of creating a definition for SOL Exceedance. Do you agree with Requirement R6?

4. If you have any other comments regarding FAC-014-3 that you haven't already provided, please provide them here.

5. The original posting of FAC-015-1 included six requirements. Industry comments to this original version indicated significant concerns. In response to these concerns, the SDT attempted to streamline and clarify the intended interactions between relevant functional entities and to consolidate the standard into fewer requirements. To achieve this the SDT:

- Consolidated Requirements R1 – R5 in the original posting into three (R1 – R3) requirements,
- Clarified the roles of the Planning Coordinator and Transmission Planner in Requirements R1 – R3, and
- Clarified that Facility Ratings are "owner-provided" in Requirement R1.

The SDT acknowledges that some of the requirements in FAC-015-1 could alternatively be located within other standards such as TPL, MOD, etc.; however, the Project 2015-09 SAR does not currently authorize the SDT to modify those standards. The SDT is seeking feedback specific to the content of the requirement not where it should reside. Do you support the revised FAC-015-1? Please provide any other comments regarding FAC-015-1.

6. Discussions within the SDT indicated concerns with eliminating some of the components of the approved SOL definition. While the industry feedback was largely supportive of the draft SOL definition provided in the informal posting, the SDT modified the proposed definition to incorporate some of the concepts in the approved version. The SDT believes that the revised definition posted for ballot represents an improvement over the definition provided in the informal posting. Reference the SOL rationale document for more information. Do you agree with the proposed SOL definition?

7. With the retirement of FAC-010, and the elimination of Planning-based SOLs and IROLs, do you agree with the changes to CIP-014, FAC-003, FAC-013, PRC-002, PRC-023 and PRC-026?

The Industry Segments are:

1 — Transmission Owners
2 — RTOs, ISOs
3 — Load-serving Entities
4 — Transmission-dependent Utilities
5 — Electric Generators
6 — Electricity Brokers, Aggregators, and Marketers
7 — Large Electricity End Users
8 — Small Electricity End Users
9 — Federal, State, Provincial Regulatory or other Government Entities
10 — Regional Reliability Organizations, Regional Entities

1. Industry response to the draft SOL Exceedance definition indicated numerous significant concerns. Given this response, the SDT concluded that creating a definition of SOL Exceedance which adequately reflects reliable operating principles could create an unnecessary compliance burden if action is not taken to substantially modify the existing TOP and IRO standards. Therefore, the SDT maintained system performance criteria through FAC-011-4 Requirement R6, similar to the approach within the currently effective FAC standards, rather than through an SOL Exceedance definition. Do you agree with the performance criteria in Requirement R6?

Laura Nelson - IDACORP - Idaho Power Company - 1	
Answer	No
Document Name	
Comment	
Requirement R6.3 does not address SOL violations, but only checks against instability, cascading, or uncontrolled separation, even though this criteria is being used to evaluate performance on additional single or multiple contingency events (R5.2) for use in OPA and Real-time assessments. This suggests that SOL violations would be allowed for these contingencies.

Response	
The SDT appreciates your comments. Requirement R6.2.3 is applicable to stability SOL exceedances, not R6.3. Requirement R6.3 uses portions of the definition for IROL such that those contingencies which should be monitored / studied to prevent IROLs have a set criteria against which they should be measured.	
Sandra Shaffer - Berkshire Hathaway - PacifiCorp - 6	
Answer	No

Comment	

The language presented in the R6 is unclear and can lead to different interpretations. The language in R6 needs further clarification.

The drafting team needs to clarify that both actual pre-Contingency state and anticipated pre-Contingency state referred in R6.1 are referring to a TPL equivalent of P0 (system normal) state of the transmission system.

The drafting team should consider rephrasing the language in R6.2.1. Drafting team proposing not to allow usage of Emergency Ratings for contingency events irrespective of presence of operating plan is in complete variation of the planning standard requirements that allows usage of emergency ratings for contingencies described in R5.1.1.

The real time pre-Contingency state could be much different than the anticipated pre-Contingency state and the operating plan proposed for the anticipated pre-Contingency state may not be adequate during the real time pre-Contingency state. Under these conditions, not allowing the operators to use the Emergency ratings is very much disadvantageous and opposite to the intent of PRC-023 where the operator should be allowed to have flexibility to operate the system under Contingency conditions.

PacifiCorp recommends rephrasing 6.2.1 requirement as below

“Flow through Facilities are within applicable Emergency Ratings. Flow through a Facility must not be above the Facility’s highest available Rating, following an N-1 contingency.”

Response

The SDT appreciates your comments. The drafting team did not include references to the P0 state in standard TPL-001-4 due to the fact that in operations, the system is commonly not in an "all facilities in-service state" and, hence, not necessarily in the defined P0 state defined in Table 1 of TPL-001-4. Instead, the SDT sought on language general language that would work for pre and post-contingent states. The SDT has revised the language to refer to the pre-contingent state as one with "no Contingencies" and the post-contingent state by evaluating performance for single Contingencies defined in FAC-011-4.

The SDT made some language revisions in requirement R6.2.1, resulting in the following remaining language:

> "Steady state post-Contingency flow through Facilities within applicable Emergency Ratings. Steady state post-Contingency flow through a Facility must not be above the Facility's highest Emergency Rating."

The SDT left the first sentence so that time constraints in any thermal limits had to be respected (for example, a 4 hour rating could not be used for more than 4 hours), and retained the sentence you noted with regard to the highest rating use. We believe these edits largely capture your concern.

Dana Klem - MRO - 1,2,3,4,5,6 - MRO, Group Name MRO NSRF

Comment

The MRO NSRF supports the efforts of the SDT to clarify for the industry what is considered SOL exceedance in the context of the IRO and TOP Standards. We appreciate the SDT listening to the concerns raised by industry regarding the previously proposed SOL Exceedance definition and we agree with the SDT's approach to abandon that potential change. We also agree with the SDT's concept that the Reliability Coordinator's SOL Methodology must address the system performance criteria to ensure consistent identification of SOLs. However, what is still not broadly understood is if each Facility must have an associated thermal-based SOL dependent on current system topology. In Requirement R3 it addresses establishment of a voltage-based SOL at each bus, but there isn't a similar requirement for thermal ratings. Is it the expectation of the SDT that each Facility has a thermal-based SOL or can a subset (Flowgates?) be used to manage power flow on the system? This needs to be clearly stated in a requirement so that everyone is planning and operating the BES from the same understanding.

Additionally, it's not clear if exceeding the Normal Rating or normal System Voltage Limit is considered a SOL exceedance if you have a higher Emergency Rating or emergency System Voltage Limit for a specified time duration. It could be interpreted to say there isn't SOL exceedance until you're over the highest value of the Emergency Rating. This understanding translates to compliance expectations in the IRO and TOP Standards for when you must implement your Operating Plan. If we're relying on the SOL whitepaper to clarify, then some entities may choose not to follow it saying it's not mandatory and we'll continue to have disagreement and confusion in the industry.

In order to support this project, the MRO NSRF needs to understand all the compliance expectations for SOL exceedances, including those associated with the IRO/TOP standards. Is every indication where the FAC-011 R6 performance criteria is exceeded considered a violation of FAC-014 R6 and/or an inadequate real time Operating Plan? Are current operating protocols, which are agreed upon by the Transmission Operator and Reliability Coordinator and allow for temporary exceedances while control actions (such as LMP binding) are being implemented, now going to be prohibited and considered violations? As the proposed performance criteria (for post-contingent thermal and voltage exceedances) does not include any time threshold (in analogy with Tv for IROLs) does that imply the Transmission Operator and Reliability Coordinator would NOT be given any timeframe (such as 30 minutes) to correct an exceedance (particularly post-contingent thermal or voltage exceedances), before it becomes a reportable event and a potential compliance issue? Will the performance criteria be identical independently of the system state (i.e. if the system is in N-1 as opposed to N-4, or even more severe, topology conditions)? Is the Transmission Operator expected to perform a timing analysis to determine if ramp rates, start-up times and location and amount of load shedding are adequate every time it operates above the Normal Rating but below Emergency Rating to verify its Operating Plan will eliminate exceedance within the timeframe of the Emergency Rating? Would the proposed performance criteria not allow for any regional differences even in cases where a Reliability Coordinator is not registered as a Transmission Operator, but has critically important mitigating control actions under its responsibilities? We do not want to unintentionally approve a standard that creates overly burdensome compliance demonstration expectations for the industry, while the SER project is actively seeking ways to streamline and reduce these burdens. Since the SDT cannot answer all these questions, then we request NERC staff to draft a CMEP Practice Guide to inform the industry of the compliance expectations for SOLs as applied in the FAC, IRO and TOP standards.

Will entities be forced to create separation between the highest Emergency, Emergency, and Normal ratings if they are currently the same? An example is a conductor limited transmission line with a 10-minute time constant where all three ratings are identical. Does an entity have to de-rate the line by increments of sag temperature or percentage to create time between ratings or be in violation of the FAC-011-4 timing requirements. Short time frames of under 30 minutes could also lead to a violation of FAC-011-4 R6.5. Short time frames under 30 minutes aren't sufficient time for a system operator to consider "all" other available system adjustments before implementing load shedding.[A1]

To further explain, we believe the proposed performance criteria in FAC-011-4 Requirement R6 seems to capture the essence of SOL exceedance. However, we are concerned the proposed language creates a significant reliability/compliance burden for Transmission Operators and Reliability Coordinators as follows:

1. R6.2 - The language mandates evaluation of all contingencies listed in R5.1.1 of FAC-011-4 as part of the Real Time Assessment (RTA) and the Operational Planning Analysis (OPA) without exception. When coupled with R6.2.3, this language pulls in dynamic analysis of all of these contingencies for both the RTA and OPA. This is an infeasible expectation for the Transmission Operator and Reliability Coordinator to include in their RTAs and OPAs, since R5.1.1 contains no caveats to limit the list of applicable single contingencies.
2. R6.2.1 - The flows on a transmission element may exceed the applied Emergency Rating during the dynamic time period, but there is likely no risk to the system. Although the first phrase "applicable Emergency Ratings" might seem to provide the flexibility, this means an entity must know the *"applicable Emergency Rating"* for a particular dynamic loading and time period for each piece of equipment and each piece of equipment would need to be monitored in a dynamics analysis. It may be that the SDT does not intend to pull in dynamics in 6.2.2 but it is a logical reading of the standard.
3. R6.2.3 - As noted above, although this is the desired result, it is infeasible to perform dynamic analyses of all R5.1.1 contingencies as part of either an RTA or an OPA. In fact, it is an extremely expensive proposition to perform any real time dynamic simulations due to the complexities of maintaining an accurate dynamic model that incorporates traditional transmission equipment let alone the myriad of user written or proprietary dynamic models in use today for FACTs devices and variable generation.
4. R6.3 and R6.4 contain the same problems as noted above. It is infeasible to run dynamic simulations as part of the RTA and it is very complex to do so for the OPA. At least in this case, R5.2 and R5.3 allow the Reliability Coordinator to provide a very limited list of contingencies. Still, even with a limited list, the language of R6 and its sub-parts does not limit the scope of what a Transmission Operator would be required to run under FAC-014-3 (see R2 of that standard). Rather, FAC-011-4 R6 language implies that a Transmission Operator would be required to evaluate all of the contingencies identified by a Reliability Coordinator, not just those that apply to the Transmission Operator's footprint. Note that FAC-014-3 R2 limits the Transmission Operator to identifying SOLs to its footprint, but it does not limit the contingencies a Transmission Operator would need to consider.
5. R6.5 - The standard incorrectly eliminates planned load shedding from consideration when a RAS or UVLS programs may have specifically established the need to take such action to maintain system stability for the particular contingencies under consideration.

We offer the following proposed improvements to address the comments above:

- R6.1.1, R6.1.2, R6.2.1 and R6.2.2 could be improved by clarifying that these sub-requirements are only describing steady-state conditions. Each requirement could have the following leading statement added: *"Under steady-state analysis:"*.
- In addition, R6.2.1 and R6.2.2 would also benefit from adding the word *"Anticipated"* ahead of the terms *"Flow"* and *"Voltages"* in these requirements, respectively, to make it clear that these are potential system flows and voltages, not real time flows and voltages, being evaluated.

Regarding the scope of dynamic simulations, the best location to make modifications is likely the R5 and R5.1 language, not R6. Proposed modifications are as follows:

- R5 - Strike *"and performing the Operational Planning Analysis (OPAs) and Real-time Assessments (RTAs) for the area under study"* since this language is redundant to the R6 performance criteria language that will require these contingencies to be evaluated as part of the RTA and OPA. With this removed, R5 is tailored to only describe what contingency events need to be examined for the identification of SOLs.

R5.1 - Remove the language regarding *"determining stability limits and performing OPAs and RTAs"* and add *"for use in determining steady state SOLs",* since the SOL methodology should require examination of all of the single contingencies listed under R5.1.1 using steady-state analysis. The contingencies to examine for dynamics will be a very small list (hopefully) and can be adequately addressed by modifications to R5.3.

- R5.2 - Remove *"for use in performing Operational Planning Analysis and Real-time Assessments"* since, again, this is adequately covered by R6, and add in language as follows *"for use in determining steady state SOLs"*.

R5.3 - Strike the word *"additional"* from the existing R5.3 language and add the following to the end of the requirement: *"where the identified single Contingency events involving the loss of a generator, transmission circuit, transformer, shunt device, or single pole block in a monopolar or bipolar high voltage direct current system must simulate either: (a) Normal Clearing of a single phase to ground or three phase Fault (whichever is more severe) or (b) tripping without a Fault condition"*.

- Regarding the Transmission Operator performing a certain set of contingencies, the R6.2, R6.3 and R6.4 language could all be modified to state: *"The evaluation of applicable potential single Contingencies …"* (for R6.2) and *"The evaluation of the applicable potential Contingencies …"* (for R6.3 and R6.4).

R6.5 could be improved by clarifying that RAS and UVLS actions should be implemented in the stability analysis, as applicable. The SDT should also recognize that underfrequency load shedding (UFLS) may be a necessary part of system stabilization once a RAS operates if that RAS is creating a planned islanded system. As such, UFLS may also be a warranted load shedding component when performing stability analysis. R6.5 language could be modified by adding *"planned load shedding, other than Remedial Action Scheme (RAS) or UVLS action, is acceptable ..."* and then adding a new sentence that reads, *"The use of UFLS programs should only be simulated when incorporated as part of the system design to maintain stability (e.g., RAS)."*

Response

The SDT appreciates your comments. Those comments, and those of other Midwestern entities such MISO and MidAmerican Energy Co., have provided focus to the SDT's efforts since the second posting.

Those efforts have resulted in revisions to FAC-011-4, FAC-014-3, TOP-001 and IRO-008 which we believe address the concerns you raise above, and other commenters have noted. These revisions have been made to accomplish the following:

- Have SOL exceedances determined in the appropriate TOP and IRO standards rather than the FAC standards.
- The proposed FAC-011-4 requirement R6 has been revised into a framework to be used when determining SOL exceedances, which only occurs as required in the TOP and IRO standards. In addition, numerous wording changes have been implemented within requirement R6 in response to comments such as those you have above.
- FAC-011-4 has a new requirement added (R7) which requires the RC SOL methodology include "a risk-based approach for determining how SOL exceedances identified as part of Real-time monitoring and Real-time Assessments must be communicated and if so, the timeframe that communications must occur". This requirement was added to address the ill-defined SOL exceedance communications included within the TOP and IRO standards.
- The measures for a few TOP and IRO standards were revised to better describe a more complete set of potential evidence that may be sued to show compliance. In addition, the standard rationales have been revised to explain how this evidence may be used to show compliance with the standards.

We believe these changes, which were developed with the support of and feedback with staff from your company and others from within MISO, should address these commonly held industry concerns.

To summarize, the SDT's standard revisions have sought to provide a common minimum framework for industry to determine SOL exceedances, where appropriate in the TOP and IRO standards, and have added process to help improve the required communications on SOL exceedances. The SDT has done this while expanding the list of evidence to minimize any resulting compliance documentation burden. We look forward to your review of our efforts with our new posting and appreciate any comments you may offer.

In addition to these general comments, let us address some of the specific questions you pose.

The SDT worded requirement R2 such that the RC provides a method for the TOP to determine which facility-owner ratings to use. If the facility owner provides ratings for all of their assets, we would expect they are modeled. To expand upon the example you offered, if the RC's SOL methodology states that the RC needs a 10 minute, 1 hour and 24 hour thermal rating. For this example, let's assume the facility-owner only offers a 24 hour, or normal rating. The RC's methodology should describe how to use rating sets which do not perfectly match what the RC seeks. In this instance, it is likely the normal rating would be used for the 24 hour, 1 hour and 10 minute ratings. The RC would not require that the facility owner provides other ratings, but the facility owner would clearly see what ratings the RC seeks to use with its TOPs. This would not preclude the use of flowgates, but we believe does set the expectation that ratings provided would be used to operate. Likewise, this requirement does not require facility owners to provide amongst the ratings they offer.

Requirement R6.5 from the second posting, which is now requirement R6.4 in the latest version of FAC-011-4, was not intended to address what mitigation actions are acceptable for inclusion in an Operating Plan, including RAS or other post-contingency mitigation actions (including under voltage relays that are not specifically part of an overall Under Voltage Load Shed (UVLS) scheme). The SDT did capture that "planned manual load shedding", if included in an Operating Plan, should be a measure of last resort. With respect to RAS, requirement R4.6 requires that the RC document in their SOL methodology the "allowed uses of Remedial Action Schemes and other automatic post-Contingency mitigation actions in establishing stability limits used in operations". However, R4.7 requires "that the use of underfrequency load shedding (UFLS) programs and Undervoltage Load Shedding (UVLS) Programs are not allowed in the establishment of stability limits". The use of UVLS and UFLS as a safety net and not for performance criteria or in the establishment of a stability limit is consistent with FERC commission comments in FERC Order 818.

NRECA agrees that it is not necessary to create a definition of SOL Exceedance, but still believes the new FAC-011-04 R6 requirement creates undue compliance burden by prescribing an excessive number of sub-requirements. The structure of R6 is confusing. Many of the sub-requirements that are not standalone with references to other requirements in the proposed standard.

Response

The SDT appreciates your comment. The SDT has taken comments from numerous entities and attempted to improve the language and decrease some of the complexity. However, the SDT does not understand how the number of sub requirements in and of itself creates undue compliance burden. The sub requirements in R6 were derived from the existing FAC-011-3 sub requirements in R2, which are performance requirements which help determine SOL exceedances. The specificity included in FAC-011-4 R6 was to remove ambiguity that exists in the current standard. The references to other requirements in R6 only exist to note which sets of contingencies (defined by a specific requirement) ae applicable to which sets of performance requirements. Managing SOLs is a job each RC / TOP must do, and the SDT agrees R6 provides clarity in determining SOL exceedances.

The use of the undefined term 'instability' could lead to inconsistent results and result in additional compliance burdens that add little to no reliability benefit. As used in FAC-011 R6, instability is not limited to the BES or wide area but instead, as currently worded, applies to ANY instability that has ANY impact to any element or facility. R6.1.3 and 6.2.3 should be limited to the interconnection or at the very least the wide-area to prevent misunderstanding.

Response	
The SDT appreciates your comments offered. The quoted term (instability) and language was taken from the definition of IROL in the NERC glossary of terms. The SDT will consider including in R6 impact on the BES to limit the potential scope of instability, per your comment.	
Terry Harbour - Berkshire Hathaway Energy - MidAmerican Energy Co. - 1	
Answer	No

Document Name	
Comment	

MidAmerican Energy Company (MEC) understands and supports the SDT's efforts to come up with the broad industry consensus with regard to definition of SOL and associated definition of SOL Exceedance.

MidAmerican supports the SDT's proposal to create a definition of SOL exceedance, **as long as that definition would NOT cause unintended consequences in terms of setting unrealistic expectations or imposing additional and undesirable administrative compliance burden on numerous entities**. In this effort, the SDT should carefully assess repercussions on reliability and efficient market operations

We certainly appreciate the SDT's rational approach of not proceeding with the proposed definition of SOL exceedance having in mind significant number of negative comments which were received in October, 2017, primarily from MISO and SPP Regions.

Unfortunately, instead of patient continuation of efforts to adjust and improve proposed definition of SOL exceedance, the NERC Standard Drafting Team decided to take, in our view, **inappropriate approach of incorporating that controversial and arguable (although somewhat modified) definition of SOL Exceedance as a performance criteria in Requirement 6 of FAC-011-4 Standard. We consider this pathway as potentially worse and more risky in comparison with coming up with definition of SOL Exceedance. The reason for such a characterization is that by substituting definition of SOL Exceedance via embedding it as a performance criteria into FAC-011-4, the SDT would expose a number of TOPs and RCs to risk of directly violating FAC-011-4 (Requirement 6) and associated penalties, if (non-agreed upon in terms of definition) exceedances of system operating limits occur either in RTA or OPA**.

Furthermore, we believe that addressing a fundamental concept of SOL Exceedance definition needs to be done within the framework of IRO and TOP standards, where it inherently and logically belongs. We do not agree with an approach of moving that cornerstone of reliable operations from IRO/TOP set of standards to the FAC set of standards. In other words, we believe that the present context of defining what constitutes SOL exceedance **and reacting to it by initiating Operating Plan (per IRO-008-2-R2 and TOP-001-4-R14) is far better** than directly exposing large number of entities to the risk of non-compliance without appropriate considerations related to physical constraints that need to be overcome during implementation of Operating Plans, in a timely manner.

Fundamental principles and complexities of real power systems do not allow for ignoring the time dimension that always exist when implementing corrective control actions when temporary exceedances of SOL occur, especially in RTA. That was, unfortunately, overlooked in proposed versions of FAC-011-4 and FAC-014-3.

The role of SOL exceedance definition (or performance criteria within FAC-0114-R6), in our opinion, should be to clearly and unambiguously formulate critical operational borderlines of reliable operations, while **respecting existing limitations of existing transmission infrastructure and human resources that operate that infrastructure**.

Our quite specific reasons for NOT agreeing with the proposed Requirement 6 of FAC-011-4 are:

1. **Requirements 6.1.1; 6.1.2 and 6.2.1** use the phrase *"when System adjustments to return the flow/voltage within its Normal Rating/Voltage Limits could be executed and completed within the specified time duration of those Emergency Ratings/Voltage Limits"*.

We would like to show our appreciation to the SDT for their reasonable approach of listening to the industry's comments and gradually improving the definition of SOL exceedance. In this particular case we are pleased that the SDT now considers exceedance of Emergency (rather than Normal) limits as a reportable event.

However, there is a problem with using the phrase "*could be executed and completed within the specified time duration of those Emergency Ratings/Voltage Limits*" *as* clearly pointed out by Mr. Terry Volkmann. We completely agree with his comment: "*This implies that in order to use the range between normal and emergency rating for an anticipated contingency, a timing analysis needs to be performed before the contingency occurs to determine if ramp rates, start-up times and location and amount of load shedding are adequate.... TOP (in MISO and SPP reliability footprints) cannot perform such analyses, because the RC/market operator has all the data and tools to do the analysis....* ***This analysis is best served as an internal control not a compliance obligation.*** " MEC agrees with Mr. Volkmann that above mentioned quoted phrase shall be eliminated from the draft of the standard.

The implementation risk and compliance risk associated with this language is substantial and very concerning. Based on the language, TOP is expected to perform and document a timing analysis to determine if the adjustments could be executed within the specified time duration of Emergency Ratings each and every time when TOP performs RTA and find its facilities operating between Normal and Emergency Rating (either in real-time or on a contingency basis). It should be noted that such a timing analysis in real-time is difficult and requires significant time and resources. If such timing analysis cannot be performed (or is not performed due to lack of time or other reasons, or simply not logged/recorded) that may trigger non-compliance, concerning FAC-011 R6 in conjunction with FAC-014 R6

The second problem is that it is necessary to differentiate between flow exceedances and voltage exceedances in terms of risk to the equipment and the time tolerance.

We recommend the following definition:

- ***Actual steady state flow on a BES Facility is greater than the Facility's highest Emergency Rating for any time period.***

- ***Actual steady state flow on a BES Facility is above the Normal Rating but below the next Emergency Rating for longer than the time frame of the next Emergency Rating.***

- ***Actual steady state voltage on a BES Facility is greater than the emergency high voltage limit for time frame identified by the TOP.***

- ***Actual steady state voltage on a BES Facility is less than the defined emergency low voltage limit for time frame identified by the TOP.***

Alternatively, our comments can be formulated in the following red-line (highlighted in yellow changes):

1.
    i.
        a. *Steady state Flow through Facilities are within Normal Ratings; however, Emergency Ratings may be used only when System adjustments to return the flow within its Normal Rating can be executed and completed within the specified time duration of those Emergency Ratings*.
        b. *Steady state Voltages are within normal System Voltage Limits; however, emergency System Voltage Limits may be used only when System adjustments to return the voltage within its normal System Voltage Limits can be executed and completed within the specified time duration of those emergency System Voltage Limits*.

1. **Requirements 6.1.3 and 6.2.3** refer to preventing instability, cascading or uncontrolled separation.

- We find it inappropriate that **the proposed definition does not recognize time-frame associated with exceedances of established stability limits**. If not recognized, this can lead to hundreds of meaningless (nuisance) exceedances (for sake of an example, such as those that last less than 1 minute and have magnitude of less than 1%). More importantly, it should be noticed that even present definition of the IROL violation has associated Tv time threshold (or 30 minutes) before it becomes a compliance issue. Proposed formulation of 6.1.3 and 6.2.3 should include the time threshold (in analogy with Tv) so that RCs/TOPs would be given specified time frame to correct exceedance, before it becomes compliance issue.

We recommend the following definition:

- ***Any established stability limit (non-IROL) or limit that may cause cascading outages or uncontrolled separation shall not be exceeded for longer than the 30 minutes, or defined by Operating Plan.***

Alternatively, our comments can be formulated in the following red-line (highlighted in yellow changes):

1\.

i.

a. *Any established stability limit (non-IROL) is mitigated within the time-frame specified in (and in accordance with) the RC's SOL methodology and Operating Plan, or with RC's approved post-contingency action plan.*

b. *System-wide Instability, Cascading or uncontrolled separation do not occur.*

2\.

i.

a. *Any established stability limit (non-IROL) is mitigated within the time-frame specified in (and in accordance with) the RC's SOL methodology and Operating Plan, or with RC's approved post-contingency action plan.*

b. *System-wide Instability, Cascading or uncontrolled separation do not occur.*

1. **Requirement 6.2.1** is of particular importance and probably the single, most frequent concern in present industry's practice. MidAmerican Energy Company appreciates SDT's reasonable approach of listening to the industry's comments and gradually improving the definition of SOL exceedance/performance criteria. However, we would like to draw the SDT's attention to the following issues with their present formulation of the Requirement 6.2.1, which states that:

"*provided that System adjustments could be executed and completed within the specified time duration of those Emergency Ratings*. ***Flow through a Facility must not be above the Facility's highest Emergency Rating*.**"

We would like to point out several issues with regard to this formulation:

- First, **the proposed definition does not recognize time-frame associated with exceedances of the Facility's highest Emergency Rating**. If not recognized, this can lead to hundreds of meaningless (nuisance) exceedances (for sake of an example, such as those that last less than 1 minute and have magnitude of less than 1%). Others exceedances may last several minutes (5-30 minutes, just for sake of example) due to time constraints associated with operators' response to these exceedances and physical reality/timing of corrective control actions that need to be implemented. More importantly, it should be noticed that even present definition of the IROL violation has associated Tv time threshold (or 30 minutes) before it becomes a compliance issue. Proposed formulation of 6.2.1 should include the time threshold (in analogy with Tv) so that RCs/TOPs would be given specified time frame to correct exceedance, before it becomes compliance issue.

- Second, regarding the phrase "*Flow through a Facility must not be above the Facility's highest Emergency Rating*", the SDT's formulation appears to be based on the Project 2014-03 Whitepaper. We need to draw attention of the SDT that the original version of the NERC White Paper (from May 2014) was stating that "Post-contingency flow in this range is not acceptable **unless Operating Plan address reliability impact so that it has localized impact**". Subsequent version of the NERC White Paper (revision of January

2015) introduced statement that "Post-contingency flow in this range is not acceptable". **This revision, with a major impact, was never presented to the industry, never approved by the Industry and, in our opinion, was step in the wrong direction. The most recently published revision adds clarity and improved formulations, but still departs from the original concept and ignores time dimension that is necessary to implement corrective control actions, especially for inevitable short term exceedances in RTA, on a contingency basis.**

- Third, the SDT's proposed definition of the post-Contingency flow SOL exceedance **fails to recognize the important difference between actual, pre-contingency SOL exceedance and calculated, post-contingency RISK of SOL exceedance**. This attempt to include both of them under the single, generic term "performance criteria/SOL exceedance" may easily cause an incorrect expectation that TOP/RC's control actions response to these two types of exceedances should be similar, in terms of timing, logging and recording.

- Fourth, **it is perfectly clear and understandable that both of these types of exceedances require and should trigger implementation of a control action from Operating Plan, but they should be treated *differently in terms of urgency and severity of mitigating control actions*, as they have different repercussions on system reliability**.

- Fifth, there is a problem with using the phrase "*could be executed and completed within the specified time duration of those Emergency Ratings" as* clearly pointed out by Mr. Terry Volkmann. We completely agree with his comment: "*This implies that in order to use the range between normal and emergency rating for an anticipated contingency, a timing analysis needs to be performed before the contingency occurs to determine if ramp rates, start-up times and location and amount of load shedding are adequate…. TOP (in MISO and SPP reliability footprints) cannot perform such analyses, because the RC/market operator has all the data and tools to do the analysis….* ***This analysis is best served as an internal control not a compliance obligation***." MEC agrees with Mr. Volkmann that this phrase shall be eliminated from the draft of the standard.

The implementation risk and compliance risk associated with this language is substantial and very concerning. Based on the language, TOP is expected to perform and document a timing analysis to determine if the adjustments could be executed within the specified

time duration of Emergency Ratings each and every time when TOP performs RTA and find its facilities operating between Normal and Emergency Rating (either in real-time or on a contingency basis)? It should be noted that such a timing analysis in real-time is difficult and requires significant time and resources. If such timing analysis cannot be performed (or is not performed due to lack of time or other reasons, or simply not logged/recorded) that may trigger non-compliance, concerning FAC-011 R6 in conjunction with FAC-014 R6.

• Sixth, regarding the **language in FAC-011-4 (R6.2.1)** *"Flow through a Facility must not be above the Facility's highest Emergency Rating"*, let's consider the following scenario. TOP operates in REAL-TIME with one scheduled outage (N-1 topology). Then a fault occurs (single event such as bus fault or similar) and takes out of service two (or more) facilities, thus bringing the system in real-time into N-3 topology condition. Now, RTCA starts showing overloading for next single contingency (N-4).

The concern is if the language in the draft of the standard assumes that **the performance criteria are identical, independently of the system state** (i.e. if the system is in N-1 as opposed to N-3, or even more severe, topology conditions). We certainly understand that in OPA such a scheduled outage would not be approved if it causes SOL exceedances. However, what will be applicable performance criteria if that event happens in real-time due to single event? Of course TOP will implement its Operating Plan to correct the exceedance, but due to significantly deteriorated topology (for which the system was never designed) it may take longer time period to eliminate exceedance on a contingency basis. Or, analysis may show that only firm load shedding may eliminate the exceedance.

The issue is that if the same performance criteria are applicable independently of topology conditions, in order to avoid performance criteria violation (on a contingency basis) the only viable option might be pre-contingent firm load shedding to correct contingency based (not real-time) exceedance.

We recommend the following definition for 6.2.1:

- ***Projected post-Contingent loading on a BES Facility is greater than the highest Emergency Rating for longer than 30 minutes with NO agreed upon Post Contingency Action Plan that would mitigate the condition if the Contingency were to occur.***

Alternatively, our comments can be formulated in the following red-line (highlighted in yellow changes):

1.

   i. *The evaluation of potential single Contingencies listed in Part 5.1.1 for system intact and N-1 operating conditions, against the actual pre-Contingency state (Real-time monitoring and Real-time Assessments) and anticipated pre-Contingency state (Operational Planning Analysis) demonstrates the following:*

      a. *Flow through Facilities are within applicable Emergency Ratings, provided that System adjustments can be executed and completed within the specified time duration of those Emergency Ratings. Post-Contingency flow in this range that is not mitigated within the time-frame specified in (and in accordance with) the RC's SOL methodology, or without RC's approved post-contingency action plan, constitutes reportable exceedance to RC. The Operating Plan developed and mutually agreed to by TOP and RC is required to address potential impacts and post-contingent mitigating strategies, including but not limited to load shedding, while normal congestion relief control actions are being implemented, to ensure potential impact is localized. Flow through a Facility must not be above the Facility's highest Emergency Rating.*

      b. *Voltages are within emergency System Voltage Limits. Post-Contingency voltage outside of the emergency System Voltage Limits that is not mitigated within the time-frame specified in (and in accordance with) the RC's SOL methodology, or without RC's approved post-contingency action plan, constitutes reportable exceedance to RC. The Operating Plan developed and mutually agreed to by TOP and RC is required to address potential impacts and post-contingent mitigating strategies, including but not limited to load shedding, while normal control actions for eliminating System voltage exceedance are being implemented, to ensure potential impact is localized..*

Rationale for using Post-contingency action plan concept

- The main difference between our proposed definition and the SDT's proposed definition is the **concept of post-contingent action plan**. *The Post-contingency action plan is the RC's/TOP's agreed upon control action to be used* ***while the normal congestion management processes are attempting to return the projected post contingent flow within longer-term rating***. It is very important to note that the Post-contingency action plans are **NOT** a vehicle to justify continual operation where the projected post contingent flow is above Facility's highest Emergency Rating.

- **In contrast to this, we believe that the Post-contingency action plan developed by TOP and RC is required to address potential impacts and post-contingent mitigating strategies, including but not limited to load shedding or generator tripping, while normal congestion management actions are being implemented, to ensure potential impact is localized and to prevent equipment damage**.

- Therefore, we would NOT consider SOL exceedance to exist anytime the Projected post-contingency flow is above Facility's highest Emergency Rating, but only for those situations when the Projected post-contingency flow is above the Facility's highest Emergency Rating (Rate C) for longer than 30 minutes **WITHOUT associated post-contingency action plan**.

- We recognize that there may be situations in the system when normal congestion management is not effective or has been exhausted, and the projected post-contingent loading on a facility remains greater than the highest available emergency rating. In this situation, load shedding may be the sole remaining option to address the projected post-contingency loading. The TOP and RC may decide to operate in this manner and not implement load-shedding pre-contingency if the impacts would be localized. In this case the SOL exceedance would be reportable, even though a post-contingent action plan exists, since normal congestion management is no longer taking place.

- The SDT's concept insists on the concept "highest Emergency Rating". Our definition is based on the concept of "post-contingency action plan". We do recognize that issuing a new Short Term Emergency rating would be an alternative for the TOP to pursue rather than agreeing with its RC on a post-contingency action plan. **The huge practical obstacle to issuing higher emergency rating (or "Load Shed Rating**") that the Industry always faced is that each TOP would have to **get manufacturers' confirmations for using shorter term Emergency Ratings (such as 10-minute ratings) for every single piece of equipment** (breakers, switches, wave traps, CTs conductors, all pieces on transformers etc). Majority of manufacturers would not be even able nor willing to provide such a data. Therefore, **for practical reasons, it is almost impossible to get such a short-term ratings based on manufacturers' data and technical facilities justifications**. Consequently, as opposed to being "pushed/forced" to using technically unjustified short-term emergency/load shedding ratings, each TOP and RC might need to define criteria within their Operating Plan for using post-contingent action plans. These criteria might be based, for sake of example, on Relay Loadability Limits of transmission facilities.

1. **Requirements 6.3 and 6.4**:

Our comments can be formulated in the following red-line (highlighted in yellow changes):

1.

    i. *The evaluation of the potential Contingencies identified in Part 5.2 (which are not mitigated within the time-frame specified in, and in accordance with, the RC's SOL methodology) against the actual pre-Contingency state (Real-time monitoring and Real-time Assessments) and anticipated pre-Contingency state (Operational Planning Analysis) demonstrates that instability, Cascading, or uncontrolled separation does not occur.*

The evaluation of the potential Contingencies identified in Part 5.3, (which are not mitigated within the time-frame specified in, and in accordance with, the RC's SOL methodology) demonstrates that instability does not occur.

The SDT appreciates the comments of MidAmerican Energy Co. and, more so, its participation in the SDT team's efforts since the second posting. Comments such as yours have provided focus to the SDT's efforts since the second posting.

Those efforts have resulted in revisions to FAC-011-4, FAC-014-3, TOP-001 and IRO-008 which we believe address the concerns you raise above, and other commenters have noted. These revisions have been made to accomplish the following:

- Have SOL exceedances determined in the appropriate TOP and IRO standards rather than the FAC standards.
- The proposed FAC-011-4 requirement R6 has been revised into a framework to be used when determining SOL exceedances, which only occurs as required in the TOP and IRO standards. In addition, numerous wording changes have been implemented within requirement R6 in response to comments such as those you have above.
- FAC-011-4 has a new requirement added (R7) which requires the RC SOL methodology include "a risk-based approach for determining how SOL exceedances identified as part of Real-time monitoring and Real-time Assessments must be communicated and if so, the timeframe that communications must occur". This requirement was added to address the ill-defined SOL exceedance communications included within the TOP and IRO standards.
- The measures for a few TOP and IRO standards were revised to better describe a more complete set of potential evidence that may be sued to show compliance. In addition, the standard rationales have been revised to explain how this evidence may be used to show compliance with the standards.

We believe these changes, which were developed with the support of and feedback with staff from your company and others from within MISO, should address these commonly held industry concerns.

To summarize, the SDT's standard revisions have sought to provide a common minimum framework for industry to determine SOL exceedances, where appropriate in the TOP and IRO standards, and have added process to help improve the required communications on SOL exceedances. The SDT has done this while expanding the list of evidence to minimize any resulting compliance documentation burden. We look forward to your review of our efforts with our new posting and appreciate any comments you may offer.

Comment	
ReliabilityFirst votes in the negative for the following two reasons. 1. For requirement R6 part 6.5, ReliabilityFirst believes not being permitted to plan to drop load prior to taking all other actions seems is not technically correct. Here are a few real life scenarios that ReliabilityFirst is aware of: there are Remedial Action Schemes that drop non-firm load for first contingency events. There is another Remedial Action Scheme that drops 1/3 of the total station load for a breaker failure event. RF recommends the following changes to Part 6.5 for consideration: "In determining the System's response to any Contingency identified in Parts 5.1 through 5.3, planned load shedding [non-firm load] is acceptable [and planned shedding of firm load is acceptable] only after all other available System adjustments have been made [or where pre-approved by state regulators, and the shedding of load with Remedial Action Schemes.] 2. For Requirement R6 parts 6.1.1, 6.1.2, and 6.2.1, these three statement assume that the ONLY way that flows, voltages can be controlled within a specified time duration is with system adjustments. There are times when it is known that voltages or flows will change without the operator making any system adjustments. The operator could know that the 2nd shift at a factory ends in 5 minutes, and that there is no 3rd shift. RF recommends the following changes to Part 6.1.1, 6.1.2 and 6.2.1 for consideration: 6.1.1 - Flow through Facilities are within Normal Ratings; however, Emergency Ratings may be used [when flows can be returned to within Normal Ratings within the specified time duration of those Emergency Ratings.] 6.1.2 - Voltages are within normal System Voltage Limits; however, emergency System Voltage Limits may be used [when voltage can be returned to within its normal System Voltage Limits within the specified time duration of those emergency System Voltage Limits.] 6.2.1 - Flow through Facilities are within applicable Emergency Ratings, [provided that flows can be returned to within Normal Ratings System within the specified time duration of those Emergency Ratings]. Flow through a Facility must not be above the Facility's highest Emergency Rating.

The SDT appreciates your comments. With respect to your first observation, the SDT believes sub requirement 6.5 in R6 allows automatic load shedding as part of a RAS and does not treat that as manual load shedding. This will be described in the rationale supporting the requirement. Therefore, the examples you note would be acceptable per to proposed language. With respect to your second observation, changes were made to the subject sub requirements removing system adjustments or adding "other System changes", with both changes being responsive to your comment.

R6 uses the term "performance criteria". This is the same term used in R6 in FAC-014-3 (see NIPSCO comments for question 4). Using the same term in two different standards with different context is confusing. For FAC-011-4 R6 NIPSCO suggests eliminating the phrase "Bulk Electric System performance criteria" and just placing a ":" after the word "following".

Response	
The SDT appreciates your offered comments. The SDT has eliminated the reference to performance criteria in FAC-014-2. In addition, the SDT has revised R6 and the use of performance criteria within the proposed standard. The SDT is retaining the term due to proposed FAC-011-4 R6 mapping to FAC-011-3 R2, which is the requirement in the existing standard which defines the expected level of system performance when SOLs are respected.

CenterPoint Energy Houston Electric, LLC ("CenterPoint Energy)" does not agree with the performance criteria in FAC-011-4 Requirement R6 and believes that the language is ambiguous and unnecessary. In particular, the use of the term "instability" in Requirements R6.1.3 and R6.2.3 without any qualifiers may broaden the scope of the language, which could lead to inconsistent results. CenterPoint Energy recommends that the SDT revise the language in Requirements R6.1.3 and R6.2.3 to clarify that instability that adversely impacts the reliability of the BES is what is intended.

AZPS does not have an issue with the performance criteria set forth in FAC-011-4 R6. However, the use of performance criteria could still result in ambiguity regarding what qualifies as a “SOL Exceedance.” For this reason, AZPS recommends that the SDT reconsider use of a defined term for “SOL Exceedance.” Additionally, if there is intent to continue to use the term “SOL exceedance” within the body of reliability standards, then both industry and the ERO Enterprise would benefit from the clarity that would result from a definition of the term.

The SDT appreciates your comment offered. While the SDT supports your perspective in the value of an explicit SOL exceedance definition, it was apparent from prior postings and comments that the industry as a whole did not. Our latest FAC-011-4 revision, with the proposed R6, is our attempt at providing a minimum set of performance criteria across the industry for establishing SOL exceedances. R6 should be the minimal basis any RC uses to define SOL exceedances within its footprint. We hope you can understand our rationale and support the proposed FAC-011-4 language in our next posting.

Comment	

NV Energy supports the SDT's proposal to create a definition of SOL exceedance, **as long as that definition would NOT cause unintended consequences in terms of setting unrealistic expectations or imposing additional and undesirable administrative compliance burden on numerous entities**. In this effort, the SDT should carefully assess repercussions on reliability and efficient market operations

NV Energy believe the SDT took an **inappropriate approach of incorporating that controversial and arguable (although somewhat modified) definition of SOL Exceedance as a performance criteria in Requirement 6 of FAC-011-4 Standard. We consider this pathway as potentially worse and more risky in comparison with coming up with definition of SOL Exceedance. The reason for such a characterization is that by substituting definition of SOL Exceedance via embedding it as a performance criteria into FAC-011-4, the SDT would expose a number of TOPs and RCs to risk of directly violating FAC-011-4 (Requirement 6) and associated penalties, if (non-agreed upon in terms of definition) exceedances of system operating limits occur either in RTA or OPA**.

Furthermore, we believe that addressing a fundamental concept of SOL Exceedance definition needs to be done within the framework of IRO and TOP standards, where it inherently and logically belongs. We do not agree with an approach of moving that cornerstone of reliable operations from IRO/TOP set of standards to the FAC set of standards. In other words, we believe that the present context of defining what constitutes SOL exceedance **and reacting to it by initiating Operating Plan (per IRO-008-2-R2 and TOP-001-4-R14) is far better** than directly exposing large number of entities to the risk of non-compliance without appropriate considerations related to physical constraints that need to be overcome during implementation of Operating Plans, in a timely manner.

Fundamental principles and complexities of real power systems do not allow for ignoring the time dimension that always exist when implementing corrective control actions when temporary exceedances of SOL occur, especially in RTA. That was, unfortunately, overlooked in proposed versions of FAC-011-4 and FAC-014-3.

The role of SOL exceedance definition (or performance criteria within FAC-0114-R6), in our opinion, should be to clearly and unambiguously formulate critical operational borderlines of reliable operations, while **respecting existing limitations of existing transmission infrastructure and human resources that operate that infrastructure**.

We appreciate that the SDT listened to the industry's comments and gradually improved the definition of SOL exceedance. In particular, we are pleased that the SDT now considers exceedance of Emergency (rather than Normal) limits as a reportable event.

However, there is a problem with using the phrase *"could be executed and completed within the specified time duration of those Emergency Ratings/Voltage Limits"*. We agree with previous commenting of: *"This implies that in order to use the range between normal and emergency rating for an anticipated contingency, a timing analysis needs to be performed before the contingency occurs to determine if ramp rates, start-up times and location and amount of load shedding are adequate.... **This analysis seems to be better served as an internal control not a compliance obligation**.'*

The implementation risk and compliance risk associated with this language is substantial and very concerning. Based on the language, TOP is expected to perform and document a timing analysis to determine if the adjustments could be executed within the specified time duration of Emergency Ratings each and every time when TOP performs RTA and find its facilities operating between Normal and Emergency Rating (either in real-time or on a contingency basis). It should be noted that such a timing analysis in real-time is difficult and requires significant time and resources. If such timing analysis cannot be performed (or is not performed due to lack of time or other reasons, or simply not logged/recorded) that may trigger non-compliance, concerning FAC-011 R6 in conjunction with FAC-014 R6

The second problem is that it is necessary to differentiate between flow exceedances and voltage exceedances in terms of risk to the equipment and the time tolerance.

We share the industry recommendation of the following definition:

- ***Actual steady state flow on a BES Facility is greater than the Facility's highest Emergency Rating for any time period.***
- ***Actual steady state flow on a BES Facility is above the Normal Rating but below the next Emergency Rating for longer than the time frame of the next Emergency Rating.***
- ***Actual steady state voltage on a BES Facility is greater than the emergency high voltage limit for time frame identified by the TOP.***
- ***Actual steady state voltage on a BES Facility is less than the defined emergency low voltage limit for time frame identified by the TOP.***

1. **Requirements 6.1.3 and 6.2.3** refer to preventing instability, cascading or uncontrolled separation.

- We find it inappropriate that **the proposed definition does not recognize time-frame associated with exceedances of established stability limits**. If not recognized, this can lead to hundreds of meaningless (nuisance) exceedances (for sake of an example, such as those that last less than 1 minute and have magnitude of less than 1%). More importantly, it should be noticed that even present definition of the IROL violation has associated Tv time threshold (or 30 minutes) before it becomes a compliance issue. Proposed formulation of 6.1.3 and 6.2.3 should include the time threshold (in analogy with Tv) so that RCs/TOPs would be given specified time frame to correct exceedance, before it becomes compliance issue.

We recommend the industry discussed following definition:

- ***Any established stability limit (non-IROL) or limit that may cause cascading outages or uncontrolled separation shall not be exceeded for longer than the 30 minutes, or defined by Operating Plan.***
-

1. **Requirement 6.2.1** is of particular importance and probably the single, most frequent concern in present industry's practice. MidAmerican Energy Company appreciates SDT's reasonable approach of listening to the industry's comments and gradually improving the definition of SOL exceedance/performance criteria. However, we would like to draw the SDT's attention to the following issues with their present formulation of the Requirement 6.2.1, which states that:

"*provided that System adjustments could be executed and completed within the specified time duration of those Emergency Ratings*. ***Flow through a Facility must not be above the Facility's highest Emergency Rating*.**"

We would like to point out several issues with regard to this formulation:

- First, **the proposed definition does not recognize time-frame associated with exceedances of the Facility's highest Emergency Rating**. If not recognized, this can lead to hundreds of meaningless (nuisance) exceedances (for sake of an example, such as those that last less than 1 minute and have magnitude of less than 1%). Others exceedances may last several minutes(5-30 minutes, just for sake of example) due to time constraints associated with operators' response to these exceedances and physical reality/timing of corrective control actions that need to be implemented. More importantly, it should be noticed that even present definition of the IROL violation has associated Tv time threshold (or 30 minutes) before it becomes a compliance issue. Proposed formulation of 6.2.1 should include the time threshold (in analogy with Tv) so that RCs/TOPs would be given specified time frame to correct exceedance, before it becomes compliance issue.

- Second, regarding the phrase "*Flow through a Facility must not be above the Facility's highest Emergency Rating*", the SDT's formulation appears to be based on the Project 2014-03 Whitepaper. We need to draw attention of the SDT that the original version of the NERC White Paper (from May 2014) was stating that "Post-contingency flow in this range is not acceptable **unless Operating Plan address reliability impact so that it has localized impact**". Subsequent version of the NERC White Paper (revision of January 2015) introduced statement that "Post-contingency flow in this range is not acceptable" . **This revision, with a major impact, was never presented to the industry, never approved by the Industry and, in our opinion, was step in the wrong direction. The most recently published revision adds clarity and improved formulations, but still departs from the original concept and ignores time dimension that is necessary to implement corrective control actions, especially for inevitable short term exceedances in RTA, on a contingency basis.**

- Third, the SDT's proposed definition of the post-Contingency flow SOL exceedance **fails to recognize the important difference between actual, pre-contingency SOL exceedance and calculated, post-contingency RISK of SOL exceedance**. This attempt to include both of them under the single, generic term "performance criteria/SOL exceedance" may easily cause an incorrect expectation that TOP/RC's control actions response to these two types of exceedances should be similar, in terms of timing, logging and recording.

Fourth, **it is perfectly clear and understandable that both of these types of exceedances require and should trigger implementation of a control action from Operating Plan, but they should be treated *differently in terms of urgency and severity of mitigating control actions*, as they have different repercussions on system reliability**.

- **The implementation risk and compliance risk associated with this language is substantial and very concerning. Based on the language, TOP is expected to perform and document a timing analysis to determine if the adjustments could be executed within the specified time duration of Emergency Ratings each and every time when TOP performs RTA and find its facilities operating between**

Normal and Emergency Rating (either in real-time or on a contingency basis)? It should be noted that such a timing analysis in real-time is difficult and requires significant time and resources. If such timing analysis cannot be performed (or is not performed due to lack of time or other reasons, or simply not logged/recorded) that may trigger non-compliance, concerning FAC-011 R6 in conjunction with FAC-014 R6.

• Fifth, regarding the **language in FAC-011-4 (R6.2.1)** *“Flow through a Facility must not be above the Facility’s highest Emergency Rating”*, let’s consider the following scenario. TOP operates in REAL-TIME with one scheduled outage (N-1 topology). Then a fault occurs (single event such as bus fault or similar) and takes out of service two (or more) facilities, thus bringing the system in real-time into N-3 topology condition. Now, RTCA starts showing overloading for next single contingency (N-4).

The concern is if the language in the draft of the standard assumes that **the performance criteria are identical, independently of the system state** (i.e. if the system is in N-1 as opposed to N-3, or even more severe, topology conditions). We certainly understand that in OPA such a scheduled outage would not be approved if it causes SOL exceedances. However, what will be applicable performance criteria if that event happens in real-time due to single event? Of course TOP will implement its Operating Plan to correct the exceedance, but due to significantly deteriorated topology (for which the system was never designed) it may take longer time period to eliminate exceedance on a contingency basis. Or, analysis may show that only firm load shedding may eliminate the exceedance.

The issue is that if the same performance criteria are applicable independently of topology conditions, in order to avoid performance criteria violation (on a contingency basis) the only viable option might be pre-contingent firm load shedding to correct contingency based (not real-time) exceedance

We recommend the following industry discussed definition for 6.2.1:

- ***Projected post-Contingent loading on a BES Facility is greater than the highest Emergency Rating for longer than 30 minutes with NO agreed upon Post Contingency Action Plan that would mitigate the condition if the Contingency were to occur.***

We believe there is need for using a Post-contingency action plan concept

- The main difference between our proposed definition and the SDT's proposed definition is the **concept of post-contingent action plan**. *The Post-contingency action plan is the RC's/TOP's agreed upon control action to be used* ***while the normal congestion management processes are attempting to return the projected post contingent flow within longer-term rating****.* It is very important to note that the Post-contingency action plans are **NOT** a vehicle to justify continual operation where the projected post contingent flow is above Facility's highest Emergency Rating.

In contrast to this, we believe that the Post-contingency action plan developed by TOP and RC is required to address potential impacts and post-contingent mitigating strategies, including but not limited to load shedding or generator tripping, while normal congestion management actions are being implemented, to ensure potential impact is localized and to prevent equipment damage.

- Therefore, we would NOT consider SOL exceedance to exist anytime the Projected post-contingency flow is above Facility's highest Emergency Rating, but only for those situations when the Projected post-contingency flow is above the Facility's highest Emergency Rating (Rate C) for longer than 30 minutes **WITHOUT associated post-contingency action plan**.

- We recognize that there may be situations in the system when normal congestion management is not effective or has been exhausted, and the projected post-contingent loading on a facility remains greater than the highest available emergency rating. In this situation, load shedding may be the sole remaining option to address the projected post-contingency loading. The TOP and RC may decide to operate in this manner and not implement load-shedding pre-contingency if the impacts would be localized. In this case the SOL exceedance would be reportable, even though a post-contingent action plan exists, since normal congestion management is no longer taking place.

- The SDT's concept insists on the concept "highest Emergency Rating". Our definition is based on the concept of "post-contingency action plan". We do recognize that issuing a new Short Term Emergency rating would be an alternative for the TOP to pursue rather than agreeing with its RC on a post-contingency action plan. **The huge practical obstacle to issuing higher emergency rating (or "Load Shed Rating**") that the Industry always faced is that each TOP would have to **get manufacturers' confirmations for using shorter term Emergency Ratings (such as 10-minute ratings) for every single piece of equipment** (breakers, switches, wave traps, CTs conductors, all pieces on transformers etc). Majority of manufacturers would not be even able nor willing to provide such a data. Therefore, **for practical reasons, it is almost impossible to get such a short-term ratings based on manufacturers' data and technical facilities justifications**. Consequently, as opposed to being "pushed/forced" to using technically unjustified short-term emergency/load shedding ratings, each TOP and RC might need to define criteria within their Operating Plan for using post-contingent action plans. These criteria might be based, for sake of example, on Relay Loadability Limits of transmission facilities.

The SDT appreciates the comments you offered. The SDT has made changes to Requirement R6 that it believes provides additional clarity. The SDT believes this is an important and critical part of creating consistency as to what constitutes an SOL exceedance which provides uniformity for the industry and a commensurate improvement to reliability. These changes are consistent with the SOL Whitepaper. The SDT has attempted to address some concerns of unnecessary compliance burden to include addition verbiage in proposed TOP-001-6 M14 as well as providing FAC-011-4 R7 and corresponding inclusion of the SOL methodology into TOP-001-6 R15.

The SDT has tried to provide clarity in performance requirements captured in R6 such that it is clear that not meeting performance requirements constitutes an SOL exceedance, which then triggers other requirements to mitigate and communicate such exceedances as identified in the IRO and TOP standards (e.g. implementation of Operating Plan). SOL exceedance does not equate to a violation of the requirements and there is no required timeframe to mitigate an SOL exceedance other than the subset identified to be IROLs. However, an entity is required to implement its Operating Plan as identified in TOP-001 R14. So not meeting performance requirements (i.e. SOL exceedance) does not constitute a violation, but rather a violation would occur only if the responsible entity did not fulfill the obligations of the requirements that surround how to respond to SOL exceedances for example.

We believe the SOL exceedance definition did create an unnecessary compliance burden. However, the approach the SDT took does not reduce the compliance burden by moving the SOL Exceedance definition to a requirement. Requirement R6 is overly complicated and confusing. It has 11 sub-parts and references other requirements four separate times. Compliance standards should be clear and should be able to stand alone without the need to cross reference other requirements.

The SPP Standards Review Group (SSRG) believes that the performance criteria as described in R6 should be simplified and imbedded where appropriate in the other requirements of FAC-011-4. For example, performance criteria pertaining to steady state voltage should be included in R3.

Response	
The SDT appreciates your comments. The SDT has revised the language in R6 to simplify it based on comments. However, the SDT believes separating the performance criteria into the other requirements would make the revised standards more confusing. The proposed FAC-011-4 R6 maps to the existing FAC-011-3 R2, which is a separate set of requirements that establishes performance expectations when meeting SOLs per the RC's SOL methodology. The SDT believes maintaining R6 separately minimizes the complexity of a complex topic.

The SDT appreciates your comment. The SDT initially wrote the sub requirements in R6 just as your comment noted, but subsequent discussion showed that unexpected real time condition changes, such as variations in load level or transfers, can result in System changes which may push thermal or voltage performance beyond normal limits. This led the SDT to include the use of emergency limits potentially for pre-contingency conditions for non-contingent events and maintain consistency with the SOL white paper.

Comment	
Duke Energy requests further clarification on the use of "pre-Contingency state" in R6.2. Was it the drafting team's intent that an RC should anticipate a "pre-Contingency state"? Was this a typographical error? Should "post-Contingency state" be used instead? Duke Energy is unclear on the expectations for R6.4. Is it the drafting team intent that with the use of the term "demonstrates" in R6.4, that entities are required to do stability studies in Real-time? The drafted language appears to be more suitable for Planning Coordinators and Transmission Planners, not for Operators of the BES in Real-time. We suggest the drafting team consider the following language for R6.4: *"The evaluation of the potential Contingencies identified in Part 5.3 demonstrates that the system will be operated within stability limits."* Should other Time Horizons be considered for R6 as well, (Same Day)?	
Likes 0	
Dislikes 0	
Response	
The SDT appreciates your comments. The SDT has removed the pre-contingency state reference in 6.2 and hopefully provided more clear and concise language in the proposed requirement. With respect to your second question, the SDT does not expect operating entities to perform real time stability analyses. Based on this and other comments, previously proposed R6.4 has been removed. The SDT considered Same Day, but thought it best to include the furthest out Time Horizon (Operations Planning), recognizing that SOL exceedances, due to the inclusion of Real Time Assessments, would be Same Day and Real Time also.

General Observation

The companies believe reliability and establishing compliance thresholds are better served by keeping performance criteria within the performance Standards, e.g. TOP and IRO Standards, and keeping Standards that establish a methodology free from such performance criteria.

Like the SDT's statement in Question 3, the companies agree that to address the issue, revisions would likely need to be made within a TOP or IRO standard and the Project 2015-09 SAR does not specifically authorize the SDT to modify those standards.

Suggestion: Add Flexibility

The companies recognize each Registered Entities' system is unique in design, complexity, footprint, and Facilities. To address the differences between systems across the BES, the companies suggest FAC-011-4 R6 language provide flexibility to accomplish the reliability outcomes offered in the proposed revisions by leveraging entities' FAC-008 Facility Rating Methodology and applicable internal documents to guide:

- When Normal and Emergency Ratings/Voltage limits are used under pre or post-contingent conditions, and
- The allowable time duration for the applicable condition.

Suggestion: Remove Prescriptive Language

Also, the companies suggest removing prescriptive language to provide entities more flexibility executing Requirement 6. Replacing the NERC Glossary Terms, "Normal Ratings" and "Emergency Ratings" with the words "applicable ratings" or "applicable voltage limits" will provide the suggested flexibility without compromising BES reliability.

The SDT appreciates your comments. The SDT explored revisions to the TOP and IRO standards to better incorporate the performance requirements and their implications with SOL exceedances. After much effort and dialogue within the SDT and with other industry representatives, the SDT is revising R6 to allow the RC, within its methodology, to define what constitutes an SOL exceedance, using as a starting basis the performance criteria listed in a revised version of R6.

With that said, and while recognizing the stated interpretation of the standards, the SDT did not see the TOP and IRO standards with any obvious location to define System performance criteria. In addition, while the TOP and IROL standards use "SOL exceedance" numerous times, there is no definition of the term anywhere within the standards. Recognizing this and past comments on the SDT's prior postings on FAC-011, the SDT is revising FAC-011-4 R6 to allow each RC to define SOL exceedances in their methodology, using as an initial basis the performance criteria in R6. This tact should allow each RC the flexibility needed to account for any unique concerns within its footprint while allowing a more seamless use of SOL exceedances defined by this methodology in the TOP and IRO standards.

With regard to your comments on ratings, the FACT SDT has, over its three years of existence, discussed the ratings provided by FAC-008 numerous times, and believes that the ratings supplied by the facility owners via FAC-008 should be those used by the TOPs and RCs. Furthermore, proposed R2 and R3.2 in FAC-011-4 note that owner facility ratings should be respected for thermal and voltage, respectively.

The SDT discussed at length whether Normal / Emergency limits versus "applicable" limits were the better terms to be used in the proposed standards. The consensus was that "applicable" ratings was too general a term, and Normal and Emergency limits could accommodate any ratings / limits provided by the facility owners. The language in R3 already allows numerous methods by which a TOP can devise a set of voltage limits for all, or some, of the set of facilities within its footprint for the purpose of determining SOLs, which should be responsive to your comment on using "applicable voltage limits".

Comment	

Although the current FAC standards include performance criteria, MISO believes that they should reside in IRO and TOP standards. The FAC standard should focus on defining acceptable Operating Limit methodologies. With respect to the proposed performance criteria, MISO has the following concerns:

- Revised standard and SOL exceedance definition appears to imply that exceeding the System Operating Limit (SOL) is not allowed. This makes SOLs more restrictive in management than IROLs, for which there is an allowance to exceed the rating as long as the load is reduced to below the rating prior to exceeding the Tv of the facility. There is no Tv allowance for SOLs, as the definition is currently written.

In particular, the performance criteria as written fail to allow time for the RC or TOP to respond to an event, and readjust the system without immediately putting them in violation of the performance criteria. For example, RTA will show all elements within their emergency ratings per the criteria, but then a contingency occurs and the next RTA shows one or more elements above the highest emergency rating.

- Transmission system could be underutilized, if the SOL Exceedance definition is implemented as currently written.
- Planning standards recognize exceedances of operating limits will occur, and require a plan to mitigate those exceedances. This definition does not allow for the same to occur in Operations

- R6.5 appears to disallow load shedding that may have been specifically designed as part of a RAS or UFLS scheme.

Finally, any change to SOL exceedance in the IRO and TOP standards need to be clear that exceeding a non-IROL SOL, particularly post contingency, is not a violation of any operating standard or criteria.

The SDT appreciates your comments. The SDT appreciates the comments you have provided. The SDT has made several edits to Requirements R4, R5, and R6 and their subparts that the SDT believes addresses many of the comments. The SDT has tried to provide clarity in performance requirements captured in R6 such that it is clear that not meeting performance requirements constitutes an SOL exceedance which then triggers other requirements to mitigate and communicate such exceedances as identified in the IRO and TOP standards. So not meeting performance requirements does not constitute a violation, but rather a violation would occur only if the responsible entity did not fulfill the obligations of the requirements that surround how to respond to SOL exceedances for example.

Requirement R6.5 from the second posting, which is now requirement R6.4 in the latest version of FAC-011-4, was not intended to address what mitigation actions are acceptable for inclusion in an Operating Plan, including RAS or other post-contingency mitigation actions (including under voltage relays that are not specifically part of an overall Under Voltage Load Shed (UVLS) scheme). The SDT did capture that "planned manual load shedding", if included in an Operating Plan, should be a measure of last resort. With respect to RAS, requirement R4.6 requires that the RC document in their SOL methodology the "allowed uses of Remedial Action Schemes and other automatic post-Contingency mitigation actions in establishing stability limits used in operations". However, R4.7 requires "that the use of underfrequency load shedding (UFLS) programs and Undervoltage Load Shedding (UVLS) Programs are not allowed in the establishment of stability limits". The use of UVLS and UFLS as a safety net and not for performance criteria or in the establishment of a stability limit is consistent with FERC commission comments in FERC Order 818.

The language mandates evaluation of all contingencies listed in R5.1.1 of FAC-011-4 as part of the Real Time Assessment (RTA) and the Operational Planning Analysis (OPA) without exception.

R6.2.1 - The flows on transmission element may exceed the applied Emergency Rating during the dynamic time period but there is likely no risk to the system. Although the first phrase "applicable Emergency Ratings" might seem to provide the flexibility, this means an entity must know the "applicable Emergency Rating" for a particular dynamic loading and time period for each piece of equipment and each piece of equipment would need to be monitored in a dynamics analysis

R6.2.3, this language pulls in dynamic analysis of all of these contingencies for both the RTA and OPA

6.3. The evaluation of the potential Contingencies identified in Part 5.2 against the actual pre-Contingency state (Real-time monitoring and Real-time Assessments) and anticipated pre-Contingency state (Operational Planning Analysis) demonstrates that instability, Cascading, or uncontrolled separation does not occur.

6.4. The evaluation of the potential Contingencies identified in Part 5.3 demonstrates that instability does not occur.

R6.3 and R6.4 contain the same problems. It is infeasible to run dynamic simulations as part of the RTA and it is very complex to do so for the OPA. At least in this case, R5.2 and R5.3 allow the RC to provide a very limited list of contingencies.

6.5. In determining the System's response to any Contingency identified in Parts 5.1 through 5.3, planned load shedding is acceptable only after all other available System adjustments have been made.

R6.5 - The standard incorrectly eliminates planned load shedding from consideration when RAS or UVLS programs may have specifically established to take such action to maintain system stability for the particular contingencies under consideration.

Response

The SDT appreciates your comments. The SDT believes steady state contingency analysis of the System should include all contingencies defined in R5.1.1 of FAC-011-4. However, the SDT has revised R4.2 such that only those contingencies expected to produce the most severe stability results need to be examined. This prevents having to test the entire contingency list for stability, as you commented for sub requirement 6.2.3.

The SDT included the phrase "steady state" to allow transient flow / voltage conditions to not be applicable to these sub requirements.

R6.3 has been rewritten and previously proposed R6.4 removed. IT was never the intent that either R6.3 or R6.4 require real time stability analysis. The SDT was silent on the question in R6 to allow entities to continue their present practices, whether it was using off-line analyses to establish defined stability limits which are monitored in terms of pre-contingent conditions in real time or performing real-time stability analysis. This will be documented in the rationale for this requirement.

Finally, with regard to your comment on R6.5, there is no preclusion to using RAS or UVLS programs for load shedding. The sub requirement speaks only to manual load shedding needing to occur after all other actions are taken. RAS and UVLS are not manual load shedding. The SDT has included "manual" to FAC-011-4 R6.4 to clarify that automatic load shedding schemes would not be used to meet performance criteria and that load shed is a measure of last resort. The use of UVLS as a safety net and not for performance criteria or in the establishment of a stability limit is consistent with FERC commission comments in FERC Order 818.

Comment

American Transmission Company LLC (ATC) supports the efforts of the SDT to clarify for the industry what is considered SOL exceedance in the context of the IRO and TOP Standards. We appreciate the SDT listening to the concerns raised by industry regarding the previously proposed SOL Exceedance definition and we agree with the SDT's approach to abandon that potential change. We believe the proposed performance criteria in FAC-011-4 Requirement R6 seems to capture the essence of SOL exceedance. We do agree with the SDT's concept that the Reliability Coordinator's (RC) SOL Methodology must address the system performance criteria to ensure consistent identification of SOLs.

However, ATC is concerned the proposed language creates a significant reliability/compliance burden for RCs and Transmission Operators (TOP) as follows:

- R6.2 - The language mandates evaluation of all contingencies listed in R5.1.1 of FAC-011-4 as part of the Real Time Assessment (RTA) and the Operational Planning Analysis (OPA) without exception. When coupled with R6.2.3, this language pulls in dynamic analysis of all of these contingencies for both the RTA and OPA. This is an infeasible expectation for the RC and TOP to include in their RTAs and OPAs, since R5.1.1 contains no caveats to limit the list of applicable single contingencies.
- R6.2.1 - The flows on a transmission element may exceed the applied Emergency Rating during the dynamic time period, but there is likely no risk to the system. Although the first phrase "applicable Emergency Ratings" might seem to provide the flexibility, this means an entity must know the *"applicable Emergency Rating"* for a particular dynamic loading and time period for each piece of equipment and each piece of equipment would need to be monitored in a dynamics analysis. It may be that the SDT does not intend to pull in dynamics in 6.2.2 but it is a logical reading of the standard.
- R6.2.3 - As noted above, although this is the desired result, it is infeasible to perform dynamic analyses of all R5.1.1 contingencies as part of either an RTA or an OPA. In fact, it is an extremely expensive proposition to perform any real time dynamic simulations due to the complexities of maintaining an accurate dynamic model that incorporates traditional transmission equipment let alone the myriad of user written or proprietary dynamic models in use today for FACTs devices and variable generation.
- R6.3 and R6.4 contain the same problems as noted above. It is infeasible to run dynamic simulations as part of the RTA and it is very complex to do so for the OPA. At least in this case, R5.2 and R5.3 allow the RC to provide a very limited list of contingencies. Still, even with a limited list, the language of R6 and its sub-parts does not limit the scope of what a TOP would be required to run under FAC-014-3 (see R2 of that standard). Rather, FAC-011-4 R6 language implies that a TOP would be required to evaluate all of the contingencies identified by an RC, not just those that apply to the TOP's footprint. Note that FAC-014-3 R2 limits the TOP to identifying SOLs to its footprint, but it does not limit the contingencies a TOP would need to consider.
- R6.5 - The standard incorrectly eliminates planned load shedding from consideration when a RAS or UVLS programs may have specifically established the need to take such action to maintain system stability for the particular contingencies under consideration.

ATC offers the following proposed improvements to address the comments above:

- R6.1.1, R6.1.2, R6.2.1 and R6.2.2 could be improved by clarifying that these sub-requirements are only describing steady-state conditions. Each requirement could have the following leading statement added: "*Under steady-state analysis:*".
- In addition, R6.2.1 and R6.2.2 would also benefit from adding the word "*Anticipated*" ahead of the terms "*Flow*" and "*Voltages*" in these requirements, respectively, to make it clear that these are potential system flows and voltages, not real time flows and voltages, being evaluated.

Regarding the scope of dynamic simulations, the best location to make modifications is likely the R5 and R5.1 language, not R6. Proposed modifications are as follows:

- R5 - Strike "*and performing the Operational Planning Analysis (OPAs) and Real-time Assessments (RTAs) for the area under study*" since this language is redundant to the R6 performance criteria language that will require these contingencies to be evaluated as part of the RTA and OPA. With this removed, R5 is tailored to only describe what contingency events need to be examined for the identification of SOLs.
- R5.1 - Remove the language regarding "*determining stability limits and performing OPAs and RTAs*" and add "*for use in determining steady state SOLs*", since the SOL methodology should require examination of all of the single contingencies listed under R5.1.1 using steady-state analysis. The contingencies to examine for dynamics will be a very small list (hopefully) and can be adequately addressed by modifications to R5.3.should require examination of all of the single contingencies listed under R5.1.1 using steady-state analysis. The contingencies to examine for dynamics will be a very small list (hopefully) and can be adequately addressed by modifications to R5.3.
- R5.2 - Remove "*for use in performing Operational Planning Analysis and Real-time Assessments*" since, again, this is adequately covered by R6, and add in language as follows "*for use in determining steady state SOLs*".
- R5.3 - Strike the word "*additional*" from the existing R5.3 language and add the following to the end of the requirement: "*where the identified single Contingency events involving the loss of a generator, transmission circuit, transformer, shunt device, or single pole block in a monopolar or bipolar high voltage direct current system must simulate either: (a) Normal Clearing of a single phase to ground or three phase Fault (whichever is more severe) or (b) tripping without a Fault condition*".

- Regarding the TOP performing a certain set of contingencies, the R6.2, R6.3 and R6.4 language could all be modified to state: *"The evaluation of applicable potential single Contingencies …"* (for R6.2) and *"The evaluation of the applicable potential Contingencies …"* (for R6.3 and R6.4).
- R6.5 could be improved by clarifying that RAS and UVLS actions should be implemented in the stability analysis, as applicable. The SDT should also recognize that underfrequency load shedding (UFLS) may be a necessary part of system stabilization once a RAS operates if that RAS is creating a planned islanded system. As such, UFLS may also be a warranted load shedding component when performing stability analysis. R6.5 language could be modified by adding *"planned load shedding, other than Remedial Action Scheme (RAS) or UVLS action, is acceptable …"* and then adding a new sentence that reads, *"The use of UFLS programs should only be simulated when incorporated as part of the system design to maintain stability (e.g., RAS)."*

Response

The SDT appreciates the comments you have provided. The SDT has made several edits to R4, R5, and R6 and their subparts that the SDT believes addresses many of the comments.

The SDT has revised the sub requirement in R4.2 to clarify that a subset of Contingencies may be used that are expected to produce more severe System impacts on its portion of the BES.

The SDT has revised the sub requirements in R6 that deal with stability and have tried to remove that text which implies a need to perform real-time stability analysis. It is not the intent of the SDT to require any entity to perform real-time stability analysis as part of their Real Time Assessments.

Requirement R6.5 from the second posting, which is now requirement R6.4 in the latest version of FAC-011-4, was not intended to address what mitigation actions are acceptable for inclusion in an Operating Plan, including RAS or other post-contingency mitigation actions (including under voltage relays that are not specifically part of an overall Under Voltage Load Shed (UVLS) scheme). The SDT did capture that "planned manual load shedding", if included in an Operating Plan, should be a measure of last resort. With respect to RAS, requirement R4.6

requires that the RC document in their SOL methodology the "allowed uses of Remedial Action Schemes and other automatic post-Contingency mitigation actions in establishing stability limits used in operations". However, R4.7 requires "that the use of underfrequency load shedding (UFLS) programs and Undervoltage Load Shedding (UVLS) Programs are not allowed in the establishment of stability limits". The use of UVLS and UFLS as a safety net and not for performance criteria or in the establishment of a stability limit is consistent with FERC commission comments in FERC Order 818.

The criteria given are not clear as written such that they appear to occur in the Real-time horizon and apply to real-time operations rather than in the Operations Horizon as stated. As a consequence, the criteria do not seem to meet a methodology requirement but an operating one. Specifically, the identification of real-time monitoring and assessment as a demonstration is inappropriate for a FAC methodology requirement and belongs in TOP and IRO standards relating to operations. We believe there should not be an operating requirement in FAC-011 and in our opinion this is a poor practice and should be shelved. The Standard "families" set certain expectations and should be respected because to do otherwise will create risks of inconsistency. If the TOP and IRO standards need amending, then amend them!

Response

The SDT appreciates the comments you have offered. Your comments about applicability of the performance criteria to either the FAC or TOP/IRO standards is one made by numerous entities. The SDT has discussed this at length, while considering that the existing FAC-011-3 has performance requirements (R2 and sub requirements), no specificity exists in the present TOP and IRO standards regarding thermal, voltage and stability performance, other than stating that SOLs must be respected and SOLs exceedances acted upon, while not definition of SOL exceedance exists. Since SOL exceedances (or potential ones) can be determined from the Operational Planning Time Horizon up to and including Real Time, the SDT thought having a single common set of requirements for SOL exceedances made sense. If those existing in the TOP and IRO standards for real time, then they would have to exist for outage coordination and operating planning analyses. Rather than

include duplicates of language for SOLs throughout the TOP and IRO standards, the FAC SDT sought to include in one location, the RC methodology, the verbiage used to define SOL exceedances for the entire RC footprint. To a certain extent, that is already done with existing R2 in FAC-011-3. The SDT's revised FAC-011-4 R6 proposes to have the RC define SOL exceedances using a common initial basis with the performance criteria in the sub requirements of R6. This application seems consistent with what an SOL methodology should contain, and currently does for many RCs at present. The SDT has however proposed modifications to IRO-008 and TOP-001 to coordinate between those two standards and FAC-011-4. The SDT believes these modifications best address the noted concerns in a balanced fashion with other comments and feedback while maintaining some amount of flexibility for the RC in the SOL methodology.

SRP is concerned the language in 6.5 may be too limiting, specifically the phrase "only after **all** other available System adjustments". SRP suggests either adjusting the language to state "after other reasonable System adjustments have been made", or to state "while other system adjustments are being made". It may be necessary to respond first with load shed while other system adjustments are being made, then returning the load. The language should allow entities to use all available tools and determine the best process for maintaining stability of the system. Also, SRP recommends retaining some of the language in FAC-011-3 R2.3 and R2.4 explicitly identifying acceptable post-Contingency actions. Consideration of post-Contingency actions is appropriate in an SOL methodology because the available actions delineate the "specified System configuration". Furthermore, including the language in the standard and as a result in the RC's SOL Methodology, helps ensure the performance criteria in the Operations Horizon is not more limiting than the performance criteria used in the Near-term or Long-term Planning Horizons.

The SDT appreciates your comments. The SDT discussed language choices on proposed R6.5 at length. The first option you offered with the word "reasonable" was thought to be subjective, and not language that should be in a standard. The second option you offered, "while other system adjustments are being made" again seemed to suggest load could be shed when there were other options that could be deployed to preclude the load shed, for example, dispatch of uneconomic generation.

The SDT chose the language it did in the proposed sub requirement to emphasize that manual shedding of load should be done as a matter of last recourse. This does not include planned RAS or UVLS, which would have been examined with other options by the operating entities. If conditions do not allow the application of alternatives, then of course load can be shed to maintain system reliability. In this respect, the SDT agrees with your comment that load may have to be shed before other actions can be taken. This language removes no tools for maintaining system reliability; it merely states that manual load shed should be used only after exhausting all other options. Additional description is offered in the posted rationale.

With regard to your comment to retaining language from FAC-011-3 R2.3 and R2.4, proposed R6 retains the option to shed load. Existing R2.3.1 goes without saying except for the final phrase "or by the affected area"; radial or faulted elements result in lost load when those elements are lost. R2.3.2 is a less specific, more flexible way of stating what the SDT did in R6. The SDT did not believe there was a need to describe how an operating entity operates the system as FAC-011-3 R2.3.3 and R2.4 attempt to do.

Finally, with respect to your comment that performance criteria in the Operations Horizon is no more limiting than that in the Planning Horizons, it is not the SDT's opinion that the language proposed in R6, or any other portion of FAC-011-4 supports that position. It is our understanding that the RC is the ultimate authority for operating criteria just as the PC is the ultimate authority for planning criteria, and FAC-011 is not the mechanism by which to coordinate the two sets of criteria.

ITC agrees with MEC and believes that addressing the fundamental concept of defining SOL Exceedance needs to be done within the framework of IRO and TOP standards, where it inherently and logically belongs. We do not agree with the approach of moving that cornerstone of reliable operations from IRO/TOP set of standards to the FAC set of standards. In other words, we believe that the present context of defining what constitutes SOL exceedance and reacting to it by initiating an Operating Plan (per IRO-008-2-R2 and TOP-001-4-R14) is far better than directly exposing large number of entities to the risk of non-compliance without appropriate considerations related to physical constraints that need to be overcome during implementation of Operating Plans, in a timely manner.

The FAC standards should facilitate the creation of SOL's, not define operating criteria. SOL's should; (1) at a minimum be equal to Facility thermal or voltage limits and (2) consider system stability (voltage or transient) limits that may require limits more restrictive than Facility thermal or voltage limits.

The FAC standards should in no way infer that dynamic analysis needs to be performed as part of RTAs. Requirement R6 of FAC-011-4 as currently written could be inferred to require real time dynamic analysis. Specifically, it is unclear if requirements R6.1.3, R6.2.3, R6.3 and R6.4 require that RTA's include dynamic analysis to determine if Instability would occur or if operating to the pre-identified SOL's would provide this determination.

ITC agrees with MEC that the phrase "could be executed and completed within the specified time duration" throughout requirement R6. This could be interpreted as requiring a timing analysis before the contingency occurs to determine if ramp rates, start-up times and location and amount of load shedding are adequate. The implementation risk and compliance risk associated with this language is substantial and very concerning. Based on the language, TOP is expected to perform and document a timing analysis to determine if the adjustments could be executed within the specified time duration of Emergency Ratings each and every time when TOP performs RTA and find its facilities operating between Normal and Emergency Rating (either in real-time or on a contingency basis). It should be noted that such a timing analysis in real-time is difficult and requires significant time and resources.

Instability, as used throughout the existing standards is an undefined term which leaves room for broad interpretation. This term should be removed or defined to clarify that single unit instability would not constitute “instability” as it is used in these proposed standards.

The SDT appreciates the comments you have provided. The SDT received similar comments with regard to where in the standards to implement some form of SOL exceedance definition or determination. While the TOP and IRO standards may seem to be the appropriate place, the current standards have no standard which requires a uniform method be used between an RC and its TOPs when defining SOL exceedances. Furthermore, the cited existing requirements (TOP-001-4 R14 and IRO-008-2 R2) merely state merely have an operating plan to use when SOL exceedances are identified with no mention of how those SOL exceedances are determined. The SDT has however proposed modifications to IRO-008 and TOP-001 to coordinate between those two standards and FAC-011-4. The SDT believes these modifications best address the noted concerns in a balanced fashion with other comments and feedback while maintaining some amount of flexibility for the RC in the SOL methodology. The SDT, through our three years of discussion and industry consultation, believe it is appropriate that each RC have a defined SOL exceedance determination methodology for use within its footprint. In addition, the broad outlines of what may constitute an SOL exceedance, per the proposed R6 and its sub requirements, seemed a reasonable place for each RC to use as an initial basis when developing their SOL exceedance method since the existing FAC-011-3 R2 requires the system to be “within their Facility Ratings and within their thermal, voltage and stability limits (R2.1)”. The SDT has revised the sub requirements in R6 that deal with stability and have tried to remove that text which implies a need to perform real-time stability analysis. It is not the intent of the SDT to require any entity to perform real-time stability analysis as part of their Real Time Assessments. In addition, the SDT has removed or changed the wording dealing with “the specified time duration” and more generally applied the appropriate limits for the condition (thermal or voltage) in question.	

Finally, the SDT used the word “instability” as it is currently used in the definition for IROL as found in the NERC glossary of terms. The SDT will consider adding a clarifying phrase to limit the instability consideration to the BES.

Texas RE has concerns with the performance criteria specified in FAC-011-4 Requirement R6. As an initial matter, until FAC-014-3 Requirement R6 is read, it isn't understood that the performance criteria in FAC-011-4 R6 is referring to SOL exceedances.

That said, Texas RE is concerned that the way the performance criteria is written, and that an SOL exceedance would not occur until the highest Emergency Rating is exceeded. Therefore, the RC and TOP may not develop an Operating Plan for exceedances of the Normal Rating identified through the OPA (TOP-002-4 and IRO-008-2), and would not be required take action to return flow to Normal Ratings when Real-time flows exceed the Normal Rating (TOP-001-4), since there is no exceedance occurring in the Parts 6.1 and 6.2 scenarios:

- FAC-011-4 Part 6.1 - Operating Plans should be created anytime the anticipated pre-Contingency state (Operational Planning Analysis) demonstrates flow above the normal Rating or voltage outside of the normal System Voltage Limits. Additionally, Operating Plans should be initiated when the actual pre-Contingency state (Real-time monitoring) identifies flows or System Voltage Limits exceeding the normal Rating.
- FAC-011-4 Part 6.2 should still require entities to create an Operating Plan that is available to System Operators if evaluation of potential single Contingencies listed in Part 5.1.1 against the anticipated pre-Contingency state (Operational Planning Analysis) indicates flow above normal Ratings. There is no way to know if System adjustments could be executed within time duration of Emergency Ratings without creating an Operating Plan to address the issue, and identifying a time-frame in which the Operating Plan could be executed. Since FAC-014-3 R6 states determination of SOL exceedances during the OPA is required to be in accordance with RC SOL Methodology, this language would not require a the creation of an Operating Plan to mitigate an exceedance of the normal Rating that is identified during the OPA.

- Real-time flows may legitimately exceed Normal Ratings as a result of conditions unanticipated by OPA, initiating the use of Emergency Ratings and their associated time limits in order to return flows to below Normal Ratings without an Operating Plan. This is the intended purpose of Emergency Ratings. It is unrealistic to assume that all operating conditions are captured by OPA, as OPA is based on preconceived contingent states.
- The same does not hold true for “anticipated pre-Contingency states” based on OPA. An anticipated pre-Contingency overload beyond the Normal Rating indicated by OPA is a base case overload which requires mitigating actions or an Operating Plan before the condition which would cause the overload occurs. Using Emergency Ratings and their associated time limits for this situation is not their intended purpose.

RCs and TOPs should be prepared when flow is outside of Normal Ratings. In order to maintain reliability, Texas RE recommends immediate action through the use of an Operating Plan to mitigate any flows or voltages outside the Normal ratings or System Voltage Limits.

Response

The SDT appreciates the comments. The SDT has made several edits to R6 based on industry comments. The SDT has, however, preserved the understanding identified in the SOL whitepaper that pre-contingency flow beyond a Normal Rating but below an Emergency Rating for a finite period of time less than the associated time with the Emergency Rating (e.g. 2 hours) is acceptable system performance and thus would not be required to constitute an SOL exceedance. Similarly post contingency flow beyond a Normal Rating but below an Emergency Rating for which there is reasonable time to address the exceedance before the finite period of time associated with the Emergency Rating (e.g. 2 hours) is acceptable system performance and thus would not be required to constitute and SOL exceedance. Nothing precludes an RC from applying more conservative criteria such as that as described by Texas RE’s comments, however, this standard would not require such performance criteria.

The SDT understands the comments surrounding the OPA and Operating Plans and real time conditions, however the SDT is focusing responses on the subject matter of FAC standards and not the corresponding IRO/TOP standard requirements and what constitutes an acceptable Operating Plan.

Comment	

Southern California Edison (SCE) believes that the NERC Standard Drafting Team approach of defining SOL Exceedance through a performance criteria in Requirement 6 of FAC-011-4 is inappropriate. If the Standards Drafting Team decides to include the undefined term "SOL Exceedance" within the performance criteria of FAC-011-4, the SDT effectively exposes a number of TOPs and RCs to the risk of violating FAC-011-4 (Requirement 6) if/when exceedances of system operating limits occur either in RTA or OPA. SCE believes that NERC should mitigate the regulatory uncertainty of using the undefined terminology within the performance criteria of FAC-011-4, and create a standard definition of SOL Exceedance. SCE is particularly sensitive to this issue due to Peak RC ceasing operations in 2019.

Additionally, SCE believes NERC should create a definition for "SOL Exceedance" by using existing framework of IRO and TOP standards. SCE believes that the present context of defining what constitutes SOL exceedance and reacting to it by initiating Operating Plan (per IRO-008-2-R2 and TOP-001-4-R14) is far better than directly exposing large number of entities to the risk of non-compliance without appropriate considerations related to physical constraints that need to be overcome during implementation of Operating Plans, in a timely manner.

Finally, SCE supports the examples presented by MidAmerican and the MRO NSRF that demonstrate the unintended consequences of using the undefined term "SOL Exceedance" within FAC-011-4 Requirement R6.

Response

The SDT appreciates the comments. The SDT notes your comments, however a previous attempt to create a definition for SOL exceedance received feedback that a majority of the commenters did not agree the proposed definition and that a definition was not needed. The SDT has chosen to use a similar approach to the current FAC-011-3 which specifies system performance criteria and allows the RC to define what constitutes an SOL exceedance for its RC Area so long as it meets or exceeds the system performance criteria.

We are in general agreement over the proposed changes as they essentially maintain the system performance criteria, similar to the approach in the currently effective FAC standards. Our main comments are:	

- The proposed standards should require the Reliability Coordinator's (RC) methodology to establish stability limits when those limits also impact other RC Areas, and that the criteria for the selection of contingency events is defined and applied consistently in all the RC areas, in order to ensure that all IROLs within a defined scope are detected and properly studied.

- Throughout the standard development process for the revisions of the IRO/TOP standards the IESO continued to comment on our serious concern over the proposed retirement of Requirement R4 of TOP-004-2 without having it reinstated in TOP-001-3 or having some of the requirements in TOP-001-3 revised to addressing the reliability need for confirming or reestablishing valid SOLs/IROLs in an unknown or unstudied state. We recognized that by virtue of the proposed definition of Operational Planning Analysis (OPA) and Real-time Assessment (RTA), as well as the new requirement for TOPs to update their OPA results through the performance of a RTA every 30 minutes, that the entities will always be assessing the reliability of the BES. However, this falls short of requiring an entity to determine new/revised limits to begin with. Without knowing the boundaries, performing real-time analysis every 30 minutes does not give the entity an indication if current operations (power flow or voltage levels) exceed the limits that are valid and applicable for the present conditions. These conditions pose unacceptable risks of instability since the operator does not know whether the next contingency will result in system instability.

We recognize that this issue is not within the scope of this project, but is directly related through the methodology that will be used to determine operating limits for these unknown states. In order to better coordinate the development of standards, we recommend that the scope of future NERC projects should better identify relationships between families of standards at the onset, and encourage potential revisions to related requirements.

We are in general agreement over the proposed changes as they essentially maintain the system performance criteria, similar to the approach in the currently effective FAC standards. Our main comments are:

· The proposed standards should require the Reliability Coordinator's (RC) methodology to establish stability limits when those limits also impact other RC Areas, and that the criteria for the selection of contingency events is defined and applied consistently in all the RC areas, in order to ensure that all IROLs within a defined scope are detected and properly studied.

· Throughout the standard development process for the revisions of the IRO/TOP standards the IESO continued to comment on our serious concern over the proposed retirement of Requirement R4 of TOP-004-2 without having it reinstated in TOP-001-3 or having some of the requirements in TOP-001-3 revised to addressing the reliability need for confirming or reestablishing valid SOLs/IROLs in an unknown or unstudied state. We recognized that by virtue of the proposed definition of Operational Planning Analysis (OPA) and Real-time Assessment (RTA), as well as the new requirement for TOPs to update their OPA results through the performance of an RTA every 30 minutes, that the entities will always be assessing the reliability of the BES. However, this falls short of requiring an entity to determine new/revised limits to begin with. Without knowing the boundaries, performing real-time analysis every 30 minutes does not give the entity an indication if current operations (power flow or voltage levels) exceed the limits that are valid and applicable for the present conditions. These conditions pose unacceptable risks of instability since the operator does not know whether the next contingency will result in system instability.

We recognize that this issue is not within the scope of this project, but is directly related through the methodology that will be used to determine operating limits for these unknown states. In order to better coordinate the development of standards, we recommend that the scope of future NERC projects should better identify relationships between families of standards at the onset, and encourage potential revisions to related requirements.

Response

The SDT appreciates the comments. The SDT has added to FAC-011-4 R4.3 the phrase "or other Reliability Coordinator Areas." The SDT recognizes the comments surrounding the retirement of TOP-004-2 R4, however the SDT is focusing responses on the subject matter of FAC standards and not the corresponding IRO/TOP standard requirements and would direct the commenters to previous responses to similar comments issues as part of that Project 2014-03 SDT as those comments attempted to address the concerns noted. The SDT reaffirms its scope to focus on the SOL methodology and subsequent required content and performance criteria contained within.

We support the FAC revisions.

We have the following comments:

Subrequirements R7.1 andR 7.2

We agree with comments submitted by the NPCC RSC in regards to requirements 7.1 and 7.2. The subrequirements R7.1 and R7.2 require the identification of SOL that are IROL and the criteria for identifying SOL violations that are IROL. We do not understand the difference and our compliance department do not see how the evidence of those two subrequirements would be distinct.

Requirement R5.1

We have a minor comment regarding the addition in R5.1 of "Specify the" makes the use in 5.1.1 of "any" more ambiguous than it is in the current version. Consider that R5 now requires

a) identify in its SOL methodology…

b) Specify the following single contingency event…

c) Loss of "any" of the following.

Before it clearly "included" the following "list" of single contingency events. It would be better for the language to clearly state in 5.1.1. "Loss of each of the following" or return to language that clearly mandates the inclusion of the loss of all the listed elements. Requirement 9 Also, the last sentence of the Rationale for Requirement R9 for FAC-011-4 should be modified as follows. "(…) mandates provision of the SOL Methodology to non-adjacent RCs [or to adjacent RCs in another Interconnection] that have specifically requested (…)"	
Likes 0	
Dislikes 0	
Response	
Thank you for your comments. With regard to your query on subrequirements R7.1 and R7.2, those exist in today's FAC-011-3 as R1.3 and R3.7. They have been included, unchanged, from the existing FAC-011-3 other than being relocated to single common standard (R7). If you wish to propose a revision, perhaps joining the two subrequirements (maybe something like "A description of how to identify the subset of SOLs that qualify as Interconnection Reliability Operating Limits (IROLs), including the criteria for determining when violating a SOL qualifies as an IROL and criteria for developing any associated IROL Tv."), please do so. Regarding your question on R5.1 and R5.1.1, the drafting team made the revisions as shown to provide the flexibility for contingency lists created for stability analysis to not have to examine every single facility contingency when engineering judgement would allow the contingency list to be distilled down to the likely most limiting. Real time steady state analysis could and should use a contingency list that includes most of the single element contingencies, but even that list could exclude a subset of contingencies that could not be most limiting, for example loss of a small load serving transformer or a small generator. Finally, with regard to requirement 9, we included subrequirement 9.1 so that any RC could request an RC's SOL methodology and subrequirement 9.2.4, which allows any RC to request another RC's SOL methodology, should there be a reliability based need, before it becomes effective. These two subrequirements should allow adjacent RCs in another interconnection to request the appropriate SOL methodology of their choice.

Regarding R3.3 What is the purpose of this subrequirement? The methodology should not prevent or limit the use of undervoltage load shedding by the Reliability Coordinator in the operational time frame. Suggest changing the wording to allow for undervoltage load shedding within the operational time frame as long at the reliability coordinator is aware. The methodology could have the requirement that the use of UVLS requires RC approval.	
Likes 0	
Dislikes 0	
Response	
We appreciate your comment. This subrequirement (R3.3) was derived after much drafting team and observer discussion. The consensus was that while under-voltage load shedding (UVLS) schemes can be useful, they should not be the premise upon which acceptable system performance is solely based. When there are other operating actions which can be taken, such as dispatch of generation, those actions should be taken, while the under-voltage load shedding schemes can act to mitigate unexpected poor system performance should it occur. As an example, if the lowest acceptable post-contingent voltage was 90% of nominal, the UVLS scheme could have an actuation voltage setting of 89% of nominal.

Numbering typos exist in Measure Nos. M7, M8, and M9. Requirement Nos. R7, R8, and R9 should be referenced accordingly.

Revised language in Requirement R1 is not included in the Violation Security Levels table. Specifically, the term “documented” was added to Requirement R1. ERCOT suggests including the term in the Violation Severity Levels table order to be consistent.

Similarly, the revised language in Requirement R2 is not included in the Violation Security Levels table. Specifically, “the applicable” was replaced with “which” and “are” in Requirement R2. ERCOT suggests including the same revisions in the Violation Severity Levels table.

In requirement R9, “and any changes to the SOL Methodology prior to the effective date of the SOL Methodology” was deleted. ERCOT suggests aligning the Violation Severity Levels table to align with this revision and the specific language of the applicable requirements. For Part 9.1, there is no distinction between “new or revised” in the wording of the requirement, but it is explicitly stated in the Violation Severity Levels table.

ERCOT suggests capitalizing “methodology” in Requirement R9, Part 9.2.

Requirement R2 specifically states that the RC "shall include in its SOL Methodology the method for Transmission Operators to determine which owner-provided Facility Ratings are to be used in operations". This requirement needs to be bounded such that the RC is not specifying in its methodology how a Transmission Operator and thus a Transmission Owner is required to rate its transmission facilities, up to and including the use of real time ratings. This would determine the amount of risk a Transmission Owner is subject to for its facilities. The standard should only specify the end objective and not the process to achieve that objective.	

Requirement R8 is redundant with IRO-010-2 R1. SOLs are inputs to OPA and RTAs. As such, R1 of IRO-010-2 already requires the RC to maintain a documented specification of the data necessary for it to perform its Operational Planning Analyses, Real-time monitoring and Real-time Assessments. This requirement included requirements for periodicity of providing the data. As such, R8 of proposed FAC-011-4 is redundant and should be deleted from the proposed standard.

Response	
Thank you for your comment. The language in requirement R2 was chosen to allow the RC to describe how it wishes the TOP to use the facility-owners ratings to meet the rating needs of the RC. The RC is allowed to determine what it needs for rating information to function. By doing so, the RC does not dictate to either the facility owner now TOP what ratings need to be provided. For example, the RC may state it wants a normal rating and a 1 hour emergency rating. Per requirement R2, the RC may instruct the TOPS, through its SOL methodology, that it wishes to have its rating set filled with the rating whose time duration most closely approximates the desired duration of the RC's rating, with the rating chosen always having a time duration at least equaling that of the RC's rating. Therefore, if the facility owner provided ratings for 24 hour, 2 hour and 30 minutes, the TOP would use the 24 hour rating for the normal rating and the 2 hour rating to meet the RC's 1 hour rating. This example illustrates how the RC describing how the facility ratings may be used to meet the RC's rating needs does not determine how the facility owner rates equipment.

Comment	

FMPA is concerned that Project 2015-09 does not consider the work done by the MEITF (Methods for Establishing IROLs Task Force). There are defined terms used in R6 that the MEITF has proposed changes to, and that have been endorsed by the NERC PC and OC. FMPA asks that the implementation plan be changed so that FAC-011-4 would only be effective once the new definitions proposed by the MEITF become effective

Likes 0

Response

We thank you for the comment. The drafting team, in consultation with NERC, have decided that the work, and terms, defined by the MEITF, as well as the IROL topic, can wait while the FAC standards that are within scope of the drafting team are resolved. It is the opinion of the SDT and NERC that the terms defined by the MEITF are not needed to revise FAC-011.

Douglas Johnson - American Transmission Company, LLC - 1

Comment

ATC does have other comments on FAC-011-4:

- Requirement R3 addresses the establishment of a voltage-based SOL at each bus. No similar requirement is given for thermal ratings. It is unclear if the SDT expects each Facility to have a thermal-based SOL. Alternatively, can TOPs and RCs use multi-element or proxy flowgates to manage power flow on the system? The expectation regarding thermal related SOLs needs to be clearly stated in any requirement such that entities can fulfill the requirements and all entities are operating the BES from the same understanding.
- R3.3 should be improved by clarifying what undervoltage load shedding (UVLS) systems are in view (i.e. owned by the Transmission Owner, the Distribution Provider, end-use customer). It would seem that R3.3 should not be limited by UVLS relay settings implemented by a distribution utility or an end-use customer. A suggested edit is to clarify these are BES systems as follows: "*in-service BES relay settings for undervoltage load shedding…*".

• Similar to comments provided in question #1 related to R6.5, Requirement R4.7 should be modified to remove the restriction on using UVLS Programs when setting stability limits. It is generally accurate to state that UFLS should not be relied upon to maintain stability, although the SDT needs to recognize that UFLS may be a necessary component to maintain stability of a portion of a system deliberately islanded by a Remedial Action Scheme. As such, R4.7 should be modified to read, *"State that the use of underfrequency load shedding (UFLS) programs are not allowed in the establishment of stability limits except in specific, documented circumstances (e.g., Remedial Action Schemes)."*

Dislikes 0	
Response	
Thank you for your comments. The wording of requirement R2 in FAC-011-4 is such that the RC is setting a method for adoption of ratings for all elements for which the facility-owner provides thermal ratings. This is done with the expectation that the RC models and uses thermal ratings for each system element with a rating provided. With that said, there is no preclusion that prevents the TOP or RC using a multi-element or proxy flow gate to assist in maintaining reliability, as long as the provided ratings are used also, and respected in at least their Real-time monitoring, Real-time Assessments, and Operational Planning Analyses. With respect to your comment on subrequirement R3.3, we have adopted your language suggestion. Finally, with respect to your comment on using UVLS and UFLS on setting stability ratings, the SDT discussed both at length. With regard to UVLS, and the setting of traditional stability limits, such as those recognizing angular stability, shedding load via UVLS will not improve stability but instead will either do nothing or exacerbate the concern, so UVLS is not a solution to unit / angular stability nor transient voltage recovery. The preclusion for using UFLS has to do with maintaining stability on the interconnected BES and not disconnected islands, so the standards as proposed do not apply to individual islands created as a consequence of system events, and as such, do not speak to UFLS use within those created islands.	
Amy Casuscelli - Amy Casuscelli On Behalf of: Michael Ibold, Xcel Energy, Inc., 3, 1, 5; - Amy Casuscelli

Comment	
We offer the following specific comments: Sub-Requirement R4.1.3:	

It is not clear what is meant by "unit" stability. We suggest reverting back to using the current term "angular" stability as it is a term well understood by the industry.

Sub-Requirement R4.3:

A main concern is the lack of criteria to define contingencies for the establishment of IROLs. Today, some RCs respect single contingencies, while other respect double contingencies. Given the impact on the Interconnection, it is crucial that criteria for the selection of contingency events is defined and applied consistently in all the RC areas, in order to ensure that all IROLs within a defined scope are detected and properly studied. We recommend that the following wording is added to Sub-Requirement R4.3 to establish SOLs that impact on the Interconnection:

"Describe how the Reliability Coordinator establishes stability limits when there is an impact to more than one Transmission Operator in its Reliability Coordinator Area or other Reliability Coordinator Areas in accordance with its SOL Methodology."

Sub-Requirements R5.2 and R5.3

Sub-Requirements R5.2 and R5.3 require the RC to identify any additional single or multiple Contingency events. We believe that specifying, at a minimum, which contingencies must be respected (similar to Sub-Requirement R5.1.1. for single Contingencies) would improve reliability. In particular, to the extent there is an alignment in respecting the same set of contingencies and performance criteria for IROLs.

Furthermore, the loss of small or radial portions of the system should be acceptable provided the performance requirements are not violated for the remaining bulk power system.

Sub-Requirement R6.2.2

Sub-Requirement R6.2.2 should include the same wording as sub-requirement 6.1.2:

"Voltages are within normal System Voltage Limits; however, emergency

System Voltage Limits may be used when System adjustments to return

the voltage within its normal System Voltage Limits could be executed

and completed within the specified time duration of those emergency System Voltage Limits."

Sub-Requirements R6.3 and R6.4

For consistency purposes, we recommend that Sub-Requirements R6.3 and R6.4 also require to demonstrate that flow through Facilities are within Normal Ratings, similar to Sub-Requirements 6.1.1 and 6.2.1:

"Flow through Facilities are within Normal Ratings; however, Emergency

Ratings may be used when System adjustments to return the flow within its Normal Rating could be executed and completed within the specified time duration of those Emergency Ratings."

Sub-Requirements R7.1 and 7.2

Sub-requirements R7.1 and R7.2 require to describe how to identify IROLs, and to identify the criteria for IROLs which is basically the same thing. We recommend merging these sub-requirements into one:

7.1. A description of the criteria to identify the subset of SOLs that qualify as Interconnection Reliability Operating Limits (IROLs) and for developing any associated IROL Tv.

R3

Sub-Requirement 3.5 combines two requirements, (1) require a method for determining… and (2) require common use. Sub-Requirement 3.5 should be re-written as "require a method for determining…" as shown below.

We assume that 3.6 and 3.7 intend to "address coordination" within the "method for determining" the limit. As such, that consideration should be rolled into the requirement for "a method for determining.."

Since System Voltage Limits are SOLs, it is unnecessary to explicitly require the operation within the restrictions of System Voltage Limits. Also it is inappropriate to place any system operation requirement (Require the use…) within an operating parameter development methodology. There are already requirements for the system to always be studied and operated within the SOL restrictions of the local reliability entity as well as the SOL of adjacent reliability entities. All requirements for "require the use of common" should be deleted.

3.5 Provide the method for determining the common System Voltage Limits in coordination with adjacent Reliability Coordinators and Transmission Operators.

R4

What is the point of R4.2? If R5 requires that all stability analysis to evaluate the contingencies listed in "5.1. Specify the following single Contingency events for use in determining stability limits and performing OPAs and RTAs." How can one violate 5 without also violating 4.2? Is this not double jeopardy? The identical requirements are applied to both general SOL stability analysis and OPA/RTA stability analysis. R4.2 is a requirement to comply with R5.1.

Sub requirements 5.3 and 5. 4 are double jeopardy and should be deleted. How can there be any contingencies used “determining the stability limits to be used in operations” that are not completely identical to the contingencies used in “determining stability limits and performing OPAs and RTAs.” It is impossible to violate 5.3 or 5.4 without simultaneously violating 5.2

We suggest the SDT Re-write 4.2 determining the stability limits to be used in operations as follows and eliminate R5 its entirety.

4.2 Specify the following single Contingency events for use in determining stability limits

4.2.1. Loss of any of the following either by single phase to ground or three phase Fault (whichever is more severe) with Normal Clearing, or without a Fault:

• generator;

• transmission circuit;

• transformer;

• shunt device; or

• Single pole block, with Normal Clearing, in a monopole or bipolar high voltage direct current system.

4.2.2. Identify any additional single or multiple Contingency events or types of Contingency events for use in performing Operational Planning Analysis and Real-time Assessments.

R5

What is the point of R5.2? If 5.2 requires that all stability analysis to evaluate the contingencies listed in “5.1. Specify the following single Contingency events for use in determining stability limits and performing OPAs and RTAs.” How can one violate 5.1 without also violating 4.2? Is this not double jeopardy? The identical requirements are applied to both general SOL stability analysis and OPA/RTA stability analysis. R4.2 is a requirement to comply with R5.1.

Sub requirements 5.3 and 5. 4 are double jeopardy and should be deleted. It is impossible to violate 5.3 or 5.4 without simultaneously violating 5.2

Re-write 4.2 as follows and eliminate R5 its entirety.

4.2 Specify the following single Contingency events for use in determining stability limits

4.2.1. Loss of any of the following either by single phase to ground or three phase Fault (whichever is more severe) with Normal Clearing, or without a Fault:

• generator;

• transmission circuit;

• transformer;

• shunt device; or

• Single pole block, with Normal Clearing, in a monopole or bipolar high voltage direct current system.

4.2.2. Identify any additional single or multiple Contingency events or types of Contingency events for use in performing Operational Planning Analysis and Real-time Assessments.

Response
Thank you for your comments. We accepted your change and now use "angular" stability. With regard to your comment on subrequirement R4.3, the parent requirement, R4, states that the "Reliability Coordinator shall include in its SOL methodology the method for determining the stability limits to be used in operations. The method shall: . . . " which already makes subrequirement R4.3 subject to the RC's SOL methodology. We believe the suggested text addition is not necessary in R4.3. With respect to your suggested additions to subrequirements R5.2 and R5.3, while the topic was discussed, there was not enough consensus on the topic to include your suggested in the requirements. With respect to your suggested revision for subrequirement R6.2.2, the SDT did not think it appropriate to suggest post-contingent voltages need to be within normal System Voltage Limits. The SDT agreed that emergency System Voltage Limits are appropriate for use in the post-contingent state. The SDT further recognized that emergency System Voltage Limits make take on a variety of forms, with varying potential time applicability, and as such, thought the each TOP / RC would use their emergency System Voltage Limits appropriately as they transitioned the system to a new pre-contingent state to prepare for the next contingency without the need for further language in the standard. The SDT discussed at length new subrequirements R6.3 and R6.4, including which reliability criteria should be applicable. The SDT could only agree that any contingencies included in the RC's contingency list per subrequirement R5.2 should only have to demonstrate the performance described in subrequirement R6.3. RCs are not precluded from having more prescriptive criteria for any contingency they specify per subrequirement R5.2. In addition, subrequirement R6.2.1 already establishes appropriate thermal performance in the post-contingent state and is not required to be restated in subrequirement R6.4. The SDT has accepted your suggestion of combining subrequirements R7.1 and R7.2 into a single requirement. The SDT has revised subrequirement R3.5 to only defining the method to be used to determine voltage limits for the conditions described. Subrequirements R3.5, R3.6 and R3.7 have been combined into a single subrequirement (R3.5). The SDT retained the concept of defining the method for determining common System Voltage Limits found in the old and new subrequirements due to multiple participants in the drafting process noting it as a real operating concern. There is nothing in the subrequirment that mandates the establishment of common System Voltage Limits, and whatever System Voltage Limits results, the most limiting will be respected in operating the system.

Subrequirement R4.2 was established due to numerous comments by industry and members of the SDT. The subrequirment allows an RC or TOP to uses those contingencies that produce the more Severe system impacts when establishing stability limits. Commenters correctly pointed out that without such a subrequirement, all contingencies would have to be tested to establish contingency limits, including those that had no reasonable likelihood of setting a stability limit. Subrequirement R5.1 establishes the minimum contingency list, and subrequirement defines the subset of those contingencies that may be tested to establish stability limits. Subrequirement R5.3 has been removed. Subrequirement has been changed to conform with removing FAC-015 and including a new requirement R7 in FAC-014. The SDT does not believe the revised subrequirement R5.3 is "double jeopardy" in any way; instead, the subrequirement is included so that contingencies identified in annual planning assessments causing stability issues can be evaluated to see if any additional contingencies should be respected in operating the system based upon the supplied information. The subrequirement does not require inclusion of additional contingencies. The subrequirement is based upon information already required for provision in FAC-014-2, subrequirements R6.1 and R6.2.

Do not agree with R3.3, too restrictive. Should be allowed to have UVLS relays set higher then SOL voltage limits.	
Likes 0	
Dislikes 0	
Response	
The SDT appreciates your comment. Your perspective was discussed at length by the SDT with regard to this subrequirement. That discussion, and resulting comments from observers and drafting team members recognized that allowing UVLS relays to actuate above System Voltage Limits would potentially allow a TOP to not take all appropriate actions to remain within System Voltage Limits, which was not believed to be appropriate when operating the system. That is the reason why this subrequirement was written with this choice of language.	

Terry BIlke - Midcontinent ISO, Inc. - 2	
Answer	
Document Name	
Comment	
R5.1.1 includes all generators and all shunt devices. There is minimal benefit to attempting to study the impact of the unavailability of every shunt device on the transmission system. Defining some criteria on which shunt devices will be studied would be ideal, to avoid creating an unnecessarily burdensome requirement for studies being performed. RCs should specify their criteria for including these, recognizing the size and potential impact of individual elements, the design of system protection, and the needs of their area.

Response	
Thank you for your comments. The SDT revised requirement R5 to state that "Each Reliability Coordinator shall identify in its SOL methodology the set of Contingency events for use in determining stability limits and the set of Contingency events for use in performing Operational Planning Analysis (OPAs) and Real-time Assessments (RTAs)." These sets of Contingency events, while based upon the contingency events listed in subrequirements R5.1.1, R5.2 and R5.3, may be adjusted to account for concerns such as the one you describe.

Recommendation: Replace "Instability" with "System instability"

Proposed FAC-011-4. The companies suggest replacing "instability" with "System instability" to provide context and boundaries to the proposed Requirements.

The companies recognize the word "instability" is used without a modifier in the NERC Reliability Standards and Glossary Terms but equally so, it is used with a modifier to provide a boundary to the word. For example:

- Glossary Term: ULVS Shedding Program, "…leading to voltage instability, voltage collapse…"
- Glossary Term: Adverse Reliability Impact, "…an event that results in frequency-related instability…"
- TPL-001-4 R6, "…system instability…voltage instability…"
- PRC-012-2 R4.1.3, "…angular instability, voltage instability…"
- PRC-024-2 R1, "…instability in power conversion…"

Significant Administrative Burden. The effect of using "instability" without a modifier will require entities to report every single instance of "instability" developed from a significant number of contingency events identified during the annual Planning Assessments, including unit instability under TPL-001-4.

Recommendation 1

Replace "instability" with "System instability" throughout the proposed FAC-011-4 revision. "System instability" is already used in TPL-001-4. Replacing the term provides an effective parameter to reporting by requiring reporting of coordinated instances of instability that necessitate a Correction Action Plan and, in turn, relieve entities of a time-consuming and overly-burdensome reporting requirement.

Recommendation 2

Requirements 6.1.3 and 6.2.3

The companies suggest 30-minute time thresholds, Tv, be added to the proposed revisions to FAC-011-4 R6.1.3 and R6.2.3. This provides RCs / TOPs a time certain threshold to correct exceedance for determinations of compliance.

R6.1.3 and R6.2.3 refer to preventing instability, cascading or uncontrolled separation.

- The present definition of IROL Violation has a Tv time threshold (< 30 minutes) before it becomes a compliance issue.
- The proposed language does not recognize time-frames associated with exceedances of established stability limits.
- Effect: Without a time-frame, it is conceivable a system could experience a significant number of exceedances that possibly last less than 1-minute with a magnitude less than 1%. In such a case, to report would be an onerous compliance burden.

To mitigate potentially over burdensome reporting of a significant number of *di minimis* exceedances, the companies recommend establishing a parameter by requiring reporting of only coordinated instances of instability that necessitate a Correction Action Plan.

Response

Thank you for your comments. The SDT, over its existence, has discussed the very edit you suggest – changing "instability" to "system instability". Since this suggested edit is linked to the topic of IROLs, and this topic did not lend itself to resolution in this phase of the SDT's efforts, the SDT, as suggested by NERC, is deferring the suggested wording change until the topic of IROLs is dealt with after the SDT revises the FAC standards within the scope of its SAR. Your suggested wording revision will be seriously considered in the next phase of the SDT's work.

The SDT did not include any defined Tv within requirement R6 and its subrequirements. Based upon comments from industry, the SDT revised FAC-011 and FAC-014 and left to the TOP and IRO standards the determination of SOL exceedances using the framework established with requirement R6. Instead, the SDT added a new requirement R7 that required inclusion in the SOL methodology "a risk-based approach for determining how SOL exceedances identified as part of Real-time monitoring and Real-time Assessments must be communicated and if so, the timeframe that communications must occur." This addition provides structure around existing TOP and IRO standards which require communication of SOL exceedance information between RCs and TOPs and allows the RC to determine a single method for communication

of SOL exceedances, with a defined timeframes. The new requirement R7 establishes minimum requirements for set of SOL exceedances in regards to communication, but leaves the remaining details to be determined by the RC.

Comment	
The SPP Standards Review Group (SSRG) recommends that the drafting team consider IROLs in Phase 2 of this project. As discussed at the September 2018 Planning Committee (PC) Meeting, although this project includes IROLs, the drafting team's feedback to the PC was to focus on only the SOL for this commenting period (Phase I). During Phase II, the drafting team will put more focus on the IROL. This is a reasonable suggestion given that all relevant materials pertaining to the IROL were approved at that most recent meeting and couldn't be implemented in the Phase I comment period.

Comment	
NV Energy understands and supports the SDT's efforts to come up with the broad industry consensus with regard to definition of SOL and associated definition of SOL Exceedance. However, we believe that addressing a fundamental concept of SOL Exceedance definition needs to be done within the framework of IRO and TOP standards, where it inherently and logically belongs. Due to reasons that we outlined in response to the question 1 (see above) we find it inappropriate to incorporate the definition of SOL Exceedance as a performance criteria in	

Requirement 6 of FAC-011-4 Standard and significantly worse and more risky in comparison with coming up with definition of SOL Exceedance**.**

NV Energy shares the industry concern that the proposed changes to Standards FAC-011-4 and FAC-014-3 would cause the following unintended consequences and repercussion:

- If approved, new versions of the NERC Standards FAC-011-4 and FAC-014-3 **would expose a large number of TOPs and RC to the SIGNIFICANTLY increased compliance risk (direct violation of the FAC-014 R6 in conjunction with FAC-011-4 R6) unless enormous resources and efforts are added within each TOP's/RC's organization.**

- **If the interpretation is correct that TOP/RC would not violate FAC standards in case of exceeding performance criteria as long as they implement their Operating Plan (per TOP-001 R14), our above mentioned concern transforms into another concern about huge administrative, compliance related, burden. Namely, TOP/RC would have to have** (as evidence of compliance), logging and recording documentation that it implemented its Operating Plan in response **to each and every instance when projected post-contingent flow on RTCA exceeds highest emergency rating, even for short time period (such as several minutes).**

- Therefore, due to the absence of time-frame considerations for exceedances of projected post-contingent flows or voltages, the new versions of the NERC Standards FAC-011-4 and FAC-014-3 would cause frequent SOL exceedances (and therefore frequent violations of the new FAC-011 performance criteria) and prohibitively costly and time consuming administrative burden.

- **This definition may decrease reliability as opposed to the SDT's intention of increasing reliability, because of the overwhelming pressure on transmission operators and reliability coordinators to record and communicate frequent SOL exceedances as opposed of being focused on monitoring and implementing control actions to maintain system reliability in real-time.**

- We believe the definition would **delay implementation of the Operating Plan in real-time** due to logging and documentation requirements, as this functionality is not a built-in feature of many SCADA systems in use today.

- We believe that another unintended outcome would be operation **in an unnecessarily conservative state, as TOP would have to operate with higher reliability margin from the highest emergency rating, to ensure that following a forced outage or other system disturbance, that the next execution of real-time contingency analysis would not show any facility beyond its highest emergency thermal rating or emergency voltage rating**

- **The proposed standards would significantly constrain the business in the industry** as conservative limits would **not allow for many of scheduled outages to proceed** without risk of SOL exceedance/performance criteria violation.

We re-iterate our ***recommendation that SDT re-considers adoption of the performance criteria/SOL exceedance per above mentioned suggestions.*** We believe that these modifications would provide the following benefits:

- They are *more realistic in recognizing reality of existing transmission infrastructure and human resources allocated to operate such an infrastructure*
- *They would provide for significantly less administrative burden* on numerous Industry's entities related to providing evidences of compliance.
- They would provide *comparably reliable operation* of power systems.
- They are *based on physical limitations of various components of transmission facilities*.
- They would *prevent potentially huge increase of cost* of market operations.
- They provide *more clarity and avoid ambiguity and interpretation issues*.

Response	

The SDT appreciates your comments. Your comments on these impacts were made by many industry participants. As such, the SDT listened and revised the FAC standards. In addition, the SDT is proposing to make changes to the TOP-001 and IRO-008 standards to address the concern you and other industry commenters have raised. Based on the concerns, the SDT revised FAC-011 and made requirement R6 and its subrequirements a framework for use in determining SOL exceedances. The SDT has made revisions in TOP-001 and IRO-008 that when SOL exceedances are determined in those standards, the determination is made using the framework established by FAC-011-4 requirement R6. In addition, recognizing the communication and documentation concerns raised by using the SOL exceedance framework and existing requirements in TOP-001 and IRO-008, the SDT included a new requirement (R7) in FAC-011-4 which required inclusion in the SOL methodology "a risk-based approach for determining how SOL exceedances identified as part of Real-time monitoring and Real-time Assessments must be communicated and if so, the timeframe that communications must occur.". This allows the RC and its TOPs to manage communication of the SOL exceedances using a method defined by the RC. In addition, the SDT modified some of the measure language in TOP-001 and IRO-008 such that examples of acceptable documentation have been expanded to demonstrate compliance with those requirements where communication of SOL exceedances is required. Some of those examples in electronic communications, the Reliability Coordinator's SOL methodology, system logs/records showing successfully mitigated SOL exceedances in conjunction with Operating Plans (e.g. mutually agreed operating protocols between TOPs and their Reliability Coordinator, Operating Procedures, Operating Processes, operating policies, generator redispatch logs, equipment settings for automatically switched equipment and reactive power/voltage control devices, switching schedules, etc.).

The SDT goal with these changes was to lessen any administrative burden caused by the revised FAC standards and instead allow system operators focus on operating the system within these new standards and allow reasonable efforts for compliance documentation.

Comment	

We believe R1 should be the only requirement in FAC-011-4. The SDT can accomplish their goal by having Requirement R1 that requires an entity to cover the performance criteria within a newly created appendix. There are 9 requirements and approximately 34 sub-parts in FAC-0011 that increases compliance risk without commensurate benefits to reliability.

Response	
The SDT appreciates you offering comments on our efforts. Much of the conversation regarding FAC-011 and its current form has focused on inconsistent application of the standard across industry. Those comments, combined with the fact that the edit you suggest would have to be shown to cause no adverse impact on reliable operation of the system on the reliability standard revision process, make your suggested revision untenable, after SDT review.

Answer	
Document Name	Proposed text for FAC-011-4 R5, R6, and R7.docx
Comment	
a. Stability Limit should be capitalized as it is a defined term b. The wording of FAC-011-4 R5 implies that stability studies are required for OPAs and RTAs. This would be a new requirement and does not correspond with the SDT's intent. We suggest the edits to R5 shown in the attached WORD document to clarify that stability studies are not needed for OPAs and RTAs, but, rather, stability limits derived by other studies need to be respected in OPAs and RTAs. c. Please clarify the need for the word "potential" in R6 as the word is not used in other places, such as the TPL standards, where single contingencies are also referred to without the word "potential." We suggest the following language to R6 and R7. d. The word "potential" is not used elsewhere to modify contingencies, which are, by their nature, "potential." For example, in the TPL standards, single contingencies are referred to without the word "potential." For this reason, AZPS recommends that the SDT clarify the need for inclusion of the word "potential" in R6. If such need is not identified, AZPS suggests the following language to R6 and R7. Further, AZPS	

notes that performance criteria is established in Requirement 6.1 as well as in FAC-014, requirement R6. For this reason, its inclusion in Requirement R6.3 appears redundant. AZPS recommends deletion as set forth below. Finally, AZPS recommends consistency when referring to the operation of the BES within SOLs. For this reason, AZPS recommends replacing "violating" with "exceeding" in Requirement R7. e. The wording of FAC-011-4 R6.1.3 and R6.2.3 seems to imply that dynamic studies are required for OPAs and RTAs. This would be a new requirement and does not correspond with the SDT's intent. AZPS also suggests adding the word "widespread" under R6.1.3 and R6.2.3 to exclude local area instability or instability of a small generator. We suggest the following edits to R6 to clarify that dynamic studies are not needed for OPAs and RTAs, but, rather, stability limits derived by other studies need to be respected in OPAs and RTAs. f. As written, FAC-011-4 R6.1.1 and R6.2.1 leaves the burden of proof on the TOP to be able to demonstrate that the operating actions can be taken within the appropriate time of the Facility Rating which is a very difficult and extensive task. g. Regarding R6.2.1, if RTCA shows that emergency ratings are exceeded, there should be a recognized time frame in which to correct the problem prior to it becoming a compliance issue. As written, the proposed definition does not recognize a time-frame associated with exceedances of the facility's highest emergency rating. If not recognized, this could lead to a large volume of inconsequential exceedances such as those less than one minute and have magnitude of less than one percent. h. AZPS suggests R6.1, R6.2, and R6.3 be broken into two separate sub-requirements: one related to Real-time monitoring and Real-time Assessment, and one related to Operational Planning Analysis.

Response	
The SDT appreciate the comments you offered on our posting. The SDT did not use the capitalized term Stability Limit in FAC-011 because the SDT did not believe the definition captured what was intended the intended use for stability limits within the revised FAC-011 standard. For example, one drafting team member stated that they used a short circuit calculation to determine if additional conventional generation needed to be committed to allow proper operation of non-conventional generator controls. This "limit" did not fit within any defined limit, including Stability Limit, and as such, the SDT decided to use instead the more flexible "stability limits" term to capture those limits that otherwise would fit in no other category.	

The wording of requirement R5 has been revised and should no longer imply the need for stability studies for OPAs and RTAs. The SDT has revised all of requirement R6 and removed the word “potential”. The SDT has revised requirement R6, and specifically subrequirements R6.1.3 and R6.2.3 and removed the implication that dynamic studies are needed for OPAs and RTAs. The SDT had extensive discussion in regards to the wording in subrequirements R6.1.1 and R6.2.1 with use of emergency limits and any specified time duration of those Emergency Ratings. This is a current issue and not one created by use of the language in this subrequirement. Using this language in the subrequirements, though, does make clear that this issue cannot be ignored by the TOP when using Emergency ratings, which the SDT and many observers felt was appropriate. With regard to your comments on time frames for SOL exceedance correction in subrequirement R6.2.1, the SDT did not feel it as appropriate to include a time frame within the SOL exceedance determination framework within requirement 6. Instead, the SDT create a new requirement 7 which required the SOL methodology include “a risk-based approach for determining how SOL exceedances identified as part of Real-time monitoring and Real-time Assessments must be communicated and if so, the timeframe that communications must occur.” In addition, subrequirements R7.2 and R7.2.1 state that post-contingency SOL thermal exceedances not mitigated within 30 minutes must be communicated. In this way, no timeframe was created to dictate when an SOL exceedance much be mitigated, but this new requirement does define the maximum amount of time that may be taken to mitigate a post-contingent SOL thermal exceedance before it is communicated per the RC’s SOL methodology and per appropriate TOP and IRO requirements. Finally, with respect to your revision suggestion to subrequirements R6.1, R6.2 and R6.3, the SDT believes that our revisions meet the needs you have described and no longer would benefit from such a revision.

Laurie Williams - PNM Resources - Public Service Company of New Mexico - 1	
Answer	
Document Name	
Comment	

This standard in its current form allows a single entity the ability to dictate operating and effectively planning criteria. PNM believes that the development of the SOL methodology should be a joint effort including RCs, TOPs, and PAs.

PNM believes R2 gives the RC that ability to dictate how an entity uses its own Facility Ratings effectively modifying FAC-008. PNM agrees the requirement does not specifically change, limit, or modify Facility Rating determined by the equipment owner; however, there is no point for an entity to establish a Facility rating that can't be used when operating the system. PNM recommend removal of R2 and revision of FAC-008-3 to address any concerns regarding the coordination of Facility Ratings.

PNM questions the reliability basis of R3.3. PNM believes that there may be reasons to have the UVLS setting higher than the limits for certain critical contingencies. FERC order No. 818 specifies not using UVLS for N-1; however, this requirement doesn't have that qualifier. If the SDT feels this concept should be included in the standard that requirement should move under R4.6 and shall clearly specify that it is only applicable to single contingencies.

Response

The SDT appreciates the comments you have offered on our posting. The SDT discussed your first comment at length. During the discussion that it is the RC is the entity with the ultimate authority to operate the system. As such, it can clearly establish the criteria used to determine which system operating limits (SOLs) are used in operations. Similarly, the PC is the entity that has the ultimate authority to plan the system. As such, the RC can develop its SOL methodology on any basis, and is not precluded from discussing any aspect of its SOL methodology with any other entity, including PCs. However, the SDT saw that effort as not mandatory, but elective, on the part of the RC as it develops its SOL methodology.

The SDT appreciates your comment on requirement R2. As we have noted to other similar commenters, the RC needs to determine, among many things, the rating set it needs to operate within its footprint. For example, if the RC determines it needs a 15 minute, a 4 hour and a normal, 24 hour thermal rating for each branch in the network, the asset owner can determine if they wish to provide those ratings or not. The RC cannot dictate a facility owner provide a specific rating, but instead can only use the ratings provided within the rating set it

establishes. The SDT felt this wording of requirement R2 was appropriate given the RC's and asset owners responsibilities. As such, since the RC has the responsibility to respect all limits including thermal, and the SDT believes the RC has the right to determine which ratings it needs to operate, the SDT will not remove requirement R2. With respect to your comment on subrequirement R3.3, the System Voltage Limits are only used for post-contingent conditions for the contingencies identified in subrequirement R5.1, per subrequirement R6.2.2. All of the other contingencies identified in subrequirement R5.2 only has to meet the performance framework described subrequirement 6.3, which does not include System Voltage Limits.

The construct of the current active version, FAC-011-3, makes for a lengthy RSAW response with respect to Requirements that lump all SOL types (thermal, voltage, stability) into a single Requirement. The SDT efforts to split these types up into their individual areas, should make	

for a much more consistent, focused & streamlined RSAW, appreciated by both the Applicable Functional Entity, and their incoming audit teams alike.

For the SDT's consideration

In all areas (Standard, Rationale, Mapping, etc.)

- R3.1 "Reliability Coordinators" should be either "Reliability Coordinator" or "Reliability Coordinator's"; (Note: Given that R3 is talking about the RC SOL Methodology, one could argue that the full reference to the RC SOL Methodology again in R3.1 is duplicative, and could be replaced with "Methodology");
- R5: Repetitive language around determining stability limits and performing OPA & RTA could be remedied for greater clarity by splitting into one requirement focused on stability limits and one requirement focused on OPA & RTA. Otherwise, to stick to the same structure you have for R5.1, R5.2 & R5.3 could be merged into one sub-requirement.
- R8: Inconsistency between Standard language. "Reliability Coordinator." vs "Reliability Coordinator(s)."
- M7, M8, M9: Incorrect references to M6, M7 & M8 respectively.

The rationale document for FAC-011-4 has the following typos:

- R3.1 "specificall" should be "specifically"
- R6.1.1 "normal rating" should be capitalized "Normal Rating"
- R8 Rationale discusses R7, when it's referring to R8.

Likes 0	
Dislikes 0	

Response

Thank you for your comments. We will review our use of "Reliability Coordinators" throughout the document accordingly.

The SDT revised requirement R5 and its subrequirements and eliminated duplicative references to OPA & RTA.

The SDT also corrected the noted references in measure M7, M8 and M9 or FAC-011-4.

Finally, we appreciate your review of the rationale document and will attempt to correct the concerns you have noted.

NIPSCO is in MISO and it appears that the prescribed performance criteria here will change the MISO SOL exceedance methodolgy that we presently operate under for TOP-001 R14 and R15. This may be a concern.

We were triple-booked for the related 2015-09 informational webinar. We were hoping to view the streaming replay but never saw it posted. We inquired and were told it would soon be posted but never saw it. Please post promptly next time if possible. Thanks.

BPA believes Requirement 3.5 should be modified for clarity: change "provide" to "define." *"Require the use of common System Voltage Limits between the Transmission Operator and its Reliability Coordinator and "define" the method for determining the common System Voltage Limits to be used in Operations."*

BPA believes that in Requirement 4.1.3, the term should remain "angular stability" as this is industry standard. "Unit stability" is not a defined term and is not as understood as angular stability.

BPA recommends consolidating requirements 5.2 and 5.3 and requirements 6.3 and 6.4 to make it so an RC may specify additional single or multiple Contingency events or types of Contingency events for use in determining stability limits and performing OPAs and RTAs. BPA does not support the RC being allowed to specify two additional lists (as allowed by 5.2 and 5.3 when not consolidated) of single or multiple Contingency events or types of Contingency events because BPA believes this could complicate the RC's SOL Methodology without benefiting reliability. If there is a reliability benefit, BPA would like to request the SDT include that in the White Paper.

BPA proposed edits:

5.2. Identify any additional single or multiple Contingency events or types of Contingency events for use in determining stability limits and performing OPAs and RTAs.

Delete 5.3

6.3. The evaluation of the potential Contingencies identified in Part 5.2 against the actual pre-Contingency state (Real-time monitoring and Real-time Assessments) and anticipated pre-Contingency state (Operational Planning Analysis) demonstrates that instability, Cascading, or uncontrolled separation does not occur.

Delete 6.4

Likes 0	
Dislikes 0	

Response

Thank you for your comments.
The SDT revised subrequirement R3.5 based upon your replacement word suggestion.

The SDT retained "angular stability" in subrequirement R4.1.3.

The SDT recognizes your comment for suggested edits in subrequirements R5.2 and R5.3. Subrequirment R5.3 was removed. Subrequirement R5.2 was revised and simplified as follows:

5.2. Specify additional single or multiple Contingency events or types of Contingency events, if any.

The SDT, based on your comments, those or others, and our discussion, decided to remove the attributions to the contingency's use. It was felt that the RC should have discretion on how to apply these added contingencies, especially based upon SDT discussion which noted examples that already exist of RCs applying unique contingency types beyond single contingent events to subsets of reliability criteria (for example, for establishment of IROLs only).

Subrequirement R6.4 from the second posting has been removed. Revisions to requirement R6 and subrequirement R6.3, based upon comments such as yours, we believe have addressed your concern.

Comment	

MidAmerican Energy Company (MEC) understands and supports the SDT's efforts to come up with the broad industry consensus with regard to definition of SOL and associated definition of SOL Exceedance. However, we believe that addressing a fundamental concept of SOL Exceedance definition needs to be done within the framework of IRO and TOP standards, where it inherently and logically belongs. Due to reasons that we outlined in response to the question 1 (see above) we find it inappropriate to incorporate the definition of SOL Exceedance as a performance criteria in Requirement 6 of FAC-011-4 Standard and significantly worse and more risky in comparison with coming up with definition of SOL Exceedance.

MidAmerican believes that the proposed changes to Standards FAC-011-4 and FAC-014-3 would cause the following unintended consequences and repercussion:

- If approved, new versions of the NERC Standards FAC-011-4 and FAC-014-3 would expose a large number of TOPs and RC to significant increased compliance risk (direct violation of the FAC-014 R6 in conjunction with FAC-011-4 R6) unless enormous resources and efforts are added within each TOP's/RC's organization.
- If the interpretation is correct that a TOP/RC would not violate FAC standards in case of exceeding performance criteria as long as they implement their Operating Plan (per TOP-001 R14), our above mentioned concern transforms into another concern about huge administrative, compliance related, burden. Namely, TOP/RC would have to have (as evidence of compliance), logging and recording documentation that it implemented its Operating Plan in response to each and every instance when projected post-contingent flow on RTCA exceeds highest emergency rating, even for short time period (such as several minutes).
- Therefore, due to the absence of time-frame considerations for exceedances of projected post-contingent flows or voltages, the new versions of the NERC Standards FAC-011-4 and FAC-014-3 would cause frequent SOL exceedances (and therefore frequent violations of the new FAC-011 performance criteria) and prohibitively costly and time consuming administrative burden.
- This definition may decrease reliability as opposed to the SDT's intention of increasing reliability, because of the overwhelming pressure on transmission operators and reliability coordinators to record and communicate frequent SOL exceedances as opposed of being focused on monitoring and implementing control actions to maintain system reliability in real-time.
- The definition would delay implementation of the Operating Plan in real-time due to logging and documentation requirements, as this functionality is not a built-in feature of many SCADA systems in use today.
- Another unintended outcome would be operation in an unnecessarily conservative state, as TOP would have to operate with higher reliability margin from the highest emergency rating, to ensure that following a forced outage or other system disturbance, that the next execution of real-time contingency analysis would not show any facility beyond its highest emergency thermal rating or emergency voltage rating
- The proposed standards would significantly constrain the business in the industry as conservative limits would not allow for many of scheduled outages to proceed without risk of SOL exceedance/performance criteria violation.

The SDT should reconsider adoption of the performance criteria/SOL exceedance per above mentioned suggestions, which are in accordance with current definition of SOL exceedance that is in effect in MISO Reliability footprint. These modifications would provide the following benefits: • They are *more realistic in recognizing reality of existing transmission infrastructure and human resources allocated to operate such an infrastructure* • *They would provide for significantly less administrative burden* on numerous Industry's entities related to providing evidences of compliance. • They would provide *comparably reliable operation* of power systems. • They are *based on physical limitations of various components of transmission facilities*. • They would *prevent potentially huge increase of cost* of market operations. • They provide *more clarity and avoid ambiguity and interpretation issues*.

Response
The SDT appreciates the comments of MidAmerican Energy Co. and, more so, its participation in the SDT team's efforts since the second posting. Those efforts have resulted in revisions to FAC-011-4, FAC-014-3, TOP-001 and IRO-008 which we believe address the concerns you raise above, and other commenters have noted. These revisions have been made to accomplish the following: - Have SOL exceedances determined in the appropriate TOP and IRO standards rather than the FAC standards. - The proposed FAC-011-4 requirement R6 has been revised into a framework to be used when determining SOL exceedances, which only occurs as required in the TOP and IRO standards

- FAC-011-4 has a new requirement added (R7) which requires the RC SOL methodology include “a risk-based approach for determining how SOL exceedances identified as part of Real-time monitoring and Real-time Assessments must be communicated and if so, the timeframe that communications must occur”. This requirement was added to address the ill-defined SOL exceedance communications included within the TOP and IRO standards.
- The measures for a few TOP and IRO standards were revised to better describe a more complete set of potential evidence that may be sued to show compliance. In additional, the standard rationales have been revised to explain how this evidence may be used to show compliance with the standards.

We believe these changes, which were developed with the support of and feedback from your company and others from within MISO, should address these commonly held industry concerns.

Comment	

We offer the following specific comments:

Sub-Requirement R4.1.3:

It is not clear what is meant by "unit" stability. We suggest reverting back to using the current term "angular" stability as it is a term well understood by the industry.

Sub-Requirement R4.3:

A main concern is the lack of criteria to define contingencies for the establishment of IROLs. Today, some RCs respect single contingencies, while other respect double contingencies. Given the impact on the Interconnection, it is crucial that criteria for the selection of contingency events is defined and applied consistently in all the RC areas, in order to ensure that all IROLs within a defined scope are detected and properly studied. We recommend that the following wording is added to Sub-Requirement R4.3 to establish SOLs that impact on the Interconnection:

"Describe how the Reliability Coordinator establishes stability limits when there is an impact to more than one Transmission Operator in its Reliability Coordinator Area or other Reliability Coordinator Areas in accordance with its SOL Methodology."

Sub-Requirements R5.2 and R5.3

Sub-Requirements R5.2 and R5.3 require the RC to identify any additional single or multiple Contingency events. We believe that specifying, at a minimum, which contingencies must be respected (similar to Sub-Requirement R5.1.1. for single Contingencies) would improve reliability. In particular, to the extent there is an alignment in respecting the same set of contingencies and performance criteria for IROLs.

Furthermore, the loss of small or radial portions of the system should be acceptable provided the performance requirements are not violated for the remaining bulk power system.

Sub-Requirement R6.2.2

Sub-Requirement R6.2.2 should include the same wording as sub-requirement 6.1.2:

"Voltages are within normal System Voltage Limits; however, emergency

System Voltage Limits may be used when System adjustments to return

the voltage within its normal System Voltage Limits could be executed

and completed within the specified time duration of those emergency System Voltage Limits."

Sub-Requirements R6.3 and R6.4

For consistency purposes, we recommend that Sub-Requirements R6.3 and R6.4 also require to demonstrate that flow through Facilities are within Normal Ratings, similar to Sub-Requirements 6.1.1 and 6.2.1:

"Flow through Facilities are within Normal Ratings; however, Emergency

Ratings may be used when System adjustments to return the flow within its Normal Rating could be executed and completed within the specified time duration of those Emergency Ratings."

Sub-Requirements R7.1 and 7.2

Sub-requirements R7.1 and R7.2 require to describe how to identify IROLs, and to identify the criteria for IROLs which is basically the same thing. We recommend merging these sub-requirements into one:

7.1. A description of the criteria to identify the subset of SOLs that qualify as Interconnection Reliability Operating Limits (IROLs) and for developing any associated IROL Tv.

Response

Thank you for your comments. We note the similarities between your offered comments and those of NPCC. As such, we have supplied essentially the same responses below to those comments also offered by NPCC.

The SDT revised subrequirement R4.1.3 and used "angular stability".

With regard to your comment on subrequirement R4.3, the parent requirement, R4, states that the "Reliability Coordinator shall include in its SOL methodology the method for determining the stability limits to be used in operations. The method shall: . . . " which already makes subrequirement R4.3 subject to the RC's SOL methodology. We believe the suggested text addition is not necessary in R4.3.
With respect to your suggested changes for subrequirements R5.2 and R5.3, the SDT discussed your concern at length. Based on that discussion, and an inability to find industry consensus, and other industry comments, the SDT combined subrequirements R5.2 and R5.3 into one subrequirement, and simplified it.

In addition, your point with regard to small portions of the system is duly noted and reasonable, but the SDT did not find a location within the standards where this seemed a good fit. As such, it was not included in our revised standards.

With respect to your suggested revision for subrequirement R6.2.2, the SDT did not think it appropriate to suggest post-contingent voltages need to be within normal System Voltage Limits. The SDT agreed that emergency System Voltage Limits are appropriate for use in the post-contingent state. The SDT further recognized that emergency System Voltage Limits make take on a variety of forms, with varying potential time applicability, and as such, thought the each TOP / RC would use their emergency System Voltage Limits appropriately as they transitioned the system to a new pre-contingent state to prepare for the next contingency without the need for further language in the standard.

The SDT discussed at length new subrequirements R6.3 and R6.4, including which reliability criteria should be applicable. The SDT could only agree that any contingencies included in the RC's contingency list per subrequirement R5.2 should only have to demonstrate the performance described in subrequirement R6.3. RCs are not precluded from having more prescriptive criteria for any contingency they specify per subrequirement R5.2. In addition, subrequirement R6.2.1 already establishes appropriate thermal performance in the post-contingent state and is not required to be restated in subrequirement R6.4.

The SDT has accepted your suggestion of combining subrequirements R7.1 and R7.2 into a single requirement.

1. R 4.1.3: why SDT used "unit stability" instead of "angular"? We believe it is better to match the language in PRC-26 R1.
2. R.4.7: We would recommend revising the requirement R4.7 to state that the use of UFLS and UVLS is not allowed in the establishment of stability limits for the single contingencies identified in R5.1.1.

Dislikes 0	

Response

Thank you for your comments.

We have replaced "unit" with "angular" in subrequirement R4.1.3, as you have suggested.

The SDT recognizes the comment you have offered with regard to subrequirement R4.7. The SDT discussed of UVLS and UFLS at length with regard to stability limit determination. The consensus with regard to UVLS use was that, for typical stability concerns, such as angular stability and transient voltage recovery, UVLS would not typically provide any performance improvement, and actually might exacerbate the stability concern, so UVLS should not be used to determine stability limits. While UVLS would not be used to establish a stability limit, modeling UVLS for potential actuation would be useful to determine what the value of the stability limit should be. With regard to UFLS and stability limits, the group consensus was that if a simulation was indicating UFLS actuation within portions of the interconnected system that was still part of the interconnection and not some small island created due to a contingency or RAS action, then UFLS is not an appropriate relay action to rely upon to "save the system" and establish a stability limit.

Comment	

The MRO NSRF does have other comments on FAC-011-4:

- R3.3 should be improved by clarifying what undervoltage load shedding (UVLS) systems are in view (i.e. owned by the Transmission Owner, the Distribution Provider, end-use customer). It would seem that R3.3 should not be limited by UVLS relay settings implemented by a distribution utility or an end-use customer. A suggested edit is to clarify these are BES systems as follows: *"in-service BES relay settings for undervoltage load shedding…"*.
- Similar to comments provided in question #1 related to R6.5, Requirement R4.7 should be modified to remove the restriction on using UVLS Programs when setting stability limits. It is generally accurate to state that UFLS should not be relied upon to maintain stability, although the SDT needs to recognize that UFLS may be a necessary component to maintain stability of a portion of a system deliberately islanded by a Remedial Action Scheme. As such, R4.7 should be modified to read, *"State that the use of underfrequency load shedding (UFLS) programs are not allowed in the establishment of stability limits except in specific, documented circumstances (e.g., Remedial Action Schemes)."*

We also support the recently developed SAR, submitted as a result of phase 1 of the Standards Efficiency Review project, to retire many non-essential or redundant requirements. To reduce the need for a similar effort in the future, the MRO NSRF requests the SDT to consider if Requirement R8 is sufficiently covered with the IRO-010-2 Requirements. In accordance with IRO-010-2 R1 the Reliability Coordinator can specify any information it needs to support its Operational Planning Analyses, Real-time monitoring, and Real-time Assessments. The primary purpose of these activities is to identify SOL exceedances. Therefore, it's essential that the Reliability Coordinator would include in its data specifications SOLs from all Transmission Operators, which should remove the need for R8. If kept, there may be overlapping compliance obligations with two requirements for the same activity.

Dislikes 0	

Response

Thank you for your comments.

The SDT agreed with your point on subrequirement R3.3 and included the phrase "in-service BES" to better describe the subject UVLS relays. The SDT recognizes the comment you have offered with regard to subrequirement R4.7. The SDT discussed of UVLS and UFLS at length with regard to stability limit determination. The consensus with regard to UVLS use was that, for typical stability concerns, such as angular stability and transient voltage recovery, UVLS would not typically provide any performance improvement, and actually might exacerbate the stability concern, so UVLS should not be used to determine stability limits. If you would like to discuss the particular technical concerns, please contact the SDT; we would be willing to listen to more details to better understand your concern in this regard

.

With regard to your comment on IRO-010-2 and requirement 8, the SDT reviewed its potential use within the standards considered for the SDT. The SDT has proposed revisions to FAC-011, FAC-014, TOP-001 and IRO-008 where we attempted to specify the minimum data expectations to determine SOL exceedances, and allow that any further RC data needs can indeed be captured per IRO-010 and its requirements.

Kayleigh Wilkerson - Lincoln Electric System - 5, Group Name Lincoln Electric System

Answer	
Document Name	

Comment

R3.1 introduces ambiguity and potential inconsistency by allowing the Reliability Coordinator to decide whether to require that a BES bus/station have an associated System Voltage Limit without also requiring any sort of technical rationale or criteria. If the intent of R3.1 is to address a specific issue, LES recommends the drafting team clarify their intent within the requirement.

R3.2 is confusing and unnecessary with an in-place definition of System Voltage Limit. As written, R3.2 appears to provide two different methods for an entity to determine voltage limits.

R3.3 should state: "Require that **the upper (or higher)** System Voltage Limits…" for improved clarity.

R3.4 should be removed in consideration that the definition of System Voltage Limit already requires a "minimum steady-state voltage limit". Combining the language from the definition and R3.4 would essentially read "Identify the lowest allowable minimum steady-state voltage limit…" LES is concerned that R2 does not provide adequate assurance that the RC will respect the Facility Ratings established by the TO or the TO's FAC-008 methodology. As written, the language is vague and appears to allow the RC to determine the Facility Ratings that a TO must use. Also, based on the NERC definition of Facility Rating, there is a potential conflict between System Voltage Limits and Facility Ratings as both could utilize voltage ratings. These conflicts between FAC-011-4 and FAC-008-3 and the definition of Facility Rating need addressed.

Response	
Thank you for your comments. We believe your comment regarding subrequirement R3.1 was unique and not commonly held. The subrequirement was worded in that fashion to allow flexibility for those who wished to specify System Voltage Limits for every station to do so while allowing other entities which used set of voltage limits for a selected set of system stations for the same purpose. Therefore, we will not choose to act on your suggestion at this time. The definition for System Voltage Limits, which pasted ballot on second posting, is shown below: "The maximum and minimum steady-state voltage limits (both normal and emergency) that provide for acceptable System performance." The definition for System Voltage Limit does not make reference voltage-based Facility Ratings, and as such, the SDT believes subrequirement R3.2 should be retained. The SDT does not agree with your revision suggestion for subrequirement R3.3. System Voltage Limits were commonly discussed by the SDT as ones that have upper and lower bounds, and with respect to UVLS, or undervoltage load shedding, the low bound, not upper, would be the applicable and pertinent System Voltage Limit per this subrequirement. As a result, while appreciated, your suggested revision is not being used at this time.	

The SDT has considered your suggestion that subrequirement R3.4 be removed. It is true that the definition for System Voltage Limit includes the phrase "minimum steady-state voltage limit", the "lowest allowable" voltage limit identified per subrequirement R3.5 may not be the "minimum steady-state voltage limit . . . that provide(s) acceptable performance". As such, the SDT has elected to retain the subrequirement. Finally, the SDT appreciates your comment on requirement R2. As we have noted to other similar commenters, the RC needs to determine, among many things, the rating set it needs to operate within its footprint. For example, if the RC determines it needs a 15 minute, a 4 hour and a normal, 24 hour thermal rating for each branch in the network, the asset owner can determine if they wish to provide those ratings or not. The RC cannot dictate a facility owner provide a specific rating, but instead can only use the ratings provided within the rating set it establishes. The SDT felt this wording of requirement R2 was appropriate given the RC's and asset owners responsibilities. As such, since the RC has the responsibility to respect all limits including thermal, and the SDT believes the RC has the right to determine which ratings it needs to operate, the SDT will not remove requirement R2.

Comment
With respect to R5.4, requiring Reliability Coordinators to identify Contingency events to use in determining stability limits for the Near Term Planning Horizon (FAC-015-1 R4) which also includes 5-year horizon is added burden to both Reliability Coordinators and the Planning Coordinators/Transmission Planners without added benefit. The drafting team should consider limiting this requirement to 0-1 year period which would be the most concerning for the Reliability Coordinators.

It is not clear what other additional single contingency events are there that are not already included in R5.1.1.

Some guidance/criteria in selecting/identifying multiple contingency events (R5.2) for use in OPAs & Real-time Assessments would not only be helpful but ensure that the set of contingencies that meet basic minimum criteria are being evaluated.

Likes 0	
Dislikes 0	

Response

Thank you for your comments. One example of a single contingent event that is not included in the current version of subrequirement R5.1.1 is loss of a single breaker. For certain substation designs, either under all facilities in-service or facility out (breaker out) conditions, the loss of a single breaker could cause a line end open condition and cause a post-contingent high voltage condition. The SDT, in collaboration with the drafting team's observers, agreed to not expand the single event contingency list descried in R5.1.1.

With regard to your comment on guidance / criteria in selecting/identifying multiple contingency events, the SDT discussed this issue at length. While SDT members offered some of their practices with respect to multiple element contingencies they respected in their own footprints, consensus could not be reached beyond the inclusion of subrequirement R5.2 as worded for the second, and soon to come posting, neither of which includes such guidance / criteria.

Comment

Just a general comment on the use of the term "owner-provided Facility Ratings" used in FAC-011, FAC-014, and FAC-015. I believe this reference is referring to the FAC-008 Facility Ratings that TOs and GOs are required to determine and make available to various reliability entities. This may or may not be true. If it is true, any ambiguity could be eliminated by changing the reference to "Transmission Owner and Generator Owner provided Facility Ratings determined in accordance with FAC-008."

Please at least address the issue in the response to this comment especially if there is a different owner provided facility rating that these standards are referring to. Thanks.	
Likes 0	
Dislikes 0	
Response	
Thank you for your comment. You are correct in that the phrase quoted – "owner-provided Facility Ratings" – are with respect to those Facility Ratings provided per FAC-008 by Transmission and Generation Owners. The SDT thought the phrase was clear enough, and based upon your comment being the only one to note this specific ambiguity, the SDT has left the phrasing in the interest of brevity in the standard language.	

3. The SDT acknowledges that requirement R6 could alternatively be located within a TOP or IRO standard; however, the Project 2015-09 SAR does not specifically authorize the SDT to modify those standards. The SDT is seeking feedback specific to the content of the requirement not where it should reside. Proposed Requirement R6 was created to correspond with FAC-011-4 Requirement R6 in lieu of creating a definition for SOL Exceedance. Do you agree with Requirement R6?

Comment	

However, we have the same comment as with Question 1:

Throughout the standard development process for the revisions of the IRO/TOP standards the IESO continued to comment on our serious concern over the proposed retirement of Requirement R4 of TOP-004-2 without having it reinstated in TOP-001-3 or having some of the

requirements in TOP-001-3 revised to addressing the reliability need for confirming or reestablishing valid SOLs/IROLs in an unknown or unstudied state. We recognize that this issue is not within the scope of this project, but is directly related through the methodology that will be used to determine operating limits for these unknown states. In order to better coordinate the development of standards, we recommend that the scope of future NERC projects should better identify relationships between families of standards at the onset, and encourage potential revisions to related requirements.

Response	
Thank you for your response. However, after considering feedback from this posting the FAC-011-4 R6 requirement has been improved and the drafting team is proposing to effectively remove the language from FAC-014-3 R6 previously proposed and add it to both IRO-008 and TOP-001 such that requirements for when SOL exceedances are determined are in the appropriate TOP and IRO standards rather than the FAC standards.	

The proposed FAC-011-4 requirement R6 has been revised into a framework to be used when determining SOL exceedances, which only occurs as required in the TOP and IRO standards. FAC-011-4 has a new requirement added (R7) which requires the RC SOL methodology include “a risk-based approach for determining how SOL exceedances identified as part of Real-time monitoring and Real-time Assessments must be communicated and if so, the timeframe that communications must occur”. This requirement was added to address the ill-defined SOL exceedance communications included within the TOP and IRO standards.

The wording of FAC-011-4 R6.1.1 and 6.1.2 is unclear. Words appear to be missing in the phrase “may be used when System adjustments to return the voltage…”. Reclamation recommends the SDT review R6.1.1. and R6.1.2 to ensure clarity.	
Likes 0	
Dislikes 0	
Response	
Thank you for your comments. The drafting team is unclear about which words you believe to be missing and believes the requirement is clear. The concept is that if the steady-state flow through facilities (or the voltage) exceeds that of normal ratings on the facility, emergency ratings (for those that allow higher flows/voltages than normal ratings) may only be used so long as the time they are valid for is not exceeded. As such, the system adjustments necessary to return flows/voltages to below the normal rating but must be complete before the time the emergency rating is valid for runs out.

Comment	
While AEP supports, in general, the proposed revisions to FAC-011, we believe additional clarity is needed within 6.1.3 to make it clear these obligations are only in reference to known stability limits and do *not* require TOP-provided, dynamic, real-time stability studies. While there are entities that do perform such real-time stability studies, this requirement should not impose that sort of analysis on *all* TOPs. AEP has chosen to vote negative on this revised standard driven by the current lack of clarity in this regard.

The MRO NSRF is not clear if the question is addressing FAC-014-3 R6, but we believe it is. Although we understand the SDT's intent of placing R6 in FAC-014-3, it's inappropriate to place an operating requirement within the FAC family of standards and doing so is contrary to the improvements being made to the NERC Reliability Standards via various forums, including the Standards Efficiency Review project. More importantly, we believe that the existing relevant IRO and TOP standards adequately cover what FAC-014-3 R6 intends to implement. For example, TOP-001-4 requires an RTA to be performed by the Transmission Operator in requirement R13. The Transmission Operator is required to examine both the pre-Contingency and post-Contingency states based on the definition of Real Time Assessment. By creating	

FAC-011-3 R5 and R6, the SDT has adequately covered what Contingencies need to be evaluated to identify or monitor SOLs as part of RTAs and OPAs. Similarly, we believe the language of IRO-008-2 R1 and R4 as well as TOP-001-4 R10 and TOP-002-4 R1 adequately address the SDT's concern and language of proposed FAC-014-3 R6.	
Likes 0	
Dislikes 0	
Response	
Thank you for your comments. The question is addressing FAC-014-3 R6; sorry for the confusion. Although TOP-001-4 R10 does require monitoring for SOL exceedances and R13 does require an RTA to be performed, neither requirement ties both concepts together for determining SOL exceedances. Furthermore, TOP-002-4 R1, IRO-008-2 R1 and R4 do not reference how SOL exceedances should be defined; which is what the drafting team had attempted in proposed FAC-011-4 R6. Therefore, the drafting team believes the existing standards quoted do not sufficiently address the issue of uniformity for proper treatment of SOL exceedances necessary for maintaining BES reliability. While the TOP and IROL standards use “SOL exceedance” numerous times, there is no definition of the term anywhere within the standards. Recognizing this and past comments on the SDT’s prior postings on FAC-011, the proposed FAC-011-4 requirement R6 has been revised into a framework to be used when determining SOL exceedances, which only occurs as required in the TOP and IRO standards. As a result, the previously proposed R6 requirement has been removed from FAC-014-3 and effectively added to both IRO-008 and TOP-001 such that requirements for when SOL exceedances are determined are in the appropriate TOP and IRO standards rather than the FAC standards. the SDT is revising FAC-011-4 R6 to allow each RC to define SOL exceedances in their methodology, using as an initial basis the performance criteria in R6. This tact should allow each RC the flexibility needed to account for any unique concerns within its footprint while allowing a more seamless use of SOL exceedances defined by this methodology in the TOP and IRO standards. Furthermore, FAC-011-4 has a new requirement added (R7) which requires the RC SOL methodology include “a risk-based approach for determining how SOL exceedances identified as part of Real-time monitoring and Real-time Assessments must be communicated and if so, the timeframe that communications must occur”. This requirement was added to address the ill-defined SOL exceedance communications included within the TOP and IRO standards.

Additional, patient efforts by the SDT to develop a flexible definition of SOL exceedance is a superior approach versus a FAC-011 and FAC-014 performance requirement. The language of IRO-008-2 R1 and R4 as well as TOP-001-4 R10, R13 and R14 and TOP-002-4 R1 would be sufficient and would adequately address the SDT's concerns and industry's needs. MidAmerican shares the MRO NSRF position regarding FAC-014-3 R6 that *"it's inappropriate to place an operating requirement within the FAC family of standards and doing so is contrary to the improvements being made to the NERC Reliability Standards via various forums"*. General principles and good utility practice within the industry is to align and coordinate definition of SOL and SOL exceedance/performance criteria between RC and TOP's within the RC's reliability footprint,. Consequently, all arguments presented in answering Questions 1 and 2 would apply and be of a significant concern to the TOPs.

The SDT appreciates your comment offered. While the SDT supports your perspective in the value of an explicit SOL exceedance definition, it was apparent from prior postings and comments that the industry as a whole did not. Our latest FAC-011-4 revision, with the proposed R6, is our attempt at providing a minimum set of performance criteria across the industry for establishing SOL exceedances. R6 should be the minimal basis any RC uses to define SOL exceedances within its footprint. Thank you for your comments. The previously proposed R6 requirement has been removed from FAC-014-3 and effectively added to both IRO-008 and TOP-001 such that requirements for when SOL exceedances are determined are in the appropriate TOP and IRO standards rather than the FAC standards.	

The proposed FAC-011-4 requirement R6 has been revised into a framework to be used when determining SOL exceedances, which only occurs as required in the TOP and IRO standards. FAC-011-4 has a new requirement added (R7) which requires the RC SOL methodology include "a risk-based approach for determining how SOL exceedances identified as part of Real-time monitoring and Real-time Assessments must be communicated and if so, the timeframe that communications must occur". This requirement was added to address the ill-defined SOL exceedance communications included within the TOP and IRO standards. We hope you can understand our rationale and support the proposed FAC-011-4 language in our next posting. For further responses to your comments, please see the response provided to the MRO NSRF.

NIPSCO feels that R6 belongs in the TOP and IRO standards. We understand the SDT does not currently have access to these standards but that should not mean that this requirement is not placed in the appropriate standard. There will need to be a review of the TOP and IRO standard to place R6 in the appropriate place.

CenterPoint Energy does not believe that the added requirements in Requirement R6 nor a definition for SOL Exceedance is necessary. Furthermore, CenterPoint Energy believes the SDT unnecessarily broadened the scope of the language by using the term "SOL	

exceedances" without additional focus on those exceedances that adversely impact the reliability of the BES. CenterPoint Energy recommends that the SDT clarify the intent of Requirement R6.

Response	
Thank you for your comments. The drafting team feels the treatment of SOL exceedances both lacks uniformity and is not being performed as intended by the current set of standards. Therefore, the drafting team is working to clarify the existing standards by creating a requirement in FAC-011-4, R6, outlining the performance criteria minimum framework that each RC footprint must meet in defining determining SOL exceedances in lieu of a prescribed SOL Exceedance definition. Without proper treatment of all types of SOL exceedances, they may need to adverse system impacts. As such, and to provide clarity across the industry, the drafting team is trying to address them all. The SDT did include in its R6 impact on the "BES"to limit the potential scope of instability, per your comment. The SDT also made many other revisions to R6 to improve its clarity. Please also note that the previously proposed R6 requirement in FAC-014-3 has been removed and has been effectively added to both IRO-008 and TOP-001 such that requirements for when SOL exceedances are determined are in the appropriate TOP and IRO standards rather than the FAC standards.

No, AZPS is concerned that as proposed, requirement R6 of FAC-014-3 results in a redundancy that could result in ambiguity and confusion. For this reason, AZPS recommends that "SOL exceedance" be defined in FAC-014-3 R6, or FAC-014-3 R6 refers to FAC-011-4 R6 performance criteria instead of referencing "SOL exceedance."

The SDT appreciates your comment offered. While the SDT supports your perspective in the value of an explicit SOL exceedance definition, it was apparent from prior postings and comments that the industry as a whole did not. Our latest FAC-011-4 revision, with the proposed R6R6, is our attempt at providing a minimum set of performance framework for determining SOL exceedances as required by the TOP and IRO standards criteria across the industry for establishing SOL exceedances. R6 should be the minimal basis any RC uses to define SOL exceedances within its footprint. We hope you can understand our rationale and support the proposed FAC-011-4 language in our next posting.

We acknowledge the drafting team's question regarding the substance of R6 for FAC-014-3. We do not have any specific concerns regarding the language used. While we understand that the drafting team is not soliciting comment on where a requirement should reside, we would be remiss not to comment that this requirement is indeed out of place as proposed. The proposed R6 is a Real-time performance requirement surrounded by other requirements pertaining to methodology, and not the execution of said methodology. We understand that the SAR does not allow for an alternative approach at this time, but believe that this may need to be revisited at a later date.

SAR Scope Issue	

The companies believe the proposed revisions to FAC-014-3 R6 are, for all intents and purposes, incorporated into TOP-001 and TOP-002, and, as such, creates a potential conflict with Requirements in TOP-001 and TOP-002.

If that is the case, the proposed FAC-011-3 R6 revisions create a challenge to the SDT by basically requiring revision to TOP-001 and TOP-002 and, as such, the revisions fall outside the scope of the SAR.

Observation: SOL Exceedance Glossary Term

The companies would note, and we are confident the SDT is aware, TOP-001 and TOP-002 could be strengthened by a SOL Exceedance Glossary Term and the proposed R6 revisions do not eliminate the need for a SOL Exceedance Glossary Term.

See comments to question 1. Because the SDT is not authorized to make changes to the TOP or IROs is not sufficient reason to place requirements in standards to which they don't belong. The performance criteria should rightly be debated and crafted in the context of system operations by a SDT with appropriate focus and expertise.

Dislikes 0	
Response	

Requirement R6.5 from the second posting, which is now requirement R6.4 in the latest version of FAC-011-4, was not intended to address what mitigation actions are acceptable for inclusion in an Operating Plan, including RAS or other post-contingency mitigation actions (including under voltage relays that are not specifically part of an overall Under Voltage Load Shed (UVLS) scheme). The SDT did capture that "planned manual load shedding", if included in an Operating Plan should be a measure of last resort. With respect to RAS, requirement R4.6 requires that the RC document in their SOL methodology the "allowed uses of Remedial Action Schemes and other automatic post-Contingency mitigation actions in establishing stability limits used in operations" R4.7 specifically requires however "that the use of underfrequency load shedding (UFLS) programs and Undervoltage Load Shedding (UVLS) Programs are not allowed in the establishment of stability limits". The use of UVLS and UFLS as a safety net and not for performance criteria or in the establishment of a stability limit is consistent with FERC commission comments in FERC Order 818.

However, we have the same comment as with Question 1: Throughout the standard development process for the revisions of the IRO/TOP standards the IESO continued to comment on our serious concern over the proposed retirement of Requirement R4 of TOP-004-2 without having it reinstated in TOP-001-3 or having some of the requirements in TOP-001-3 revised to addressing the reliability need for confirming or reestablishing valid SOLs/IROLs in an unknown or unstudied state. We recognize that this issue is not within the scope of this project, but is directly related through the methodology that will be used to determine operating limits for these unknown states. In order to better coordinate the development of standards, we recommend that the scope of future NERC projects should better identify relationships between families of standards at the onset, and encourage potential revisions to related requirements.

ATC is not clear if the question is addressing FAC-014-3 R6, but we believe it is given that the previous question asked for any further comments on FAC-011-4 and the next question asks for any further comments on FAC-014-3.

Although we understand the SDT's intent of placing R6 in FAC-014-3, it is inappropriate to place an operating requirement within the FAC family of standards and doing so is contrary to the improvements being made to the NERC Reliability Standards via various forums, including the Standards Efficiency Review project. More importantly, we believe that the existing relevant IRO and TOP standards adequately cover what FAC-014-3 R6 intends to implement. For example, TOP-001-4 requires an RTA to be performed by the TOP in requirement R13. The TOP is required to examine both the pre-Contingency and post-Contingency states based on the definition of Real Time Assessment. By creating FAC-011-3 R5 and R6, the SDT has adequately covered what Contingencies need to be evaluated to identify or monitor SOLs as part of RTAs and OPAs. Similarly, we believe the language of IRO-008-2 R1 and R4 as well as TOP-001-4 R10 and TOP-002-4 R1 adequately address the SDT's concern and language of proposed FAC-014-3 R6.

The criteria given are not clear as written such that they appear to occur in the Real-time horizon and apply to real-time operations rather than in the Operations Horizon as stated. As a consequence, the criteria do not seem to meet a methodology requirement but an operating one. Specifically, the identification of real-time monitoring and assessment as a demonstration is inappropriate for a FAC methodology requirement and belongs in TOP and IRO standards relating to operations. We believe there should not be an operating requirement in FAC-011 and in our opinion is a poor practice and should be shelved. The Standard "families" set certain expectations and should be respected because to do otherwise will create risks of inconsistency. If the TOP and IRO standards need amending, then amend them!

Comment

ITC agrees with the MRO NSRF that it is not clear if the question is addressing FAC-014-3 R6, but we believe it is. Although we understand the SDT's intent of placing R6 in FAC-014-3, it's inappropriate to place an operating requirement within the FAC family of standards and doing so is contrary to the improvements being made to the NERC Reliability Standards via various forums, including the Standards Efficiency Review project. More importantly, we believe that the existing relevant IRO and TOP standards adequately cover what FAC-014-3 R6 intends to implement.

ITC agrees with MEC that if the SDT can formulate a broad and flexible definition of SOL exceedance, the language of IRO-008-2 R1 and R4 as well as TOP-001-4 R10, R13 and R14 and TOP-002-4 R1 would be sufficient and would adequately address the SDT's concerns and industry's needs.

Without the option of modifying TOP and IRO standards to accommodate a SOL Exceedence definition, it is reasonable to add the performance criteria to FAC-011-4 R6. However, the language in R6 is unclear. While it is clear in 6.1 that we may exceed the Normal Rating without a contingency if we return to Normal within the Emergency Rating time duration, it is not clear in 6.2 that the system response (or anticipated system response) to a single contingency must be within Emergency Ratings. Similarly for 6.3, it is not clear that the criteria is for the system response to the contingency.	
Likes 0

IRC Standards Review Committee understands that the current Standards Authorization Request (SAR) doesn't provide the authority to revise the TPL, MOD, etc. standards that have a potential affiliation with FAC-015. Notwithstanding, the SRC recommends that the drafting team consider that FAC-015 data requirements are redundant with other families of standards and, therefore, provide no additional reliability benefit but add additional compliance burden to responsible entities. For example, MOD-32-1 and TPL-001-4 Requirements both require data provisions that overlap with FAC-015. Since the SDT for this Project recognized that there might be a better placement of the Project Requirements, yet apparently felt that a process to consider addressing Standards other than those in the Project's SAR was not available, NERC should consider a process to allow expediting revised SARs that would enable the SDT to address Standards that were not contemplated in the original SAR, while the Project is ongoing.	

The IRC would also like to note that the Standard Efficiency Review Project has made similar observations with respect to consolidation of or better coordination of standards. We would suggest that the SDT work with NERC Staff to follow the approach and principles of the SER team to ensure those efficiencies are realized on this project.

The SDT considered and explored all avenues to place requirements in the correct families of Reliability Standards and to limit unnecessary requirements. Ultimately, through exhaustive discussions/debates with industry and regulatory stakeholders, the decision was made to retain the notion of coordination of SOL-related performance criteria between planning and operating entities in the FAC family of Reliability Standards.

SCE shares the opinion of the MRO NSRF regarding FAC-014-3 R6. Specifically, SCE "agrees with the proposed SOL definition. However, as stated in our (MRO NSRF's) response to question 1, we need additional clarification on the SOL expectation of the SDT." Additionally, SCE believes "it's inappropriate to place an operating requirement within the FAC family of standards and doing so is contrary to the improvements being made to the NERC Reliability Standards via various forums." Finally, SCE believes it is good industry practice to align and coordinate definition of SOL and SOL exceedance/performance criteria between RC and TOP's within the RC's reliability footprint.

Thank you for your comments. The previously proposed R6 requirement has been removed from FAC-014-3 and effectively added to both IRO-008 and TOP-001 such that requirements for when SOL exceedances are determined are in the appropriate TOP and IRO standards rather than the FAC standards. The proposed FAC-011-4 requirement R6 has been revised into a framework to be used when determining SOL exceedances, which only occurs as required in the TOP and IRO standards. FAC-011-4 has a new requirement added (R7) which requires the RC SOL methodology include “a risk-based approach for determining how SOL exceedances identified as part of Real-time monitoring and Real-time Assessments must be communicated and if so, the timeframe that communications must occur”. This requirement was added to address the ill-defined SOL exceedance communications included within the TOP and IRO standards.

Response	
Thank you for your comment. The drafting teams assumes your comment pertains to FAC-011-4 R6.5. The drafting team has revised R6.5 to clarify the requirement is specifically to prevent manual load shedding before all other System adjustments have been made. Requirement R6.5 from the second posting, which is now requirement R6.4 in the latest version of FAC-011-4, was not intended to address what mitigation actions are acceptable for inclusion in an Operating Plan, including RAS or other post-contingency mitigation actions (including under voltage relays that are not specifically part of an overall Under Voltage Load Shed (UVLS) scheme). The SDT did capture	

that "planned manual load shedding", if included in an Operating Plan should be a measure of last resort. With respect to RAS, requirement R4.6 requires that the RC document in their SOL methodology the "allowed uses of Remedial Action Schemes and other automatic post-Contingency mitigation actions in establishing stability limits used in operations". R4.7 specifically requires however "that the use of underfrequency load shedding (UFLS) programs and Undervoltage Load Shedding (UVLS) Programs are not allowed in the establishment of stability limits". The use of UVLS and UFLS as a safety net and not for performance criteria or in the establishment of a stability limit is consistent with FERC commission comments in FERC Order 818.

Regarding R6: The requirement does not provide sufficient clarity with regard to how SOL methodology is incorporated into RTA and real-time monitoring. For example is the expectation that the methodology be implemented in both RTA and real-time monitoring, or can the real-time monitoring schemes be used to incorporate some aspects of the methodology where the RTA tool lacks capability.

ITC agrees with MRO NSRF that in order to reduce the need for a future Standards Efficiency Review effort, ITC requests the SDT to consider if Requirement R3 is unnecessary and sufficiently covered with the IRO-010-2 Requirements. In accordance with IRO-010-2 R1 the Reliability Coordinator can specify any information it needs to support its Operational Planning Analyses, Real-time monitoring, and Real-time Assessments. The primary purpose of these activities is to identify SOL exceedances. Therefore, it’s essential that the Reliability Coordinator would include in its data specifications SOLs from all Transmission Operators. Once the data specification is sent to the Transmission Operators in accordance with IRO-010-2 R2, the Transmission Operators must provide its SOLs to the Reliability Coordinator to meet the obligations of IRO-010-2 R3. This should remove the need for the proposed FAC-014-3 Requirement R3. If kept, there may be overlapping compliance obligations with two requirements for the same activity.

Response	

Requirement R3 requires TOPs to provide the SOLs it established (under Requirement R2) to the RC in accordance with the RC's SOL methodology.

The SDT recognizes that the provision of SOL information from the TOP to the RC may also be addressed via IRO-010-2. While IRO-010 and its requirements allow an RC to request SOLs of its TOPs, R3 in FAC-014 sets a common expectation across industry of the minimum actions any TOP can take when supplying SOLs to their RC. It is opinion of the SDT after lengthy review and industry comment that R3 in FAC-014 provides a sound reliability basis that should be expected in any RC footprint which is not found anywhere else in the current set of standards.

Comment	

R5 – This should require providing SOL information to Transmission Planners, not just Planning Coordinators, because there is no requirement for Planning Coordinators to provide this information to Transmission Planners. In addition, in FAC-015-1, Transmission Planners are required to coordinate with the SOLs established by the Reliability Coordinators and Transmission Operators. As such, the Transmission Planners should receive SOL information directly from the Reliability Coordinators and Transmission Operators, rather than second hand information from Planning Coordinators. If the SDT decides to proceed with FAC-015-1 as a standard, FAC-014-3 Part 5.1 and Part 5.2 should be reworded to *"Each Planning Coordinator and each Transmission Planner within . . . "*

Requirement R4:

Similar to our comment on Sub-Requirement 4.3 (FAC-011-4) in Question 2, a main concern is the lack of criteria to define contingencies for the establishment of IROLs. Today, some RCs respect single contingencies, while other respect double contingencies. Given the impact on the Interconnection, it is crucial that criteria for the selection of contingency events is defined and applied consistently in all the RC areas, in order to ensure that all IROLs within a defined scope are detected and properly studied. We recommend that the following wording is added to Requirement R4 to establish SOLs that impact on the Interconnection:

"Each Reliability Coordinator shall establish stability limits to be used in operations when the limit impacts more than one Transmission Operator in its Reliability Coordinator Area or other Reliability Coordinator Areas in accordance with its SOL Methodology."

Sub-Requirement R5.2.5

A description of the associated system conditions is normally included in the RC's methodology as part of Requirement R4.4 in FAC-011-4. The sub-requirement R5.2.5 can be removed as it is redundant with Requirement R4.4 in FAC-011-4.

Response	
The SDT agrees with regards to FAC-014-3 R4. The SDT has modified R4.	

FAC-011-4 R4.4 is a general requirement for each RC to have in its SOL methodology description how stability limits are determined, considering levels of transfers, Load and generation dispatch, and System conditions including any changes to System topology such as Facility outages; whereas, FAC-014-3 R5.2.5 is a requirement for RC to communicate the specific system condition associated with each of the stability limit or IROL. For example under FAC-011-4 R4.4 an RC may require studies to be performed for both summer and winter seasons considering peak load condition during summer and high transfer during winter off-peak condition. It is possible that following the study results, an IROL is only established during summer but not during winter. This conclusion needs to be communicated under FAC-014-3 R5.2.5

Comment	
MISO believes that the TPL-001-4 covers SOLs and IROLs in the long-term planning horizon. Therefore MISO agrees that the Planning Coordinator should not be the applicable entity that establishes and communicates SOLs and IROLs. The requirement for the RC to provide the PC the SOL and IROLs should reside in FAC-015-1, not FAC-014. R5 – Share results of Operations assessments with Planning: Operations uses real time assessment to identify operating limits. This information has value for Operations assessment, however the value of identifying and sharing these limits with the Planning Coordinator is anticipated to have minimal value to planning assessments. This is in part due to the variability of the scenarios studied in Operations, and how closely those will align to scenarios studied in the Planning Horizon.

Response	
The purpose of FAC-014 is to establish and communicate. The RC is currently have the responsibility to communicate SOL/IROL; and therefore it is left for FAC-014.	

Requirement R5 Part 5.1 requires the RC to provide the PCs and TPs in its RC Area all SOLs and relevant SOL information at least once every 12 calendar months. This provides the PCs and TPs the relevant information necessary for its assessments. It is expected that PCs do not need more frequent updates as most of their assessments are performed on an annual cycle. Transmission Service Providers were not retained as an entity that would have a reliability related need for stability limit and IROL related information. Nothing prohibits an RC from sharing such information outside of a NERC Reliability Standard for other non-reliability related purposes.

Requirement R5 Part 5.2 requires the RC to provide the impacted PCs and TPs additional specific information (consistent with FAC-014-2 R5.1.1 - R5.1.4) for stability limits and IROLs at least once every 12 calendar months. It is expected that PCs and TPs do not need more frequent updates as most of their assessments (and their respective TPs assessments) are performed on an annual cycle. In addition, it requires the RC to provide the impacted PCs the system conditions associated with the Stability Limit or IROL, for example: “summer peak”, “winter peak”, “high import” and etc.

Comment	

Cowlitz PUD agrees that the establishment of SOLs and IROLs should be consistent for both operational and planning aspects of the BES. Having a single source for SOL Methodology from the Reliability Coordinator, implementation of the SOL Methodology by the Transmission Operator, and requiring the Planning Coordinator and Transmission Planner to coordinate the Planning Assessments with SOLs and IROLs provided by the Reliability Coordinator will improve Reliability. However, Cowlitz PUD cautions that IROLs should be carefully identified such that local isolated limitations remain as SOLs.

The companies suggest FAC-014 would be strengthened if it better aligned or explicitly addressed the following precepts:

The RC is in the best position to establish guidelines or criteria for determining System voltage limit.

The companies recognize each entities' system is unique in design, complexity, footprint, and Facilities, as is the RC's. To address the differences between systems across the BES, the companies suggest BES reliability will be strengthened by considering the uniqueness of these systems and letting the RC set guidelines or criteria for determining System voltage limits.

The TOP is in the best position to determine limits and avoid conflicts with Facility Ratings.

The revised proposed Glossary Term, while establishing boundaries, may create circumstances that add complexity to determining Facility Ratings, System Voltage Limits, and stability limits. Generally, adding complexity to Standards adds opportunity for undesired results in operating the BES.

To simplify the determination of System Voltage Limits and stability limits, the companies suggest that the TOP determine these values to ensure they do not conflict with Facility Ratings.

Likes 0	
Dislikes 0	
Response	

The SDT believes that the TOP is the best position to establish SOL in accordance with the RC SOL methodology including System voltage limit. FAC-011 R3.2 does requires that System Voltage Limits respect voltage-based Facility Ratings. In addition, the SDT believes that TOP is also the best entity to establish stability limit when it only impacts one TOP. These limits could exist at the same time and all three limits are considered SOL that should be respected at all times.

No changes made in the proposed FAC-014 standards

Comment

The SPP Standards Review Group (SSRG) recommends that the drafting team consider IROLs in Phase II of this project. As discussed at the September 2018 Planning Committee (PC) Meeting, although this project includes IROLs, the drafting team's feedback to the PC was to focus on only the SOL for this commenting period (Phase I). During Phase II, the drafting team will put more focus on the IROL. This is a reasonable suggestion given that all relevant materials pertaining to the IROL were approved at that most recent meeting and couldn't be implemented in the Phase I comment period.

The sub-Requirements of R5.2 are a list of specific criteria with the exception of the newly added 5.2.5. Sub-part 5.2.5 is unnecessary and is too general of a statement and could include a variety of system conditions. It is unclear what the SDT is trying to accomplish with 5.2.5. Further in Requirement R6, OPAs and RTAs are listed as acronyms and have not been previously defined in the standard. This issue should also be addressed.

In R6 what is the definition of "performance criteria"? NIPSCO believes that "performance criteria" is used in R3 in the establishment of SOLs. It is not something separate from that process. R3 states that the TOP supplies SOLs to the RC according to the RC's SOL Methodology. R6 implies that "performance criteria" is in addition to what is used to establish SOLs. NIPSCO believes that "performance criteria specified in the Reliability Coordinator's SOL Methodology" should be replaced with "SOLs established as part of R3".

AECI supports comments provided by NRECA. Appears that the drafting team meant to include a specific question on the revisions to FAC-014-03 prior asking for comments on the standard that were not already provided. NRECA believes the format of R5 and sub-requirement 5.2 is cumbersome and suggest the following "bolded" modifications for consideration to provide clarity. 5.2 Each impacted Planning Coordinator within its Reliability Coordinator Area, shall provide the following information for each	

established stability limit and each established IROL at least once every twelve calendar months: 5.2.1 The value of the stability limit or IROL; 5.2.2 Identification of the Facilities that are included in the derivation to determine the stability limit or IROL; 5.2.3 The associated IROL Tv for any IROL; 5.2.4 The associated Contingency(ies); 5.2.5 A description of the associated system conditions that impacted the determination of the stability limit or IROL; and 5.2.6 The type of limitation represented by the stability limit or IROL (e.g., voltage collapse, angular stability).	
Likes 0	
Dislikes 0	
Response	

The intent for R5 is to require the RC to provide various data to the various entities based on impacts and needs:

- R5.1 require each RC to provide SOLs to each PC and TP.
- R5.2 requires each RC to provide more information, as specified under sub-bullet 5.2.1-5.2.6, to impacted PC and impacted TP
- R5.3 requires each RC to provide information to impacted TOP
- R5.4 requires each RC to provide information to impacted TOP
- R5.5 requires each RC to provide information to requesting TOP

The SDT has also clarified FAC-014-3 R5.2.5 to better describe the intent and how it complement FAC-011-4 R4.4.

FAC-011-4 R4.4 is a general requirement for each RC to have in its SOL methodology description how stability limits are determined, considering levels of transfers, Load and generation dispatch, and System conditions including any changes to System topology such as Facility outages; whereas, FAC-014-3 R5.2.5 is a requirement for RC to communicate the specific system condition associated with each of the stability limit or IROL.

For example under FAC-011-4 R4.4 an RC may require studies to be performed for both summer and winter seasons considering peak load condition during summer and high transfer during winter off-peak condition. It is possible that following the study results, an IROL is only established during summer but not during winter. This conclusion needs to be communicated under FAC-014-3 R5.2.5

- R5.2 requires each RC to provide more information, as specified under sub-bullet 5.2.1-5.2.6, to impacted PC and impacted TP
- R5.3 requires each RC to provide information to impacted TOP
- R5.4 requires each RC to provide information to impacted TOP
- R5.5 requires each RC to provide information to requesting TOP

The SDT has also clarified FAC-014-3 R5.2.5 to better describe the intent and how it complement FAC-011-4 R4.4.

FAC-011-4 R4.4 is a general requirement for each RC to have in its SOL methodology description how stability limits are determined, considering levels of transfers, Load and generation dispatch, and System conditions including any changes to System topology such as Facility outages; whereas, FAC-014-3 R5.2.5 is a requirement for RC to communicate the specific system condition associated with each of the stability limit or IROL.

For example under FAC-011-4 R4.4 an RC may require studies to be performed for both summer and winter seasons considering peak load condition during summer and high transfer during winter off-peak condition. It is possible that following the study results, an IROL is only established during summer but not during winter. This conclusion needs to be communicated under FAC-014-3 R5.2.5

Comment	

To reduce the need for a future Standards Efficiency Review effort, the MRO NSRF requests the SDT to consider if Requirement R3 is unnecessary and sufficiently covered with the IRO-010-2 Requirements. In accordance with IRO-010-2 R1 the Reliability Coordinator can specify any information it needs to support its Operational Planning Analyses, Real-time monitoring, and Real-time Assessments. The primary purpose of these activities is to identify SOL exceedances. Therefore, it's essential that the Reliability Coordinator would include in its data specifications SOLs from all Transmission Operators. Once the data specification is sent to the Transmission Operators in accordance with IRO-010-2 R2, the Transmission Operators must provide its SOLs to the Reliability Coordinator to meet the obligations of IRO-010-2 R3.

This should remove the need for the proposed FAC-014-3 Requirement R3. If kept, there may be overlapping compliance obligations with two requirements for the same activity. If the SDT decides to proceed with FAC-015-1; then R1, R2, and R3 obligate each Planning Coordinator and each Transmission Planner to use Facility Ratings that are equally limiting or more limiting than those used by the Reliability Coordinator in its Operations Planning Horizon SOLs. Therefore, FAC-014-3 Part 5.1 and Part 5.2 should be reworded to *"Each Planning Coordinator and each Transmission Planner within . . ."* R5 – should require providing SOL information to Transmission Planners, not just Planning Coordinators, and not rely on Planning Coordinators to provide them to applicable Transmission Planners, especially since there is not a requirement for Planning Coordinators to do so. However, in FAC-015-1 Transmission Planners are required to coordinate with the Reliability Coordinators and Transmission Operators SOLs. Our preference is for the Transmission Planners to get the SOL information directly from the Reliability Coordinators and Transmission Operators, rather than second hand information from Planning Coordinators.

Response	
Requirement R3 requires TOPs to provide the SOLs it established (under Requirement R2) to the RC in accordance with the RC's SOL methodology. The SDT recognizes that the provision of SOL information from the TOP to the RC may also be addressed via IRO-010-2. While IRO-010 and its requirements allow an RC to request SOLs of its TOPs, R3 in FAC-014 sets a common expectation across industry of the minimum actions any TOP can take when supplying SOLs to their RC. It is opinion of the SDT after lengthy review and industry comment that R3 in FAC-014 provides a sound reliability basis that should be expected in any RC footprint which is not found anywhere else in the current set of standards. With regards to FAC-014-3 Part 5.1 and 5.2, the SDT has made modification in R5.1 and R5.2

Comment	
AEP believes much of the proposed changes would be beneficial and provide clarity, but would like to provide feedback on some key areas: While AEP has no objections to the proposed changes to R6, and while acknowledging that no changes were proposed to R2, we still would like to again express our concern how the lack clarity in FAC-011 R6.1.3 potentially impacts these requirements in FAC-014. Once again, clarity is needed in FAC-011 to make it clear these obligations are only in reference to known stability limits and do *not* require TOP-provided, dynamic, real-time stability studies as part of OPAs, RTAs, and Real-time Monitoring. AEP has chosen to vote negative on this revised standard driven by the current lack of clarity in this regard. The text “in accordance with” is subjective, and could be interpreted inconsistently across RE footprints as well as within RE footprints. For example, would the language from FAC-015-1 “equally limiting or more limiting than” be considered “in accordance with?” AEP does not object to R1 as proposed, we believe that Transmission Operators should be afforded opportunity to provide input into the process, even if not specifically designated within the standard.

With regards to R6: The SDT has updated the proposed FAC-011-4 R6 to clarify that RC’s SOL methodology shall include certain performance framework in determining SOL exceedance when performing Real-time monitoring, RTA, and OPA. The SDT also added a footnote that states “Stability evaluations and assessments of instability, Cascading, and uncontrolled separation can be performed using real-time stability assessments, predetermined stability limits or other offline analysis techniques” The SDT has also proposed TOP-001-5 R25 and IRO-008-3 R7 to require both TOP and RC to utilize the RC’s SOL methodology in determining SOL exceedance when performing Real-time monitoring, RTA, and OPA. With regards to the utilization of the phrase “In accordance with”: The SDT believes that the phrase “in accordance with” is commonly used in the approved NERC Reliability Standard	

With regards to R1: The SDT believes that in both R1 and R4, RC has the authority to establish limits when it impacts wide area. In Requirement R5.3-R5.5, the RC is required to provide all necessary information to impacted TOP so that TOP will have the ability to review RC's determination of SOL

5. The original posting of FAC-015-1 included six requirements. Industry comments to this original version indicated significant concerns. In response to these concerns, the SDT attempted to streamline and clarify the intended interactions between relevant functional entities and to consolidate the standard into fewer requirements. To achieve this the SDT:

- **Consolidated Requirements R1 – R5 in the original posting into three (R1 – R3) requirements,**
- **Clarified the roles of the Planning Coordinator and Transmission Planner in Requirements R1 – R3, and**
- **Clarified that Facility Ratings are "owner-provided" in Requirement R1.**

The SDT acknowledges that some of the requirements in FAC-015-1 could alternatively be located within other standards such as TPL, MOD, etc.; however, the Project 2015-09 SAR does not currently authorize the SDT to modify those standards. The SDT is seeking feedback specific to the content of the requirement not where it should reside. Do you support the revised FAC-015-1? Please provide any other comments regarding FAC-015-1.

Sandra Shaffer - Berkshire Hathaway - PacifiCorp - 6	
Answer	No

Comment	

FAC-015-1 R4 should more specifically state that each Planning Coordinator and Transmission Planner shall communicate any instability, Cascading or uncontrolled separation identified in either its Operational Planning Analysis or a Transfer Capability assessment in the Operations Horizon to each impacted Reliability Coordinator, Transmission Operator, Transmission Owner and Generation Owner. The current draft wording may be interpreted as requiring the Planning Coordinator and Transmission Planner to coordinate with the Reliability Coordinator for results of 5-year planning assessment, which is not only burdensome to TP/PC but also non-beneficial to the RC where RC focus is on 0-1 year horizon. As an additional comment, any new requirements put on a Near-Term Transmission Planning Horizon assessment or Transfer Capability assessment in the Planning Horizon would more appropriately reside in the respective Standards for those assessments, TPL-001 and MOD-001, not the new FAC-015-1.

Response	
The SDT appreciates the comments. It would not be correct to refer to operational analysis performed by planning entities as this is not consistent with the requirements of these entities per the NERC Functional Model. Further, the language posted only requires levels of coordination of performance criteria and not the actual assessment. The SDT has made further changes to withdraw FAC-015 and consolidate the intent of the previous 4 requirements into 3 requirements in a modified version of FAC-014

Dislikes 0	
Response	
The SDT appreciates the comments. See response to MRO comment. There are viable instances where planning entities may use less limiting criteria as documented in the posted rationale for this standard. Further, the standard requires a documented technical rationale from planners for these instances. It is the opinion of the SDT that not allowing these exceptions would not be consistent with the NERC Functional Model in that the RC does not have authority over planning entities.

Comment	

The MRO NSRF understands the SDT isn't requesting industry input on the location of the requirements. However, to reduce the need for a future Standards Efficiency Review effort, the MRO NSRF requests the SDT to consider if the proposed FAC-015-1 altogether is needed or if its purpose can be fulfilled with existing standards and/or compliance monitoring processes as described below.

The Data Reporting Requirements in Attachment 1 of MOD-032-1 contains a tabular listing of *"information that is required to effectively model the interconnected transmission system for the Near-Term Transmission Planning Horizon and Long-Term Transmission Planning Horizon"*. It's also stated in the paragraph above the table *"A Planning Coordinator may specify additional information that includes specific information required for each item in the table below"*. Item 4c in the table is *ratings (normal and emergency)**. The asterisk refers to a note that states *"(Items marked with an asterisk indicate data that vary with system operating state or conditions. Those items may have different data provided for different modeling scenarios)*. It appears these statements along with Requirement R1 of TPL-001-4 establish a compliance expectation for models to *"represent projected System conditions"*, which should include the most limiting Facility Ratings applicable to the modeling scenario. Additionally, if Planning Coordinators, Transmission Planners, Transmission Operators and Reliability Coordinators are not all using the same set of Facility Ratings provided by the Transmission Owner in accordance with FAC-008 R8, then that inaccuracy can be addressed via compliance monitoring for FAC-014, TPL-001 and various IRO/TOP requirements. During its webinar regarding Project 2015-09, the SDT indicated that it would be a very rare occurrence where a Reliability Coordinator would have a more limiting rating than those already provided by Transmission Owners and available to Planning Coordinators and Transmission Planners. Therefore, where is the reliability gap that necessitates creation of Requirement R1 in FAC-015-1?

In a similar manner, if the compliance expectation in Requirements R5 and R6 of TPL-001-4 is for the Transmission Planner and Planning Coordinator to demonstrate a technically sound rationale for voltage and stability criteria applicable to the modeling scenario, then where is the reliability gap that necessitates creation of Requirements R2 and R3 in FAC-015-1?

To ensure relevant entities are considering the information described in FAC-015-1 Requirement R4, it could be added as sub-requirement in FAC-011-4 Requirement R4. To ensure those entities can get the information, it could be requested from the Planning Coordinator and Transmission Planner in accordance with TPL-001-4 Requirement R8. Therefore, is there a need for Requirement R4 in FAC-015-1?

Another consideration in lieu of the new FAC-015-1 standard is to develop compliance guidance, which can improve the industry's understanding of the importance and value in a consistent approach to aligning planning and operational limits.

However, If the SDT decides to proceed with FAC-015, then the MRO NSRF provides the following suggestions for improvement.

Since the FAC-015-1 R1, R2, and R3 obligate each Planning Coordinator and each Transmission Planner to develop SOLs that are equally limiting or more limiting than the Operations Planning Horizon SOLs, then FAC-014-3 Part 5.1 and Part 5.2 should be reworded to *"Each Planning Coordinator and each Transmission Planner within . . . "*

The FAC-015-1 title does not match its stated purpose. We suggest "Coordination of System Planning Criteria and Methodologies with Reliability Coordinator SOL Methodology. The stated purpose of FAC-015-1 is to ensure that Facility Ratings, voltage limits, and stability criteria are coordinated with the Reliability Coordinator's SOL methodology, but R4 is calls for providing selected Planning Assessment and Transfer Capability assessment results to Reliability Coordinators and Transmission Operators. We agree with obligating Planning Coordinators and Transmission Planners to communicate selected assessment results information with Reliability Coordinators and Transmission Operators, but propose that the obligations be added to the respective FAC-013 and TPL-001 standards, not FAC-015-1.

We believe that purpose of FAC-015 would be better fulfilled if it required Planning Coordinators and Transmission Planners to provide their planning horizon Facility Ratings, voltage limits, stability criteria, and methodologies (i.e. TPL-001-4 R5 and R6) to their applicable Reliability Coordinators. This would allow Reliability Coordinators to know what criteria and methodologies Planning Coordinators and Transmission Planners are using in Planning Assessments and better understand how their SOL Methodology might be adjusted to achieve better coordination with the planning horizon criteria and methodologies.

R1, R2, and R3 – We are skeptical that requiring Planning Coordinator and Transmission Planner system planning criteria and methodologies to be equally limiting or more limiting than Facility Ratings, voltage limits, and stability criteria derived from the Reliability Coordinator SOL methodologies is an appropriate coordination strategy.

R4 – The requirement calls for the communication of CEII information from Planning Assessments and Transfer Capability assessment to impacted Transmission Owners and Generator Owners. This obligation should not be included until it is verified that compliance with the FERC Standards of Conduct can be guaranteed.

Consider the following ideas for sub-parts of a requirement to communicate selected Planning Assessment and Transfer Capability assessment results.

R4.1 – The MRO NSRF agrees with including the type of identified instability but suggest revising the list of examples to match those listed in FAC-011-4 Part 4.1 *“. . . (e.g. steady state voltage instability, transient overvoltage or undervoltage instability, unacceptable tie-line phase angle instability, generating unit loss of synchronism, unacceptable generating unit phase angle damping).* Steady state voltage instability criteria can be a percentage of margin from the expected voltage collapse point in a P-V analysis. The term *“voltage collapse”* incorrectly implies that all Planning Coordinators and Transmission Planners choose the voltage collapse point in a P-V analysis as their voltage stability limit. FAC-011-4 changed *“angular stability”* to *“unit stability”*. *“Transient voltage dip criteria violation”* is not a type of instability. If *“transient voltage dip criteria”* is to be retained, then it should be included in R4.2, as an example of an *“associated stability criteria”* for voltage instability. *“Angular instability”* is a very broad type of instability. Consider providing the Planning Coordinator and Transmission Planner with more understanding of what types of specific angular instability by mentioning some specific sub-elements of the category like those suggested above.

R4.2 – Consider adding some stability criteria examples for the benefit of Planning Coordinators and Transmission Planners, such as steady state P-V curve criteria, steady state high and low voltage protective relay trip levels, transient voltage dip criteria, transient overvoltage spike criteria, transient high and low voltage protective relay trip levels, generating unit loss of synchronism criteria, generating unit phase angle damping criteria.

R4.3 – The MRO NSRF requests the SDT consider the following suggestions for clarification:

1.

- o Asociated Contingencies and Facilities are two different items and should be two separate sub-sections.
- o The Contingencies used in Planning Assessments and Transfer Capability assessments include contingencies beyond the Contingencies used in Operational Planning Analysis.
- o *“Facilities critical to . . .”* does not have a clear meaning and uses the ‘loaded’ wording of *“critical to”*. Consider wording like, *“The Elements that exceed the system performance criteria”*.

R4.4 – No suggested wording change. However after Planning Coordinators and Transmission Planners describe the studied System conditions, it should explained that the System conditions, which will be used for Operational Planning Analysis, may be considerably different from the studies System conditions (e.g. different known outages, different load forecasts,

interchange with economic transfers, different generation resource dispatches), so the reliability impacts identified in the Operations Planning Horizon may be very different from those based on the Near-Term Planning Horizon System conditions. R4.5 – The automatic controls and expected system operator actions that are expected to address potential instability, Cascading, or uncontrolled separation in the Operations Planning Horizon should be split into two sub-bullets or be split into two separate sub-sections. o A sub-section for automatic control actions could say, “Automatic controls expected to address potential instability, Cascading, or uncontrolled separation available in the Operations Planning Horizon, such as Remedial Action Schemes (RASs), undervoltage load shedding (UVLS), underfrequency load shedding (UFLS). o A sub-section for system operator actions could say, “Operating Procedures expected to address potential instability, Cascading, or uncontrolled. R4.6 – We suggest that the wording be modified slightly to something like “Any Corrective Action Plans intended to mitigate or reduce identified instability, Cascading or uncontrolled separation.

The SDT appreciates the comments. The SDT, through coordination with industry and regulatory stakeholders, made the determination that the requirements in the posted FAC-015 were necessary to accomplish the goal of retiring FAC-010. This determination was made because the original intent of FAC-010 and FAC-011 being a mechanism for planning and operating entities to coordinate SOL-related information was not properly accomplished. Therefore, it was necessary to modify the construct of the SOL standards to ensure planning and operations are adequately coordinating the performance criteria that is used in their respective studies. Wording suggestions are duly noted. The SDT has consolidated the language contained in FAC-015 into a modified FAC-014.

LES recommends the following changes to the bulleted list in FAC-015-1 R1.

- Bullet #1: Recommend removing the first bullet since it is not an exception to the RC's SOL Methodology.
- Bullet #2: Recommend revising the second bullet as follows to be more general and not associated with variations in ambient temperature assumptions only: "Facility Ratings differences are due to variations in **seasonal assumptions such as in** ambient temperature assumptions".

Additionally, the reference to "Near-Term Transmission Planning Horizon" in R1-R3 should only refer to the Planning Assessment with the Near-Term removed. For example, in R1 the required PC/TP process would likely not specify different Facility Ratings between the Near-Term versus Long-Term planning horizons. Use of the phrase "Near-Term Transmission Planning Horizon" in R4 seems appropriate.

The use of the undefined term 'instability' in R4.4 could lead to inconsistent results and result in additional compliance burdens that add little to no reliability benefit. As used in FAC-011 R6, instability is not limited to the BES or wide area but instead, as currently worded, applies to ANY instability that has ANY impact to any element or facility. R4.4 should be limited to the interconnection or at the very least the wide-area to prevent misunderstanding.

FAC-015-1 R4.1 should be limited to TPL-001-4 P1-P7 events. Regarding FAC-015-1 R4.5, TPL-001-4 requires that studies are run with RAS, and if no instability is found, then no additional stability studies are run to determine if RAS was needed to maintain the stability. Also, when a RAS is established, the reason for establishing the RAS (i.e., to address instability or thermal problems) is known. FAC-015-1 R4.5 as written would require additional studies in order to determine whether the RAS is needed to maintain stability, and there is no justification for this additional work because the information would not provide any value. Further, TPL-001-4 P1-P7 events do not permit the use of Under Voltage Load Shedding and Under Frequency Load Shedding to address instability, cascading, or uncontrolled separation, which is referenced in FAC-015-1 R4.5. For this reason, AZPS recommends that those actions not be included in FAC-015-1 R4.5.	

Each requirement of FAC-015-1 appears to already be included in existing standards, or should be incorporated into existing standards as opposed to creating a new standard. The content of FAC-015-1 R1 should be included in MOD-032. The content of FAC-015-1 R2 and R3 should be included in TPL-001. The Planning Assessment requirements referenced in FAC-015-1 R4 should be incorporated into TPL-001-4, and the Transfer Capability Assessment requirements referenced in FAC-015-1 R4 should be incorporated into FAC-013-3 R5. AZPS urges a change in SAR scope or a new SAR to review all of the affiliated requirements and determine whether there is overlap or potential concern with creating a new standard.

The SDT appreciates the comments. Through substantial discussions with industry and regulatory stakeholders, the SDT did not pursue a generic requirement for the entities to coordinate with each other because of the lack of clarity with such a requirement. Rather, the coordination of planning performance criteria with operating performance criteria was determined to be a much more appropriate method to ensure the desired communication occurred. This change removes some of the reliability gaps in the current version of the standards because it requires enhanced communication practices between planning and operating entities.

Response	
The SDT appreciates the comments. Facility Rating information is part of the steady state data requirements of MOD-032. This data is provided by the owner for use in planning and, ultimately operational models. The intent is for the ratings that are provided by the owner to be used consistently between planning and operations. For example, an owner may provide several time-limited Emergency Ratings. If the RC only operates to a 30-minute Emergency rating, planning should not plan the system to a 15-minute Emergency Rating. There is no current provision for this instance in the MOD standards.

The SPP Standards Review Group (SSRG) understands that the current Standards Authorization Request (SAR) doesn't provide the authority to revise the TPL, MOD, etc. standards that have a potential affiliation with FAC-015. Notwithstanding, the SSRG recommends that the drafting team consider that FAC-015 data requirements are redundant with other families of standards and, therefore, provide no additional reliability benefit but add additional compliance risk to responsible entities. For example, MOD-32-1 and TPL-001-4 Requirements both require data provisions that overlap with FAC-015. Additionally, the SSRG recommends coordinated efforts with the Standards Efficiency Review (SER) Team to see if those particular standards can be modified in the Phase II of the SER without having to revise the current SAR. The SSRG understands that Phase II of the SER is dedicated to Requirements that could be combined and/or modified. From our perspective, this coordinated effort will provide value and efficiencies to both projects by identifying and removing redundancy issues.	

Finally, the SSRG, while recognizing the IROL is not a part of the current comment period, suggests that during Phase II of the project the drafting team re-evaluate the use of references to Planning Assessments of the Near-Term Transmission Planning Horizon that show results of "instances of instability, Cascading, or uncontrolled separation." The SSRG is concerned that the drafting team may have inadvertently omitted how this reference includes TPL-001-4 Table 1 Extreme Events, as well as Planning Events. The SSRG recommends that the drafting team either clarify that the proposed replacement language for IROLs in associated Reliability Standards, as well as FAC-015-1, is only referring to TPL-001-4 Table 1 Planning Events, or, explicitly direct the planning entities to document those Extreme Events that cause instances of instability, Cascading, or uncontrolled separation if they are not specifically identified in Planning Assessments.

The SDT appreciates the comments. The SDT considered and explored all avenues to place requirements in the correct families of Reliability Standards. Ultimately, through exhaustive discussions/debates with industry and regulatory stakeholders, the decision was made to retain the notion of coordination of SOL-related performance criteria between planning and operating entities in the FAC family of Reliability Standards. The intent of the requirements in the posted FAC-015 is to include planning events only. Additional wording has been added in current versions of the SDT's proposal.

Comment	
Duke Energy is unclear on the expectations listed in the sub-bullets for R1. Can a PC or TP use a less limiting Facility Rating with the justification of one of the sub-bullets, or do all sub-bullets need to be satisfied in order to use a less limiting Facility Rating? The use of the word "or" in the 3rd bullet adds tp the confusion. If the intent is that only one sub-bullet must be satisfied, we suggest the following: *"The process may allow the use of less limiting Facility Ratings due to one of the following:"* Also, the second sub-bullet is not clear on where the ambient temperature assumptions are coming from. Would this be referencing a difference between Planning and Operations?	
Likes 0	
Dislikes 0	
Response	
The SDT appreciates the comments. The source for the confusion is unclear. The word "or" was included to make clear that all bullets do not need to apply for an instance. Additionally, the technical rationale is at the discretion of the planner and is to be utilized to document any needed exceptions (including bulleted items or any others the planner deems appropriate).

Requirement 1 *The intent of Requirement 1 stated in the Rationale for FAC-015-1 "is not to change, limit, or modify Facility Ratings determined by the equipment owner per FAC-008. The intent is to utilize those owner-provided Facility Ratings such that the System is planned to support the reliable operation of that System." Requiring the Planning Coordinator to change ratings to what is provided to the Reliability Coordinator is contrary to established NERC criteria.* *The requirement as written would require planning to use different ratings than what is provided for the purposes of planning under MOD-032-1 and FAC-008-3 which is contrary to the stated purpose of the standard. As the Transmission Owners are already obligated to provide*	

planning and operating ratings under FAC-008-3 and MOD-032-1, the burden of establishing a technical justification for potentially different ratings used in planning and operations should be placed upon Functional Entities who own facilities (such as Transmission or Generation).

Requirement 2

The rationale provided for Requirement #2 has strong ties to NERC TPL-001. The intent of this requirement is to try and ensure that Planning is fulfilling its role to determine potential reliability deficiencies of the future planned system and to develop Corrective Action Plans to resolve the reliability concerns. This requirement is viewed as a supplement of TPL-001-4 R5.

The voltage requirements stated in TPL-001-4 R5 essentially state that Planning TPL assessments need to have criteria (and document that criteria) for:

- Acceptable system steady state voltage limits
- Post-contingency voltage deviations
- Transient voltage response

o For this criteria at minimum the criteria need to specific a low voltage level and maximum length of time that the transient voltages may remain below that level.

The idea to implement R2 would be to state our requirements as exactly what is put forward in the RC SOL methodology. In reviewing the criteria for the RC SOL methodology, the above criteria for the TPL standard are all achieved with the exception of post-contingency voltage deviation.

Our recommendation would be that FAC-011-4 R4 list include criteria for post-contingency voltage deviation.

Requirement 3

While the rationale provided for Requirement #3 attempts to have ties to NERC TPL-001, no specific requirement of the TPL standard is identified (like there is in FAC-015-1 R2's rationale).

Requirement 4

The rationale for R4 does not provide justification for the inclusion of Transfer Capability Assessments to be included in this requirement. NERC should clarify as to how referencing to FAC-013 plays a role in the requested communication in FAC-015 R4. Further, if the Transfer Capability Assessment respects known SOLS (R1.2) there would be no reporting in FAC-015 regarding Transfers. Further FAC-015 R4.6 requires discussion of corrective action plans which are not required as part of the Assessment of Transfer Capability.

It seems that their argument for rationalizing this standard is circular to existing standards. For example, the rationale states, "the details required by Requirement R4 will supplement the severe system conditions identified in Requirements R4 Parts 4.4 and 45 of the TPL-001-4". The TPL standard requires that entities evaluate the events that may produce the more severe system impacts. It is unclear about how reporting this information per the FAC-015 standard will improve the TPL assessments. It is also unclear how this information in the near-term planning horizon will benefit the entities to which this information is provided. Instead, when violations are observed in the Planning Horizon, corrective Action Plans should be developed which resolve the violation.

Response

The SDT appreciates the comments. Regarding the comment on Facility Ratings: The SDT proposal does not change the requirements for owners to provide Facility Ratings per FAC-008 and does not change the PC and TP responsibilities per MOD-032. The intent is for performance criteria between planning and operations to be better coordinated. For example, an owner may provide several time-limited

Emergency Ratings. If the RC only operates to a 30-minute Emergency rating, planning should not plan the system to a 15-minute Emergency Rating. There is no current provision for this instance in the MOD standards.

Comment	
While we appreciate the constraints the SAR places on the SDT, FMPA cannot support FAC-015-1. FMPA still questions if R1-R3 of the proposed FAC-015-1 is even necessary. From the previous comment period: “We question what the value of R1-R3 is and if the	

requirements are even needed. R1-R3 are really dealing with TPL-001-4 and there shouldn't be three additional requirements in FAC-015-1 to deal with the uncommon occurrence of a PC using less limiting Facility Ratings, System steady-state voltage limits, or stability performance criteria. It certainly shouldn't require a technical justification, it should only require coordination"

Comment	
The FAC-015-1 title does not match its stated purpose. We suggest "Coordination of System Planning Criteria and Methodologies with Reliability Coordinator SOL Methodology. The stated purpose of FAC-015-1 is to ensure that Facility Ratings, voltage limits, and stability criteria are coordinated with RC SOL Methodology, but R4 is calls for providing selected Planning Assessment and Transfer Capability assessment results to RCs and TOPs. We agree with obligating PCs and TPs to communicate selected assessment results information with RCs and TOPs, but propose that the obligations be added to the respective FAC-013 and TPL-001 standards, not FAC-015-1. We believe that purpose of FAC-015 would be better fulfilled if it required PCs and TPs to provide their planning horizon Facility Ratings, voltage limits, stability criteria, and methodologies (i.e. TPL-001-4 R5 and R6) to their applicable RCs. This would allow RCs to know what criteria and methodologies PCs and TPs are using in Planning Assessments and better understand how their SOL Methodology might be adjusted to achieve better coordination with the planning horizon criteria and methodologies.	

R1, R2, and R3 – We are skeptical that requiring PC and TP system planning criteria and methodologies to be equally limiting or more limiting than Facility Ratings, voltage limits, and stability criteria derived from RC SOL Methodologies is an appropriate coordination strategy.

In addition, for R2 and R3, note that edits are needed to these requirements if they will be retained. Specifically, the "stability performance" and "System steady-state voltage" language in each of the sub-bullets of R2 and R3 are reversed (i.e. "stability performance" should appear in R3 and "System stead-state voltage" should appear in R2).

R4 – The requirement calls for the communication of CEII information from Planning Assessments and Transfer Capability assessment to impacted Transmission Owners and Generator Owners. This obligation should not be included until it is verified that compliance with the FERC Standards of Conduct can be guaranteed.

Consider the following ideas for sub-parts of a requirement to communicate selected Planning Assessment and Transfer Capability assessment results.

4.1 We agree with including the type of identified instability but suggest revising the list of examples to match those listed in FAC-011-4 Part 4.1 ". . . (e.g. steady state voltage instability, transient voltage response instability, unit instability, System damping). Steady state voltage instability criteria can be a percentage of margin from the expected voltage collapse point in a P-V analysis. The term "voltage collapse" incorrectly implies that all PCs and TPs choose the voltage collapse point in a P-V analysis as their voltage stability limit. FAC-011-4 changed "angular stability" to "unit stability". "Transient voltage dip criteria violation" is not a type of instability, but rather a reference to a type of criteria, which should be cited in Part 4.2.

4.2 Consider adding some stability criteria examples for the benefit of PCs and TPS, such as steady state P-V curve criteria, steady state high and low voltage protective relay trip levels, transient voltage dip criteria, transient overvoltage spike criteria, transient high and low voltage protective relay trip levels, generating unit loss of synchronism criteria, generating unit phase angle damping criteria.

4.3 Consider the following suggestions:

- Associated Contingencies and Associated Facilities are two different items and should be split into two separate sub-sections.

- The Contingencies used in Planning Assessments and Transfer Capability assessments include contingencies beyond the Contingencies used in Operational Planning Analysis.

- “Facilities critical to . . .” does not have a clear meaning and uses the ‘loaded’ wording of “critical to”. Consider wording like, “The Elements that exceed the system performance criteria”.

4.4 No suggested wording change. However after PCs and TPs describe the studied System conditions, it should explained that the System conditions, which will be used for Operational Planning Analysis, may be considerably different from the studies System conditions (e.g. different known outages, different load forecasts, interchange with economic transfers, different generation resource dispatches), so the reliability impacts identified in the Operations Planning Horizon may be very different from those based on the Near-Term Planning Horizon System conditions.

4.5 The automatic controls and expected system operator actions that are expected to address potential instability, Cascading, or uncontrolled separation in the Operations Planning Horizon should be split into two sub-bullets or be split into two separate sub-sections.

- A sub-section for automatic control actions could say, “Automatic controls expected to address potential instability, Cascading, or uncontrolled separation available in the Operations Planning Horizon, such as Remedial Action Schemes (RASs), undervoltage load shedding (UVLS), underfrequency load shedding (UFLS).

- A sub-section for system operator actions could say, “Operating Procedures expected to address potential instability, Cascading, or uncontrolled.

4.6 We suggest that the wording be modified slightly to something like “Any Corrective Action Plans intended to mitigate or reduce identified instability, Cascading or uncontrolled separation.

We agree that transmission owner-provided Facility (thermal) Ratings should be used in R1 and that the ratings of existing facilities should be coordinated between RC, PC, and TP entities to ensure system model accuracy. Thermal ratings of future facilities planned for the near-term planning horizon would not be coordinated with the RC as these facilities do not exist in the operating horizon. As proposed, the use of System Voltage Limits described in R2 and stability performance criteria described in R3 would not require coordination between entities, but would be based on the RC methodology and not on local TO planning criteria, which has been filed with FERC and the States. The use of more stringent limits set by the RC would provide the means to unilaterally drive the planning assessment results developed by the PC and TP and could force significant future system expansion above existing planned levels. In our opinion, the language in R2 and R3 needs to be changed to require a more collaborative use of PC and TP existing planning criteria with the RC methodology.

SRP agrees with the clarification of "owner-provided" Facility Ratings and restructuring of the requirements. However, SRP has concerns with the language found in R1, R2 and R3. In each of these requirements, the Transmission Planner or Planning Coordinator may use less limiting criteria, limits or ratings if they provide technical rationale to affected Transmission Planners, Planning Coordinators or Reliability Coordinators. SRP is concerned because there is no requirement for the affected entities to agree with the technical rationale. In addition, technical rationale is not a NERC defined term so SRP is concerned with what will be considered technical rationale and what will not. What happens if there is a disagreement between the Transmission Planner and the affected entity as to the technical rationale that was used?	
Likes 0	
Dislikes 0	
Response	
The SDT appreciates the comments. The entities the technical rationale is distributed to do not have authority over the planning entities per the NERC Functional Model so it would not be appropriate to allow for an approval of the rationale. The technical rationale does not have to be a NERC defined term and is up to the discretion of the entity creating the document.

ITC agrees with MEC and the MRO NSRF recommendations to SDT "to consider if the proposed FAC-015-0 altogether is needed". The general feeling within numerous industry's entities is that there is a risk of "over-regulation" as numerous additional requirements within various families of NERC Standards attempt to regulate aspects of the industry in a "micro-managing" manner. That leads to duplication and difficulties regarding interpretation of requirements. The Data Reporting Requirements in Attachment 1 of MOD-032-1 contains a tabular listing of *"information that is required to effectively model the interconnected transmission system for the Near-Term Transmission Planning Horizon and Long-Term Transmission Planning Horizon"*. It's also stated in the paragraph above the table *"A Planning Coordinator may specify additional information that includes specific*	

information required for each item in the table below". Item 4c in the table is *ratings (normal and emergency)**. The asterisk refers to a note that states *"(Items marked with an asterisk indicate data that vary with system operating state or conditions. Those items may have different data provided for different modeling scenarios)*. It appears these statements along with Requirement R1 of TPL-001-4 establish a compliance expectation for models to *"represent projected System conditions"*, which should include the most limiting Facility Ratings applicable to the modeling scenario. Additionally, if Planning Coordinators, Transmission Planners, Transmission Operators and Reliability Coordinators are not all using the same set of Facility Ratings provided by the Transmission Owner in accordance with FAC-008 R8, then that inaccuracy can be addressed via compliance monitoring for FAC-014, TPL-001 and various IRO/TOP requirements. During its webinar regarding Project 2015-09, the SDT indicated that it would be a very rare occurrence where a Reliability Coordinator would have a more limiting rating than those already provided by Transmission Owners and available to Planning Coordinators and Transmission Planners. Therefore, where is the reliability gap that necessitates creation of Requirement R1 in FAC-015-1?

In a similar manner, if the compliance expectation in Requirements R5 and R6 of TPL-001-4 is for the Transmission Planner and Planning Coordinator to demonstrate a technically sound rationale for voltage and stability criteria applicable to the modeling scenario, then where is the reliability gap that necessitates creation of Requirements R2 and R3 in FAC-015-1?

R1, R2, and R3 – We are skeptical that requiring Planning Coordinators and Transmission Planners system planning criteria and methodologies to be equally limiting or more limiting than Facility Ratings, voltage limits, and stability criteria derived from the Reliability Coordinator SOL methodologies is an appropriate coordination strategy. They also require a documentation burden that may ultimately be eliminated in a later NERC Standards Efficiency Review.

Requirement 4 should not be included in a FAC standard. The TPL standard already provides a provision for anyone with a reliability need to obtain the TPL Assessment. Any of these entities must request the TPL Assessment from the PC or TP and identify the reliability need. They must also demonstrate that they can maintain that the communication of CEII information is not outside the bounds of the FERC Standards of Conduct. R4 provides far too much of an open ended list of information on the transmission system and does not guarantee the required confidentiality.

Finally, ITC, while recognizing the IROL is not a part of the current comment period, suggests that during Phase II of the project the drafting team re-evaluate the use of references to Planning Assessments of the Near Term Transmission Planning Horizon that show results of “instances of instability, Cascading, or uncontrolled separation.” ITC is concerned that the drafting team may have inadvertently omitted how this reference includes TPL-001-4 Table 1 Extreme Events, as well as Planning Events. ITC recommends that the drafting team either clarify that the proposed replacement language for IROLs in associated Reliability Standards, as well as FAC-015-1, is only referring to TPL-001-4 Table 1 Planning Events. If it were to explicitly have the planning entities include and document those Extreme Events that cause instances of instability, Cascading, or uncontrolled separation if they are not specifically identified in Planning Assessments, this list would most likely be extremely long and cause issues for planning entities in their completion of all associated studies.

Texas RE is concerned with the use of a technical rationale to use less limiting Facility Ratings (R1), less limiting System Voltage Limits (R2), and less limited stability performance criteria (R3). There is nothing that states what should go into the technical rationale, who should determine whether or not the technical rational provides a valid reason for not using the most limiting factor, and what shall occur if the technical rationale is not valid. As written, an entity could put any reason whatsoever for not using the most limiting factor and have no consequence if it is not a valid reason.	

Texas RE strongly recommends there be some sort of criteria for a technical rationale, it go through an approval process, and, if not approved, it be sent back to the entity who submitted the technical rationale. At the very least, the technical rationale should explain how reliability is or is not impacted. Texas RE has the following additional comments regarding Requirement R1: • PCs and TPs should request facility owners to provide ratings based on the ambient temperature assumptions in the Planning Assessments, and for each ambient temperature assumption in the Planning Assessment, the PCs and TPs should not be able to use a rating which is less limiting than the corresponding owner-provided Facility Rating. • Higher Facility Ratings for a planned upgrade or addition should only be allowed to be utilized in studies the year the upgrade or addition is expected to be in service and for following years. Facility Rating increases that are only proposed as part of a Corrective Action Plan should not be used in the analysis performed to determine if the System meets performance requirements in Table 1 of TPL-001-4, but may be used to address deficiencies identified as part of the analysis.

IRC Standards Review Committee understands that the current Standards Authorization Request (SAR) doesn't provide the authority to revise the TPL, MOD, etc. standards that have a potential affiliation with FAC-015. Notwithstanding, the SRC recommends that the drafting team consider that FAC-015 data requirements are redundant with other families of standards and, therefore, provide no additional	

reliability benefit but add additional compliance burden to responsible entities. For example, MOD-32-1 and TPL-001-4 Requirements both require data provisions that overlap with FAC-015. Since the SDT for this Project recognized that there might be a better placement of the Project Requirements, yet apparently felt that a process to consider addressing Standards other than those in the Project's SAR was not available, NERC should consider a process to allow expediting revised SARs that would enable the SDT to address Standards that were not contemplated in the original SAR, while the Project is ongoing. The IRC would also like to note that the Standard Efficiency Review Project has made similar observations with respect to consolidation of or better coordination of standards. We would suggest that the SDT work with NERC Staff to follow the approach and principles of the SER team to ensure those efficiencies are realized on this project.

Comment	

The purpose of the FAC-015 standard is to ensure the Facility Ratings, steady-state voltage limits, and stability criteria used in the Planning Assessments are coordinated with the RC's SOL Methodology.

Requirement R4 in FAC-015-1 requires Transmission Planner to communicate its Stability Assessment results to the impacted Reliability Coordinator, Transmission Operator, Transmission Owner, and Generation Owner. We agree that Transmission Planner should communicate their Stability Assessment results to impacted entities, but we believe that this requirement belongs to TPL-001 standard and should not be a part of FAC-015 standard.

GTC is in agreement with the SDT's proposed FAC-015-1. The coordination of limits between planning and operations is an improvement over the current construct of having separate SOL methodologies for the planning and operations horizons. GTC is in agreement that some requirements in FAC-015-1 could alternatively be located within other standards such as TPL, MOD, etc. but recognizes the limits of the Project 2015-09 SAR.

We believe it would be acceptable for the PC to use the RC's SOL methodology or develop their own methodology that does not conflict with the RC's approach. Once this standard is approved in final form, FAC-008 should be checked for interoperability and conformity with FAC-015 such that all ratings are covered(i.e., thermal, voltage, stability).

Requirement R1 references application to "[e]ach Planning Coordinator and each of its Transmission Planners." However, Measure M1 only refers to the "Planning Coordinator." The same issue exists with respect to Requirements R2 and R3. ERCOT suggests aligning Measures M1, M2, and M3, with Requirements R1, R2, and R3 so that "Transmission Planners" are included in the Measures.

Measures M1, M2 and M3 must be revised to include the Transmission Planner. Also we support NYISO's comment in regards to R1 and the conditions for using less limiting Facility Ratings. We support the first clause ("The Facility has higher Facility Ratings as a result…"). Allowing for less restrictive Facility Ratings because of differences in temperature	

seems inappropriate. If a different temperature is used by a planner, they should obtain the Facility Rating for that temperature. As for the possibility of submitting technical rationales to other entities, the requirement does not require buy-in by the receiving entities. Since the objective of this requirement is to align planning and operations, we respectfully submit that the Facility Ratings should be consistent in planning and operating models. Where there is disagreement, the more conservative value should be retained. This follows the approach in other standards where, in disagreement, the more conservative option is retained (for example, IRO-014). The same comment applies to R2 and R3 - that is, we consider that the receiving entity, in particular when it is the RC, should be able to enforce the use of the more conservative assumption. However, for those two requirements we note that a "planned upgrade, addition, or Corrective Action Plans" (like in R1) are not explicitly included as reasons to modify the limits. They should be included like in R1. We reiterate that the most conservative rating, limit should be used. However, we agree that facility upgrades or additions do not need to be referred to the RC for its confirmation. The VSL for R4, with its concern with the number of missing characteristics, does not make sense. If a PC or TP were to incorrectly communicate an instability - but only incorrect in one characteristic - this would be a lower VSL, but it could, if that error was important, make the communication useless and put the system at risk. The VSL should be severe, unless the error without consequence from an operational point of view. That is, if the RC was able to take correct actions as a consequence, then the error is without consequence. If the RC's actions were incorrect as a consequence of the error, then it should be Severe.

6. Discussions within the SDT indicated concerns with eliminating some of the components of the approved SOL definition. While the industry feedback was largely supportive of the draft SOL definition provided in the informal posting, the SDT modified the proposed definition to incorporate some of the concepts in the approved version. The SDT believes that the revised definition posted for ballot represents an improvement over the definition provided in the informal posting. Reference the SOL rationale document for more information. Do you agree with the proposed SOL definition?

SRP generally agrees with the proposed definition. However, when read separately from the technical rationale, the phrase "specified System configuration" is ambiguous and does not add clarity to the definition. SRP recommends adjusting the proposed definition to more completely explain the relationship between limits and specified System configurations.

Response	
Response: Thank you for your feedback. The drafting team discussed this issue at length and determined that it is important to retain the "specified System configuration" language in the revised definition. The rationale document specifically addresses the reasoning for this position: *The SDT proposes to retain the reference to "specified system configuration" due to the fact that stability limits in particular are typically dependent on system configuration. While Facility Ratings and System Voltage Limits are not typically dependent upon system configuration,*	

there may be times where they may be dependent on System configuration. For example, if a transmission line is connected by two circuit breakers at one end of the line, and one of those two circuit breakers is open, the value of the Facility Rating for line could be reduced due to current carrying capability of the remaining in-service circuit breaker.	
David Jendras - Ameren - Ameren Services - 3	
Answer	No
Document Name	
Comment	
While the proposed definition is indeed a vast improvement over the existing, ambiguity is introduced when specifying "facility ratings" if the current definition of IROL (which relies on the definition of SOL) is kept. The singular of facility implies one facility but in practice, IROLs are often established a combination flows not specific to one facility but aggregations of facilities. These IROL MW flow limits may not trigger voltage or stability concerns. The definition should be modified to reflect this concept either by replacing "facility" with "facility(ies)" or by adding a dependent clause such as "facility ratings, either individually or taken in combinations, system voltage..."	
Likes 0	
Dislikes 0	
Response	
Thank you for your feedback. Per the proposed revised definition, a Facility Rating is an SOL. While IROLs may be monitored as a sum of flows on several Facilities, this does not change the fact that a Facility Rating is an SOL. Phase two of the project will address IROLs and may include a revision of the IROL definition. The drafting team will keep your comments under consideration for that future work.	
Terry BIlke - Midcontinent ISO, Inc. - 2	
Answer	No
Document Name	
Comment	

While the definition is cleaner, the rationale document needs to be clear that exceeding a non-IROL SOL, particularly post contingency, is not a violation of any operating standard or criteria.

Thank you for your feedback. While the drafting team agrees that the additional language (the second sentence in APS' proposed definition) is true, we do not believes that it substantially enhances the definition.	
Joe O'Brien - NiSource - Northern Indiana Public Service Co. - 6	
Answer	No
Document Name	

Comment	
NIPSCO believes that the start of the definition should read “SOL is the most limiting of”, as all limits should not be considered a System Operating Limit. We believe only the most limiting of the limits on a facility should be considered a System Operating Limit. If “all” ratings need to be monitored this would present a problem for many software platforms as there is no way to insert more than 3 or 4 ratings into a facility record.	
Likes 0	
Dislikes 0	
Response	
Thank you for your feedback. The drafting team discussed this issue at length and determined that the “most limiting of” language is inconsistent with the essence of the revision. Page 7 of the rationale document addresses this issue at length.	
Aaron Cavanaugh - Bonneville Power Administration - 1,3,5,6 - WECC	
Answer	No
Document Name	
Comment	
“Monitoring and assessing” implies the process that is gone through to develop and use an SOL. This definition should focus on what an SOL is, not the process by which SOLs are found or how SOLs are used. *BPA suggested definition:* *All Facility Ratings, System Voltage Limits, and stability limits, applicable to specified System configurations, to ensure reliable operation of the Bulk Electric System in both the pre- and post-Contingency operating states.*	
Likes 0	
Dislikes 0	
Response	

Thank you for your feedback. While the drafting team generally agrees with your comments, the monitoring and assessing language was added at the specific request of FERC staff. The proposed definition is problematic because of the use of the "to ensure reliable operation of" language.

The MRO NSRF agrees with the proposed SOL definition. However, as stated in our response to question 1, we need additional clarification on the SOL expectation of the SDT. Is it your intent that each Facility has a thermal-based SOL or can a subset (Flowgates) be used to manage power flow on the system? This needs to be clearly stated in a requirement so that everyone is planning and operating the BES from the same understanding. Additionally, it's not clear if Normal Ratings and normal System Voltage Limits are considered SOLs, if you have higher Emergency Ratings or emergency System Voltage Limits for the Facilities. It could be interpreted to say Normal Ratings and normal System Voltage Limits aren't SOLs if you have higher Emergency Ratings and emergency System Voltage Limits. This understanding translates to compliance expectations in the IRO and TOP Standards for exceedances and when you must implement your Operating Plan. If we're relying on the SOL whitepaper to clarify, then some entities may choose not to follow it saying it's not mandatory. Since the SDT may not be able to answer compliance questions, we request NERC staff to draft a CMEP Practice Guide to inform the industry of the compliance expectations for SOLs as applied in the FAC, IRO and TOP standards.

Response	
Thank you for your feedback. Each Facility has Facility Ratings, which are comprised of both a Normal Rating and one or more Emergency Ratings. For a given Facility, the full set of Facility Ratings, both the Normal Rating and all Emergency Ratings are SOLs at all times. Flowgates can certainly be used as a mechanism to manage power flow on the system; however, by definition, flowgate limits are not SOLs unless the flowgate defines a stability limit. Normal System Voltage Limits and Emergency System Voltage Limits are SOLs. All of these are SOLs all the time. The drafting team will communicate your recommendation to draft a CMEP Practice Guide as suggested.

7. With the retirement of FAC-010, and the elimination of Planning-based SOLs and IROLs, do you agree with the changes to CIP-014, FAC-003, FAC-013, PRC-002, PRC-023 and PRC-026?

Ginette Lacasse - Seattle City Light - 1,3,4,5,6 - WECC, Group Name Seattle City Light Ballot Body	
Answer	No
Document Name	
Comment	
On behalf of our City Light SME: There is confusion about why the terms "SOL" and "IROL" need to be removed from some of these standards. In FAC-003, for example, shouldn't any element identified as part of a currently effective IROL be considered under the applicability section, not just things identified in the Planning Assessment?	
Likes 0	
Dislikes 0	
Response	
The term SOL and IROL as labels in the planning horizon are being retired, replaced by the concepts in the revised TPL 001 standard. As such any standard that used the term SOL or IROL as an identified facility from the Planning horizon needed a new method of identifying those important facilities. Standards that use the SOL or IROL from the Operating Horizon did not have the term removed.	
Sandra Shaffer - Berkshire Hathaway - PacifiCorp - 6	
Answer	No
Document Name	
Comment	

FAC-003-5 should be revised to align with the comments to FAC-015-1 in #5 above. Any requirements associated with a Near-Term Planning Assessment should align with the specific requirements in the approved TPL-001 Standard either the Operations Horizon or to a specific requirement within the TPL-001 Standard – R3.5 and R4.2.

Comments specifically for CIP-014-3: Applicability 4.1.1.3 should simply be removed. The proposed wording change causes confusion with the actual CIP-014 assessment, the whole purpose of which is to identify those Transmission substations that if rendered inoperable or damaged as a result of a physical attach could result in instability, Cascading or uncontrolled separation. The new proposed 4.1.1.3 would either create a circular argument or could inadvertently be interpreted to expand the scopes of TPL-001 and MOD-001. Any revisions to the requirements of the assessments in TPL-001 and MOD-001 should be made in those Standards, not through CIP-014.

Response

The drafting team believes the language offered in FAC-003 regarding a facility that if lost or degraded are expected to result in instances of instability, Cascading or uncontrolled separation does align with the TPL standard including the requirements that you referenced. The language offered in CIP-014 by the drafting team used similar language to FAC-003 and aligns with the analysis already done as part of the TPL 001 standard. The drafting team does not believe that it would create a circular argument, since it places no direct burden on the Planning Coordinator beyond communication. The team is assuming by MOD-001 you actually meet FAC-013, since MOD-001 address the determination of Available Transfer Capability and is not referenced in the standard.

Thomas Foltz - AEP - 5

Answer	No

Comment

While AEP has no objections to the proposed changes to CIP-014, FAC-013, PRC-002, PRC-023 and PRC-026, we do have concerns regarding 4.2.2, Transmission Facilities, within FAC-003. We believe additional text is needed here to ensure no lines are unintentionally excluded by

a) the timing of their being identified as part of an IROL and b) the timing of any facilities identified, which could lead to instability, Cascading, or uncontrolled separation within associated planning assessments. AEP recommends that this section be clarified in the following manner… *“Each overhead transmission line operated below 200kV, identified by the Planning Coordinator or Transmission Planner, per its Planning Assessment of the Near-Term Transmission Planning Horizon or its Transfer Capability Assessment (Planning Coordinator only) as a Facility that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation* ***or overhead transmission line operated below 200kV that have been established as part of an IROL by the Reliability Coordinator per IRO-014-3 R1.****”* AEP has chosen to vote negative on the proposed revisions to FAC-003, driven by the concerns expressed in this response.

Response	
The drafting team believes that FAC-003 in addressing vegetation management applies to a longer period of time. As such the drafting team does not believe the designation of an IROL by the RC should be included in 4.2.2 since such a designation may be temporary or transitory in nature. The designation would not result in immediate vegetation management, and so it could be months or years before the vegetation management caught up with the designation, providing no practical benefit. If the RC does have an IROL below 200 kV that is expected to remain in place long enough that they would like it captured under FAC-003, they can coordinate with the Planning Coordinator or Transmission Planner to make sure it is captured in their study. Keep in mind this is only for facilities below 200 kV, all facilities above 200 kV Are captured by the standard.	
Don Schmit - Nebraska Public Power District - 5	
Answer	No
Document Name	
Comment	
FAC-003-5 should have an implementation period once a study identifies a new Facility below 200 kV (Applicability Section) that could lead to instability, Cascading or uncontrolled separation. An entity needs the time to get that new Facility into it’s vegetation plan and meet the	

clearences. The way the **current FAC-003-4 and proposed Standard FAC-003-5** is written an entity is out of compliance once the new studied Facility is identified if it does not meet clearences and the entity would then need to self report. NPPD recommends an implementation period of up to 24 months to allow for the newly identified facility to be incorporated into it's vegetation plan and for clearences to be met. For the other Standards NPPD supports the comments submitted by the MRO NSRF.

Comment	
The MRO NSRF supports the effort of the SDT to eliminate planning-based SOLs and IROLs, but to ensure clarity of expectations the revisions to these standards need to directly map to the applicable TPL-001-4 contingency results that indicate unacceptable instances of instability, Cascading, or uncontrolled separation. As currently proposed, every instance of instability or tripping of multiple elements could be considered in scope for IROLs. Additionally, the SDT should consider that requirements to perform transfer capability studies were determined by the Standards Efficiency Review project to be for commercial purposes and proposed for retirement in the phase 1 SAR. Even though we realize the changes to CIP-002-6 are not in scope for this question and the modifications to the standard were given to the CIP SDT, the 2015-09 SDT is the one who understands the concept of IROLs. Therefore, we would appreciate the SDT passing the following concerns to the CIP SDT. The changes to CIP-002-6 criterion 2.6 and 2.9 do not add clarity. Unfortunately, the proposed changes to criterion 2.9 would bring in most SPS/RAS in the country because these systems are typically designed to avoid instability or a cascading outage scenario. Similarly, the proposed changes to criterion 2.6 substantially expands the scope of analysis. The current CIP-002-5.1 criterion 2.6	

language is very clear and narrow because it limits the evaluation to those Facilities that have been shown to impact a large area of the system (i.e. what it means to be an IROL). With the proposed changes, many more Facilities will need to be evaluated for instability, but the end result will still be very few Facilities on the list (and those that make it on the list probably have an SPS/RAS to mitigate the concern). This appears to be an unneeded expansion of the criterion whereas the current language is precise. The SDT should keep in mind that IROLs will still exist under the proposed FAC standard revisions for the operating horizon and, therefore, no change is needed to R2.6 or R2.9. We are not opposed to removing the Planning Coordinator in PRC-002 as an applicable functional entity and having the Reliability Coordinator as the only applicable regional function entity. However, we propose that the Time Horizon of all the Requirements be changed from "Long-term Planning" to "Operations Planning", to be consistent with the direct and indirect applicability of the Requirements to the Reliability Coordinator.

Response	
The current drafts discuss facilities that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation that adversely impact the reliability of the Bulk Electric System. So as drafted the TP and PC would be identifying those facilities from their study that they believe meets that criteria, which may or may not include every instance of instability or tripping of elements if they do not adversely impact the reliability of the Bulk Electric System. The drafting team is aware of the effort to remove the FAC-013 transfer capability studies but until such time as they are actually removed the team must address them. Time Horizon: The drafting believes that these requirements are long term planning (1 year or greater) because when there is a violation there is a window of time to recover from the violation. The Time Horizon is the period of time to mitigate a violation, as such certainly some of the Reliability Coordinator functions are in the Operations Planning horizon, but data recording equipment issues are not a violation that has to be resolved within a day or even within the current season, nor can they be resolved that quickly depending on the lead time on the equipment. Because this equipment is for after the fact analysis, and not the real time prevention of an issue, the longer time horizon continues to be appropriate.

Response	

Thank you for the support on CIP-014, FAC-003, FAC-013, PRC-002, and PRC-023. For PRC-026 the responsibility is placed on the Planning Coordinator in the existing standard to provide the information to the Generator Owner and Transmission Owner and the drafting team maintained that requirement just moving away from the SOL and IROL language to better match the proposed paradigm. If the current practice in your area is that the Reliability Coordinator provides this information to the Planning Coordinator to fulfill this function than nothing in the revised standard would preclude that action.

BPA recommends that CIP-014, FAC-003, FAC-015, PRC-023 and any other standards that reference "instability, uncontrolled separation, or Cascading" with the intent of replacing the term IROL be modified to include the qualifying phrase "*that adversely impact the reliability of either the interconnection or other Reliability Coordinator Area(s)*." This change aligns with the current NERC definitions for IROL and IROL Tv. NERC definitions: **Interconnection Reliability Operating Limit (IROL):** A System Operating Limit that, if violated, could lead to instability, uncontrolled separation, or Cascading outages *that adversely impact the reliability of the* Bulk Electric System. **Interconnection Reliability Operating Limit Tv (IROL Tv):** The maximum time that an Interconnection Reliability Operating Limit can be violated before the risk to the *interconnection or other Reliability Coordinator Area(s)* becomes greater than acceptable. Each Interconnection Reliability Operating Limit's Tv shall be less than or equal to 30 minutes. BPA believes that the two NERC definitions work in conjunction to define when IROLs should be declared. The IROL definition identifies the BES, while the IROL Tv definition identifies an IROL Tv is used to protect the interconnection as a whole or other RC areas.

Comment	
Replacement of IROLs with vague unbounded terminology of “instability, uncontrolled separation, and cascading" isn't appropriate and is inferior to the current IROL approach. If IROLs aren't maintained, at a minimum, instability should be quantified with terms such as wide-area or a MW threshold such as the loss of 1,000 MW. The benefit of IROLs is the understanding of an impact threshold clearly understood and outlined in current IROL methodologies. Vague terminology in zero defect standards results in unnecessary violations, interpretations, and compliance guidance.

CenterPoint Energy supports the elimination of Planning-based SOLs and IROLs; however, CenterPoint Energy does not agree with the changes to the standards listed above. By not incorporating language such as “that adversely impact the reliability of the BES” or some equivalent limiting phrasing into the proposed language used to replace IROL in these standards, the SDT may have expanded the scope of the applicability or requirement. Not all instances of instability rise to the level of adversely impacting the reliability of the BES, and these should not be considered in scope for the standards above.

Comment	

The proposed responsibility shift in Requirement R5 from Responsible Entity (Planning Coordinator, where presently applicable) to Reliability Coordinator is outside of the scope of Project 2015-09 set forth by the SAR and does not align with the Long-term Planning Time Horizon of PRC-002, as the RC is responsible for real-time operating reliability of its area.

Additionally, Santee Cooper has concerns over shifting the responsibilities of Requirement R5 from the Responsibility Entity (Planning Coordinator) to the Reliability Coordinator at this stage in the existing PRC-002-2 implementation plan.

- The initial implementation deadline for Requirement R5 has past. Capital expenditure decisions have already been made based on the initial identification by the Responsible Entity of BES Elements for which DDR data is required per the prescriptive requirements of the standard.
- Changing the evaluator and spreading the minimum DDR coverage requirement over the Reliability Coordinator's historical simultaneous peak System Demand vs. the Responsible Entity could potentially change the results of the evaluation, and could potentially require additional equipment from an entity that is unbudgeted at this point.

Furthermore, there is a gap in the Implementation Plan for Project 2015-09 with regard to PRC-002-3.

- In the elements listed that shall remain applicable to the Implementation of PRC-002-3 R2, R3, R4, R6, R7, R8, R9, R10, R11, the Implementation Plan for Project 2015-09 does not address compliance requirements for a re-evaluated list from Requirement R1 or R5. The original PRC-002-2 gives entities three (3) years to be 100 percent compliant with a re-evaluated list from R1 or R5, allowing entities time to budget, design and commission any additional equipment that may be needed to comply. This omission creates a gap in the Implementation Plan, as R1 and R5 include mandatory re-evaluation at least once every five (5) years.

Multiple references to PRC-002-2 within the text of the draft standard have not been redlined, and should be replaced with PRC-002-3.

Multiple references to PRC-023-4 within the text of the draft standard have not been redlined, and should be replaced with PRC-023-5.

Multiple references to PRC-026-1 within the text of the draft standard have not been redlined, and should be replaced with PRC-026-2.

Response	
The SDT believes placing responsibility solely on the Reliability Coordinator adds clarity and consistency for the task of identifying the BES Elements for which Dynamic Disturbance Recording (DDR) is required. The RC and TOP are the entities that identifies and monitors SOLs/IROLs within real time operations. Furthermore the RC is responsible for leading any investigation into events that would use this data. The TP and PC may assist in these efforts or even effectively lead them, but the standards and processes assign the responsibility to the RC. We have addressed the time window for implementation in the PRC-002 implementation plan and updated the standard references in all the documents.

With the elimination of Planning –based SOLs and IROLs, the Standards drafting team has attempted to come up with alternate means of identification of facilities to fill the void, such as under Applicability Criterion 4.1.1.3 in CIP-014-3. The concern is that the use of terms like "instances of instability," "Cascading," and "uncontrolled separation" in place of IROL definition, is very vaguely defined in existing NERC standards and is highly subjective to individual entity's interpretation and application methodology. Further, there are no thresholds suggested that can be applied to derive these facilities from Near Term Transmission Planning Assessments. Such a list of facilities could vary considerably even between the Planning Coordinator's Assessment and the Transmission Planner's Assessment. Use of such vaguely defined criteria will subject entities to undue burden of evaluating lot more facilities under all of the above standards (CIP-014, FAC-003,	

FAC-013, PRC-002, PRC-023 and PRC-026) with increased risk of additional cost to be incurred. Suggest the standard drafting team come up with more specific methodology in place of IROL or delete this Criterion in CIP-014-3 and other applicable standards.

AZPS requests clarification on what contingencies are included in: · "Facilities that if lost or degraded" in CIP-014 and FAC-003; · "Planning Assessments that identify instances of instability, Cascading, or uncontrolled separation" in B2 of Attachment B in PRC-023; and · "Elements associated with angular instability identified in Planning Assessments." AZPS suggests the following changes to FAC-013-3: · Remove R3	

· Remove "Reserved for future use" in R1.2 and update numbering accordingly Additionally, Planning Assessments, completed through TPL-001-4, include multiple categories of contingencies (P0-P7) and Extreme Events as detailed in Table 1 of TPL-001-4. Extreme Events referenced in TPL-001-4 should be excluded from those addressed through CIP-014, FAC-003, FAC-013, PRC-023 and PRC-026. To fail to do so could result in double-counting of contingencies. Further, to fail to do so could result in local impact contingencies being considered as a result of other contingency evaluations. For example, evaluation of Extreme Events under CIP-014 can bring in low impact substations despite the fact that the instability identified would only have a very small impact that is confined to a local area. Such identified local instability does not and should not result in required hardening under CIP-014. For this reason, only Planning Events from Table 1 of TPL-001-4 should be included. AZPS is further concerned that studies that have previously been completed would need to be restudied in accordance with the new standard in order to satisfy the 12 month timeline in the implementation plan even if the timeline prescribed in the existing requirement has a longer timeframe. For example, CIP-014-2 R1 requires studies every 30 calendar months. AZPS does not support doing an additional study for CIP-014-2 R1 before the 30 month deadline that we will have already created a scheduled for in order to be compliant with the new standard before the 12 month implementation date.

Response
Thank you for the comments. The contingencies that apply would be any contingencies studied under the TPL 001 that resulted in the described phenomena. For FAC-013 the drafting team made the minimum amount of changes since there is also an effort underway to retire FAC-013. To help clarify the types of system responses that could result in facility identification the team expanded the language to include "that adversely impact the reliability of the Bulk Electric System" so it better matches the current IROL. Given this caveat the team believes that all contingencies from the TPL assessment would be included unless they are excluded by the language in the particular standard. The "double counting" is a moot point since listing the same facility more than once would not result in any more burden than listing it a single time.

The changes for PRC-002 seems unrelated to the proposed FAC changes.

The proposed changes for CIP-014, PRC-023, and FAC-003 the replacement language is too broad. The Planning Assessment looks at extreme events which have low probability of occurring and for which corrective actions are not required. It doesn't seem reasonable that extreme events which result in instability, Cascading, or uncontrolled separation are now pulled into scope for CIP-014, PRC-023, and FAC-003 when CAP are not required by the TPL-001.

The proposed change to FAC-013 R1.3 seems unrelated to the proposed FAC change.

NV Energy believes there is inconsistency with the language used in the CIP-002-6 Draft of the impact of instability, Cascading, or uncontrolled separation. NV Energy would request that the SDT include "Wide Area Impacts" to the language revisions in CIP-014, FAC-003, and PRC-023:

CIP-014 Applicability 4.1.1.3 should read:

4.1.1.3 *Transmission Facilities at a single station or substation location that are identified by the Planning Coordinator or Transmission Planner, per its Planning Assessment of the Near-Term Transmission Planning Horizon or its Transfer Capability Assessment (Planning Coordinator only), as Facilities that if lost or degraded are expected to result instances of* ***Wide Area impacts*** *such as instability, Cascading, or uncontrolled separation.*

FAC-003-5 Applicability 4.2.2 and 4.3.1.2 should read:

4.2.2. *Each overhead transmission line, operated below 200kV, identified by the Planning Coordinator or Transmission Planner, per its Planning Assessment of the Near-Term Transmission Planning Horizon or its Transfer Capability Assessment (Planning Coordinator only), as Facilities that if lost or degraded are expected to result in instances of* ***Wide Area impacts*** *such as instability, Cascading, or uncontrolled separation.*

4.3.1.2. *Operated below 200kV and are identified by the Planning Coordinator or Transmission Planner, per its Planning Assessment of the Near-Term Transmission Planning Horizon or its Transfer Capability Assessment (Planning Coordinator only), as Facilities that if lost or degraded are expected to result in instances of* ***Wide Area impacts*** *such as instability, Cascading, or uncontrolled separation; or …*

PRC-023-5 Attachment B (Criterion 2) should read:

B2. *The circuit is selected by the Planning Coordinator based on Planning Assessments that identify instances of* ***Wide Area impacts*** *such as instability, Cascading, or uncontrolled separation.*

Comments: An administrative revision to PRC-023-5 is recommended to carry forward the approved implementation timing language from the PRC-023-3 Implementation Plan and the Errata to the Implementation Plan for the Revised Definition of "Remedial Action Scheme" (which included the PRC-023-4 revision). This non-substantive change to bring the current standard under revision into line with the currently approved version (and implementation notes) is necessary to avoid possible future errata revisions. A suggested revision is to include a footnote for the relevant sections in Section 4.2 Circuits (Sections 4.2.1.2, 4.2.1.3, 4.2.1.5, and 4.2.1.6) as follows: **4.2.1.2** Transmission lines operated at 100 kV to 200 kV selected by the Planning Coordinator in accordance with Requirement R6. *1* **4.2.1.3** Transmission lines operated below 100 kV that are part of the BES and selected by the Planning Coordinator in accordance with Requirement R6.*1* **4.2.1.5** Transformers with low voltage terminals connected at 100 kV to 200 kV selected by the Planning Coordinator in accordance with Requirement R6. *1* **4.2.1.6** Transformers with low voltage terminals connected below 100 kV that are part of the BES and selected by the Planning Coordinator in accordance with Requirement R6. *1* *Footnote 1 suggested language:* *1.* Circuits identified by the Planning Coordinator in accordance with Requirement R6 shall be compliant the later of the first day of the first calendar quarter 39 months following notification by the Planning Coordinator of a circuit's inclusion on a list of circuits per application of Attachment B, or the first day of the first calendar year in which any criterion in Attachment B applies, unless the Planning Coordinator removes the circuit from the list before the applicable effective date.

Comment	
For CIP-014, FAC-003, PRC-023, and PRC-026, I think there needs to be a revison to every proposed redline change, that states "per its Planning Assessment of the Near-Term Transmission Planning Horizon or its Transfer Capability Assessment as Facilities that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation." To those proposed change statements, I believe we need to add at the end of each one in all the referenced above Standards, the simple phrase ", or other Study." I believe this is needed because the TPL Assessments or Transfer Capability Assessments in themselves, don't necessarily require the type of extreme contingencies to be studied that would cause instability, Cascading, or uncontrolled separation. Hence to demonstrate the impact of these type of extreme contingencies (such as was done for the CIP-014 analysis), studies other than the Annual TPL Assessment or Transfer Capabilty Assessments might need to be completed.

Thank you for your comment. The drafting team had discussed this extensively and while we agree that such conditions might be identified in other studies, the team did not want to include language in the standard that could create a shadow requirement for the Planning Coordinator or Transmission Planner to run additional studies beyond those required in TPL 001. The Planning Coordinator could provide those additional studies for the other party to use on a voluntary basis or the Planning Coordinator could insure that the next years TPL-001 includes the conditions that would trigger the event, and thereby be able to communicate it in a binding fashion.

Comment	

Duke Energy has concerns with the language proposed as a replacement to the IROL language in these standards. The language, *"per its Planning Assessment of the Near-Term Transmission Planning Horizon or its Transfer Capability Assessment (Planning Coordinator only) as Facilities that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation,"* is too broad as written, and appears to bring TPL-001-4 Extreme Events into scope and other single & multiple contingency events well beyond the scope of the original single contingencies specified in R2 of FAC-010/011 and specified in R5.1.1 of the proposed FAC-011-4 to identify SOL's and IROl's. We believe more limiting language is appropriate. CIP-014- Duke Energy feels that the draft language is too broad (see above). FAC-003- As stated above, we have concerns with the appearance of an expansion of scope. This would be in conflict with the original intent of the standard which did not include such events. We believe more limiting language is appropriate. Also, there appears to be inconsistent use of Planning Coordinator or Transmission Planner (as used in the Applicability section), and Categories 1A-4B which references the Planning Coordinator only. Was it the drafting team's intent that only the Planning Coordinator apply to those Categories? PRC-002- Duke Energy does not support the change from Responsible Entity to Reliability Coordinator in R5. This would be a significant departure from current industry practices since the RC does not currently have assess operation in the Long Term Planning Horizon. This would prompt the need for Reliability Coordinators to revise current processes, and include steps to reach out to entities in its RC Area for this information. We fail to see the reliability benefit of transferring historically planning related activities to the Reliability Coordinator. PRC-023- Duke Energy feels that the draft language is too broad (see above). We believe more limiting language is appropriate. PRC-026- Duke Energy feels that the draft language is too broad (see above). We believe more limiting language is appropriate. Also, there appears to be a grammatical error in R1. Consider removing the "a" before "limiting the output of a generator".

IROL Replacement language: The team agrees and revised the language to include the phrase as listed in the definition of IROL, "instability, uncontrolled separation, or Cascading outages that adversely impact the reliability of the Bulk Electric System".	

CIP-014: See revised replacement language above, in addition CIP-014 FAC-003: The team felt it was best to have a single entity responsible in those criteria. PRC-002: The SDT believes placing responsibility solely on the Reliability Coordinator adds clarity and consistency for the task of identifying the BES Elements for which Dynamic Disturbance Recording (DDR) is required. The RC and TOP are the entities that identifies and monitors SOLs/IROLs within real time operations. Furthermore the RC is responsible for leading any investigation into events that would use this data. The TP and PC may assist in these efforts or even effectively lead them, but the standards and processes assign the responsibility to the RC. We have addressed the time window for implementation in the PRC-002 implementation plan and updated the standard references in all the documents. PRC-023: Please see if our revised language addresses your concern. PRC-026: Please see if our revised language addresses your concern.

FAC-013-3 The companies recommend keeping FAC-013-3 R1.3 without revision and preserve the words “planning practices.”	

The proposed R1.3 revisions, replacing “planning practices” with the NERC Glossary term, “Planning Assessments,” effectively assigns TPL assessment criteria and requirements to FAC-013. Such an outcome is inconsistent with the FAC-013 purpose to “…reliably transfer energy in the Near-Term Transmission Planning Horizon.” Also, by effectively assigning TPL assessment criteria and requirements to FAC-013, assessments are duplicated and establish similar compliance obligations over multiple Standards. Furthermore, by having similar compliance obligations over multiple Standards creates a compliance conundrum when either Standards yield a similar issue of noncompliance. **CIP-014 FAC-003 PRC-002 PRC-023 and PRC-026** The companies support the proposed revisions.

Response	
Thank you for your comments. The SDT believes that leaving the language “planning practice” in place is too broad and unclear as to what planning practice, when, should be used in the FAC-013 study. Keep in mind 1.3 only requires a statement that the assumptions and criteria used are consistent with the Planning Assessment, but they don’t require them to be identical. 1.4 then provides the opportunity for the Planning Coordinator to explain what they are doing.

The proposed redline changes in CIP-014 and FAC-003 limit the application of facility identification that may result in instances of instability, Cascading or uncontrolled separation to only Planning Coordinator's Planning Assessments of the near-term Planning Horizon and transfer assessments. This proposed change might be read to reduce the potential sources of information / analysis which entities use to today to make such identifications. The FAC-013 and PRC-002 changes are acceptable. With regard to PRC-023, the changes made to Criterion B2 have made it very unclear. The language "is selected by" infers that there is some sort of optional or judgement, but there is no indication of what that should be based on. Additionally, referring to Planning Assessment is too vague. Planning Assessments include consideration of extreme events, but these seem inappropriate for consideration in PRC-023. If the decision is made to keep B2 similar to what has been drafted, please change "Planning Assessments" to "assessments", as this would allow for consideration of any available inputs. Proposed language is shown below. Similarly, for PRC-026, R1 criterion 2 is too restrictive by using the term "Planning Assessments". This should be changed to "technical assessment" as shown below. Also in PRC-026, page numbers should be added to the Guidelines and Technical Basis section.

PRC-023 Criterion B2 further modification in bold below:

*The circuit is selected **identified** by the Planning Coordinator based on assessments **of P0 – P7 Planning Events** that identify instances of instability, Cascading, or uncontrolled separation.* *Additional revision for PRC-026, R1 criterion 2 in bold below:* *Elements associated with angular instability identified in **technical assessments including but not limited to** Planning Assessments.*

For CIP-014, FAC-003, PRC-023 and PRC-026 the drafting team believes that specifying the Planning Coordinator TPL 001 Planning Assessment is the correct study to point at. The team discussed allowing other studies and assessments as well, but ultimately believed that leaving this to broad could have unintended consequences, such as implying that the Planning Coordinator should have these other studies and make them available. If the Planning Coordinator finds issues that need to be addressed through other studies, those can always be incorporated in to the next years TPL 001 Planning assessment Requiring them to be in the Planning Assessment also means that the items identified by the Planning Coordinator may also be triggering a corrective action plan. Thank you for your support on FAC-013 and PRC-002 For PRC-023 the drafting team further limited the events to the near term horizon and planning events.

MISO agrees with retiring FAC-010.

With regard to PRC-026_R1, the first sub-bullet appears to either have a grammatical error or it should be revised for clarity. "Generator(s) where an angular stability constraint exists that is addressed by a limiting the output of a generator or RAS…". Suggestion is to remove the words "…addressed by a…".

Likes 0

The Standard Drafting Team needs to address whether the proposed redlines in Projects 2016-02 and 2015-09 are meant to clarify existing practices for identifying BES assets, or are intended to modify current approaches, specifically with regard to identifying generation resources under CIP-002.

The proposed redline changes in CIP-002 and CIP-014 limit the application of facility identification that may result in instances of instability, Cascading or uncontrolled separation to only Planning Coordinator's Planning Assessments of the near-term Planning Horizon and transfer assessments. This proposed change might be read to reduce the potential sources of information / analysis which entities use to today to make such identifications. Lastly, the Project 2016-02 Standard Drafting Team must coordinate with the Project 2015-09 Standard Drafting Team since these redlines appear not only for modifications to CIP-002 but also to CIP-014, and the requisite and primary technical expertise to understand IROLs is in the Project 2015-09 SDT.

For CIP-002 please forward questions to the CIP team. The team discussed extensively using language that allowed the Planning Coordinator and Transmission Planner to bring in other studies or assessments in addition to their Planning Assessment. However ultimately the team decided that the required Assessment that places requirement on the Planning Coordinator and Transmission Planner was the only study that should be referenced. First of all because it is a study where the Planning Coordinator and Transmission Planner are required to do something with the results and second to avoid creating questions regarding "what other studies/assessments". There is nothing that would preclude a Planning Coordinator or Transmission Planner from identifying something in studies or assessments through the year, and then including that study/assessment in their annual Planning Assessment – thereby passing the information on to the end user in the context of the standard.

It is our understanding that 'Planning Assessment' in the proposed change from referring to IROLs to "..., per its Planning Assessment of the Near-Term Transmission Planning Horizon or its Transfer Capability Assessment (Planning Coordinator only) as Facilities that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation" refers to studies performed for the Near-Term Transmission Planning Horizon per NERC Reliability Standard TPL-001-4. The term Planning Assessment is in the NERC 'Glossary of Terms Used in NERC Reliability Standards' defined as "Documented evaluation of future Transmission System performance and Corrective Action Plans to remedy identified deficiencies." To reduce the risk of continued inconsistency, we propose to add "technical analyses such as its" to the text replacing the previous reference to IROLs as well as a minor editorial change to the reference to Transfer Capability assessment in all applicable NERC Reliability Standards listed in Project 2015-09 as well as, if approved, to NERC Reliability Standard CIP-006-2. Hence, we proposed the text replacing the reference to IROLs to read "..., per technical analyses such as its Planning Assessment of the Near-Term Transmission Planning Horizon or the Planning Coordinator's Transfer Capability assessment, as Facilities, that, if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation."

We agree with changes to reflect the elimination of Planning-based SOLs and IROLs for CIP-014, FAC-003, FAC-013, PRC-002, and PRC-023.

However, we do not agree with the change to the PRC-026 standard. The Planning Coordinator requires the Reliability Coordinator to provide those SOLS that are based on angular stability in order to assess Criteria 1 and 2 of Requirement R1. We suggest revising Requirement R1 to require the Reliability Coordinator provide the Planning Coordinator with those SOLs that are based on angular stability.

CIP-014:

The SDT proposed the following language for CIP-014-3 Applicability 4.1.1.3:

Transmission Facilities at a single station or substation location that are identified by the Planning Coordinator or Transmission Planner, per its Planning Assessment of the Near-Term Transmission Planning Horizon or its Transfer Capability Assessment (Planning Coordinator only) as Facilities that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation.

ERCOT proposes that "instability" be changed to "system instability."

ERCOT believes the use of the term "instability" is too broad and could be interpreted to include localized instability events that do not have a widespread impact. This suggestion is consistent with the concern noted in the NERC Methods for Establishing IROLs Task Force (MEITF) report at p. vii:

Specifically, the PRR acknowledged that the use of the word "instability" in the IROL definition is particularly problematic as this term can be interpreted to include any and every instance of instability that spans the entire spectrum of consequences and severity of impact—ranging from one extreme where instability results in the loss of a single small unit to the other extreme where instability results in widespread outage of a major portion of an RC area or beyond. The PRR contended that localized, contained instances of instability that affect a small amount of load have little to no impact on the reliability of the BES and do not warrant IROL establishment.

The MEITF report defines the term "system instability" as:

The inability of the Bulk Power System,* for a given initial operating condition, to regain a state of operating equilibrium after being subjected to a Disturbance.

*Refers to the remaining portion of the interconnected Bulk Power System, with the exception of the Elements disconnected as a result of the Disturbance.

ERCOT agrees that not all instances of instability warrant IROL establishment. For this reason, and to remain consistent with the MEITF report, ERCOT recommends that the proposed language for CIP-014-3 Applicability 4.1.1.3 be modified to include "system instability" rather than "instability."

ERCOT notes there are other instances in various Requirements where the use of "system instability" may be more appropriate than "instability."

FAC-003: None

NERC
NORTH AMERICAN ELECTRIC
RELIABILITY CORPORATION

FAC-013: None

FAC-015:

It appears there may be a copy/paste typo. ERCOT suggests using “steady-state voltage,” instead of “stability.”

PRC-002: None

PRC-023: None

PRC-026:

ERCOT is concerned that the phrase, “Elements associated with angular instability identified in Planning Assessments” in R2, Criteria No. 2 creates ambiguity and an unintended expansion in the scope of PRC-026.

ERCOT suggests deleting the current draft Criteria 1 & 2 and replacing them with the following in order to more closely align with the intent of both PRC-026 and Project 2015-09:

1. Generator(s) where an angular stability constraint exists that is addressed by limiting the output of the generator or by a Remedial Action Scheme (RAS), and those Elements terminating at the Transmission station associated with the generator(s). 2. Elements that are monitored in order to enforce an existing angular stability constraint.

CIP-014-3: Per the CIP-014 Guidance, ITC believes the CIP-014 Applicability 4.1.1.1 to 4.1.1.4 should mirror the CIP-002-5.1a Attachment 1 criterion 2.4-2.7. The proposed changes for CIP-014 Applicability 4.1.1.3 do match the proposed (Project 2016-02 Modifications to CIP Standards) changes for CIP-002-5.1a Attachment 1 criterion 2.6. However, ITC believes any discussion pertaining to CIP-014 Applicability is

better suited for "Project 2016-02 Modifications to CIP Standards. In addition, ITC remains concern that the originating changes from FAC Reliability standards diminish the need for a process to ensure the RC/PC/TO entities are including for evaluation facilities and assets to support the intent of the NERC CIP standards. " PRC-002-3: Changes made do not affect ITC's current PRC-002 process.

Comment
Regarding 4.1.1.3 in the Functional Entities section of CIP-014-3, Southern believes that the verbiage ***"would adversely affect reliability of the Bulk Electric System"*** should be added to the proposed wording to ensure that the changes are more in line with the current definition of an IROL (see below): **4.1.1.3** Transmission Facilities at a single station or substation location that are identified by the Planning Coordinator or Transmission Planner, per its Planning Assessment of the Near-Term Transmission Planning Horizon or its Transfer Capability Assessment (Planning Coordinator only) as Facilities that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation ***would adversely affect reliability of the Bulk Electric System***.

Regarding 4.2.2 in the Functional Entities section of FAC-003-5, Southern believes that the verbiage ***"would adversely affect reliability of the Bulk Electric System"*** should be added to the proposed wording to ensure that the changes are more in line with the current definition of an IROL.

4.2.2. Each overhead transmission line operated below 200kV, identified by the Planning Coordinator or Transmission Planner, per its Planning Assessment of the Near-Term Transmission Planning Horizon or its Transfer Capability Assessment (Planning Coordinator only) as a Facility that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation ***would adversely affect reliability of the Bulk Electric System.***

Regarding B2 in the Criteria section of PRC-023-5, Southern believes that the verbiage "***would adversely affect reliability of the Bulk Electric System"*** should be added to the proposed wording to ensure that the changes are more in line with the current definition of an IROL (see below):

B2. The circuit is selected by the Planning Coordinator based on Planning Assessments that identify instances of instability, Cascading, or uncontrolled separation that ***would adversely affect reliability of the Bulk Electric System***.

Regarding PRC-002-3, Southern does not believe that the Responsible Entity (under Functional Entities 4.1) should be changed.

Southern Company's main concern with the proposed changes is not the substitution of the IROL term with the three outcomes – instability, Cascading, or uncontrolled separation – our main concern is the prescriptive nature of naming Planning Coordinator studies which is beyond existing IROL methodologies, and the use of the unbounded term "instability". For example, compliance with present TPL-001-4 standard for Planning (P) events (and proposed TPL-001-5) requires that any future instability, Cascading, or uncontrolled separation circumstances to be identified and mitigated as per the Corrective Action Plan. While instability, Cascading, or uncontrolled separation do not have to be mitigated for Extreme Events in TPL-001-4/(future 5), as the name implies, Extreme Events are rare events.

Southern Company, like many other companies, has an IROL methodology that is largely based in RC and PC stability input. This methodology identifies SOLs and any subset of the identified SOLs that should be elevated to IROLs. As such, we suggest that references to

specific compliance-based studies such as TPL-001 and FAC-013 be removed and allow the use of in-place proven study methodologies to determine and communicate scenarios that are realistic potential instances of instability, Cascading, or uncontrolled separation. (reference CIP-014, FAC-003, PRC-023 and PRC-026).

CIP-014 & PRC-023: The team agrees and revised the language to include the phrase as listed in the definition of IROL, "instability, uncontrolled separation, or Cascading outages that adversely impact the reliability of the Bulk Electric System".

PRC-002: The SDT believes placing responsibility solely on the Reliability Coordinator adds clarity and consistency for the task of identifying the BES Elements for which Dynamic Disturbance Recording (DDR) is required. The RC and TOP are the entities that identifies and monitors SOLs/IROLs within real time operations. Furthermore the RC is responsible for leading any investigation into events that would use this data. The TP and PC may assist in these efforts or even effectively lead them, but the standards and processes assign the responsibility to the RC. We have addressed the time window for implementation in the PRC-002 implementation plan and updated the standard references in all the documents.

The team discussed extensively using language that allowed the Planning Coordinator and Transmission Planner to bring in other studies or assessments in addition to their Planning Assessment. However ultimately the team decided that the TPL Assessment was the best reference point. Using variations on the expression "studies, assessments" without the term Planning Assessment could allow a Planning Coordinator or Transmission Planer to not do any studies and thereby not pass any data. Referencing other studies in addition to the Planning Assessment would than raise questions on what other studies were the Planning Coordinator and Transmission Planner expected to perform. There is nothing that would preclude a Planning Coordinator or Transmission Planner from identifying something in studies or assessments through the year, and then including that study/assessment in their annual Planning Assessment – thereby passing the information on to the end user in the context of the standard.

CIP-014:

- The applicability section 4.1.1.3 in CIP-014-3 specifies that if instances of instability, Cascading or uncontrolled separation occurred due to the loss of a facility in the Near-term planning assessment, it would be applicable to the CIP-014 analysis.
- The term "instances of instability" is not clear and needs to be defined clearly to eliminate confusion of what qualifies a facility to be assessed in CIP-014.

FAC-003:

- Violation Severity Levels (Table 1) (pgs. 13-16)
- Since R2 was removed from the table on pg. 14, there is no documentation of the severity levels for lines above 200 kV that are not "identified by the Planning Coordinator, per its Planning Assessment of the Near-Term Transmission Planning Horizon or its Transfer Capability Assessment (Planning Coordinator only) as Facilities that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation"
- FAC-003 1.4 Additional Compliance Information (pg. 10)
    - There appears to be a typo regarding the footnote that is referenced:

▪ "Periodic Data Submittal: The applicable Transmission Owner and applicable Generator Owner will submit a quarterly report to its Regional Entity, or the Regional Entity's designee, identifying all Sustained Outages of applicable lines operated within their Rating and all Rated Electrical Operating Conditions as determined by the applicable Transmission Owner or applicable Generator Owner to have been caused by vegetation, except as excluded in footnote 2, and including as a minimum the following:" ▪ Should this be changed to "footnote 4"? This typo has been in FAC-003-3 & FAC-003-4 versions. ▪ This change will ensure we are not required to submit tree related outages that are "beyond our control".

The modifications to the standards are not consistent.

We note three key differences:

1. In PRC-002-2, the PC function is removed leaving the RC function, whereas in the other standards (e.g. CIP-014-3), the RC function is removed, leaving the PC function. We disagree with this change.

When PRC-002-2 was being developed, the Drafting Team was aware that different Functional Entities across the continent would be the appropriate parties to be responsible for the Standard's requirements. This was presented to industry in the Request for Comments posted November 1, 2013 through December 16, 2013. The Responsible Entity was defined in Section 4 of the Introduction in PRC-002-2 accordingly. Nothing in section R5 supposes that the SOL are planning SOL; the PC can obtain the relevant SOL for their determination per requirement R5 of FAC-014-3.

2. In the CIP-013 and FAC-003, the Near-Term Transmission Planning Horizon of the Planning Assessment is specified, whereas it is not specified in for the two PRC standards. The two PRC standards should use the same approach. In particular, issues in the long-term horizon of the Planning Assessment should not be relevant to the application of the PRC-023 and PRC-026 standards.

3. In PRC-023, the text "that identify instances of instability, Cascading, or uncontrolled separation" is different than the text "Facilities that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation" used in the other standards. The use of different text implies differences that are hard to interpret. We support that the same text should be used in these different standards.

Also, we point out a minor typo in PRC-026-2 : R1 – (…) Criteria: 1. Generator(s) where an angular stability constraint exists that is addressed by [a] limiting the output of a generator (…)

Response	
PRC-002: The SDT believes placing responsibility solely on the Reliability Coordinator adds clarity and consistency for the task of identifying the BES Elements for which Dynamic Disturbance Recording (DDR) is required. The RC and TOP are the entities that identifies and monitors SOLs/IROLs within real time operations. Furthermore the RC is responsible for leading any investigation into events that would use this data. The TP and PC may assist in these efforts or even effectively lead them, but the standards and processes assign the responsibility to the RC. We have addressed the time window for implementation in the PRC-002 implementation plan and updated the standard references in all the documents. PRC-023: The drafting team revised the language to be more consistent with the other standards and to be limited to planning events. The language allows the Planning Coordinator or Transmission Planner to select circuits that meet those criteria, but doesn't require the PC or TP to select every circuit that meets the criteria, since not every circuit that meets that criteria may be a good candidate for PRC-023. PRC-026: Thank you the typo was addressed.

Recommend adding the word "Facility" to the below applicability item from FAC-003-5. With the current wording, radial lines that are 200kV or higher are in-scope of FAC-003-5. This modificaiton allows the radial line exclusion to be utilized, but should not otherwise impact the scope of FAC-003. **4.2.1.** Each overhead transmission line **Facility** operated at 200kV or higher.

Response	
Thank you for the comment, the drafting team discussed making this change but ultimately did not since it was not within our scope and we didn't believe the addition of the word substantially changed the meaning of the requirement sub part.	
Anthony Jablonski - ReliabilityFirst - 10	
Answer	Yes

Comment	
ReliabilityFirst Votes in the Affirmative but provides the following comment for consideration. For PRC-026-2, R1. Criteria 1, ReliabilityFirst comment on the following proposed language: "Generator(s) where an angular stability constraint exists that is addressed by a limiting the output of a generator or a Remedial Action Scheme (RAS), and those Elements terminating at the Transmission station associated with the generator(s)." The "a" between "by" and "limiting" seems out of place and ReliabilityFirst recommends removal.

GTC agrees with the modifications to the standards impacted by the retirement of FAC-010. Further GTC notes the following: • The removal of the Planning Coordinator as an entity responsible for Requirement 5 in PRC-002 represents a material change to the Applicability section of the standard. GTC agrees with this change and the SDT's rationale that "placing responsibility solely on the Reliability Coordinator adds clarity and consistency for the task of identifying the BES Elements for which dynamic Disturbance recording (DDR) data is Required." • The proposed modification to FAC-013 is an improvement to this standard. • The streamlined language in the proposal for FAC-003 is a much needed improvement. • The other modifications represent an appropriate replacement for the planning SOL/IROLs.

- We believe the proposed language FAC-003, 4.2.2 should be revised for clarity. The proposed R 4.2.2 identifies a line to which the standard is applicable, "Each overhead transmission line operated below 200kV, identified by the Planning Coordinator or Transmission Planner, per its Planning Assessment of the Near-Term Transmission Planning Horizon or its Transfer Capability Assessment (Planning Coordinator only) as a Facility that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation."

Based on recent planning assessments and studies related to transfer capability, the PC would not ever add such facilities. If a loss of a single line (whether or not below 200kV) would result in cascading, that would result in the utility failing to comply with TPL-001. Since a PC would have to be compliant with TPL-001-4, the PC would ensure such a sub-200kV line would never be added to the system, resulting in a null set for such lines, rendering 4.2.2 meaningless.

- We also recommend adding the language: "that adversely impact the reliability of the Bulk Electric system" following references to "uncontrolled separation." This addition would bring the language in alignment with the Glossary of terms definition of IROL.

Likes 0

Response

Thank you for your comment. There may be a window of time between when the PC identified the facility and when a corrective action plan or other project was in place to address the issue where FAC-003 could be applied. We also expanded the language to include "adversely impact the reliability of the Bulk Electric System for planning events."

Preston Walker - PJM Interconnection, L.L.C. - 2 - SERC,RF

Answer	Yes
Document Name	

Comment

Clarifying language should be added to PRC-026 Requirement R1 Criteria 1 to indicate that the Reliability Coordinator will provide the information concerning angular stability constraints to the Planning Coordinator. This would be in alignment with the intent of revised FAC-014 R5.2 and its sub-requirements.

Likes 0

Response	
The Drafting team discussed this and did not believe it was necessary to prescribe that the Planning Coordinator receive those constraints from the Reliability Coordinator. The standard is written as the Planning Coordinator is responsible for either developing those limits or gathering those limits from the Reliability Coordinator and passing them on. Given that PRC-026 involves relay protection, which is a long term investment, it's appropriate that it be based on longer term problems that the Planning Coordinator studies.

Comment	
We agree with the changes as they are applied consistently throughout the standards. However, if the SDT changes the approach as stated in the previous comments, these areas will need to be revisited. In terms of FAC-003-5 and CIP-014-3, there may be an un-intended consequence of potentially pulling in facilities below 200 kV for compliance with both standards. The language is also not consistent in the FAC-003-5 applicability section, and the Sustained Outage categories beginning on page 10. Thank you for the opportunity to comment.

Thank you for your support and the comment on Page 10, the drafting team has addressed the inconsistency.	
Shannon Mickens - Southwest Power Pool, Inc. (RTO) - 2 - MRO, Group Name SPP Standards Review Group	
Answer	Yes

Document Name	
Comment	
The SPP Standards Review Group (SSRG) recommends that the drafting team consider IROLs in Phase 2 of this Project 2015-09. As discussed at the September 2018 Planning Committee (PC) Meeting, although this project includes IROLs, the drafting team's feedback to the PC was to focus on only the SOL for this commenting period (Phase I). During Phase II, the drafting team will put more focus on the IROL. This is a reasonable suggestion given that all relevant materials pertaining to the IROL were approved at that most recent meeting and couldn't be implemented in the Phase I comment period.	
Likes 0	
Dislikes 0	
Response	
Thank you for your comment, the drafting team agrees that IROL's are not within scope for this phase.	
Rachel Coyne - Texas Reliability Entity, Inc. - 10

Texas RE appreciates the SDT reviewing the standards to identify those impacted by the retirement of FAC-010. Regarding the Implementation Plan, under General Considerations, it states that for PRC-002-3, PRC-023-4, and PRC-005-3, the elements of the prior implementations plans shall remain applicable and are incorporated herein by reference. Texas RE's understanding is that although the effective date of the new proposed versions of these standards is "the first day of the first calendar quarter that is twelve calendar months after the effective date of the applicable governmental authority's order approving the standards", the prior versions of	

the implementation plans indicated in the general considerations section remains in place. If this is the case, it may be more clear to list out those exact dates that remain in place for the prior versions of the standards. Texas RE also recommends including a question about the implementation plan on each comment form going forward to encourage stakeholders to review the implementation plans.

ATC is not opposed to removing the Planning Coordinator in PRC-002 as an applicable functional entity and having the Reliability Coordinator as the only applicable regional functional entity. However, ATC proposes that the Time Horizon for all the Requirements be revised from "Long-term Planning" to "Operations Planning," to be consistent with the direct and indirect applicability of the Requirements to the Reliability Coordinator.	
Likes 0	
Dislikes 0	
Response	

Time Horizon: The drafting believes that these requirements are long term planning (1 year or greater) because when there is a violation there is a window of time to recover from the violation. The Time Horizon is the period of time to mitigate a violation, as such certainly some of the Reliability Coordinator functions are in the Operations Planning horizon, but data recording equipment issues are not a violation that has to be resolved within a day or even within the current season, nor can they be resolved that quickly depending on the lead time on the equipment. Because this equipment is for after the fact analysis, and not the real time prevention of an issue, the longer time horizon continues to be appropriate.

Oshani Pathirane - Oshani Pathirane On Behalf of: Paul Malozewski, Hydro One Networks, Inc., 1, 3; - Oshani Pathirane

Answer	
Document Name	

Comment

While Hydro One is in general agreement with the proposed retirements and modifications, we recommend the addition of "identified by the Transmission Planner" as follows to the phrase that is to replace occurrences of SOL/IROL:

"Facilities identified by the Transmission Planner that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation"

This change would clarify that it is the TPs that are expected to identify these facilities for the TOs and TOPs.

Thank you for the comment. The SDT revised the wording in all these standards and hopefully the revised wording address your concern.

Updated
Standards Announcement

Project 2015-09 Establish and Communicate System Operating Limits

Formal Comment Period Open through October 17, 2018

Now Available

A 45-day formal comment period has been extended through **8 p.m. Eastern, Wednesday, October 17, 2018** for the following standards, implementation plan and proposed definition:

- CIP-014-3 – Physical Security
- FAC-003-5 – Transmission Vegetation Management
- FAC-010-3 - System Operating Limits Methodology for the Planning Horizon (retirement)
- FAC-011-4 - System Operating Limits Methodology for the Operations Horizon
- FAC-013-3 – Assessment of Transfer Capability for the Near-term Transmission Planning Horizon
- FAC-014-3 – Establish and Communicate System Operating Limit
- FAC-015-1 - Coordination of Planning Assessments with the Reliability Coordinator's SOL Methodology (Updated)
- PRC-002-3 – Disturbance Monitoring and Reporting Requirements
- PRC-023-5 – Transmission Relay Loadability
- PRC-026-2 – Relay Performance During Stable Power Swings
- Implementation Plan
- Proposed Definition - System Operating Limit

The following have been reposted due to identified typographical errors. The comment period has been extended to provide stakeholders adequate time to review the updated documents:

- FAC-015-1 - Coordination of Planning Assessments with the Reliability Coordinator's SOL Methodology
- FAC-015-1 - Requirement Rationale

The standard drafting team's considerations of the responses received from the last comment period are reflected in these drafts of the standards.

Commenting

Use the electronic form to submit comments on the proposed revisions to the FM and FMTD. If you experience any difficulties in using the electronic form, contact Linda Jenkins. An unofficial Word version of the comment form is posted on the project page.

Join the Ballot Pools

Ballot pools are being formed through **8 p.m. Eastern, Monday, September 24, 2018.** Registered Ballot Body members can join the ballot pools here.

If you are having difficulty accessing the SBS due to a forgotten password, incorrect credential error messages, or system lock-out, contact NERC IT support directly at https://support.nerc.net/ (Monday – Friday, 8 a.m. - 8 p.m. Eastern).

- *Passwords expire every* ***6 months*** *and must be reset.*
- *The SBS* ***is not*** *supported for use on mobile devices.*
- *Please be mindful of ballot and comment period closing dates. We ask to* ***allow at least 48 hours*** *for NERC support staff to assist with inquiries. Therefore, it is recommended that users try logging into their SBS accounts* ***prior to the last day*** *of a comment/ballot period.*

Next Steps

Initial and additional ballots for the standards and non-binding polls of the associated Violation Risk Factors and Violation Severity Levels will be conducted August 24 – October 17, 2018.

For information on the Standards Development Process, refer to the Standard Processes Manual**.**

For more information or assistance, contact Principal Technical Advisor, Darrel Richardson (via email), or at (609) 613-1848.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	08/19/15
SAR posted for comment	08/20/15 – 09/21/15
Draft Reliability Standard posted for Informal Comment Period	07/14/16 – 08/12/16
45-day formal comment period with initial ballot	09/29/17 – 11/14/17
45-day formal comment period with additional ballot	08/27/18 – 10/17/18

Anticipated Actions	Date
45-day formal comment period with additional ballot	June 2020
10-day final ballot	August 2020
NERC Board adoption	November 2020

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s):
None.

A. Introduction

1. **Title:** System Operating Limits Methodology for the Operations Horizon
2. **Number:** FAC-011-4
3. **Purpose:** To ensure that System Operating Limits (SOLs) used in the reliable operation of the Bulk Electric System (BES) are determined based on an established methodology or methodologies.
4. **Applicability:**

   4.1. Functional Entities:

   4.1.1. Reliability Coordinator
5. **Effective Date:** See Implementation Plan for Project 2015-09.

B. Requirements and Measures

R1. Each Reliability Coordinator shall have a documented methodology for establishing SOLs (i.e., SOL methodology) within its Reliability Coordinator Area. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

M1. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation of its SOL methodology.

R2. Each Reliability Coordinator shall include in its SOL methodology the method for Transmission Operators to determine which owner-provided Facility Ratings are to be used in operations such that the Transmission Operator and its Reliability Coordinator use common Facility Ratings. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

M2. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation of its SOL methodology that addresses the items listed in Requirement R2.

R3. Each Reliability Coordinator shall include in its SOL methodology the method for Transmission Operators to determine the System Voltage Limits to be used in operations. The method shall: *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

3.1. Require that each BES bus/station have an associated System Voltage Limits, unless its SOL methodology specifically allows the exclusion of BES buses/stations from the requirement to have an associated System Voltage Limit;

3.2. Require that System Voltage Limits respect voltage-based Facility Ratings;

3.3. Require that System Voltage Limits are greater than or equal to in-service BES relay settings for undervoltage load shedding systems and Undervoltage Load Shedding Programs;

3.4. Identify the lowest allowable System Voltage Limit;

3.5. Define the method for determining common System Voltage Limits between the Reliability Coordinator and its Transmission Operators, between adjacent Transmission Operators, and between adjacent Reliability Coordinators within an Interconnection.

M3. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation of its SOL methodology that addresses the items listed in Requirement R3.

R4. Each Reliability Coordinator shall include in its SOL methodology the method for determining the stability limits to be used in operations. The method shall: *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

4.1. Specify stability performance criteria, including any margins applied. The criteria shall, at a minimum, include the following:

4.1.1. steady-state voltage stability;

4.1.2. transient voltage response;

4.1.3. angular stability; and

4.1.4. System damping.

4.2. Require that stability limits are established to meet the criteria specified in Part 4.1 for the Contingencies identified in Requirement R5 applicable to the establishment of stability limits that are expected to produce more severe System impacts on its portion of the BES.

4.3. Describe how the Reliability Coordinator establishes stability limits when there is an impact to more than one Transmission Operator in its Reliability Coordinator Area or other Reliability Coordinator Areas.

4.4. Describe how stability limits are determined, considering levels of transfers, Load and generation dispatch, and System conditions including any changes to System topology such as Facility outages.

4.5. Describe the level of detail that is required for the study model(s), including the portion modeled of the Reliability Coordinator Area, and the critical modeling details from other Reliability Coordinator Areas, necessary to determine different types of stability limits.

4.6. Describe the allowed uses of Remedial Action Schemes and other automatic post-Contingency mitigation actions in establishing stability limits used in operations.

4.7. State that the use of underfrequency load shedding (UFLS) programs and Undervoltage Load Shedding Programs are not allowed in the establishment of stability limits.

M4. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation of its SOL methodology that addresses the items listed in Requirement R4.

R5. Each Reliability Coordinator shall identify in its SOL methodology the set of Contingency events for use in determining stability limits and the set of Contingency events for use in performing Operational Planning Analysis (OPAs) and Real-time Assessments (RTAs). The SOL methodology for each set shall: *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

5.1. Specify the following single Contingency events:

5.1.1. Loss of any of the following either by single phase to ground or three phase Fault (whichever is more severe) with Normal Clearing, or without a Fault:

- generator;
- transmission circuit;
- transformer;
- shunt device; or
- single pole block in a monopolar or bipolar high voltage direct current system.

5.2. Specify additional single or multiple Contingency events or types of Contingency events, if any.

5.3. Describe the method(s) for identifying which, if any, of the Contingency events provided by the Planning Coordinator or Transmission Planner in accordance with FAC-014-3, Requirement R7, to use in determining stability limits.

M5. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation of its SOL methodology that addresses the items listed in Requirement R5.

R6. Each Reliability Coordinator shall include the following performance framework in its SOL methodology to determine SOL exceedances when performing Real-time monitoring, Real-time Assessments, and Operational Planning Analyses: *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

6.1. System performance for no Contingencies demonstrates the following:

6.1.1. Steady state flow through Facilities are within Normal Ratings; however, Emergency Ratings may be used when System adjustments to return the flow within its Normal Rating could be executed and completed within the specified time duration of those Emergency Ratings.

6.1.2. Steady state voltages are within normal System Voltage Limits; however, emergency System Voltage Limits may be used when System adjustments to return the voltage within its normal System Voltage Limits could be executed and completed within the specified time duration of those emergency System Voltage Limits.

6.1.3. Predetermined stability limits are not exceeded.

6.1.4. Instability, Cascading or uncontrolled separation that adversely impact the reliability of the Bulk Electric System does not occur.[1]

6.2. System performance for the single Contingencies listed in Part 5.1 demonstrates the following:

6.2.1. Steady State post-Contingency flow through Facilities within applicable Emergency Ratings. Steady state post-Contingency flow through a Facility must not be above the Facility's highest Emergency Rating.

6.2.2. Steady state post-Contingency voltages are within emergency System Voltage Limits.

6.2.3. The stability performance criteria defined in the Reliability Coordinator's SOL methodology are met[1].

6.2.4. Instability, Cascading or uncontrolled separation that adversely impact the reliability of the Bulk Electric System does not occur[1].

6.3. System performance for applicable Contingencies identified in Part 5.2 demonstrates that: instability, Cascading, or uncontrolled separation that adversely impact the reliability of the Bulk Electric System does not occur.

6.4. In determining the System's response to any Contingency identified in Requirement R5, planned manual load shedding is acceptable only after all other available System adjustments have been made.

M6. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation of its SOL methodology that addresses the items listed in Requirement R6.

R7. Each Reliability Coordinator shall include in its SOL methodology a risk-based approach for determining how SOL exceedances identified as part of Real-time monitoring and Real-time Assessments must be communicated and if so, the timeframe that communications must occur. The approach shall include: *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

7.1. A requirement that the following SOL exceedances will always be communicated, within a timeframe identified by the Reliability Coordinator.

7.1.1. IROL exceedances;

7.1.2. SOL exceedances of stability limits;

---

[1] Stability evaluations and assessments of instability, Cascading, and uncontrolled separation can be performed using real-time stability assessments, predetermined stability limits or other offline analysis techniques.

7.1.3. Post-contingency SOL exceedances that are identified to have a validated risk of instability, Cascading Outages, and uncontrolled separation;

7.1.4. Pre-contingency SOL exceedances of Facility Ratings; and

7.1.5. Pre-contingency SOL exceedances of normal low System Voltage Limits.

7.2. A requirement that the following SOL exceedances must be communicated, if not resolved within 30 minutes, within a timeframe identified by the Reliability Coordinator.

7.2.1. Post-contingency SOL exceedances of Facility Ratings and emergency System Voltage limits, and

7.2.2. Pre-contingency SOL exceedances of normal high System Voltage Limits.

M7. Acceptable evidence may include, but is not limited to dated electronic or hard copy documentation of its SOL methodology that addresses the items listed in Requirement R7.

R8. Each Reliability Coordinator shall include in its SOL methodology: *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

8.1. A description of how to identify the subset of SOLs that qualify as Interconnection Reliability Operating Limits (IROLs).

8.2. Criteria for determining when exceeding a SOL qualifies as exceeding an IROL and criteria for developing any associated IROL T_v.

M8. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation of its SOL methodology that addresses the items listed in Requirement R8.

R9. Each Reliability Coordinator shall provide its SOL methodology to: *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*

9.1. Each Reliability Coordinator that requests and indicates it has a reliability-related need within 30 days of a request.

9.2. Each of the following entities prior to the effective date of the SOL methodology:

9.2.1. Each adjacent Reliability Coordinator within the same; Interconnection;

9.2.2. Each Planning Coordinator and Transmission Planner that is responsible for planning any portion of the Reliability Coordinator Area;

9.2.3. Each Transmission Operator within its Reliability Coordinator Area; and

9.2.4. Each Reliability Coordinator that has requested to receive updates and indicated it had a reliability-related need.

M9. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation such as emails with receipts, registered mail receipts, or postings to a secure web site with accompanying notification(s).

C. Compliance

1. **Compliance Monitoring Process**

   1.1. Compliance Enforcement Authority:
   "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

   1.2. Evidence Retention:
   The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

   The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

   - The Reliability Coordinator shall keep data or evidence of compliance with Requirements R1 through R9 for the current year plus the previous 12 calendar months.

   1.3. Compliance Monitoring and Enforcement Program:
   As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

Violation Severity Levels

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s):
None.

A. Introduction

1. **Title:** System Operating Limits Methodology for the Operations Horizon
2. **Number:** FAC-011-4
3. **Purpose:** To ensure that System Operating Limits (SOLs) used in the reliable operation of the Bulk Electric System (BES) are determined based on an established methodology or methodologies.
4. **Applicability:**
   - **4.1. Functional Entities:**
     - **4.1.1.** Reliability Coordinator
5. **Effective Date:** See Implementation Plan for Project 2015-09.

B. Requirements and Measures

R1. Each Reliability Coordinator shall have a documented methodology for establishing SOLs (i.e., SOL ~~M~~methodology) within its Reliability Coordinator Area. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

M1. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation of its SOL ~~M~~methodology.

R2. Each Reliability Coordinator shall include in its SOL ~~M~~methodology the method for Transmission Operators to determine which owner-provided Facility Ratings are to be used in operations such that the Transmission Operator and its Reliability Coordinator use common Facility Ratings. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

M2. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation of its SOL ~~M~~methodology that addresses the items listed in Requirement R2.

R3. Each Reliability Coordinator shall include in its SOL ~~M~~methodology the method for Transmission Operators to determine the System Voltage Limits to be used in operations. The method shall: *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

3.1. Require that each BES bus/station have an associated System Voltage Limits, unless ~~the Reliability Coordinators~~its SOL ~~M~~methodology specifically allows the exclusion of BES buses/stations from the requirement to have an associated System Voltage Limit;

3.2. Require that System Voltage Limits respect voltage-based Facility Ratings;

3.3. Require that System Voltage Limits are greater than or equal to in-service BES relay settings for undervoltage load shedding systems and Undervoltage Load Shedding Programs;

3.4. Identify the lowest allowable System Voltage Limit;

3.5. ~~Require the use of common System Voltage Limits between the Transmission Operator and its Reliability Coordinator and provide~~ Define the method for determining ~~the~~ common System Voltage Limits between the Reliability Coordinator and its Transmission Operators, between adjacent Transmission Operators, and between adjacent Reliability Coordinators within an Interconnection. ~~to be used in operations;~~

~~**3.0.** Address coordination of System Voltage Limits between adjacent Transmission Operators in its Reliability Coordinator Area; and~~

~~**4.0.** Address coordination of System Voltage Limits between adjacent Reliability Coordinator Areas within an Interconnection.~~

~~**M5.**~~**M3.** Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation of its SOL ~~M~~methodology that addresses the items listed in Requirement R3.

R4. Each Reliability Coordinator shall include in its SOL ~~M~~methodology the method for determining the stability limits to be used in operations. The method shall: *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

4.1. Specify stability performance criteria, including any margins applied. The criteria shall, at a minimum, include the following:

4.1.1. steady-state voltage stability;

4.1.2. transient voltage response;

4.1.3. ~~unit~~ angular stability; and

4.1.4. System damping.

4.2. Require that stability limits are established to meet the criteria specified in Part 4.1 for the Contingencies identified in Requirement R5 applicable to the establishment of stability limits that are expected to produce more severe System impacts on its portion of the BES.

4.3. Describe how the Reliability Coordinator establishes stability limits when there is an impact to more than one Transmission Operator in its Reliability Coordinator Area or other Reliability Coordinator ~~.~~Areas.

4.4. Describe how stability limits are determined, considering levels of transfers, Load and generation dispatch, and System conditions including any changes to System topology such as Facility outages.

4.5. Describe the level of detail that is required for the study model(s), including the portion ~~extent~~modeled of the Reliability Coordinator Area, ~~as well as~~ and the critical modeling details from other Reliability Coordinator Areas, necessary to determine different types of stability limits.

4.6. Describe the allowed uses of Remedial Action Schemes and other automatic post-Contingency mitigation actions in establishing stability limits used in operations.

4.7. State that the use of underfrequency load shedding (UFLS) programs and Undervoltage Load Shedding Programs are not allowed in the establishment of stability limits.

~~M6.~~M4. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation of its SOL ~~M~~methodology that addresses the items listed in Requirement R4.

R5. Each Reliability Coordinator shall identify in its SOL ~~M~~methodology the set of Contingency events for use in determining stability limits and the set of Contingency events for use in performing Operational Planning Analysis (OPAs) and Real-time Assessments (RTAs)~~ for the area under study~~. The SOL ~~M~~methodology for each set shall: *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

5.1. Specify the following single Contingency events~~ for use in determining stability limits and performing OPAs and RTAs~~:

5.1.1. Loss of any of the following either by single phase to ground or three phase Fault (whichever is more severe) with Normal Clearing, or without a Fault:

- generator;
- transmission circuit;
- transformer;
- shunt device; or
- single pole block~~, with Normal Clearing,~~ in a monopolar or bipolar high voltage direct current system.

5.2. ~~Identify any~~Specify additional single or multiple Contingency events or types of Contingency events, if any~~ for use in performing Operational Planning Analysis and Real-time Assessments~~.

~~**5.3.** Identify any additional single or multiple Contingency events or types of Contingency events for use in determining stability limits.~~

~~5.4.~~5.3. Describe the method(s) for identifying which, if any, of the Contingency events provided by the Planning Coordinator or Transmission Planner in accordance with FAC-01~~5~~4-~~1~~3, Requirement R~~48~~7, to use in determining stability limits.

~~M7.~~M5. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation of its SOL ~~M~~methodology that addresses the items listed in Requirement R5.

R6. Each Reliability Coordinator shall include the following performance framework in its SOL ~~M~~methodology to determine SOL exceedances when performing Real-time monitoring, Real-time Assessments, and Operational Planning Analyses~~, at a minimum, the following Bulk Electric System performance criteria~~: *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

6.1. ~~The actual pre-~~System performance for no Contingenc~~y~~ies ~~state (Real-time monitoring and Real-time Assessment) and anticipated pre-Contingency state (Operational Planning Analysis)~~ demonstrates the following:

6.1.1. Steady state ~~F~~flow through Facilities are within Normal Ratings; however, Emergency Ratings may be used when System adjustments to return the flow within its Normal Rating could be executed and completed within the specified time duration of those Emergency Ratings.

6.1.2. Steady state ~~V~~voltages are within normal System Voltage Limits; however, emergency System Voltage Limits may be used when System adjustments to return the voltage within its normal System Voltage Limits could be executed and completed within the specified time duration of those emergency System Voltage Limits.

6.1.3. Predetermined stability limits are not exceeded-.~~Instability, Cascading or uncontrolled separation do not occur.~~

~~**6.1.3.**~~**6.1.4.** Instability, Cascading or uncontrolled separation that adversely impact the reliability of the Bulk Electric~~e~~ System does not occur.[1]

6.2. ~~The evaluation of potential~~System performance for the single Contingencies listed in Part 5.1.~~1 against the actual pre-Contingency state (Real-time monitoring and Real-time Assessments) and anticipated pre-Contingency state (Operational Planning Analysis)~~ demonstrates the following:

6.2.1. Steady State post-Contingency ~~F~~flow through Facilities ~~are~~ within applicable Emergency Ratings.~~, provided that System adjustments could be executed and completed within the specified time duration of those Emergency Ratings.~~ Steady state post-Contingency ~~F~~flow through a Facility must not be above the Facility's highest Emergency Rating.

6.2.2. Steady state post-Contingency ~~V~~voltages are within emergency System Voltage Limits.

6.2.3. The stability performance criteria~~e~~ defined in the Reliability Coordinator's SOL methodology are met[1]. ~~Instability, Cascading or uncontrolled separation do not occur.~~

Formatte

[1] Stability evaluations and assessments of instability, Cascading, and uncontrolled separation can be performed using real-time stability assessments, predetermined stability limits or other offline analysis techniques.

~~6.2.3.~~6.2.4. Instability, Cascading or uncontrolled separation that adversely impact the reliability of the Bulk Electrice System does not occur[1].

6.3. ~~The evaluation of~~ System performance for applicable ~~the potential~~ Contingencies identified in Part 5.2 ~~against the actual pre-Contingency state (Real-time monitoring and Real-time Assessments) and anticipated pre-Contingency state (Operational Planning Analysis)~~ demonstrates that: instability, Cascading, or uncontrolled separation that adversely impact the reliability of the Bulk Electric System- does not occur.

~~6.4. The evaluation of the potential Contingencies identified in Part 5.3 demonstrates that instability does not occur.~~

~~6.5.~~6.4. In determining the System's response to any Contingency identified in ~~Parts 5.1 through 5.3~~Requirement R5, planned manual load shedding is acceptable only after all other available System adjustments have been made.

~~M8.~~M6. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation of its SOL ~~M~~methodology that addresses the items listed in Requirement R6.

R7. Each Reliability Coordinator shall include in its SOL methodology a risk-based approach for determining how SOL exceedances identified as part of Real-time monitoring and Real-time Assessments must be communicated and if so, the timeframe that communications must occur. The approach shall include: *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

7.1. A requirement that the following SOL exceedances will always be communicated, within a timeframe identified by the Reliability Coordinator.

7.1.1. IROL exceedances;

7.1.2. SOL exceedances of stability limits;

7.1.3. Post-contingency SOL exceedances that are identified to have a validated risk of instability, Cascading Outages, and uncontrolled separation;

7.1.4. Pre-contingency SOL exceedances of Facility Ratings; and

7.1.5. Pre-contingency SOL exceedances of normal low System Voltage Limits.

7.2. A requirement that the following SOL exceedances must be communicated, if not resolved within 30 minutes, within a timeframe identified by the Reliability Coordinator.

7.2.1. Post-contingency SOL exceedances of Facility Ratings and emergency System Voltage limits, and

7.2.2. Pre-contingency SOL exceedances of normal high System Voltage Limits.

M7. Acceptable evidence may include, but is not limited to dated electronic or hard copy documentation of its SOL ~~M~~methodology that addresses the items listed in Requirement R7.

~~R7.~~R8. Each Reliability Coordinator shall include in its SOL ~~M~~methodology: *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

~~7.1.~~8.1. A description of how to identify the subset of SOLs that qualify as Interconnection Reliability Operating Limits (IROLs).

~~7.2.~~8.2. Criteria for determining when ~~violating~~ exceeding a SOL qualifies as exceeding an IROL and criteria for developing any associated IROL T_v.

~~M10.~~M8. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation of its SOL ~~M~~methodology that addresses the items listed in Requirement ~~R6~~R8.

~~**R8.** Each Reliability Coordinator shall include in its SOL Methodology the method for Transmission Operators to communicate their established SOLs to the Reliability Coordinator. The method shall address the periodicity for communicating established SOLs. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*~~

~~**M10.** Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation of its SOL Methodology that addresses the items listed in Requirement R7.~~

~~R10.~~R9. Each Reliability Coordinator shall provide its SOL ~~M~~methodology to: *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*

~~10.1.~~9.1. Each Reliability Coordinator that requests and indicates it has a reliability-related need within 30 days of a request.

~~10.2.~~9.2. Each of the following entities prior to the effective date of the SOL ~~m~~Mmethodology:

~~10.2.1.~~9.2.1. Each adjacent Reliability Coordinator within the same; Interconnection;

~~10.2.2.~~9.2.2. Each Planning Coordinator and Transmission Planner that is responsible for planning any portion of the Reliability Coordinator Area;

~~10.2.3.~~9.2.3. Each Transmission Operator within its Reliability Coordinator Area; and

~~10.2.4.~~9.2.4. Each Reliability Coordinator that has requested to receive updates and indicated it had a reliability-related need.

~~M11.~~M9. Acceptable evidence ~~that the Reliability Coordinator provided its SOL Methodology to the entities identified in Requirement R8~~ may include, but is not limited to, dated electronic or hard copy documentation such as emails with receipts, registered mail receipts, or postings to a secure web site with accompanying notification(s).

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority:

"Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention:

The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

- The Reliability Coordinator shall keep data or evidence of compliance with Requirements R1 through R9 for the current year plus the previous 12 calendar months.

1.3. Compliance Monitoring and Enforcement Program:

As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

10-day final ballot	August 2020
NERC Board adoption	November 2020

A. Introduction

1. **Title:** Establish and Communicate System Operating Limits

2. **Number:** FAC-014-3

3. **Purpose:** To ensure that System Operating Limits (SOLs) used in the reliable operation of the Bulk Electric System (BES) are determined based on an established methodology or methodologies and that Planning Assessment performance criteria is coordinated with these methodologies.

4. **Applicability:**

   4.1. Functional Entities:

   4.1.1. Planning Coordinator

   4.1.2. Reliability Coordinator

   4.1.3. Transmission Operator

   4.1.4. Transmission Planner

5. **Effective Date:** See Implementation Plan for Project 2015-09.

B. Requirements and Measures

R1. Each Reliability Coordinator shall establish Interconnection Reliability Operating Limits (IROLs) for its Reliability Coordinator Area in accordance with its System Operating Limit methodology (SOL methodology). *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

M1. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation that demonstrates the Reliability Coordinator established IROLs in accordance with it SOL methodology.

R2. Each Transmission Operator shall establish System Operating Limits (SOLs) for its portion of the Reliability Coordinator Area in accordance with its Reliability Coordinator's SOL methodology. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

M2. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation that demonstrates the Transmission Operator established SOLs in accordance with its Reliability Coordinator's SOL methodology.

R3. Each Transmission Operator shall provide its SOLs to its Reliability Coordinator. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning, Same-day Operations, Real-Time Operations]*

M3. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation that demonstrates the Transmission Operator provided its SOLs in accordance with its Reliability Coordinator's SOL methodology.

R4. Each Reliability Coordinator shall establish stability limits when the limit impacts adjacent Reliability Coordinator Areas or more than one Transmission Operator in its Reliability Coordinator Area in accordance with its SOL methodology. *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

M4. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation that demonstrates the Reliability Coordinator established stability limits in accordance with Requirement R4.

R5. Each Reliability Coordinator shall provide: [*Violation Risk Factor: High] [Time Horizon: Operations Planning, Same-day Operations, Real-Time Operations]*

5.1 Each Planning Coordinator and each Transmission Planner within its Reliability Coordinator Area, the SOLs for its Reliability Coordinator Area (including the subset of SOLs that are IROLs) at least once every twelve calendar months.

5.2 Each impacted Planning Coordinator and each impacted Transmission Planner within its Reliability Coordinator Area, the following information for each established stability limit and each established IROL at least once every twelve calendar months:

5.2.1 The value of the stability limit or IROL;

5.2.2 Identification of the Facilities that are critical to the stability limit or IROL;

5.2.3 The associated IROL T_v for any IROL;

5.2.4 The associated Contingency(ies);

5.2.5 A description of system conditions associated with the stability limit or IROL; and

5.2.6 The type of limitation represented by the stability limit or IROL (*e.g.*, voltage collapse, angular stability).

5.3 Each impacted Transmission Operator within its Reliability Coordinator Area, the value of the stability limits established pursuant to Requirement R4 and each IROL established pursuant to Requirement R1, in an agreed upon time frame necessary for inclusion in the Transmission Operator's Operational Planning Analyses, Real-time monitoring, and Real-time Assessments.

5.4 Each impacted Transmission Operator within its Reliability Coordinator Area, the information identified in Requirement R5 Parts 5.2.2 – 5.2.6 for each established stability limit or each IROL, and any updates to that information within an agreed upon time frame necessary for inclusion in the Transmission Operator's Operational Planning Analyses.

5.5 Each requesting Transmission Operator within its Reliability Coordinator Area, requested SOL information for its Reliability Coordinator Area, on a mutually agreed upon schedule.

M5. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation, posting to a secure website, or other electronic means, that demonstrates the Reliability Coordinator provided the information in accordance with Requirement R5.

R6. Each Planning Coordinator and each Transmission Planner shall implement a documented process to use Facility Ratings, System steady-state voltage limits and stability criteria in its Planning Assessment of Near Term Transmission Planning Horizon that are equally limiting or more limiting than the criteria for Facility Ratings, System Voltage Limits and stability described in its respective Reliability Coordinator's SOL methodology. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

- The Planning Coordinator may use less limiting Facility Ratings, System steady-state voltage limits and stability criteria if it provides a technical rationale to each affected Transmission Planner, Transmission Operator and Reliability Coordinator.
- The Transmission Planner may use less limiting Facility Ratings, System steady-state voltage limits and stability criteria if it provides a technical rationale to each affected Planning Coordinator, Transmission Operator and Reliability Coordinator.

M6. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation demonstrating the Planning Coordinator and Transmission Planner implemented its documented process in accordance with Requirement R6.

R7. Each Planning Coordinator and each Transmission Planner shall annually communicate the following information for Corrective Action Plans developed to address any instability identified in its Planning Assessment of the Near-Term Transmission Planning Horizon to each impacted Transmission Operator and Reliability Coordinator. This communication shall include: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

7.1 The Corrective Action Plan developed to mitigate the identified instability, including any automatic control or operator-assisted actions (such as Remedial Action Schemes, under voltage load shedding, or any Operating Procedures);

7.2 The type of instability addressed by the Corrective Action Plan (e.g. steady-state and/or transient voltage instability, angular instability including generating unit loss of synchronism and/or unacceptable damping);

7.3 The associated stability criteria violation requiring the Corrective Action Plan (e.g. violation of transient voltage response criteria or damping rate criteria);

7.4 The planning event Contingency(ies) associated with the identified instability requiring the Corrective Action Plan;

7.5 The System conditions and Facilities associated with the identified instability requiring the Corrective Action Plan.

M7. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation demonstrating the Planning Coordinator and Transmission Planner communicated the information in accordance with Requirement R7.

R8. Each Planning Coordinator and each Transmission Planner shall annually communicate any instability, Cascading or uncontrolled separation that adversely impact the reliability of the Bulk Electric System identified in its Planning Assessment of the Near-Term Transmission Planning Horizon to each impacted Transmission Owner and Generation Owner. This communication shall include those Facilities that comprise the Contingency(ies) (planning events only) and any Facilities critical to the instability, Cascading or uncontrolled separation identified. *[Violation Risk Factor: Medium] [Time Horizon: Long- term Planning]*

M8. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation demonstrating the Planning Coordinator and Transmission Planner communicated the information in accordance with Requirement R8.

C. Compliance

1. **Compliance Monitoring Process**

   1.1. **Compliance Enforcement Authority:**
   "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

   1.2. **Evidence Retention:**
   The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

   The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

   - The Reliability Coordinator, Transmission Operator, Transmission Planner, Planning Coordinator shall keep data or evidence of Requirements R1 through R8 for the current year plus the previous 12 calendar months.

   1.3. **Compliance Monitoring and Enforcement Program**
   As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1.	N/A	N/A	N/A	The Reliability Coordinator failed to establish Interconnection Reliability Operating Limits (IROLs) for its Reliability Coordinator Area in accordance with its System Operating Limit Methodology ("SOL methodology") as established in FAC-011-4.
R2.	N/A	N/A	N/A	The Transmission Operator failed to establish SOLs for its portion of the Reliability Coordinator Area in accordance with its Reliability Coordinator's SOL methodology.
R3.	N/A	N/A	The Transmission Operator provided its SOLs to its Reliability Coordinator, but failed to provide its SOLs at the periodicity at which the Reliability Coordinator needs	The Transmission Operator failed to provide its SOLs to its Reliability Coordinator.

			such information to perform its reliability functions.	
R4.	N/A	N/A	N/A	The Reliability Coordinator failed to establish stability limits to be used in operations when the limit impacts an adjacent Reliability Coordinator or more than one Transmission Operator in its Reliability Coordinator Area in accordance with its SOL methodology.
R5.	The Reliability Coordinator failed to provide one of the items listed in Requirement R5, Parts 5.1 through 5.5.	The Reliability Coordinator failed to provide two of the items listed in Requirement R5, Parts 5.1 through 5.5.	The Reliability Coordinator failed to provide three of the items listed in Requirement R5, Parts 5.1 through 5.5.	The Reliability Coordinator failed to provide four or more of the items listed in Requirement R5, Parts 5.1 through 5.5.
R6.	N/A	N/A	The Planning Coordinator or a Transmission Planner used less limiting Facility Ratings, System steady state voltage limits or stability criteria than the criteria for Facility Ratings, System Voltage Limits or stability described in its respective Reliability Coordinator's SOL methodology, but failed to	The Planning Coordinator or a Transmission Planner failed to implement a process to ensure that Facility Ratings, System steady state voltage limits or stability criteria used in Planning Assessment are equally limiting or more limiting than the criteria for Facility Ratings, System Voltage Limits or stability

			provide a technical rationale for allowing the use of less limiting Facility Ratings, System Voltage Limits or stability criteria	described in its respective Reliability Coordinator's SOL methodology.
R7.	The Planning Coordinator or a Transmission Planner communicated the identified instability to each impacted Reliability Coordinator and Transmission Operator, but the communication did not contain one of the elements listed in Requirement R7, Parts 7.1 through 7.5.	The Planning Coordinator or a Transmission Planner communicated the identified instability to each impacted Reliability Coordinator and Transmission Operator, but the communication did not contain two of the elements listed in Requirement R7, Parts 7.1 through 7.5.	The Planning Coordinator or a Transmission Planner communicated the identified instability to each impacted Reliability Coordinator and Transmission Operator, but the communication did not contain three elements listed in Requirement R7, Parts 7.1 through 7.5.	The Planning Coordinator or a Transmission Planner communicated the identified instability to each impacted Reliability Coordinator and Transmission Operator, but the communication did not contain four or more of the elements listed in Requirement R7, Parts 7.1 through 7.5. OR The Planning Coordinator or a Transmission Planner failed to communicate any identified instability, to each impacted Reliability Coordinator and Transmission Operator.
R8.			The Planning Coordinator or a Transmission Planner provided the instability, Cascading or uncontrolled separation information listed	The Planning Coordinator or a Transmission Planner failed to provide the instability, Cascading or uncontrolled separation information listed

			in Requirement R8 to the applicable Transmission Owner, and Generation Owner, but failed to provide them annually.	in Requirement R8 to the applicable Transmission Owner, and Generation Owner.

A. Introduction

1. **Title:** Establish and Communicate System Operating Limits
2. **Number:** FAC-014-3
3. **Purpose:** To ensure that System Operating Limits (SOLs) used in the reliable operation of the Bulk Electric System (BES) are determined based on an established methodology or methodologies and that Planning Assessment performance criteria is coordinated with these methodologies.
4. **Applicability:**

   4.1. Functional Entities:

   4.1.1. Planning Coordinator

   ~~**4.1.1.**~~**4.1.2.** Reliability Coordinator

   4.1.3. Transmission Operator

   ~~**4.1.2.**~~**4.1.4.** Transmission Planner

5. **Effective Date:** See Implementation Plan for Project 2015-09.

B. Requirements and Measures

R1. Each Reliability Coordinator shall establish Interconnection Reliability Operating Limits (IROLs) for its Reliability Coordinator Area in accordance with its System Operating Limit ~~M~~methodology (SOL ~~M~~methodology). *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

M1. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation that demonstrates the Reliability Coordinator established IROLs in accordance with it SOL ~~M~~methodology.

R2. Each Transmission Operator shall establish System Operating Limits (SOLs) for its portion of the Reliability Coordinator Area in accordance with its Reliability Coordinator's SOL ~~M~~methodology. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

M2. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation that demonstrates the Transmission Operator established SOLs in accordance with its Reliability Coordinator's SOL ~~M~~methodology.

R3. ~~The~~ Each Transmission Operator shall provide its SOLs to its Reliability Coordinator ~~in accordance with its Reliability Coordinator's SOL Methodology~~. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning, Same-day Operations, Real-Time Operations]*

M3. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation that demonstrates the Transmission Operator provided its SOLs in accordance with its Reliability Coordinator's SOL ~~M~~methodology.

R4. Each Reliability Coordinator shall establish stability limits ~~to be used in operations~~ when the limit impacts adjacent Reliability Coordinator Areas or more than one Transmission Operator in its Reliability Coordinator Area ~~or other Reliability Coordinator Areas~~ in accordance with its SOL ~~M~~methodology. *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

M4. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation that demonstrates the Reliability Coordinator established stability limits in accordance with Requirement R4.

R5. Each Reliability Coordinator shall provide: [*Violation Risk Factor: High] [Time Horizon: Operations Planning, Same-day Operations, Real-Time Operations]*

5.1 Each Planning Coordinator and each Transmission Planner within its Reliability Coordinator Area, the SOLs for its Reliability Coordinator Area (including the subset of SOLs that are IROLs) at least once every twelve calendar months.

5.2 Each impacted Planning Coordinator and each impacted Transmission Planner within its Reliability Coordinator Area, the following information for each established stability limit and each established IROL at least once every twelve calendar months:

5.2.1 The value of the stability limit or IROL;

5.2.2 Identification of the Facilities that are critical to the stability limit or IROL;

5.2.3 The associated IROL T_v for any IROL;

5.2.4 The associated Contingency(ies);

5.2.5 A description of ~~the associated~~ system conditions associated with ~~that are specific to~~ the stability limit or IROL; and

5.2.6 The type of limitation represented by the stability limit or IROL (*e.g.*, voltage collapse, angular stability).

5.3 Each impacted Transmission Operator within its Reliability Coordinator Area, the value of the stability limits established pursuant to Requirement R4 and each IROL established pursuant to Requirement R1, in an agreed upon time frame necessary for inclusion in the Transmission Operator's Operational Planning Analyses, Real-time monitoring, and Real-time Assessments.

5.4 Each impacted Transmission Operator within its Reliability Coordinator Area, the information identified in Requirement R5 Parts 5.2.2 – 5.2.~~5~~6 for each established stability limit or each IROL, and any updates to that information within an agreed upon time frame necessary for inclusion in the Transmission Operator's Operational Planning Analyses.

5.5 Each requesting Transmission Operator within its Reliability Coordinator Area, requested SOL information for its Reliability Coordinator Area, on a mutually agreed upon schedule.

M5. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation, posting to a secure website, or other electronic means, that demonstrates the Reliability Coordinator provided the information in accordance with Requirement R5.

~~**R6.** Each Transmission Operator and Reliability Coordinator shall use the Bulk Electric System performance criteria specified in the Reliability Coordinator's SOL Methodology when performing OPAs, RTAs, and Real-time monitoring to determine SOL exceedances. *[Violation Risk Factor: High] [Time Horizon: Operations Planning, Same-day Operations, Real-time Operations]*~~

~~**M6.** Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation, that demonstrates the Transmission Operator and Reliability Coordinator determined SOL exceedances in accordance with its Reliability Coordinator's SOL Methodology when performing Real-time monitoring, Real-time Assessments, and Operational Planning Analyses.used the Bulk Electric System performance criteria specified in the Reliability Coordinator's SOL methodology when performing OPAs, RTAs and Real-Time Monitoring.~~

R6. Each Planning Coordinator and each Transmission Planner shall implement a documented process to use Facility Ratings, System steady-state voltage limits and stability criteria in its Planning Assessment of Near Term Transmission Planning Horizon that are equally limiting or more limiting than the criteria for Facility Ratings, System Voltage Limits and stability described in its respective Reliability Coordinator's SOL methodology. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

- The Planning Coordinator may use less limiting Facility Ratings, System steady-state voltage limits and stability criteria if it provides a technical rationale to each affected Transmission Planner, Transmission Operator and Reliability Coordinator.
- The Transmission Planner may use less limiting Facility Ratings, System steady-state voltage limits and stability criteria if it provides a technical rationale to each affected Planning Coordinator, Transmission Operator and Reliability Coordinator.

M6. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation demonstrating the Planning Coordinator and Transmission Planner implemented its documented process in accordance with Requirement R6.

R7. Each Planning Coordinator and each Transmission Planner shall annually communicate the following information for Corrective Action Plans developed to address any instability identified in its Planning Assessment of the Near-Term Transmission

Planning Horizon to each impacted Transmission Operator and Reliability Coordinator. This communication shall include: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

7.1 The Corrective Action Plan developed to mitigate the identified instability, including any automatic control or operator-assisted actions (such as Remedial Action Schemes, under voltage load shedding, or any Operating Procedures);

7.2 The type of instability addressed by the Corrective Action Plan (e.g. steady-state and/or transient voltage instability, angular instability including generating unit loss of synchronism and/or unacceptable damping);

7.3 The associated stability criteria violation requiring the Corrective Action Plan (e.g. violation of transient voltage response criteria or damping rate criteria);

7.4 The planning event Contingency(ies) associated with the identified instability requiring the Corrective Action Plan;

7.5 The System conditions and Facilities associated with the identified instability requiring the Corrective Action Plan.

M7. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation demonstrating the Planning Coordinator and Transmission Planner communicated the information in accordance with Requirement R7.

R8. Each Planning Coordinator and each Transmission Planner shall annually communicate any instability, Cascading or uncontrolled separation that adversely impact the reliability of the Bulk Electric System identified in its Planning Assessment of the Near-Term Transmission Planning Horizon to each impacted Transmission Owner and Generation Owner. This communication shall include those Facilities that comprise the Contingency(ies) (planning events only) and any Facilities critical to the instability, Cascading or uncontrolled separation identified. *[Violation Risk Factor: Medium] [Time Horizon: Long- term Planning]*

M8. Acceptable evidence may include, but is not limited to, dated electronic or hard copy documentation demonstrating the Planning Coordinator and Transmission Planner communicated the information in accordance with Requirement R8.

C. Compliance

1. **Compliance Monitoring Process**

   1.1. Compliance Enforcement Authority:
   "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

   1.2. Evidence Retention:
   The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

   The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

   - The Reliability Coordinator, ~~or~~ Transmission Operator, Transmission Planner, Planning Coordinator shall keep data or evidence of Requirements R1 through R8 for the current year plus the previous 12 calendar months.

   1.3. Compliance Monitoring and Enforcement Program
   As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1.	N/A	N/A	N/A	The Reliability Coordinator failed to establish Interconnection Reliability Operating Limits (IROLs) for its Reliability Coordinator Area in accordance with its System Operating Limit Methodology ("SOL ~~M~~methodology") as established in FAC-011-4.

- PRC-023-4 Transmission Relay Loadability
- PRC-026-1 Relay Performance During Stable Power Swings
- TOP-001-5 Transmission Operations
- IRO-008-2 Reliability Coordinator Operational Analyses and Real-time Assessments
- Currently-effective definition of System Operating Limit

Effective Date

The effective date for proposed Reliability Standards FAC-011-4, FAC-014-3, CIP-014-3, FAC-003-5, FAC-013-3, PRC-002-3, PRC-023-5, PRC-026-2, TOP-001-6, IRO-008-3 and the NERC Glossary terms "System Voltage Limit" and System Operating Limit" is provided below:

Where approval by an applicable governmental authority is required, Reliability Standards FAC-011-4, FAC-014-3, CIP-014-3, FAC-003-5, FAC-013-3, PRC-002-3, PRC-023-5, PRC-026-2, TOP-001-6, IRO-008-3 and the NERC Glossary terms “System Voltage Limit” and “System Operating Limit” shall become effective the first day of the first calendar quarter that is twelve (12) calendar months after the effective date of the applicable governmental authority’s order approving the standards and terms, or as otherwise provided for by the applicable governmental authority.

Where approval by an applicable governmental authority is not required, Reliability Standards FAC-011-4, FAC-014-3, CIP-014-3, FAC-003-5, FAC-013-3, PRC-002-3, PRC-023-5, PRC-026-2, TOP-001-6, IRO-008-3 and the NERC Glossary terms “System Voltage Limit” and “System Operating Limit” shall become effective on the first day of the first calendar quarter that is twelve (12) calendar months after the date the standards and terms are adopted by the NERC Board of Trustees, or as otherwise provided for in that jurisdiction.

Retirement Date

Currently-Effective NERC Reliability Standards

Reliability Standards FAC-010-3, FAC-011-3, FAC-014-2, CIP-014-2, FAC-003-4, FAC-013-2, PRC-002-2, PRC-023-4, and PRC-026-1, TOP-001-6, IRO-008-3 shall be retired immediately prior to the effective date of the proposed Reliability Standards FAC-011-4, FAC-014-3, CIP-014-3, FAC-003-5, FAC-013-3, PRC-002-3, PRC-023-5, PRC-026-2, and the current definition of System Operating Limit.

Prior Implementation Plans

Unless otherwise specified herein, the elements of the Implementation Plans for FAC-003-4, CIP-014-2, PRC-002-2, PRC-023-4, and PRC-005-3 are incorporated herein by reference and shall remain applicable to FAC-003-5, CIP-014-3, PRC-002-3, PRC-023-5, and PRC-026-2. The following is a description of the elements from prior implementation plans that remain applicable without modification:

- *FAC-003-5: Newly Designated Lines time period*
    - A line operated below 200kV and identified in the Applicability under 4.2 becomes subject to this standard the later of: 1) 12 months after the date the Planning Coordinator, Transmission Planner or WECC identified the line in Applicability under 4.2, or 2) January 1 of the planning year when the line is forecasted to be identified in Applicability under 4.2. A line operating below 200kV identified in Applicability under 4.2 may be removed from that designation due to system improvements, changes in generation, changes in loads, or changes in studies, and analysis of the network.
- *PRC-002-3 Requirements R2, R3, R4, R6, R7, R8, R9, R10, R11: Initial Date:*
    - Entities shall be at least 50 percent compliant within four (4) years of the effective date of PRC-002-2 and fully compliant within six (6) years of the effective date.
    - Entities that own only one (1) identified BES bus, BES Element, or generating unit shall be fully compliant within six (6) years of the effective date of PRC-002-2.

- *PRC-002-3 Requirements R2, R3, R4, R6, R7, R8, R9, R10, R11: Time Period to Address New Designations:*
    - Entities shall be 100 percent compliant with new BES Elements identified in Requirement R1 or R5 within three (3) years following the notification by the TO or the RC.
- *PRC-023-4: Time Period to address new designations is retained:*
    - Each Transmission Owner, Generator Owner, and Distribution Provider with circuits identified by the Planning Coordinator pursuant to Requirement R6 shall meet R1 on the later of the first day of the first calendar quarter 39 months following notification by the Planning Coordinator of a circuit's inclusion on a list of circuits per application of Attachment B, or the first day of the first calendar year in which any criterion in Attachment B applies, unless the Planning Coordinator removes the circuit from the list before the applicable effective date.

Additional Provisions

The following are additional implementation provisions to address revisions in the Reliability Standards that require new or different actions by the same or different entities than the prior version of the Reliability Standards required.

- *FAC-013-2*
    - Following effective date of FAC-013-3, the Planning Coordinator shall update their methodology and perform their assessment either:
        - Within the calendar year the standard becomes effective if the assessment was not completed that calendar year under FAC-013-2
        - Within the next calendar year after the standard is effective if the assessment had been completed within that calendar year under FAC-013-2
- *CIP-014-3*
    - Following effective date of FAC-013-3, the Transmission Owner shall perform the risk assessment Required in Requirement R1 within
        - 30 calendar months of its last assessment if it had identified one or more Transmission stations or Transmission substations that if rendered inoperable or damaged could result in instability, uncontrolled separation, or Cascading within an Interconnection in that prior assessment; or
        - 60 calendar months of its last assessment if it had not identified any Transmission stations or Transmission substations that if rendered inoperable or damaged could result in instability, uncontrolled separation, or Cascading within an Interconnection.
- *PRC-002-3, Requirement R5*
    - Reliability Coordinators in the Eastern Interconnect shall be fully compliant with Requirement R5 within six (6) months of the effective date of PRC-002-3.

- *PRC-023-4*
    - Each Planning Coordinator shall conduct tits first assessment under PRC-23-4 within the next calendar year after the effective date or within 15 months of their last assessment under PRC-23-3, whichever occurs first.
- *PRC-026-2*
    - Each Planning Coordinator shall complete Requirement R1 within the calendar year of the effective date unless they have already completed Requirement R1 under PRC-026-1 for that calendar year, in which case they most complete Requirement R1 within the following year.
- *FAC-014-3, Requirement R6*
    - Requirement R6 shall be implemented by the Planning Coordinator or Transmission Planner following the effective date of FAC-014-3 when it begins its next cycle for conducting the studies to support its Planning Assessment.
- *FAC-014-3, Requirements R7 and R8*
    - Each Planning Coordinator and Transmission Planner shall comply with Requirements R7 and R8 within one year of the effective date of the standard.

RELIABILITY CORPORATION

Implementation Plan

Project 2015-09 Establish and Communicate System Operating Limits

Applicable Standard(s) and Definitions

- FAC-011-4 System Operating Limits Methodology for the Operations Horizon
- FAC-014-3 Establish and Communicate System Operating Limits
- ~~FAC-015-1 Coordination of Planning Assessments with the Reliability Coordinator's SOL Methodology~~
- CIP-014-3 Physical Security
- FAC-003-5 Transmission Vegetation Management
- FAC-013-3 Assessment of Transfer Capability for the Near-term Transmission Planning Horizon
- PRC-002-3 Disturbance Monitoring and Reporting Requirements
- PRC-023-5 Transmission Relay Loadability
- PRC-026-2 Relay Performance During Stable Power Swings
- TOP-001-6 Transmission Operations
- IRO-008-3 Reliability Coordinator Operational Analyses and Real-time Assessments
- Definition of System Voltage Limit in the Glossary of Terms Used in NERC Reliability Standards ("NERC Glossary")
- Definition of System Operating Limit in the NERC Glossary

Requested Retirement(s)

- FAC-010-3 System Operating Limits Methodology for the Planning Horizon
- FAC-011-3 System Operating Limits Methodology for the Operations Horizon
- FAC-014-2 Establish and Communicate System Operating Limits
- CIP-014-2 Physical Security
- FAC-003-4 Transmission Vegetation Management
- FAC-013-2 Assessment of Transfer Capability for the Near-term Transmission Planning Horizon
- PRC-002-2 Disturbance Monitoring and Reporting Requirements
- PRC-023-4 Transmission Relay Loadability
- PRC-026-1 Relay Performance During Stable Power Swings
- TOP-001-5 Transmission Operations
- IRO-008-2 Reliability Coordinator Operational Analyses and Real-time Assessments
- Currently-effective definition of System Operating Limit

~~Prerequisite Approvals~~

~~In addition to approval of the Reliability Standards included in this implementation plan, retirement of Reliability Standard FAC-010-3 cannot occur until the modifications in Reliability Standard CIP-~~

~~002-6 (Cyber Security – BES Cyber System Categorization), Attachment 1, Criteria 2.6 and 2.9 become effective.~~

Effective Date

The effective date for proposed Reliability Standards FAC-011-4, FAC-014-3, ~~FAC-015-1~~CIP-014-3, FAC-003-5, FAC-013-3, PRC-002-3, PRC-023-5, PRC-026-2, TOP-001-6, IRO-008-3 and the NERC Glossary terms "System Voltage Limit" and System Operating Limit" is provided below:

Where approval by an applicable governmental authority is required, Reliability Standards FAC-011-4, FAC-014-3, ~~FAC-015-1~~CIP-014-3, FAC-003-5, FAC-013-3, PRC-002-3, PRC-023-5, PRC-026-2, TOP-001-6, IRO-008-3 and the NERC Glossary terms "System Voltage Limit" and "System Operating Limit" shall become effective the first day of the first calendar quarter that is twelve (12) calendar months after the effective date of the applicable governmental authority's order approving the standards and terms, or as otherwise provided for by the applicable governmental authority.

Where approval by an applicable governmental authority is not required, Reliability Standards FAC-011-4, FAC-014-3, ~~FAC-015-1~~CIP-014-3, FAC-003-5, FAC-013-3, PRC-002-3, PRC-023-5, PRC-026-2, TOP-001-6, IRO-008-3 and the NERC Glossary terms "System Voltage Limit" and "System Operating Limit" shall become effective on the first day of the first calendar quarter that is twelve (12) calendar months after the date the standards and terms are adopted by the NERC Board of Trustees, or as otherwise provided for in that jurisdiction.

Retirement Date

Currently-Effective NERC Reliability Standards

Reliability Standards FAC-010-3, FAC-011-3, FAC-014-2, CIP-014-2, FAC-003-4, FAC-013-2, PRC-002-2, PRC-023-4, and PRC-026-1, TOP-001-6, IRO-008-3 shall be retired immediately prior to the effective date of the proposed Reliability Standards FAC-011-4, FAC-014-3, ~~FAC-015~~CIP-014-3, FAC-003-5, FAC-013-3, PRC-002-3, PRC-023-5, PRC-026-2, and the current definition of System Operating Limit.

Prior Implementation Plans

Unless otherwise specified herein, the elements of the Implementation Plans for FAC-003-4, CIP-014-2, PRC-002-2, PRC-023-4, and PRC-005-3 are incorporated herein by reference and shall remain applicable to FAC-003-5, CIP-014-3, PRC-002-3, PRC-023-5, and PRC-026-2. The following is a description of the elements from prior implementation plans that remain applicable without modification:

- *FAC-003-5: Newly Designated Lines time period*
  - A line operated below 200kV and identified in the Applicability under 4.2 becomes subject to this standard the later of: 1) 12 months after the date the Planning Coordinator, Transmission Planner or WECC identified the line in Applicability under 4.2, or 2) January 1 of the planning year when the line is forecasted to be identified in Applicability under 4.2. A line operating below 200kV identified in Applicability under 4.2 may be removed from that designation due to system improvements, changes in generation, changes in loads, or changes in studies, and analysis of the network.

- *PRC-002-3 Requirements R2, R3, R4, R6, R7, R8, R9, R10, R11: Initial Date:*
    - Entities shall be at least 50 percent compliant within four (4) years of the effective date of PRC-002-2 and fully compliant within six (6) years of the effective date.
    - Entities that own only one (1) identified BES bus, BES Element, or generating unit shall be fully compliant within six (6) years of the effective date of PRC-002-2.
- *PRC-002-3 Requirements R2, R3, R4, R6, R7, R8, R9, R10, R11: Time Period to Address New Designations:*
    - Entities shall be 100 percent compliant with new BES Elements identified in Requirement R1 or R5 within three (3) years following the notification by the TO or the RC.
- *PRC-023-4: Time Period to address new designations is retained:*
    - Each Transmission Owner, Generator Owner, and Distribution Provider with circuits identified by the Planning Coordinator pursuant to Requirement R6 shall meet R1 on the later of the first day of the first calendar quarter 39 months following notification by the Planning Coordinator of a circuit's inclusion on a list of circuits per application of Attachment B, or the first day of the first calendar year in which any criterion in Attachment B applies, unless the Planning Coordinator removes the circuit from the list before the applicable effective date.

Additional Provisions

The following are additional implementation provisions to address revisions in the Reliability Standards that require new or different actions by the same or different entities than the prior version of the Reliability Standards required.

- *FAC-013-2*
    - Following effective date of FAC-013-3, the Planning Coordinator shall update their methodology and perform their assessment either:
        - Within the calendar year the standard becomes effective if the assessment was not completed that calendar year under FAC-013-2
        - Within the next calendar year after the standard is effective if the assessment had been completed within that calendar year under FAC-013-2
- *CIP-014-3*
    - Following effective date of FAC-013-3, the Transmission Owner shall perform the risk assessment Required in Requirement R1 within
        - 30 calendar months of its last assessment if it had identified one or more Transmission stations or Transmission substations that if rendered inoperable or damaged could result in instability, uncontrolled separation, or Cascading within an Interconnection in that prior assessment; or
        - 60 calendar months of its last assessment if it had not identified any Transmission

stations or Transmission substations that if rendered inoperable or damaged could result in instability, uncontrolled separation, or Cascading within an Interconnection.

- *PRC-002-3, Requirement R5*
  - Reliability Coordinators in the Eastern Interconnect shall be fully compliant with Requirement R5 within six (6) months of the effective date of PRC-002-3.
- *PRC-023-4*
  - Each Planning Coordinator shall conduct tits first assessment under PRC-23-4 within the next calendar year after the effective date or within 15 months of their last assessment under PRC-23-3, whichever occurs first.
- *PRC-026-2*
  - Each Planning Coordinator shall complete Requirement R1 within the calendar year of the effective date unless they have already completed Requirement R1 under PRC-026-1 for that calendar year, in which case they most complete Requirement R1 within the following year.
- *FAC-014-3, Requirement R6*
  - Requirement R6 shall be implemented by the Planning Coordinator or Transmission Planner following the effective date of FAC-014-3 when it begins its next cycle for conducting the studies to support its Planning Assessment.
- *FAC-014-3, Requirements R7 and R8*
  - Each Planning Coordinator and Transmission Planner shall comply with Requirements R7 and R8 within one year of the effective date of the standard.

~~Initial Performance of Periodic Requirements~~

~~FAC-014-3 Requirement R5, Parts 5.1 and 5.2~~

~~The initial performance of FAC-014-3, Requirement R5, Parts 5.1 and 5.2 must be within 12 calendar months of the effective date of FAC-014-3.~~

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	08/19/15
SAR posted for comment	08/20/15 – 09/21/15
45-day formal comment period with initial ballot	08/27/18 - 10/17/18

Anticipated Actions	Date
45-day formal comment period with additional ballot	June 2020
10-day final ballot	August 2020
NERC Board adoption	November 2020

Upon Board adoption, the rationale boxes will be moved to the Supplemental Material Section.

A. Introduction

1. **Title:** Physical Security

2. **Number:** CIP-014-3

3. **Purpose:** To identify and protect Transmission stations and Transmission substations, and their associated primary control centers, that if rendered inoperable or damaged as a result of a physical attack could result in instability, uncontrolled separation, or Cascading within an Interconnection.

4. **Applicability:**

4.1. Functional Entities:

4.1.1 Transmission Owner that owns a Transmission station or Transmission substation that meets any of the following criteria:

4.1.1.1 Transmission Facilities operated at 500 kV or higher. For the purpose of this criterion, the collector bus for a generation plant is not considered a Transmission Facility, but is part of the generation interconnection Facility.

4.1.1.2 Transmission Facilities that are operating between 200 kV and 499 kV at a single station or substation, where the station or substation is connected at 200 kV or higher voltages to three or more other Transmission stations or substations and has an "aggregate weighted value" exceeding 3000 according to the table below. The "aggregate weighted value" for a single station or substation is determined by summing the "weight value per line" shown in the table below for each incoming and each outgoing BES Transmission Line that is connected to another Transmission station or substation. For the purpose of this criterion, the collector bus for a generation plant is not considered a Transmission Facility, but is part of the generation interconnection Facility.

Voltage Value of a Line	Weight Value per Line
less than 200 kV (not applicable)	(not applicable)
200 kV to 299 kV	700
300 kV to 499 kV	1300
500 kV and above	0

4.1.1.3 Transmission Facilities at a single station or substation location that are identified by the Planning Coordinator or Transmission Planner, per its Planning Assessment of the Near-Term Transmission Planning Horizon as Facilities that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation, that adversely impacts the reliability of the Bulk Electric System for planning events.

4.1.1.4 Transmission Facilities identified as essential to meeting Nuclear Plant Interface Requirements.

4.1.2 Transmission Operator.

Exemption: Facilities in a "protected area," as defined in 10 C.F.R. § 73.2, within the scope of a security plan approved or accepted by the Nuclear Regulatory Commission are not subject to this Standard; or, Facilities within the scope of a security plan approved or accepted by the Canadian Nuclear Safety Commission are not subject to this Standard.

5. Effective Dates: See Implementation Plan

6. Background:

Reliability Standard CIP-014-3 addresses the directives from the FERC order issued March 7, 2014, *Reliability Standards for Physical Security Measures*, 146 FERC ¶ 61,166 (2014), which required NERC to develop a physical security reliability standard(s) to identify and protect facilities that if rendered inoperable or damaged could result in instability, uncontrolled separation, or Cascading within an Interconnection.

B. Requirements and Measures

R1. Each Transmission Owner shall perform an initial risk assessment and subsequent risk assessments of its Transmission stations and Transmission substations (existing and planned to be in service within 24 months) that meet the criteria specified in Applicability Section 4.1.1. The initial and subsequent risk assessments shall consist of a transmission analysis or transmission analyses designed to identify the Transmission station(s) and Transmission substation(s) that if rendered inoperable or damaged could result in instability, uncontrolled separation, or Cascading within an Interconnection. *[VRF: High; Time-Horizon: Long-term Planning]*

1.1. Subsequent risk assessments shall be performed:

- At least once every 30 calendar months for a Transmission Owner that has identified in its previous risk assessment (as verified according to Requirement R2) one or more Transmission stations or Transmission substations that if rendered inoperable or damaged could result in instability, uncontrolled separation, or Cascading within an Interconnection; or
- At least once every 60 calendar months for a Transmission Owner that has not identified in its previous risk assessment (as verified according to Requirement R2) any Transmission stations or Transmission substations that if rendered inoperable or damaged could result in instability, uncontrolled separation, or Cascading within an Interconnection.

1.2. The Transmission Owner shall identify the primary control center that operationally controls each Transmission station or Transmission substation identified in the Requirement R1 risk assessment.

M1. Examples of acceptable evidence may include, but are not limited to, dated written or electronic documentation of the risk assessment of its Transmission stations and Transmission substations (existing and planned to be in service within 24 months) that meet the criteria in Applicability Section 4.1.1 as specified in Requirement R1. Additionally, examples of acceptable evidence may include, but are not limited to, dated written or electronic documentation of the identification of the primary control center that operationally controls each Transmission station or Transmission substation identified in the Requirement R1 risk assessment as specified in Requirement R1, Part 1.2.

R2. Each Transmission Owner shall have an unaffiliated third party verify the risk assessment performed under Requirement R1. The verification may occur concurrent with or after the risk assessment performed under Requirement R1. *[VRF: Medium; Time-Horizon: Long-term Planning]*

2.1. Each Transmission Owner shall select an unaffiliated verifying entity that is either:

- A registered Planning Coordinator, Transmission Planner, or Reliability Coordinator; or
- An entity that has transmission planning or analysis experience.

2.2. The unaffiliated third party verification shall verify the Transmission Owner's risk assessment performed under Requirement R1, which may include recommendations for the addition or deletion of a Transmission station(s) or Transmission substation(s). The Transmission Owner shall ensure the verification is completed within 90 calendar days following the completion of the Requirement R1 risk assessment.

2.3. If the unaffiliated verifying entity recommends that the Transmission Owner add a Transmission station(s) or Transmission substation(s) to, or remove a Transmission station(s) or Transmission substation(s) from, its identification under Requirement R1, the Transmission Owner shall either, within 60 calendar days of completion of the verification, for each recommended addition or removal of a Transmission station or Transmission substation:

- Modify its identification under Requirement R1 consistent with the recommendation; or
- Document the technical basis for not modifying the identification in accordance with the recommendation.

2.4. Each Transmission Owner shall implement procedures, such as the use of non-disclosure agreements, for protecting sensitive or confidential information made available to the unaffiliated third party verifier and to protect or exempt sensitive or confidential information developed pursuant to this Reliability Standard from public disclosure.

M2. Examples of acceptable evidence may include, but are not limited to, dated written or electronic documentation that the Transmission Owner completed an unaffiliated third party verification of the Requirement R1 risk assessment and satisfied all of the applicable provisions of Requirement R2, including, if applicable, documenting the technical basis for not modifying the Requirement R1 identification as specified under Part 2.3. Additionally, examples of evidence may include, but are not limited to, written or electronic documentation of procedures to protect information under Part 2.4.

R3. For a primary control center(s) identified by the Transmission Owner according to Requirement R1, Part 1.2 that a) operationally controls an identified Transmission station or Transmission substation verified according to Requirement R2, and b) is not under the operational control of the Transmission Owner: the Transmission Owner shall, within seven calendar days following completion of Requirement R2, notify the Transmission Operator that has operational control of the primary control center of

such identification and the date of completion of Requirement R2. *[VRF: Lower; Time-Horizon: Long-term Planning]*

3.1. If a Transmission station or Transmission substation previously identified under Requirement R1 and verified according to Requirement R2 is removed from the identification during a subsequent risk assessment performed according to Requirement R1 or a verification according to Requirement R2, then the Transmission Owner shall, within seven calendar days following the verification or the subsequent risk assessment, notify the Transmission Operator that has operational control of the primary control center of the removal.

M3. Examples of acceptable evidence may include, but are not limited to, dated written or electronic notifications or communications that the Transmission Owner notified each Transmission Operator, as applicable, according to Requirement R3.

R4. Each Transmission Owner that identified a Transmission station, Transmission substation, or a primary control center in Requirement R1 and verified according to Requirement R2, and each Transmission Operator notified by a Transmission Owner according to Requirement R3, shall conduct an evaluation of the potential threats and vulnerabilities of a physical attack to each of their respective Transmission station(s), Transmission substation(s), and primary control center(s) identified in Requirement R1 and verified according to Requirement R2. The evaluation shall consider the following: *[VRF: Medium; Time-Horizon: Operations Planning, Long-term Planning]*

4.1. Unique characteristics of the identified and verified Transmission station(s), Transmission substation(s), and primary control center(s);

4.2. Prior history of attack on similar facilities taking into account the frequency, geographic proximity, and severity of past physical security related events; and

4.3. Intelligence or threat warnings received from sources such as law enforcement, the Electric Reliability Organization (ERO), the Electricity Sector Information Sharing and Analysis Center (ES-ISAC), U.S. federal and/or Canadian governmental agencies, or their successors.

M4. Examples of evidence may include, but are not limited to, dated written or electronic documentation that the Transmission Owner or Transmission Operator conducted an evaluation of the potential threats and vulnerabilities of a physical attack to their respective Transmission station(s), Transmission substation(s) and primary control center(s) as specified in Requirement R4.

R5. Each Transmission Owner that identified a Transmission station, Transmission substation, or primary control center in Requirement R1 and verified according to Requirement R2, and each Transmission Operator notified by a Transmission Owner according to Requirement R3, shall develop and implement a documented physical security plan(s) that covers their respective Transmission station(s), Transmission substation(s), and primary control center(s). The physical security plan(s) shall be

developed within 120 calendar days following the completion of Requirement R2 and executed according to the timeline specified in the physical security plan(s). The physical security plan(s) shall include the following attributes: *[VRF: High; Time-Horizon: Long-term Planning]*

5.1. Resiliency or security measures designed collectively to deter, detect, delay, assess, communicate, and respond to potential physical threats and vulnerabilities identified during the evaluation conducted in Requirement R4.

5.2. Law enforcement contact and coordination information.

5.3. A timeline for executing the physical security enhancements and modifications specified in the physical security plan.

5.4. Provisions to evaluate evolving physical threats, and their corresponding security measures, to the Transmission station(s), Transmission substation(s), or primary control center(s).

M5. Examples of evidence may include, but are not limited to, dated written or electronic documentation of its physical security plan(s) that covers their respective identified and verified Transmission station(s), Transmission substation(s), and primary control center(s) as specified in Requirement R5, and additional evidence demonstrating execution of the physical security plan according to the timeline specified in the physical security plan.

R6. Each Transmission Owner that identified a Transmission station, Transmission substation, or primary control center in Requirement R1 and verified according to Requirement R2, and each Transmission Operator notified by a Transmission Owner according to Requirement R3, shall have an unaffiliated third party review the evaluation performed under Requirement R4 and the security plan(s) developed under Requirement R5. The review may occur concurrently with or after completion of the evaluation performed under Requirement R4 and the security plan development under Requirement R5. *[VRF: Medium; Time-Horizon: Long-term Planning]*

6.1. Each Transmission Owner and Transmission Operator shall select an unaffiliated third party reviewer from the following:

- An entity or organization with electric industry physical security experience and whose review staff has at least one member who holds either a Certified Protection Professional (CPP) or Physical Security Professional (PSP) certification.
- An entity or organization approved by the ERO.
- A governmental agency with physical security expertise.

- An entity or organization with demonstrated law enforcement, government, or military physical security expertise.

6.2. The Transmission Owner or Transmission Operator, respectively, shall ensure that the unaffiliated third party review is completed within 90 calendar days of completing the security plan(s) developed in Requirement R5. The unaffiliated third party review may, but is not required to, include recommended changes to the evaluation performed under Requirement R4 or the security plan(s) developed under Requirement R5.

6.3. If the unaffiliated third party reviewer recommends changes to the evaluation performed under Requirement R4 or security plan(s) developed under Requirement R5, the Transmission Owner or Transmission Operator shall, within 60 calendar days of the completion of the unaffiliated third party review, for each recommendation:

- Modify its evaluation or security plan(s) consistent with the recommendation; or
- Document the reason(s) for not modifying the evaluation or security plan(s) consistent with the recommendation.

6.4. Each Transmission Owner and Transmission Operator shall implement procedures, such as the use of non-disclosure agreements, for protecting sensitive or confidential information made available to the unaffiliated third party reviewer and to protect or exempt sensitive or confidential information developed pursuant to this Reliability Standard from public disclosure.

M6. Examples of evidence may include, but are not limited to, written or electronic documentation that the Transmission Owner or Transmission Operator had an unaffiliated third party review the evaluation performed under Requirement R4 and the security plan(s) developed under Requirement R5 as specified in Requirement R6 including, if applicable, documenting the reasons for not modifying the evaluation or security plan(s) in accordance with a recommendation under Part 6.3. Additionally, examples of evidence may include, but are not limited to, written or electronic documentation of procedures to protect information under Part 6.4.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

As defined in the NERC Rules of Procedure, “Compliance Enforcement Authority” (CEA) means NERC or the Regional Entity in their respective roles of monitoring and enforcing compliance with the NERC Reliability Standards.

1.2. Evidence Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the CEA may ask an entity to provide other evidence during an on-site visit to show that it was compliant for the full time period since the last audit.

The Transmission Owner and Transmission Operator shall keep data or evidence to show compliance, as identified below, unless directed by its Compliance Enforcement Authority (CEA) to retain specific evidence for a longer period of time as part of an investigation.

The responsible entities shall retain documentation as evidence for three years.

If a Responsible Entity is found non-compliant, it shall keep information related to the non-compliance until mitigation is complete and approved, or for the time specified above, whichever is longer.

The CEA shall keep the last audit records and all requested and submitted subsequent audit records, subject to the confidentiality provisions of Section 1500 of the Rules of Procedure and the provisions of Section 1.4 below.

1.3. Compliance Monitoring and Assessment Processes:

Compliance Audits

Self-Certifications

Spot Checking

Compliance Violation Investigations

Self-Reporting

Complaints Text

1.4. Additional Compliance Information

Confidentiality: To protect the confidentiality and sensitive nature of the evidence for demonstrating compliance with this standard, all evidence will be retained at the Transmission Owner’s and Transmission Operator’s facilities.

2. Table of Compliance Elements

R #	Time Horizon	VRF	Violation Severity Levels (CIP-014-1)			
			Lower VSL	Moderate VSL	High VSL	Severe VSL

Guidelines and Technical Basis

Section 4 Applicability

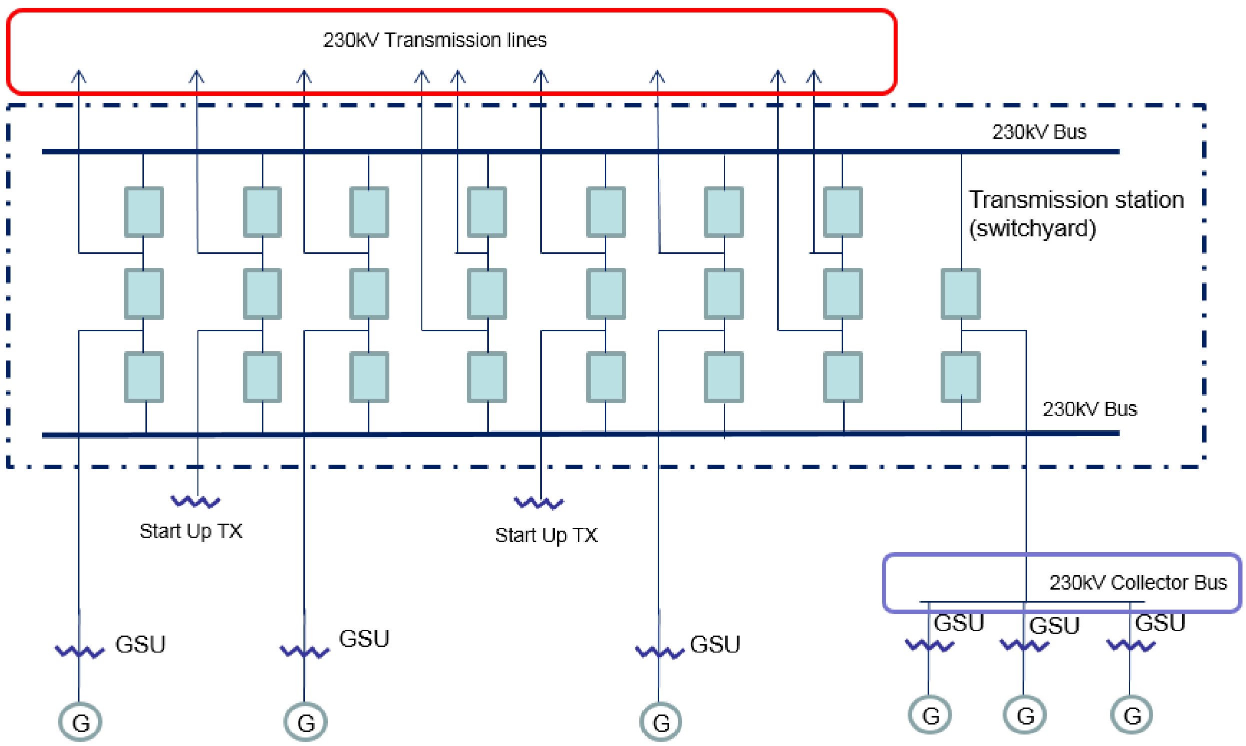
The purpose of Reliability Standard CIP-014 is to protect Transmission stations and Transmission substations, and their associated primary control centers that if rendered inoperable or damaged as a result of a physical attack could result in instability, uncontrolled separation, or Cascading within an Interconnection. To properly include those entities that own or operate such Facilities, the Reliability Standard CIP-014 first applies to Transmission Owners that own Transmission Facilities that meet the specific criteria in Applicability Section 4.1.1.1 through 4.1.1.4. The Facilities described in Applicability Section 4.1.1.1 through 4.1.1.4 mirror those Transmission Facilities that meet the bright line criteria for "Medium Impact" Transmission Facilities under Attachment 1 of Reliability Standard CIP-002-5.1. Each Transmission Owner that owns Transmission Facilities that meet the criteria in Section 4.1.1.1 through 4.1.1.4 is required to perform a risk assessment as specified in Requirement R1 to identify its Transmission stations and Transmission substations, and their associated primary control centers, that if rendered inoperable or damaged as a result of a physical attack could result in instability, uncontrolled separation, or Cascading within an Interconnection. The Standard Drafting Team (SDT) expects this population will be small and that many Transmission Owners that meet the applicability of this standard will not actually identify any such Facilities. Only those Transmission Owners with Transmission stations or Transmission substations identified in the risk assessment (and verified under Requirement R2) have performance obligations under Requirements R3 through R6.

This standard also applies to Transmission Operators. A Transmission Operator's obligations under the standard, however, are only triggered if the Transmission Operator is notified by an applicable Transmission Owner under Requirement R3 that the Transmission Operator operates a primary control center that operationally controls a Transmission station(s) or Transmission substation(s) identified in the Requirement R1 risk assessment. A primary control center operationally controls a Transmission station or Transmission substation when the control center's electronic actions can cause direct physical action at the identified Transmission station or Transmission substation, such as opening a breaker, as opposed to a control center that only has information from the Transmission station or Transmission substation and must coordinate direct action through another entity. Only Transmission Operators who are notified that they have primary control centers under this standard have performance obligations under Requirements R4 through R6. In other words, primary control center for purposes of this Standard is the control center that the Transmission Owner or Transmission Operator, respectively, uses as its primary, permanently-manned site to physically operate a Transmission station or Transmission substation that is identified in Requirement R1 and verified in Requirement R2. Control centers that provide back-up capability are not applicable, as they are a form of resiliency and intentionally redundant.

The SDT considered several options for bright line criteria that could be used to determine applicability and provide an initial threshold that defines the set of Transmission stations and Transmission substations that would meet the directives of the FERC order on physical security

(*i.e.*, those that could cause instability, uncontrolled separation, or Cascading within an Interconnection). The SDT determined that using the criteria for Medium Impact Transmission Facilities in Attachment 1 of CIP-002-5.1 would provide a conservative threshold for defining which Transmission stations and Transmission substations must be included in the risk assessment in Requirement R1 of CIP-014. Additionally, the SDT concluded that using the CIP-002-5.1 Medium Impact criteria was appropriate because it has been approved by stakeholders, NERC, and FERC, and its use provides a technically sound basis to determine which Transmission Owners should conduct the risk assessment. As described in CIP-002-5.1, the failure of a Transmission station or Transmission substation that meets the Medium Impact criteria could have the capability to result in instability, Cascading, or uncontrolled separation that adversely impact the reliability of the Bulk Electric System for planning events. The SDT understands that using this bright line criteria to determine applicability may require some Transmission Owners to perform risk assessments under Requirement R1 that will result in a finding that none of their Transmission stations or Transmission substations would pose a risk of instability, uncontrolled separation, or Cascading within an Interconnection. However, the SDT determined that higher bright lines could not be technically justified to ensure inclusion of all Transmission stations and Transmission substations, and their associated primary control centers that, if rendered inoperable or damaged as a result of a physical attack could result in instability, uncontrolled separation, or Cascading within an Interconnection. Further guidance and technical basis for the bright line criteria for Medium Impact Facilities can be found in the Guidelines and Technical Basis section of CIP-002-5.1.

Additionally, the SDT determined that it was not necessary to include Generator Operators and Generator Owners in the Reliability Standard. First, Transmission stations or Transmission substations interconnecting generation facilities are considered when determining applicability. Transmission Owners will consider those Transmission stations and Transmission substations that include a Transmission station on the high side of the Generator Step-up transformer (GSU) using Applicability Section 4.1.1.1 and 4.1.1.2. As an example, a Transmission station or Transmission substation identified as a Transmission Owner facility that interconnects generation will be subject to the Requirement R1 risk assessment if it operates at 500kV or greater or if it is connected at 200 kV – 499kV to three or more other Transmission stations or Transmission substations and has an "aggregate weighted value" exceeding 3000 according to the table in Applicability Section 4.1.1.2. Second, the Transmission analysis or analyses conducted under Requirement R1 should take into account the impact of the loss of generation connected to applicable Transmission stations or Transmission substations. Additionally, the FERC order does not explicitly mention generation assets and is reasonably understood to focus on the most critical Transmission Facilities. The diagram below shows an example of a station.



Also, the SDT uses the phrase “Transmission stations or Transmission substations” to recognize the existence of both stations and substations. Many entities in industry consider a substation to be a location with physical borders (i.e. fence, wall, etc.) that contains at least an autotransformer. Locations also exist that do not contain autotransformers, and many entities in industry refer to those locations as stations (switching stations or switchyards). Therefore, the SDT chose to use both “station” and “substation” to refer to the locations where groups of Transmission Facilities exist.

On the issue of joint ownership, the SDT recognizes that this issue is not unique to CIP-014, and expects that the applicable Transmission Owners and Transmission Operators will develop memorandums of understanding, agreements, Coordinated Functional Registrations, or procedures, etc., to designate responsibilities under CIP-014 when joint ownership is at issue, which is similar to what many entities have completed for other Reliability Standards.

The language contained in the applicability section regarding the collector bus is directly copied from CIP-002-5.1, Attachment 1, and has no additional meaning within the CIP-014 standard.

Requirement R1

The initial risk assessment required under Requirement R1 must be completed on or before the effective date of the standard. Subsequent risk assessments are to be performed at least once every 30 or 60 months depending on the results of the previous risk assessment per Requirement R1, Part 1.1. In performing the risk assessment under Requirement R1, the

Transmission Owner should first identify their population of Transmission stations and Transmission substations that meet the criteria contained in Applicability Section 4.1.1. Requirement R1 then requires the Transmission Owner to perform a risk assessment, consisting of a transmission analysis, to determine which of those Transmission stations and Transmission Substations if rendered inoperable or damaged could result in instability, uncontrolled separation, or Cascading within an Interconnection. The requirement is not to require identification of, and thus, not intended to bring within the scope of the standard a Transmission station or Transmission substation unless the applicable Transmission Owner determines through technical studies and analyses based on objective analysis, technical expertise, operating experience and experienced judgment that the loss of such facility would have a critical impact on the operation of the Interconnection in the event the asset is rendered inoperable or damaged. In the November 20, 2014 Order, FERC reiterated that "only an instability that has a "critical impact on the operation of the interconnection" warrants finding that the facility causing the instability is critical under Requirement R1." The Transmission Owner may determine the criteria for critical impact by considering, among other criteria, any of the following:

- Criteria or methodology used by Transmission Planners or Planning Coordinators in TPL-001-4, Requirement R6
- NERC EOP-004-2 reporting criteria
- Area or magnitude of potential impact

The standard does not mandate the specific analytical method for performing the risk assessment. The Transmission Owner has the discretion to choose the specific method that best suites its needs. As an example, an entity may perform a Power Flow analysis and stability analysis at a variety of load levels.

Performing Risk Assessments

The Transmission Owner has the discretion to select a transmission analysis method that fits its facts and system circumstances. To mandate a specific approach is not technically desirable and may lead to results that fail to adequately consider regional, topological, and system circumstances. The following guidance is only an example on how a Transmission Owner may perform a power flow and/or stability analysis to identify those Transmission stations and Transmission substations that if rendered inoperable or damaged as a result of a physical attack could result in instability, uncontrolled separation, or Cascading within an Interconnection. An entity could remove all lines, without regard to the voltage level, to a single Transmission station or Transmission substation and review the simulation results to assess system behavior to determine if Cascading of Transmission Facilities, uncontrolled separation, or voltage or frequency instability is likely to occur over a significant area of the Interconnection. Using engineering judgment, the Transmission Owner (possibly in consultation with regional planning or operation committees and/or ISO/RTO committee input) should develop criteria (e.g. imposing a fault near the removed Transmission station or Transmission substation) to identify a contingency or parameters that result in potential instability, uncontrolled separation, or

Cascading within an Interconnection. Regional consultation on these matters is likely to be helpful and informative, given that the inputs for the risk assessment and the attributes of what constitutes instability, uncontrolled separation, or Cascading within an Interconnection will likely vary from region-to-region or from ISO-to-ISO based on topology, system characteristics, and system configurations. Criteria could also include post-contingency facilities loadings above a certain emergency rating or failure of a power flow case to converge. Available special protection systems (SPS), if any, could be applied to determine if the system experiences any additional instability which may result in uncontrolled separation. Example criteria may include:

(a) Thermal overloads beyond facility emergency ratings;

(b) Voltage deviation exceeding ± 10%; or

(c) Cascading outage/voltage collapse; or

(d) Frequency below under-frequency load shed points

Periodicity

A Transmission Owner who identifies one or more Transmission stations or Transmission substations (as verified under Requirement R2) that if rendered inoperable or damaged could result in instability, uncontrolled separation, or Cascading within an Interconnection is required to conduct a risk assessment at least once every 30 months. This period ensures that the risk assessment remains current with projected conditions and configurations in the planned system. This risk assessment, as the initial assessment, must consider applicable planned Transmission stations and Transmission substations to be in service within 24 months. The 30 month timeframe aligns with the 24 month planned to be in service date because the Transmission Owner is provided the flexibility, depending on its planning cycle and the frequency in which it may plan to construct a new Transmission station or Transmission substation to more closely align these dates. The requirement is to conduct the risk assessment at least once every 30 months, so for a Transmission Owner that believes it is better to conduct a risk assessment once every 24 months, because of its planning cycle, it has the flexibility to do so.

Transmission Owners that have not identified any Transmission stations or Transmission substations (as verified under Requirement R2) that if rendered inoperable or damaged could result in instability, uncontrolled separation, or Cascading within an Interconnection are unlikely to see changes to their risk assessment in the Near-Term Planning Horizon. Consequently, a 60 month periodicity for completing a subsequent risk assessment is specified.

Identification of Primary Control Centers

After completing the risk assessment specified in Requirement R1, it is important to additionally identify the primary control center that operationally controls each Transmission station or Transmission substation that if rendered inoperable or damaged could result in instability, uncontrolled separation, or Cascading within an Interconnection. A primary control center "operationally controls" a Transmission station or Transmission substation when the control center's electronic actions can cause direct physical actions at the identified Transmission station and Transmission substation, such as opening a breaker.

Requirement R2

This requirement specifies verification of the risk assessment performed under Requirement R1 by an entity other than the owner or operator of the Requirement R1 risk assessment.

A verification of the risk assessment by an unaffiliated third party, as specified in Requirement R2, could consist of:

1. Certifying that the Requirement R1 risk assessment considers the Transmission stations and Transmission substations identified in Applicability Section 4.1.1.
2. Review of the model used to conduct the risk assessment to ensure it contains sufficient system topology to identify Transmission stations and Transmission substations that if rendered inoperable or damaged could cause instability, uncontrolled separation, or Cascading within an Interconnection.
3. Review of the Requirement R1 risk assessment methodology.

This requirement provides the flexibility for a Transmission Owner to select from unaffiliated registered and non-registered entities with transmission planning or analysis experience to perform the verification of the Requirement R1 risk assessment. The term unaffiliated means that the selected verifying entity cannot be a corporate affiliate (*i.e.,* the verifying or third party reviewer cannot be an entity that corporately controls, is controlled by or is under common control with, the Transmission Owner). The verifying entity also cannot be a division of the Transmission Owner that operates as a functional unit.

The prohibition on registered entities using a corporate affiliate to conduct the verification, however, does not prohibit a governmental entity (e.g., a city, a municipality, a U.S. federal power marketing agency, or any other political subdivision of U.S. or Canadian federal, state, or provincial governments) from selecting as the verifying entity another governmental entity within the same political subdivision. For instance, a U.S. federal power marketing agency may select as its verifier another U.S. federal agency to conduct its verification so long as the selected entity has transmission planning or analysis experience. Similarly, a Transmission Owner owned by a Canadian province can use a separate agency of that province to perform the verification. The verifying entity, however, must still be a third party and cannot be a division of the registered entity that operates as a functional unit.

Requirement R2 also provides that the "verification may occur concurrent with or after the risk assessment performed under Requirement R1." This provision is designed to provide the Transmission Owner the flexibility to work with the verifying entity throughout (*i.e.,* concurrent with) the risk assessment, which for some Transmission Owners may be more efficient and effective. In other words, a Transmission Owner could collaborate with their unaffiliated verifying entity to perform the risk assessment under Requirement R1 such that both Requirement R1 and Requirement R2 are satisfied concurrently. The intent of Requirement R2 is to have an entity other than the owner or operator of the facility to be involved in the risk assessment process and have an opportunity to provide input. Accordingly, Requirement R2 is designed to allow entities the discretion to have a two-step process, where the Transmission Owner performs the risk assessment and subsequently has a third party review that assessment, or a one-step process, where the entity collaborates with a third party to perform the risk assessment.

Characteristics to consider in selecting a third party reviewer could include:

- Registered Entity with applicable planning and reliability functions.
- Experience in power system studies and planning.
- The entity's understanding of the MOD standards, TPL standards, and facility ratings as they pertain to planning studies.
- The entity's familiarity with the Interconnection within which the Transmission Owner is located.

With respect to the requirement that Transmission owners develop and implement procedures for protecting confidential and sensitive information, the Transmission Owner could have a method for identifying documents that require confidential treatment. One mechanism for protecting confidential or sensitive information is to prohibit removal of sensitive or confidential information from the Transmission Owner's site. Transmission Owners could include such a prohibition in a non-disclosure agreement with the verifying entity.

A Technical feasibility study is not required in the Requirement R2 documentation of the technical basis for not modifying the identification in accordance with the recommendation.

On the issue of the difference between a verifier in Requirement R2 and a reviewer in Requirement R6, the SDT indicates that the verifier will confirm that the risk assessment was completed in accordance with Requirement R1, including the number of Transmission stations and substations identified, while the reviewer in Requirement R6 is providing expertise on the manner in which the evaluation of threats was conducted in accordance with Requirement R4, and the physical security plan in accordance with Requirement R5. In the latter situation there is no verification of a technical analysis, rather an application of experience and expertise to provide guidance or recommendations, if needed.

Parts 2.4 and 6.4 require the entities to have procedures to protect the confidentiality of sensitive or confidential information. Those procedures may include the following elements:

1. Control and retention of information on site for third party verifiers/reviewers.
2. Only "need to know" employees, etc., get the information.
3. Marking documents as confidential

4. Securely storing and destroying information when no longer needed.
5. Not releasing information outside the entity without, for example, General Counsel sign-off.

Requirement R3

Some Transmission Operators will have obligations under this standard for certain primary control centers. Those obligations, however, are contingent upon a Transmission Owner first completing the risk assessment specified by Requirement R1 and the verification specified by Requirement R2. Requirement R3 is intended to ensure that a Transmission Operator that has operational control of a primary control center identified in Requirement R1 receive notice so that the Transmission Operator may fulfill the rest of the obligations required in Requirements R4 through R6. Since the timing obligations in Requirements R4 through R6 are based upon completion of Requirement R2, the Transmission Owner must also include within the notice the date of completion of Requirement R2. Similarly, the Transmission Owner must notify the Transmission Operator of any removals from identification that result from a subsequent risk assessment under Requirement R1 or as a result of the verification process under Requirement R2.

Requirement R4

This requirement requires owners and operators of facilities identified by the Requirement R1 risk assessment and that are verified under Requirement R2 to conduct an assessment of potential threats and vulnerabilities to those Transmission stations, Transmission substations, and primary control centers using a tailored evaluation process. Threats and vulnerabilities may vary from facility to facility based on any number of factors that include, but are not limited to, location, size, function, existing physical security protections, and attractiveness as a target.

In order to effectively conduct a threat and vulnerability assessment, the asset owner may be the best source to determine specific site vulnerabilities, but current and evolving threats may best be determined by others in the intelligence or law enforcement communities. A number of resources have been identified in the standard, but many others exist and asset owners are not limited to where they may turn for assistance. Additional resources may include state or local fusion centers, U.S. Department of Homeland Security, Federal Bureau of Investigations (FBI), Public Safety Canada, Royal Canadian Mounted Police, and InfraGard chapters coordinated by the FBI.

The Responsible Entity is required to take a number of factors into account in Parts 4.1 to 4.3 in order to make a risk-based evaluation under Requirement R4.

To assist in determining the current threat for a facility, the prior history of attacks on similarly protected facilities should be considered when assessing probability and likelihood of occurrence at the facility in question.

Resources that may be useful in conducting threat and vulnerability assessments include:

- NERC Security Guideline for the Electricity Sector: Physical Security.
- NERC Security Guideline: Physical Security Response.
- ASIS International General Risk Assessment Guidelines.
- ASIS International Facilities Physical Security Measure Guideline.
- ASIS International Security Management Standard: Physical Asset Protection.
- Whole Building Design Guide - Threat/Vulnerability Assessments.

Requirement R5

This requirement specifies development and implementation of a security plan(s) designed to protect against attacks to the facilities identified in Requirement R1 based on the assessment performed under Requirement R4.

Requirement R5 specifies the following attributes for the physical security plan:

- *Resiliency or security measures designed collectively to deter, detect, delay, assess, communicate, and respond to potential physical threats and vulnerabilities identified during the evaluation conducted in Requirement R4.*

  Resiliency may include, among other things:

  a. System topology changes,

  b. Spare equipment,

  c. Construction of a new Transmission station or Transmission substation.

  While most security measures will work together to collectively harden the entire site, some may be allocated to protect specific critical components. For example, if protection from gunfire is considered necessary, the entity may only install ballistic protection for critical components, not the entire site.

- *Law enforcement contact and coordination information.*

  Examples of such information may be posting 9-1-1 for emergency calls and providing substation safety and familiarization training for local and federal law enforcement, fire department, and Emergency Medical Services.

- *A timeline for executing the physical security enhancements and modifications specified in the physical security plan.*

  Entities have the flexibility to prioritize the implementation of the various resiliency or security enhancements and modifications in their security plan according to risk, resources, or other factors. The requirement to include a timeline in the physical security plan for executing the actual physical security enhancements and modifications does not also require that the enhancements and modifications be completed within

120 days. The actual timeline may extend beyond the 120 days, depending on the amount of work to be completed.

- *Provisions to evaluate evolving physical threats, and their corresponding security measures, to the Transmission station(s), Transmission substation(s), or primary control center(s).*

  A registered entity's physical security plan should include processes and responsibilities for obtaining and handling alerts, intelligence, and threat warnings from various sources. Some of these sources could include the ERO, ES-ISAC, and US and/or Canadian federal agencies. This information should be used to reevaluate or consider changes in the security plan and corresponding security measures of the security plan found in R5.

  Incremental changes made to the physical security plan prior to the next required third party review do not require additional third party reviews.

Requirement R6

This requirement specifies review by an entity other than the Transmission Owner or Transmission Operator with appropriate expertise for the evaluation performed according to Requirement R4 and the security plan(s) developed according to Requirement R5. As with Requirement R2, the term unaffiliated means that the selected third party reviewer cannot be a corporate affiliate (*i.e.,* the third party reviewer cannot be an entity that corporately controls, is controlled by or is under common control with, the Transmission Operator). A third party reviewer also cannot be a division of the Transmission Operator that operates as a functional unit.

As noted in the guidance for Requirement R2, the prohibition on registered entities using a corporate affiliate to conduct the review, however, does not prohibit a governmental entity from selecting as the third party reviewer another governmental entity within the same political subdivision. For instance, a city or municipality may use its local enforcement agency, so long as the local law enforcement agency satisfies the criteria in Requirement R6. The third party reviewer, however, must still be a third party and cannot be a division of the registered entity that operates as a functional unit.

The Responsible Entity can select from several possible entities to perform the review:

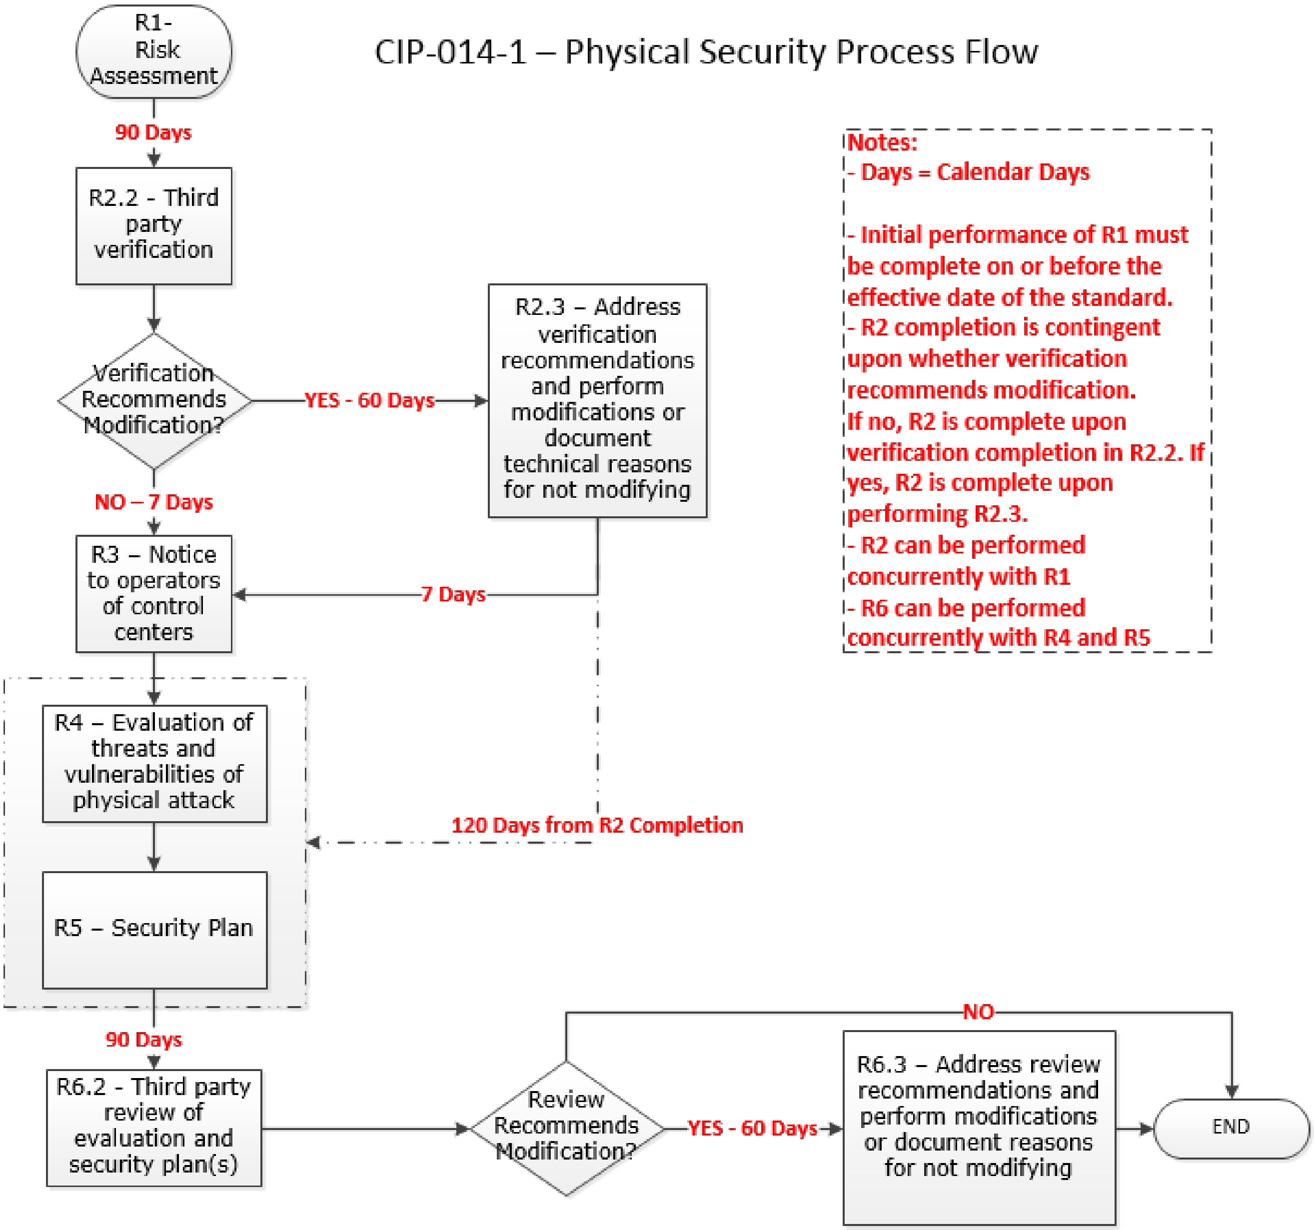
- *An entity or organization with electric industry physical security experience and whose review staff has at least one member who holds either a Certified Protection Professional (CPP) or Physical Security Professional (PSP) certification.*

  In selecting CPP and PSP for use in this standard, the SDT believed it was important that if a private entity such as a consulting or security firm was engaged to conduct the third party review, they must tangibly demonstrate competence to conduct the review. This includes electric industry physical security experience and either of the premier security industry certifications sponsored by ASIS International. The ASIS certification program was initiated in 1977, and those that hold the CPP certification are board certified in security management. Those that hold the PSP certification are board certified in physical security.

- *An entity or organization approved by the ERO.*
- *A governmental agency with physical security expertise.*
- *An entity or organization with demonstrated law enforcement, government, or military physical security expertise.*

As with the verification under Requirement R2, Requirement R6 provides that the "review may occur concurrently with or after completion of the evaluation performed under Requirement R4 and the security plan development under Requirement R5." This provision is designed to provide applicable Transmission Owners and Transmission Operators the flexibility to work with the third party reviewer throughout (*i.e.,* concurrent with) the evaluation performed according to Requirement R4 and the security plan(s) developed according to Requirement R5, which for some Responsible Entities may be more efficient and effective. In other words, a Transmission Owner or Transmission Operator could collaborate with their unaffiliated third party reviewer to perform an evaluation of potential threats and vulnerabilities (Requirement R4) and develop a security plan (Requirement R5) to satisfy Requirements R4 through R6 simultaneously. The intent of Requirement R6 is to have an entity other than the owner or operator of the facility to be involved in the Requirement R4 evaluation and the development of the Requirement R5 security plans and have an opportunity to provide input on the evaluation and the security plan. Accordingly, Requirement R6 is designed to allow entities the discretion to have a two-step process, where the Transmission Owner performs the evaluation and develops the security plan itself and then has a third party review that assessment, or a one-step process, where the entity collaborates with a third party to perform the evaluation and develop the security plan.

Timeline



CIP-014-1 – Physical Security Process Flow
R1- Risk Assessment
90 Days
R2.2 - Third party verification
Verification Recommends Modification?
YES - 60 Days
R2.3 – Address verification recommendations and perform modifications or document technical reasons for not modifying
NO – 7 Days
R3 – Notice to operators of control centers
7 Days
R4 – Evaluation of threats and vulnerabilities of physical attack
120 Days from R2 Completion
R5 – Security Plan
90 Days
R6.2 - Third party review of evaluation and security plan(s)
Review Recommends Modification?
YES - 60 Days
NO
R6.3 – Address review recommendations and perform modifications or document reasons for not modifying
END
Notes:
- Days = Calendar Days
- Initial performance of R1 must be complete on or before the effective date of the standard.
- R2 completion is contingent upon whether verification recommends modification.
If no, R2 is complete upon verification completion in R2.2. If yes, R2 is complete upon performing R2.3.
- R2 can be performed concurrently with R1
- R6 can be performed concurrently with R4 and R5

Rationale

During development of this standard, text boxes were embedded within the standard to explain the rationale for various parts of the standard. Upon BOT approval, the text from the rationale text boxes was moved to this section.

Rationale for Requirement R1:
This requirement meets the FERC directive from paragraph 6 of its March 7, 2014 order on physical security to perform a risk assessment to identify which facilities if rendered inoperable or damaged could impact an Interconnection through instability, uncontrolled separation, or cascading failures. The requirement is not intended to bring within the scope of the standard a Transmission station or Transmission substation unless the applicable Transmission Owner determines through technical studies and analyses based on objective analysis, technical expertise, operating experience and experienced judgment that the loss of such facility would have a critical impact on the operation of the Interconnection in the event the asset is rendered inoperable or damaged. In the November 20, 2014 Order, FERC reiterated that “only an instability that has a “critical impact on the operation of the interconnection” warrants finding that the facility causing the instability is critical under Requirement R1.” The Transmission Owner may determine the criteria for critical impact by considering, among other criteria, any of the following:

- Criteria or methodology used by Transmission Planners or Planning Coordinators in TPL-001-4, Requirement R6
- NERC EOP-004-2 reporting criteria
- Area or magnitude of potential impact

Requirement R1 also meets the FERC directive for periodic reevaluation of the risk assessment by requiring the risk assessment to be performed every 30 months (or 60 months for an entity that has not identified in a previous risk assessment any Transmission stations or Transmission substations that if rendered inoperable or damaged could result in instability, uncontrolled separation, or Cascading within an Interconnection).

After identifying each Transmission station and Transmission substation that meets the criteria in Requirement R1, it is important to additionally identify the primary control center that operationally controls that Transmission station or Transmission substation (*i.e.,* the control center whose electronic actions can cause direct physical actions at the identified Transmission station and Transmission substation, such as opening a breaker, compared to a control center that only has the ability to monitor the Transmission station and Transmission substation and, therefore, must coordinate direct physical action through another entity).

Rationale for Requirement R2:
This requirement meets the FERC directive from paragraph 11 in the order on physical security requiring verification by an entity other than the owner or operator of the risk assessment performed under Requirement R1.

This requirement provides the flexibility for a Transmission Owner to select registered and non-registered entities with transmission planning or analysis experience to perform the verification of the Requirement R1 risk assessment. The term "unaffiliated" means that the selected verifying entity cannot be a corporate affiliate (*i.e.*, the verifying entity cannot be an entity that controls, is controlled by, or is under common control with, the Transmission owner). The verifying entity also cannot be a division of the Transmission Owner that operates as a functional unit. The term "unaffiliated" is not intended to prohibit a governmental entity from using another government entity to be a verifier under Requirement R2.

Requirement R2 also provides the Transmission Owner the flexibility to work with the verifying entity throughout the Requirement R1 risk assessment, which for some Transmission Owners may be more efficient and effective. In other words, a Transmission Owner could coordinate with their unaffiliated verifying entity to perform a Requirement R1 risk assessment to satisfy both Requirement R1 and Requirement R2 concurrently.

Planning Coordinator is a functional entity listed in Part 2.1. The Planning Coordinator and Planning Authority are the same entity as shown in the NERC Glossary of Terms Used in NERC Reliability Standards.

Rationale for Requirement R3:
Some Transmission Operators will have obligations under this standard for certain primary control centers. Those obligations, however, are contingent upon a Transmission Owner first identifying which Transmission stations and Transmission substations meet the criteria specified by Requirement R1, as verified according to Requirement R2. This requirement is intended to ensure that a Transmission Operator that has operational control of a primary control center identified in Requirement R1, Part 1.2 of a Transmission station or Transmission substation verified according to Requirement R2 receives notice of such identification so that the Transmission Operator may timely fulfill its resulting obligations under Requirements R4 through R6. Since the timing obligations in Requirements R4 through R6 are based upon completion of Requirement R2, the Transmission Owner must also include notice of the date of completion of Requirement R2. Similarly, the Transmission Owner must notify the Transmission Operator of any removals from identification that result from a subsequent risk assessment under Requirement R1 or the verification process under Requirement R2.

Rationale for Requirement R4:
This requirement meets the FERC directive from paragraph 8 in the order on physical security that the reliability standard must require tailored evaluation of potential threats and vulnerabilities to facilities identified in Requirement R1 and verified according to Requirement R2. Threats and vulnerabilities may vary from facility to facility based on factors such as the facility's location, size, function, existing protections, and attractiveness of the target. As such, the requirement does not mandate a one-size-fits-all approach but requires entities to account for the unique characteristics of their facilities.

Requirement R4 does not explicitly state when the evaluation of threats and vulnerabilities must occur or be completed. However, Requirement R5 requires that the entity's security plan(s), which is dependent on the Requirement R4 evaluation, must be completed within 120 calendar days following completion of Requirement R2. Thus, an entity has the flexibility when to complete the Requirement R4 evaluation, provided that it is completed in time to comply with the requirement in Requirement R5 to develop a physical security plan 120 calendar days following completion of Requirement R2.

Rationale for Requirement R5:
This requirement meets the FERC directive from paragraph 9 in the order on physical security requiring the development and implementation of a security plan(s) designed to protect against attacks to the facilities identified in Requirement R1 based on the assessment performed under Requirement R4.

Rationale for Requirement R6:
This requirement meets the FERC directive from paragraph 11 in the order on physical security requiring review by an entity other than the owner or operator with appropriate expertise of the evaluation performed according to Requirement R4 and the security plan(s) developed according to Requirement R5.

As with the verification required by Requirement R2, Requirement R6 provides Transmission Owners and Transmission Operators the flexibility to work with the third party reviewer throughout the Requirement R4 evaluation and the development of the Requirement R5 security plan(s). This would allow entities to satisfy their obligations under Requirement R6 concurrent with the satisfaction of their obligations under Requirements R4 and R5.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	08/19/15
SAR posted for comment	08/20/15 – 09/21/15
45-day formal comment period with initial ballot	08/27/18 - 10/17/18

Anticipated Actions	Date
45-day formal comment period with additional ballot	June 2020
10-day final ballot	August 2020
NERC Board adoption	November 2020

Upon Board adoption, the rationale boxes will be moved to the Supplemental Material Section.

A. Introduction

1. **Title:** Physical Security
2. **Number:** CIP-014-3
3. **Purpose:** To identify and protect Transmission stations and Transmission substations, and their associated primary control centers, that if rendered inoperable or damaged as a result of a physical attack could result in instability, uncontrolled separation, or Cascading within an Interconnection.
4. **Applicability:**

4.1. Functional Entities:

4.1.1 Transmission Owner that owns a Transmission station or Transmission substation that meets any of the following criteria:

4.1.1.1 Transmission Facilities operated at 500 kV or higher. For the purpose of this criterion, the collector bus for a generation plant is not considered a Transmission Facility, but is part of the generation interconnection Facility.

4.1.1.2 Transmission Facilities that are operating between 200 kV and 499 kV at a single station or substation, where the station or substation is connected at 200 kV or higher voltages to three or more other Transmission stations or substations and has an "aggregate weighted value" exceeding 3000 according to the table below. The "aggregate weighted value" for a single station or substation is determined by summing the "weight value per line" shown in the table below for each incoming and each outgoing BES Transmission Line that is connected to another Transmission station or substation. For the purpose of this criterion, the collector bus for a generation plant is not considered a Transmission Facility, but is part of the generation interconnection Facility.

Voltage Value of a Line	Weight Value per Line
less than 200 kV (not applicable)	(not applicable)
200 kV to 299 kV	700
300 kV to 499 kV	1300
500 kV and above	0

4.1.1.3 Transmission Facilities at a single station or substation location that are identified by the ~~its Reliability Coordinator,~~ Planning Coordinator~~,~~ or Transmission Planner, per its Planning Assessment of the Near-Term Transmission Planning Horizon ~~or its Transfer Capability Assessment (Planning Coordinator only)~~ as Facilities that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation, that adversely impacts the reliability of the Bulk Electric System for planning events ~~as critical to the derivation of Interconnection Reliability Operating Limits (IROLs) and their associated contingencies~~.

4.1.1.4 Transmission Facilities identified as essential to meeting Nuclear Plant Interface Requirements.

4.1.2 Transmission Operator.

Exemption: Facilities in a "protected area," as defined in 10 C.F.R. § 73.2, within the scope of a security plan approved or accepted by the Nuclear Regulatory Commission are not subject to this Standard; or, Facilities within the scope of a security plan approved or accepted by the Canadian Nuclear Safety Commission are not subject to this Standard.

5. **Effective Dates: See Implementation Plan**

~~See Implementation Plan for CIP-014-32.~~

6. **Background:**

Reliability Standard CIP-014-~~2~~3 addresses the directives from the FERC order issued March 7, 2014, *Reliability Standards for Physical Security Measures*, 146 FERC ¶ 61,166 (2014), which required NERC to develop a physical security reliability standard(s) to identify and protect facilities that if rendered inoperable or damaged could result in instability, uncontrolled separation, or Cascading within an Interconnection.

B. Requirements and Measures

R1. Each Transmission Owner shall perform an initial risk assessment and subsequent risk assessments of its Transmission stations and Transmission substations (existing and planned to be in service within 24 months) that meet the criteria specified in Applicability Section 4.1.1. The initial and subsequent risk assessments shall consist of a transmission analysis or transmission analyses designed to identify the Transmission station(s) and Transmission substation(s) that if rendered inoperable or damaged could result in instability, uncontrolled separation, or Cascading within an Interconnection. *[VRF: High; Time-Horizon: Long-term Planning]*

1.1. Subsequent risk assessments shall be performed:

- At least once every 30 calendar months for a Transmission Owner that has identified in its previous risk assessment (as verified according to Requirement R2) one or more Transmission stations or Transmission substations that if rendered inoperable or damaged could result in instability, uncontrolled separation, or Cascading within an Interconnection; or

- At least once every 60 calendar months for a Transmission Owner that has not identified in its previous risk assessment (as verified according to Requirement R2) any Transmission stations or Transmission substations that if rendered inoperable or damaged could result in instability, uncontrolled separation, or Cascading within an Interconnection.

1.2. The Transmission Owner shall identify the primary control center that operationally controls each Transmission station or Transmission substation identified in the Requirement R1 risk assessment.

M1. Examples of acceptable evidence may include, but are not limited to, dated written or electronic documentation of the risk assessment of its Transmission stations and Transmission substations (existing and planned to be in service within 24 months) that meet the criteria in Applicability Section 4.1.1 as specified in Requirement R1. Additionally, examples of acceptable evidence may include, but are not limited to, dated written or electronic documentation of the identification of the primary control center that operationally controls each Transmission station or Transmission substation identified in the Requirement R1 risk assessment as specified in Requirement R1, Part 1.2.

R2. Each Transmission Owner shall have an unaffiliated third party verify the risk assessment performed under Requirement R1. The verification may occur concurrent with or after the risk assessment performed under Requirement R1. *[VRF: Medium; Time-Horizon: Long-term Planning]*

2.1. Each Transmission Owner shall select an unaffiliated verifying entity that is either:

- A registered Planning Coordinator, Transmission Planner, or Reliability Coordinator; or
- An entity that has transmission planning or analysis experience.

2.2. The unaffiliated third party verification shall verify the Transmission Owner's risk assessment performed under Requirement R1, which may include recommendations for the addition or deletion of a Transmission station(s) or Transmission substation(s). The Transmission Owner shall ensure the verification is completed within 90 calendar days following the completion of the Requirement R1 risk assessment.

2.3. If the unaffiliated verifying entity recommends that the Transmission Owner add a Transmission station(s) or Transmission substation(s) to, or remove a Transmission station(s) or Transmission substation(s) from, its identification under Requirement R1, the Transmission Owner shall either, within 60 calendar days of completion of the verification, for each recommended addition or removal of a Transmission station or Transmission substation:

- Modify its identification under Requirement R1 consistent with the recommendation; or
- Document the technical basis for not modifying the identification in accordance with the recommendation.

2.4. Each Transmission Owner shall implement procedures, such as the use of non-disclosure agreements, for protecting sensitive or confidential information made available to the unaffiliated third party verifier and to protect or exempt sensitive or confidential information developed pursuant to this Reliability Standard from public disclosure.

M2. Examples of acceptable evidence may include, but are not limited to, dated written or electronic documentation that the Transmission Owner completed an unaffiliated third party verification of the Requirement R1 risk assessment and satisfied all of the applicable provisions of Requirement R2, including, if applicable, documenting the technical basis for not modifying the Requirement R1 identification as specified under Part 2.3. Additionally, examples of evidence may include, but are not limited to, written or electronic documentation of procedures to protect information under Part 2.4.

R3. For a primary control center(s) identified by the Transmission Owner according to Requirement R1, Part 1.2 that a) operationally controls an identified Transmission station or Transmission substation verified according to Requirement R2, and b) is not under the operational control of the Transmission Owner: the Transmission Owner shall, within seven calendar days following completion of Requirement R2, notify the Transmission Operator that has operational control of the primary control center of

such identification and the date of completion of Requirement R2. *[VRF: Lower; Time-Horizon: Long-term Planning]*

3.1. If a Transmission station or Transmission substation previously identified under Requirement R1 and verified according to Requirement R2 is removed from the identification during a subsequent risk assessment performed according to Requirement R1 or a verification according to Requirement R2, then the Transmission Owner shall, within seven calendar days following the verification or the subsequent risk assessment, notify the Transmission Operator that has operational control of the primary control center of the removal.

M3. Examples of acceptable evidence may include, but are not limited to, dated written or electronic notifications or communications that the Transmission Owner notified each Transmission Operator, as applicable, according to Requirement R3.

R4. Each Transmission Owner that identified a Transmission station, Transmission substation, or a primary control center in Requirement R1 and verified according to Requirement R2, and each Transmission Operator notified by a Transmission Owner according to Requirement R3, shall conduct an evaluation of the potential threats and vulnerabilities of a physical attack to each of their respective Transmission station(s), Transmission substation(s), and primary control center(s) identified in Requirement R1 and verified according to Requirement R2. The evaluation shall consider the following: *[VRF: Medium; Time-Horizon: Operations Planning, Long-term Planning]*

4.1. Unique characteristics of the identified and verified Transmission station(s), Transmission substation(s), and primary control center(s);

4.2. Prior history of attack on similar facilities taking into account the frequency, geographic proximity, and severity of past physical security related events; and

4.3. Intelligence or threat warnings received from sources such as law enforcement, the Electric Reliability Organization (ERO), the Electricity Sector Information Sharing and Analysis Center (ES-ISAC), U.S. federal and/or Canadian governmental agencies, or their successors.

M4. Examples of evidence may include, but are not limited to, dated written or electronic documentation that the Transmission Owner or Transmission Operator conducted an evaluation of the potential threats and vulnerabilities of a physical attack to their respective Transmission station(s), Transmission substation(s) and primary control center(s) as specified in Requirement R4.

R5. Each Transmission Owner that identified a Transmission station, Transmission substation, or primary control center in Requirement R1 and verified according to Requirement R2, and each Transmission Operator notified by a Transmission Owner according to Requirement R3, shall develop and implement a documented physical security plan(s) that covers their respective Transmission station(s), Transmission substation(s), and primary control center(s). The physical security plan(s) shall be

developed within 120 calendar days following the completion of Requirement R2 and executed according to the timeline specified in the physical security plan(s). The physical security plan(s) shall include the following attributes: *[VRF: High; Time-Horizon: Long-term Planning]*

5.1. Resiliency or security measures designed collectively to deter, detect, delay, assess, communicate, and respond to potential physical threats and vulnerabilities identified during the evaluation conducted in Requirement R4.

5.2. Law enforcement contact and coordination information.

5.3. A timeline for executing the physical security enhancements and modifications specified in the physical security plan.

5.4. Provisions to evaluate evolving physical threats, and their corresponding security measures, to the Transmission station(s), Transmission substation(s), or primary control center(s).

M5. Examples of evidence may include, but are not limited to, dated written or electronic documentation of its physical security plan(s) that covers their respective identified and verified Transmission station(s), Transmission substation(s), and primary control center(s) as specified in Requirement R5, and additional evidence demonstrating execution of the physical security plan according to the timeline specified in the physical security plan.

R6. Each Transmission Owner that identified a Transmission station, Transmission substation, or primary control center in Requirement R1 and verified according to Requirement R2, and each Transmission Operator notified by a Transmission Owner according to Requirement R3, shall have an unaffiliated third party review the evaluation performed under Requirement R4 and the security plan(s) developed under Requirement R5. The review may occur concurrently with or after completion of the evaluation performed under Requirement R4 and the security plan development under Requirement R5. *[VRF: Medium; Time-Horizon: Long-term Planning]*

6.1. Each Transmission Owner and Transmission Operator shall select an unaffiliated third party reviewer from the following:

- An entity or organization with electric industry physical security experience and whose review staff has at least one member who holds either a Certified Protection Professional (CPP) or Physical Security Professional (PSP) certification.
- An entity or organization approved by the ERO.
- A governmental agency with physical security expertise.

- An entity or organization with demonstrated law enforcement, government, or military physical security expertise.

6.2. The Transmission Owner or Transmission Operator, respectively, shall ensure that the unaffiliated third party review is completed within 90 calendar days of completing the security plan(s) developed in Requirement R5. The unaffiliated third party review may, but is not required to, include recommended changes to the evaluation performed under Requirement R4 or the security plan(s) developed under Requirement R5.

6.3. If the unaffiliated third party reviewer recommends changes to the evaluation performed under Requirement R4 or security plan(s) developed under Requirement R5, the Transmission Owner or Transmission Operator shall, within 60 calendar days of the completion of the unaffiliated third party review, for each recommendation:

- Modify its evaluation or security plan(s) consistent with the recommendation; or
- Document the reason(s) for not modifying the evaluation or security plan(s) consistent with the recommendation.

6.4. Each Transmission Owner and Transmission Operator shall implement procedures, such as the use of non-disclosure agreements, for protecting sensitive or confidential information made available to the unaffiliated third party reviewer and to protect or exempt sensitive or confidential information developed pursuant to this Reliability Standard from public disclosure.

M6. Examples of evidence may include, but are not limited to, written or electronic documentation that the Transmission Owner or Transmission Operator had an unaffiliated third party review the evaluation performed under Requirement R4 and the security plan(s) developed under Requirement R5 as specified in Requirement R6 including, if applicable, documenting the reasons for not modifying the evaluation or security plan(s) in accordance with a recommendation under Part 6.3. Additionally, examples of evidence may include, but are not limited to, written or electronic documentation of procedures to protect information under Part 6.4.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

As defined in the NERC Rules of Procedure, "Compliance Enforcement Authority" (CEA) means NERC or the Regional Entity in their respective roles of monitoring and enforcing compliance with the NERC Reliability Standards.

1.2. Evidence Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the CEA may ask an entity to provide other evidence during an on-site visit to show that it was compliant for the full time period since the last audit.

The Transmission Owner and Transmission Operator shall keep data or evidence to show compliance, as identified below, unless directed by its Compliance Enforcement Authority (CEA) to retain specific evidence for a longer period of time as part of an investigation.

The responsible entities shall retain documentation as evidence for three years.

If a Responsible Entity is found non-compliant, it shall keep information related to the non-compliance until mitigation is complete and approved, or for the time specified above, whichever is longer.

The CEA shall keep the last audit records and all requested and submitted subsequent audit records, subject to the confidentiality provisions of Section 1500 of the Rules of Procedure and the provisions of Section 1.4 below.

1.3. Compliance Monitoring and Assessment Processes:

Compliance Audits

Self-Certifications

Spot Checking

Compliance Violation Investigations

Self-Reporting

Complaints Text

1.4. Additional Compliance Information

Confidentiality: To protect the confidentiality and sensitive nature of the evidence for demonstrating compliance with this standard, all evidence will be retained at the Transmission Owner's and Transmission Operator's facilities.

2. Table of Compliance Elements

R #	Time Horizon	VRF	Violation Severity Levels (CIP-014-1)			
			Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	Long-term Planning	High	The Transmission Owner performed an initial risk assessment but did so after the date specified in the implementation plan for performing the initial risk assessment but less than or equal to two calendar months after that date; OR The Transmission Owner that has identified in its previous risk assessment one or more Transmission stations or Transmission substations that if rendered inoperable or damaged could	The Transmission Owner performed an initial risk assessment but did so more than two calendar months after the date specified in the implementation plan for performing the initial risk assessment but less than or equal to four calendar months after that date; OR The Transmission Owner that has identified in its previous risk assessment one or more Transmission stations or Transmission substations that if rendered inoperable	The Transmission Owner performed an initial risk assessment but did so more than four calendar months after the date specified in the implementation plan for performing the initial risk assessment but less than or equal to six calendar months after that date; OR The Transmission Owner that has identified in its previous risk assessment one or more Transmission stations or Transmission substations that if rendered inoperable or damaged could	The Transmission Owner performed an initial risk assessment but did so more than six calendar months after the date specified in the implementation plan for performing the initial risk assessment; OR The Transmission Owner failed to perform an initial risk assessment; OR The Transmission Owner that has identified in its previous risk assessment one or more Transmission

Guidelines and Technical Basis

Section 4 Applicability

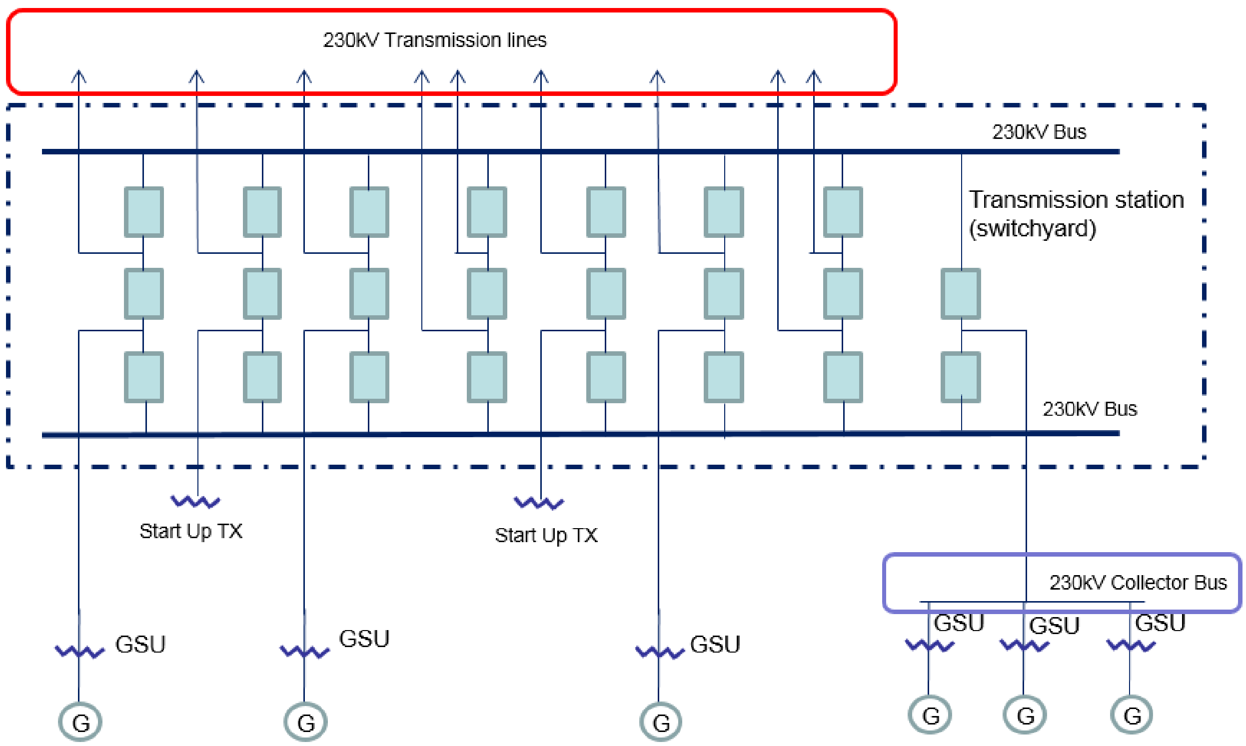
The purpose of Reliability Standard CIP-014 is to protect Transmission stations and Transmission substations, and their associated primary control centers that if rendered inoperable or damaged as a result of a physical attack could result in instability, uncontrolled separation, or Cascading within an Interconnection. To properly include those entities that own or operate such Facilities, the Reliability Standard CIP-014 first applies to Transmission Owners that own Transmission Facilities that meet the specific criteria in Applicability Section 4.1.1.1 through 4.1.1.4. The Facilities described in Applicability Section 4.1.1.1 through 4.1.1.4 mirror those Transmission Facilities that meet the bright line criteria for "Medium Impact" Transmission Facilities under Attachment 1 of Reliability Standard CIP-002-5.1. Each Transmission Owner that owns Transmission Facilities that meet the criteria in Section 4.1.1.1 through 4.1.1.4 is required to perform a risk assessment as specified in Requirement R1 to identify its Transmission stations and Transmission substations, and their associated primary control centers, that if rendered inoperable or damaged as a result of a physical attack could result in instability, uncontrolled separation, or Cascading within an Interconnection. The Standard Drafting Team (SDT) expects this population will be small and that many Transmission Owners that meet the applicability of this standard will not actually identify any such Facilities. Only those Transmission Owners with Transmission stations or Transmission substations identified in the risk assessment (and verified under Requirement R2) have performance obligations under Requirements R3 through R6.

This standard also applies to Transmission Operators. A Transmission Operator's obligations under the standard, however, are only triggered if the Transmission Operator is notified by an applicable Transmission Owner under Requirement R3 that the Transmission Operator operates a primary control center that operationally controls a Transmission station(s) or Transmission substation(s) identified in the Requirement R1 risk assessment. A primary control center operationally controls a Transmission station or Transmission substation when the control center's electronic actions can cause direct physical action at the identified Transmission station or Transmission substation, such as opening a breaker, as opposed to a control center that only has information from the Transmission station or Transmission substation and must coordinate direct action through another entity. Only Transmission Operators who are notified that they have primary control centers under this standard have performance obligations under Requirements R4 through R6. In other words, primary control center for purposes of this Standard is the control center that the Transmission Owner or Transmission Operator, respectively, uses as its primary, permanently-manned site to physically operate a Transmission station or Transmission substation that is identified in Requirement R1 and verified in Requirement R2. Control centers that provide back-up capability are not applicable, as they are a form of resiliency and intentionally redundant.

The SDT considered several options for bright line criteria that could be used to determine applicability and provide an initial threshold that defines the set of Transmission stations and Transmission substations that would meet the directives of the FERC order on physical security

(*i.e.*, those that could cause instability, uncontrolled separation, or Cascading within an Interconnection). The SDT determined that using the criteria for Medium Impact Transmission Facilities in Attachment 1 of CIP-002-5.1 would provide a conservative threshold for defining which Transmission stations and Transmission substations must be included in the risk assessment in Requirement R1 of CIP-014. Additionally, the SDT concluded that using the CIP-002-5.1 Medium Impact criteria was appropriate because it has been approved by stakeholders, NERC, and FERC, and its use provides a technically sound basis to determine which Transmission Owners should conduct the risk assessment. As described in CIP-002-5.1, the failure of a Transmission station or Transmission substation that meets the Medium Impact criteria could have the capability to result in ~~exceeding one or more Interconnection Reliability Operating Limits (IROLs)~~instability, Cascading~~uncontrolled separation~~, or uncontrolled separation ~~Cascading~~that adversely impact the reliability of the Bulk Electric System for planning events. The SDT understands that using this bright line criteria to determine applicability may require some Transmission Owners to perform risk assessments under Requirement R1 that will result in a finding that none of their Transmission stations or Transmission substations would pose a risk of instability, uncontrolled separation, or Cascading within an Interconnection. However, the SDT determined that higher bright lines could not be technically justified to ensure inclusion of all Transmission stations and Transmission substations, and their associated primary control centers that, if rendered inoperable or damaged as a result of a physical attack could result in instability, uncontrolled separation, or Cascading within an Interconnection. Further guidance and technical basis for the bright line criteria for Medium Impact Facilities can be found in the Guidelines and Technical Basis section of CIP-002-5.1.

Additionally, the SDT determined that it was not necessary to include Generator Operators and Generator Owners in the Reliability Standard. First, Transmission stations or Transmission substations interconnecting generation facilities are considered when determining applicability. Transmission Owners will consider those Transmission stations and Transmission substations that include a Transmission station on the high side of the Generator Step-up transformer (GSU) using Applicability Section 4.1.1.1 and 4.1.1.2. As an example, a Transmission station or Transmission substation identified as a Transmission Owner facility that interconnects generation will be subject to the Requirement R1 risk assessment if it operates at 500kV or greater or if it is connected at 200 kV – 499kV to three or more other Transmission stations or Transmission substations and has an "aggregate weighted value" exceeding 3000 according to the table in Applicability Section 4.1.1.2. Second, the Transmission analysis or analyses conducted under Requirement R1 should take into account the impact of the loss of generation connected to applicable Transmission stations or Transmission substations. Additionally, the FERC order does not explicitly mention generation assets and is reasonably understood to focus on the most critical Transmission Facilities. The diagram below shows an example of a station.



Also, the SDT uses the phrase "Transmission stations or Transmission substations" to recognize the existence of both stations and substations. Many entities in industry consider a substation to be a location with physical borders (i.e. fence, wall, etc.) that contains at least an autotransformer. Locations also exist that do not contain autotransformers, and many entities in industry refer to those locations as stations (switching stations or switchyards). Therefore, the SDT chose to use both "station" and "substation" to refer to the locations where groups of Transmission Facilities exist.

On the issue of joint ownership, the SDT recognizes that this issue is not unique to CIP-014, and expects that the applicable Transmission Owners and Transmission Operators will develop memorandums of understanding, agreements, Coordinated Functional Registrations, or procedures, etc., to designate responsibilities under CIP-014 when joint ownership is at issue, which is similar to what many entities have completed for other Reliability Standards.

The language contained in the applicability section regarding the collector bus is directly copied from CIP-002-5.1, Attachment 1, and has no additional meaning within the CIP-014 standard.

Requirement R1

The initial risk assessment required under Requirement R1 must be completed on or before the effective date of the standard. Subsequent risk assessments are to be performed at least once every 30 or 60 months depending on the results of the previous risk assessment per Requirement R1, Part 1.1. In performing the risk assessment under Requirement R1, the Transmission Owner should first identify their population of Transmission stations and Transmission substations that meet the criteria contained in Applicability Section 4.1.1. Requirement R1 then requires the Transmission Owner to perform a risk assessment, consisting of a transmission analysis, to determine which of those Transmission stations and Transmission Substations if rendered inoperable or damaged could result in instability, uncontrolled separation, or Cascading within an Interconnection. The requirement is not to require identification of, and thus, not intended to bring within the scope of the standard a Transmission station or Transmission substation unless the applicable Transmission Owner determines through technical studies and analyses based on objective analysis, technical expertise, operating experience and experienced judgment that the loss of such facility would have a critical impact on the operation of the Interconnection in the event the asset is rendered inoperable or damaged. In the November 20, 2014 Order, FERC reiterated that "only an instability that has a "critical impact on the operation of the interconnection" warrants finding that the facility causing the instability is critical under Requirement R1." The Transmission Owner may determine the criteria for critical impact by considering, among other criteria, any of the following:

- Criteria or methodology used by Transmission Planners or Planning Coordinators in TPL-001-4, Requirement R6
- NERC EOP-004-2 reporting criteria
- Area or magnitude of potential impact

The standard does not mandate the specific analytical method for performing the risk assessment. The Transmission Owner has the discretion to choose the specific method that best suites its needs. As an example, an entity may perform a Power Flow analysis and stability analysis at a variety of load levels.

Performing Risk Assessments

The Transmission Owner has the discretion to select a transmission analysis method that fits its facts and system circumstances. To mandate a specific approach is not technically desirable and may lead to results that fail to adequately consider regional, topological, and system circumstances. The following guidance is only an example on how a Transmission Owner may perform a power flow and/or stability analysis to identify those Transmission stations and Transmission substations that if rendered inoperable or damaged as a result of a physical attack could result in instability, uncontrolled separation, or Cascading within an Interconnection. An entity could remove all lines, without regard to the voltage level, to a single Transmission station or Transmission substation and review the simulation results to assess system behavior to determine if Cascading of Transmission Facilities, uncontrolled separation, or voltage or frequency instability is likely to occur over a significant area of the Interconnection. Using engineering judgment, the Transmission Owner (possibly in consultation with regional planning or operation committees and/or ISO/RTO committee input) should develop criteria (e.g.

imposing a fault near the removed Transmission station or Transmission substation) to identify a contingency or parameters that result in potential instability, uncontrolled separation, or Cascading within an Interconnection. Regional consultation on these matters is likely to be helpful and informative, given that the inputs for the risk assessment and the attributes of what constitutes instability, uncontrolled separation, or Cascading within an Interconnection will likely vary from region-to-region or from ISO-to-ISO based on topology, system characteristics, and system configurations. Criteria could also include post-contingency facilities loadings above a certain emergency rating or failure of a power flow case to converge. Available special protection systems (SPS), if any, could be applied to determine if the system experiences any additional instability which may result in uncontrolled separation. Example criteria may include:

(a) Thermal overloads beyond facility emergency ratings;

(b) Voltage deviation exceeding ± 10%; or

(c) Cascading outage/voltage collapse; or

(d) Frequency below under-frequency load shed points

Periodicity

A Transmission Owner who identifies one or more Transmission stations or Transmission substations (as verified under Requirement R2) that if rendered inoperable or damaged could result in instability, uncontrolled separation, or Cascading within an Interconnection is required to conduct a risk assessment at least once every 30 months. This period ensures that the risk assessment remains current with projected conditions and configurations in the planned system. This risk assessment, as the initial assessment, must consider applicable planned Transmission stations and Transmission substations to be in service within 24 months. The 30 month timeframe aligns with the 24 month planned to be in service date because the Transmission Owner is provided the flexibility, depending on its planning cycle and the frequency in which it may plan to construct a new Transmission station or Transmission substation to more closely align these dates. The requirement is to conduct the risk assessment at least once every 30 months, so for a Transmission Owner that believes it is better to conduct a risk assessment once every 24 months, because of its planning cycle, it has the flexibility to do so.

Transmission Owners that have not identified any Transmission stations or Transmission substations (as verified under Requirement R2) that if rendered inoperable or damaged could result in instability, uncontrolled separation, or Cascading within an Interconnection are unlikely to see changes to their risk assessment in the Near-Term Planning Horizon. Consequently, a 60 month periodicity for completing a subsequent risk assessment is specified.

Identification of Primary Control Centers

After completing the risk assessment specified in Requirement R1, it is important to additionally identify the primary control center that operationally controls each Transmission station or

Transmission substation that if rendered inoperable or damaged could result in instability, uncontrolled separation, or Cascading within an Interconnection. A primary control center "operationally controls" a Transmission station or Transmission substation when the control center's electronic actions can cause direct physical actions at the identified Transmission station and Transmission substation, such as opening a breaker.

Requirement R2

This requirement specifies verification of the risk assessment performed under Requirement R1 by an entity other than the owner or operator of the Requirement R1 risk assessment.

A verification of the risk assessment by an unaffiliated third party, as specified in Requirement R2, could consist of:

1. Certifying that the Requirement R1 risk assessment considers the Transmission stations and Transmission substations identified in Applicability Section 4.1.1.
2. Review of the model used to conduct the risk assessment to ensure it contains sufficient system topology to identify Transmission stations and Transmission substations that if rendered inoperable or damaged could cause instability, uncontrolled separation, or Cascading within an Interconnection.
3. Review of the Requirement R1 risk assessment methodology.

This requirement provides the flexibility for a Transmission Owner to select from unaffiliated registered and non-registered entities with transmission planning or analysis experience to perform the verification of the Requirement R1 risk assessment. The term unaffiliated means that the selected verifying entity cannot be a corporate affiliate (*i.e.,* the verifying or third party reviewer cannot be an entity that corporately controls, is controlled by or is under common control with, the Transmission Owner). The verifying entity also cannot be a division of the Transmission Owner that operates as a functional unit.

The prohibition on registered entities using a corporate affiliate to conduct the verification, however, does not prohibit a governmental entity (e.g., a city, a municipality, a U.S. federal power marketing agency, or any other political subdivision of U.S. or Canadian federal, state, or provincial governments) from selecting as the verifying entity another governmental entity within the same political subdivision. For instance, a U.S. federal power marketing agency may select as its verifier another U.S. federal agency to conduct its verification so long as the selected entity has transmission planning or analysis experience. Similarly, a Transmission Owner owned by a Canadian province can use a separate agency of that province to perform the verification. The verifying entity, however, must still be a third party and cannot be a division of the registered entity that operates as a functional unit.

Requirement R2 also provides that the "verification may occur concurrent with or after the risk assessment performed under Requirement R1." This provision is designed to provide the

Transmission Owner the flexibility to work with the verifying entity throughout (*i.e.,* concurrent with) the risk assessment, which for some Transmission Owners may be more efficient and effective. In other words, a Transmission Owner could collaborate with their unaffiliated verifying entity to perform the risk assessment under Requirement R1 such that both Requirement R1 and Requirement R2 are satisfied concurrently. The intent of Requirement R2 is to have an entity other than the owner or operator of the facility to be involved in the risk assessment process and have an opportunity to provide input. Accordingly, Requirement R2 is designed to allow entities the discretion to have a two-step process, where the Transmission Owner performs the risk assessment and subsequently has a third party review that assessment, or a one-step process, where the entity collaborates with a third party to perform the risk assessment.

Characteristics to consider in selecting a third party reviewer could include:

- Registered Entity with applicable planning and reliability functions.
- Experience in power system studies and planning.
- The entity's understanding of the MOD standards, TPL standards, and facility ratings as they pertain to planning studies.
- The entity's familiarity with the Interconnection within which the Transmission Owner is located.

With respect to the requirement that Transmission owners develop and implement procedures for protecting confidential and sensitive information, the Transmission Owner could have a method for identifying documents that require confidential treatment. One mechanism for protecting confidential or sensitive information is to prohibit removal of sensitive or confidential information from the Transmission Owner's site. Transmission Owners could include such a prohibition in a non-disclosure agreement with the verifying entity.

A Technical feasibility study is not required in the Requirement R2 documentation of the technical basis for not modifying the identification in accordance with the recommendation.

On the issue of the difference between a verifier in Requirement R2 and a reviewer in Requirement R6, the SDT indicates that the verifier will confirm that the risk assessment was completed in accordance with Requirement R1, including the number of Transmission stations and substations identified, while the reviewer in Requirement R6 is providing expertise on the manner in which the evaluation of threats was conducted in accordance with Requirement R4, and the physical security plan in accordance with Requirement R5. In the latter situation there is no verification of a technical analysis, rather an application of experience and expertise to provide guidance or recommendations, if needed.

Parts 2.4 and 6.4 require the entities to have procedures to protect the confidentiality of sensitive or confidential information. Those procedures may include the following elements:

1. Control and retention of information on site for third party verifiers/reviewers.

2. Only “need to know” employees, etc., get the information.
3. Marking documents as confidential
4. Securely storing and destroying information when no longer needed.
5. Not releasing information outside the entity without, for example, General Counsel sign-off.

Requirement R3

Some Transmission Operators will have obligations under this standard for certain primary control centers. Those obligations, however, are contingent upon a Transmission Owner first completing the risk assessment specified by Requirement R1 and the verification specified by Requirement R2. Requirement R3 is intended to ensure that a Transmission Operator that has operational control of a primary control center identified in Requirement R1 receive notice so that the Transmission Operator may fulfill the rest of the obligations required in Requirements R4 through R6. Since the timing obligations in Requirements R4 through R6 are based upon completion of Requirement R2, the Transmission Owner must also include within the notice the date of completion of Requirement R2. Similarly, the Transmission Owner must notify the Transmission Operator of any removals from identification that result from a subsequent risk assessment under Requirement R1 or as a result of the verification process under Requirement R2.

Requirement R4

This requirement requires owners and operators of facilities identified by the Requirement R1 risk assessment and that are verified under Requirement R2 to conduct an assessment of potential threats and vulnerabilities to those Transmission stations, Transmission substations, and primary control centers using a tailored evaluation process. Threats and vulnerabilities may vary from facility to facility based on any number of factors that include, but are not limited to, location, size, function, existing physical security protections, and attractiveness as a target.

In order to effectively conduct a threat and vulnerability assessment, the asset owner may be the best source to determine specific site vulnerabilities, but current and evolving threats may best be determined by others in the intelligence or law enforcement communities. A number of resources have been identified in the standard, but many others exist and asset owners are not limited to where they may turn for assistance. Additional resources may include state or local fusion centers, U.S. Department of Homeland Security, Federal Bureau of Investigations (FBI), Public Safety Canada, Royal Canadian Mounted Police, and InfraGard chapters coordinated by the FBI.

The Responsible Entity is required to take a number of factors into account in Parts 4.1 to 4.3 in order to make a risk-based evaluation under Requirement R4.

To assist in determining the current threat for a facility, the prior history of attacks on similarly protected facilities should be considered when assessing probability and likelihood of occurrence at the facility in question.

Resources that may be useful in conducting threat and vulnerability assessments include:

- NERC Security Guideline for the Electricity Sector: Physical Security.
- NERC Security Guideline: Physical Security Response.
- ASIS International General Risk Assessment Guidelines.
- ASIS International Facilities Physical Security Measure Guideline.
- ASIS International Security Management Standard: Physical Asset Protection.
- Whole Building Design Guide - Threat/Vulnerability Assessments.

Requirement R5

This requirement specifies development and implementation of a security plan(s) designed to protect against attacks to the facilities identified in Requirement R1 based on the assessment performed under Requirement R4.

Requirement R5 specifies the following attributes for the physical security plan:

- *Resiliency or security measures designed collectively to deter, detect, delay, assess, communicate, and respond to potential physical threats and vulnerabilities identified during the evaluation conducted in Requirement R4.*

  Resiliency may include, among other things:

  a. System topology changes,

  b. Spare equipment,

  c. Construction of a new Transmission station or Transmission substation.

  While most security measures will work together to collectively harden the entire site, some may be allocated to protect specific critical components. For example, if protection from gunfire is considered necessary, the entity may only install ballistic protection for critical components, not the entire site.

- *Law enforcement contact and coordination information.*

  Examples of such information may be posting 9-1-1 for emergency calls and providing substation safety and familiarization training for local and federal law enforcement, fire department, and Emergency Medical Services.

- *A timeline for executing the physical security enhancements and modifications specified in the physical security plan.*

Entities have the flexibility to prioritize the implementation of the various resiliency or security enhancements and modifications in their security plan according to risk, resources, or other factors. The requirement to include a timeline in the physical security plan for executing the actual physical security enhancements and modifications does not also require that the enhancements and modifications be completed within 120 days. The actual timeline may extend beyond the 120 days, depending on the amount of work to be completed.

- *Provisions to evaluate evolving physical threats, and their corresponding security measures, to the Transmission station(s), Transmission substation(s), or primary control center(s).*

  A registered entity's physical security plan should include processes and responsibilities for obtaining and handling alerts, intelligence, and threat warnings from various sources. Some of these sources could include the ERO, ES-ISAC, and US and/or Canadian federal agencies. This information should be used to reevaluate or consider changes in the security plan and corresponding security measures of the security plan found in R5.

  Incremental changes made to the physical security plan prior to the next required third party review do not require additional third party reviews.

Requirement R6

This requirement specifies review by an entity other than the Transmission Owner or Transmission Operator with appropriate expertise for the evaluation performed according to Requirement R4 and the security plan(s) developed according to Requirement R5. As with Requirement R2, the term unaffiliated means that the selected third party reviewer cannot be a corporate affiliate (*i.e.,* the third party reviewer cannot be an entity that corporately controls, is controlled by or is under common control with, the Transmission Operator). A third party reviewer also cannot be a division of the Transmission Operator that operates as a functional unit.

As noted in the guidance for Requirement R2, the prohibition on registered entities using a corporate affiliate to conduct the review, however, does not prohibit a governmental entity from selecting as the third party reviewer another governmental entity within the same political subdivision. For instance, a city or municipality may use its local enforcement agency, so long as the local law enforcement agency satisfies the criteria in Requirement R6. The third party reviewer, however, must still be a third party and cannot be a division of the registered entity that operates as a functional unit.

The Responsible Entity can select from several possible entities to perform the review:

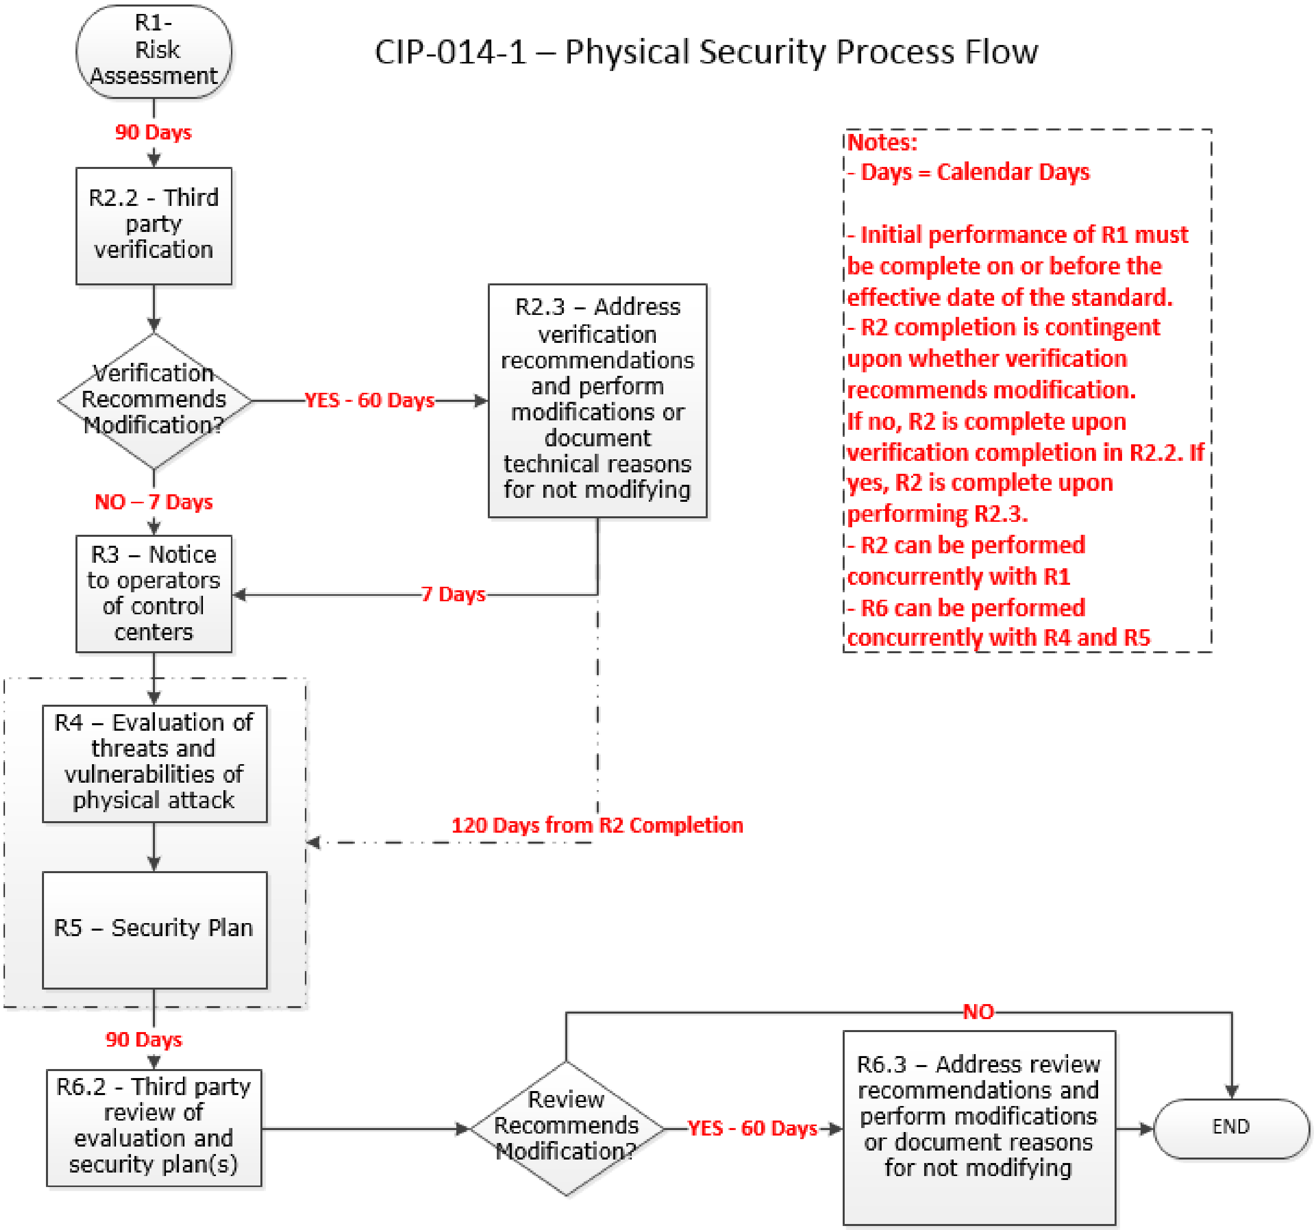
- *An entity or organization with electric industry physical security experience and whose review staff has at least one member who holds either a Certified Protection Professional (CPP) or Physical Security Professional (PSP) certification.*

In selecting CPP and PSP for use in this standard, the SDT believed it was important that if a private entity such as a consulting or security firm was engaged to conduct the third party review, they must tangibly demonstrate competence to conduct the review. This includes electric industry physical security experience and either of the premier security industry certifications sponsored by ASIS International. The ASIS certification program was initiated in 1977, and those that hold the CPP certification are board certified in security management. Those that hold the PSP certification are board certified in physical security.

- *An entity or organization approved by the ERO.*
- *A governmental agency with physical security expertise.*
- *An entity or organization with demonstrated law enforcement, government, or military physical security expertise.*

As with the verification under Requirement R2, Requirement R6 provides that the "review may occur concurrently with or after completion of the evaluation performed under Requirement R4 and the security plan development under Requirement R5." This provision is designed to provide applicable Transmission Owners and Transmission Operators the flexibility to work with the third party reviewer throughout (*i.e.,* concurrent with) the evaluation performed according to Requirement R4 and the security plan(s) developed according to Requirement R5, which for some Responsible Entities may be more efficient and effective. In other words, a Transmission Owner or Transmission Operator could collaborate with their unaffiliated third party reviewer to perform an evaluation of potential threats and vulnerabilities (Requirement R4) and develop a security plan (Requirement R5) to satisfy Requirements R4 through R6 simultaneously. The intent of Requirement R6 is to have an entity other than the owner or operator of the facility to be involved in the Requirement R4 evaluation and the development of the Requirement R5 security plans and have an opportunity to provide input on the evaluation and the security plan. Accordingly, Requirement R6 is designed to allow entities the discretion to have a two-step process, where the Transmission Owner performs the evaluation and develops the security plan itself and then has a third party review that assessment, or a one-step process, where the entity collaborates with a third party to perform the evaluation and develop the security plan.

Timeline



CIP-014-1 – Physical Security Process Flow
R1- Risk Assessment
90 Days
R2.2 - Third party verification
Verification Recommends Modification?
YES - 60 Days
R2.3 – Address verification recommendations and perform modifications or document technical reasons for not modifying
NO – 7 Days
R3 – Notice to operators of control centers
7 Days
R4 – Evaluation of threats and vulnerabilities of physical attack
120 Days from R2 Completion
R5 – Security Plan
90 Days
R6.2 - Third party review of evaluation and security plan(s)
Review Recommends Modification?
NO
YES - 60 Days
R6.3 – Address review recommendations and perform modifications or document reasons for not modifying
END
Notes:
- Days = Calendar Days
- Initial performance of R1 must be complete on or before the effective date of the standard.
- R2 completion is contingent upon whether verification recommends modification.
If no, R2 is complete upon verification completion in R2.2. If yes, R2 is complete upon performing R2.3.
- R2 can be performed concurrently with R1
- R6 can be performed concurrently with R4 and R5

Rationale

During development of this standard, text boxes were embedded within the standard to explain the rationale for various parts of the standard. Upon BOT approval, the text from the rationale text boxes was moved to this section.

Rationale for Requirement R1:
This requirement meets the FERC directive from paragraph 6 of its March 7, 2014 order on physical security to perform a risk assessment to identify which facilities if rendered inoperable or damaged could impact an Interconnection through instability, uncontrolled separation, or cascading failures. The requirement is not intended to bring within the scope of the standard a Transmission station or Transmission substation unless the applicable Transmission Owner determines through technical studies and analyses based on objective analysis, technical expertise, operating experience and experienced judgment that the loss of such facility would have a critical impact on the operation of the Interconnection in the event the asset is rendered inoperable or damaged. In the November 20, 2014 Order, FERC reiterated that "only an instability that has a "critical impact on the operation of the interconnection" warrants finding that the facility causing the instability is critical under Requirement R1." The Transmission Owner may determine the criteria for critical impact by considering, among other criteria, any of the following:

- Criteria or methodology used by Transmission Planners or Planning Coordinators in TPL-001-4, Requirement R6
- NERC EOP-004-2 reporting criteria
- Area or magnitude of potential impact

Requirement R1 also meets the FERC directive for periodic reevaluation of the risk assessment by requiring the risk assessment to be performed every 30 months (or 60 months for an entity that has not identified in a previous risk assessment any Transmission stations or Transmission substations that if rendered inoperable or damaged could result in instability, uncontrolled separation, or Cascading within an Interconnection).

After identifying each Transmission station and Transmission substation that meets the criteria in Requirement R1, it is important to additionally identify the primary control center that operationally controls that Transmission station or Transmission substation (*i.e.,* the control center whose electronic actions can cause direct physical actions at the identified Transmission station and Transmission substation, such as opening a breaker, compared to a control center that only has the ability to monitor the Transmission station and Transmission substation and, therefore, must coordinate direct physical action through another entity).

Rationale for Requirement R2:
This requirement meets the FERC directive from paragraph 11 in the order on physical security requiring verification by an entity other than the owner or operator of the risk assessment performed under Requirement R1.

This requirement provides the flexibility for a Transmission Owner to select registered and non-registered entities with transmission planning or analysis experience to perform the verification of the Requirement R1 risk assessment. The term “unaffiliated” means that the selected verifying entity cannot be a corporate affiliate (*i.e.*, the verifying entity cannot be an entity that controls, is controlled by, or is under common control with, the Transmission owner). The verifying entity also cannot be a division of the Transmission Owner that operates as a functional unit. The term “unaffiliated” is not intended to prohibit a governmental entity from using another government entity to be a verifier under Requirement R2.

Requirement R2 also provides the Transmission Owner the flexibility to work with the verifying entity throughout the Requirement R1 risk assessment, which for some Transmission Owners may be more efficient and effective. In other words, a Transmission Owner could coordinate with their unaffiliated verifying entity to perform a Requirement R1 risk assessment to satisfy both Requirement R1 and Requirement R2 concurrently.

Planning Coordinator is a functional entity listed in Part 2.1. The Planning Coordinator and Planning Authority are the same entity as shown in the NERC Glossary of Terms Used in NERC Reliability Standards.

Rationale for Requirement R3:
Some Transmission Operators will have obligations under this standard for certain primary control centers. Those obligations, however, are contingent upon a Transmission Owner first identifying which Transmission stations and Transmission substations meet the criteria specified by Requirement R1, as verified according to Requirement R2. This requirement is intended to ensure that a Transmission Operator that has operational control of a primary control center identified in Requirement R1, Part 1.2 of a Transmission station or Transmission substation verified according to Requirement R2 receives notice of such identification so that the Transmission Operator may timely fulfill its resulting obligations under Requirements R4 through R6. Since the timing obligations in Requirements R4 through R6 are based upon completion of Requirement R2, the Transmission Owner must also include notice of the date of completion of Requirement R2. Similarly, the Transmission Owner must notify the Transmission Operator of any removals from identification that result from a subsequent risk assessment under Requirement R1 or the verification process under Requirement R2.

Rationale for Requirement R4:
This requirement meets the FERC directive from paragraph 8 in the order on physical security that the reliability standard must require tailored evaluation of potential threats and vulnerabilities to facilities identified in Requirement R1 and verified according to Requirement R2. Threats and vulnerabilities may vary from facility to facility based on factors such as the facility’s location, size, function, existing protections, and attractiveness of the target. As such, the requirement does not mandate a one-size-fits-all approach but requires entities to account for the unique characteristics of their facilities.

Requirement R4 does not explicitly state when the evaluation of threats and vulnerabilities must occur or be completed. However, Requirement R5 requires that the entity's security plan(s), which is dependent on the Requirement R4 evaluation, must be completed within 120 calendar days following completion of Requirement R2. Thus, an entity has the flexibility when to complete the Requirement R4 evaluation, provided that it is completed in time to comply with the requirement in Requirement R5 to develop a physical security plan 120 calendar days following completion of Requirement R2.

Rationale for Requirement R5:
This requirement meets the FERC directive from paragraph 9 in the order on physical security requiring the development and implementation of a security plan(s) designed to protect against attacks to the facilities identified in Requirement R1 based on the assessment performed under Requirement R4.

Rationale for Requirement R6:
This requirement meets the FERC directive from paragraph 11 in the order on physical security requiring review by an entity other than the owner or operator with appropriate expertise of the evaluation performed according to Requirement R4 and the security plan(s) developed according to Requirement R5.

As with the verification required by Requirement R2, Requirement R6 provides Transmission Owners and Transmission Operators the flexibility to work with the third party reviewer throughout the Requirement R4 evaluation and the development of the Requirement R5 security plan(s). This would allow entities to satisfy their obligations under Requirement R6 concurrent with the satisfaction of their obligations under Requirements R4 and R5.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	08/19/15
SAR posted for comment	08/20/15 – 09/21/15
45-day formal comment period with initial ballot	08/24/18-10/17/18

Anticipated Actions	Date
45-day formal comment period with initial ballot	June 2020
10-day final ballot	August 2020
NERC Board adoption	November 2020

A. Introduction

1. **Title:** Transmission Vegetation Management
2. **Number:** FAC-003-5
3. **Purpose:** To maintain a reliable electric transmission system by using a defense-in-depth strategy to manage vegetation located on transmission rights of way (ROW) and minimize encroachments from vegetation located adjacent to the ROW, thus preventing the risk of those vegetation-related outages that could lead to Cascading.
4. **Applicability:**

4.1. Functional Entities:

4.1.1. Applicable Transmission Owners

4.1.1.1. Transmission Owners that own Transmission Facilities defined in 4.2.

4.1.2. Applicable Generator Owners

4.1.2.1. Generator Owners that own generation Facilities defined in 4.3.

4.2. Transmission Facilities: Defined below (referred to as "applicable lines"), including but not limited to those that cross lands owned by federal[1], state, provincial, public, private, or tribal entities:

4.2.1. Each overhead transmission line operated at 200kV or higher.

4.2.2. Each overhead transmission line operated below 200kV, identified by the Planning Coordinator or Transmission Planner, per its Planning Assessment of the Near-Term Transmission Planning Horizon as a Facility that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation that adversely impacts the reliability of the Bulk Electric System for a planning event.

4.2.3. Each overhead transmission line operated below 200 kV identified as an element of a Major Western Electricity Coordinating Council (WECC) Transfer Path in the Bulk Electric System by WECC.

4.2.4. Each overhead transmission line identified above (4.2.1. through 4.2.3.) located outside the fenced area of the switchyard, station or substation and any portion of the span of the transmission line that is crossing the substation fence.

[1] EPAct 2005 section 1211c: *"Access approvals by Federal agencies."*

4.3. Generation Facilities: Defined below (referred to as "applicable lines"), including but not limited to those that cross lands owned by federal[2], state, provincial, public, private, or tribal entities:

4.3.1. Overhead transmission lines that (1) extend greater than one mile or 1.609 kilometers beyond the fenced area of the generating station switchyard to the point of interconnection with a Transmission Owner's Facility or (2) do not have a clear line of sight[3] from the generating station switchyard fence to the point of interconnection with a Transmission Owner's Facility and are:

4.3.1.1. Operated at 200kV or higher; or

4.3.1.2. Operated below 200kV and are identified by the Planning Coordinator or Transmission Planner, per its Planning Assessment of the Near-Term Transmission Planning Horizon as a Facility that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation that adversely impacts the reliability of the Bulk Electric System for a planning event; or

4.3.1.3. Operated below 200 kV identified as an element of a Major WECC Transfer Path in the Bulk Electric System by WECC.

5. Effective Date: See Implementation Plan

6. Background: This standard uses three types of requirements to provide layers of protection to prevent vegetation related outages that could lead to Cascading:

a) Performance-based defines a particular reliability objective or outcome to be achieved. In its simplest form, a results-based requirement has four components: *who, under what conditions (if any), shall perform what action, to achieve what particular bulk power system <u>performance result or outcome</u>?*

b) Risk-based preventive requirements to reduce the risks of failure to acceptable tolerance levels. A risk-based reliability requirement should be framed as: *who, under what conditions (if any), shall perform what action, to achieve what particular result or outcome that <u>reduces a stated risk</u> to the reliability of the bulk power system?*

c) Competency-based defines a minimum set of capabilities an entity needs to have to demonstrate it is able to perform its designated reliability functions. A competency-based reliability requirement should be framed as: *who, under what conditions (if any), shall have <u>what capability</u>, to achieve what particular result or*

[2] *Id.*

[3] "Clear line of sight" means the distance that can be seen by the average person without special instrumentation (e.g., binoculars, telescope, spyglasses, etc.) on a clear day.

outcome to perform an action to achieve a result or outcome or to reduce a risk to the reliability of the bulk power system?

The defense-in-depth strategy for Reliability Standards development recognizes that each requirement in a NERC Reliability Standard has a role in preventing system failures, and that these roles are complementary and reinforcing. Reliability Standards should not be viewed as a body of unrelated requirements, but rather should be viewed as part of a portfolio of requirements designed to achieve an overall defense-in-depth strategy and comport with the quality objectives of a Reliability Standard.

This standard uses a defense-in-depth approach to improve the reliability of the electric Transmission system by:

- Requiring that vegetation be managed to prevent vegetation encroachment inside the flash-over clearance (R1 and R2);
- Requiring documentation of the maintenance strategies, procedures, processes and specifications used to manage vegetation to prevent potential flash-over conditions including consideration of 1) conductor dynamics and 2) the interrelationships between vegetation growth rates, control methods and the inspection frequency (R3);
- Requiring timely notification to the appropriate control center of vegetation conditions that could cause a flash-over at any moment (R4);
- Requiring corrective actions to ensure that flash-over distances will not be violated due to work constrains such as legal injunctions (R5);
- Requiring inspections of vegetation conditions to be performed annually (R6); and
- Requiring that the annual work needed to prevent flash-over is completed (R7).

For this standard, the requirements have been developed as follows:

- Performance-based: Requirements 1 and 2
- Competency-based: Requirement 3
- Risk-based: Requirements 4, 5, 6 and 7

Requirement R3 serves as the first line of defense by ensuring that entities understand the problem they are trying to manage and have fully developed strategies and plans to manage the problem. Requirements R1, R2, and R7 serve as the second line of defense by requiring that entities carry out their plans and manage vegetation. Requirement R6, which requires inspections, may be either a part of the first line of defense (as input into the strategies and plans) or as a third line of defense (as a check of the first and second lines of defense). Requirement R4 serves as the final line of defense, as it addresses cases in which all the other lines of defense have failed.

Major outages and operational problems have resulted from interference between overgrown vegetation and transmission lines located on many types of lands and ownership situations. Adherence to the standard requirements for applicable lines on any kind of land or easement, whether they are Federal Lands, state or provincial lands, public or private lands, franchises, easements or lands owned in fee, will reduce and manage this risk. For the purpose of the standard the term "public lands" includes municipal lands, village lands, city lands, and a host of other governmental entities.

This standard addresses vegetation management along applicable overhead lines and does not apply to underground lines, submarine lines or to line sections inside an electric station boundary.

This standard focuses on transmission lines to prevent those vegetation related outages that could lead to Cascading. It is not intended to prevent customer outages due to tree contact with lower voltage distribution system lines. For example, localized customer service might be disrupted if vegetation were to make contact with a 69kV transmission line supplying power to a 12kV distribution station. However, this standard is not written to address such isolated situations which have little impact on the overall electric transmission system.

Since vegetation growth is constant and always present, unmanaged vegetation poses an increased outage risk, especially when numerous transmission lines are operating at or near their Rating. This can present a significant risk of consecutive line failures when lines are experiencing large sags thereby leading to Cascading. Once the first line fails the shift of the current to the other lines and/or the increasing system loads will lead to the second and subsequent line failures as contact to the vegetation under those lines occurs. Conversely, most other outage causes (such as trees falling into lines, lightning, animals, motor vehicles, etc.) are not an interrelated function of the shift of currents or the increasing system loading. These events are not any more likely to occur during heavy system loads than any other time. There is no cause-effect relationship which creates the probability of simultaneous occurrence of other such events. Therefore these types of events are highly unlikely to cause large-scale grid failures. Thus, this standard places the highest priority on the management of vegetation to prevent vegetation grow-ins.

B. Requirements and Measures

R1. Each applicable Transmission Owner and applicable Generator Owner shall manage vegetation to prevent encroachments into the Minimum Vegetation Clearance Distance (MVCD) of its applicable line(s), operating within their Rating and all Rated

Electrical Operating Conditions of the types shown below[4] *[Violation Risk Factor: High] [Time Horizon: Real-time]*:

1.1. An encroachment into the MVCD as shown in FAC-003-Table 2, observed in Real-time, absent a Sustained Outage,[5]

1.2. An encroachment due to a fall-in from inside the ROW that caused a vegetation-related Sustained Outage,[6]

1.3. An encroachment due to the blowing together of applicable lines and vegetation located inside the ROW that caused a vegetation-related Sustained Outage[7],

1.4. An encroachment due to vegetation growth into the MVCD that caused a vegetation-related Sustained Outage.[8]

M1. Each applicable Transmission Owner and applicable Generator Owner has evidence that it managed vegetation to prevent encroachment into the MVCD as described in R1. Examples of acceptable forms of evidence may include dated attestations, dated reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-time observations of any MVCD encroachments. (R1)

R2. [Reserved for future use]

M2. [Reserved for future use]

R3. Each applicable Transmission Owner and applicable Generator Owner shall have documented maintenance strategies or procedures or processes or specifications it uses to prevent the encroachment of vegetation into the MVCD of its applicable lines that accounts for the following: *[Violation Risk Factor: Lower] [Time Horizon: Long Term Planning]:*

3.1. Movement of applicable line conductors under their Rating and all Rated Electrical Operating Conditions;

---

[4] This requirement does not apply to circumstances that are beyond the control of an applicable Transmission Owner or applicable Generator Owner subject to this Reliability Standard, including natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the applicable Transmission Owner or applicable Generator Owner or an applicable regulatory body, ice storms, and floods; human or animal activity such as logging, animal severing tree, vehicle contact with tree, or installation, removal, or digging of vegetation. Nothing in this footnote should be construed to limit the Transmission Owner's or applicable Generator Owner's right to exercise its full legal rights on the ROW.

[5] If a later confirmation of a Fault by the applicable Transmission Owner or applicable Generator Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the equivalent of a Real-time observation.

[6] Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period.

[7] *Id.*

[8] *Id.*

3.2. Inter-relationships between vegetation growth rates, vegetation control methods, and inspection frequency.

M3. The maintenance strategies or procedures or processes or specifications provided demonstrate that the applicable Transmission Owner and applicable Generator Owner can prevent encroachment into the MVCD considering the factors identified in the requirement. (R3)

R4. Each applicable Transmission Owner and applicable Generator Owner, without any intentional time delay, shall notify the control center holding switching authority for the associated applicable line when the applicable Transmission Owner and applicable Generator Owner has confirmed the existence of a vegetation condition that is likely to cause a Fault at any moment *[Violation Risk Factor: Medium] [Time Horizon: Real-time].*

M4. Each applicable Transmission Owner and applicable Generator Owner that has a confirmed vegetation condition likely to cause a Fault at any moment will have evidence that it notified the control center holding switching authority for the associated transmission line without any intentional time delay. Examples of evidence may include control center logs, voice recordings, switching orders, clearance orders and subsequent work orders. (R4)

R5. When an applicable Transmission Owner and an applicable Generator Owner are constrained from performing vegetation work on an applicable line operating within its Rating and all Rated Electrical Operating Conditions, and the constraint may lead to a vegetation encroachment into the MVCD prior to the implementation of the next annual work plan, then the applicable Transmission Owner or applicable Generator Owner shall take corrective action to ensure continued vegetation management to prevent encroachments [*Violation Risk Factor: Medium*] [*Time Horizon: Operations Planning*].

M5. Each applicable Transmission Owner and applicable Generator Owner has evidence of the corrective action taken for each constraint where an applicable transmission line was put at potential risk. Examples of acceptable forms of evidence may include initially-planned work orders, documentation of constraints from landowners, court orders, inspection records of increased monitoring, documentation of the de-rating of lines, revised work orders, invoices, or evidence that the line was de-energized. (R5)

R6. Each applicable Transmission Owner and applicable Generator Owner shall perform a Vegetation Inspection of 100% of its applicable transmission lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.) at least once per calendar

year and with no more than 18 calendar months between inspections on the same ROW[9] [*Violation Risk Factor: Medium*] [*Time Horizon: Operations Planning*].

M6. Each applicable Transmission Owner and applicable Generator Owner has evidence that it conducted Vegetation Inspections of the transmission line ROW for all applicable lines at least once per calendar year but with no more than 18 calendar months between inspections on the same ROW. Examples of acceptable forms of evidence may include completed and dated work orders, dated invoices, or dated inspection records. (R6)

R7. Each applicable Transmission Owner and applicable Generator Owner shall complete 100% of its annual vegetation work plan of applicable lines to ensure no vegetation encroachments occur within the MVCD. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made (provided they do not allow encroachment of vegetation into the MVCD) and must be documented. The percent completed calculation is based on the number of units actually completed divided by the number of units in the final amended plan (measured in units of choice - circuit, pole line, line miles or kilometers, etc.). Examples of reasons for modification to annual plan may include [*Violation Risk Factor: Medium*] [*Time Horizon: Operations Planning*]:

7.1. Change in expected growth rate/environmental factors

7.2. Circumstances that are beyond the control of an applicable Transmission Owner or applicable Generator Owner[10]

7.3. Rescheduling work between growing seasons

7.4. Crew or contractor availability/Mutual assistance agreements

7.5. Identified unanticipated high priority work

7.6. Weather conditions/Accessibility

7.7. Permitting delays

7.8. Land ownership changes/Change in land use by the landowner

7.9. Emerging technologies

M7. Each applicable Transmission Owner and applicable Generator Owner has evidence that it completed its annual vegetation work plan for its applicable lines. Examples of acceptable forms of evidence may include a copy of the completed annual work plan

[9] When the applicable Transmission Owner or applicable Generator Owner is prevented from performing a Vegetation Inspection within the timeframe in R6 due to a natural disaster, the TO or GO is granted a time extension that is equivalent to the duration of the time the TO or GO was prevented from performing the Vegetation Inspection.

[10] Circumstances that are beyond the control of an applicable Transmission Owner or applicable Generator Owner include but are not limited to natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, ice storms, floods, or major storms as defined either by the TO or GO or an applicable regulatory body.

(as finally modified), dated work orders, dated invoices, or dated inspection records. (R7)

C. Compliance

1. **Compliance Monitoring Process**

1.1. Compliance Enforcement Authority:
"Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention:
The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

- The applicable Transmission Owner and applicable Generator Owner retains data or evidence to show compliance with Requirements R1, R3, R5, R6 and R7, for three calendar years.
- The applicable Transmission Owner and applicable Generator Owner retains data or evidence to show compliance with Requirement R4, Measure M4 for most recent 12 months of operator logs or most recent 3 months of voice recordings or transcripts of voice recordings, unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.
- If an applicable Transmission Owner or applicable Generator Owner is found non-compliant, it shall keep information related to the non-compliance until found compliant or for the time period specified above, whichever is longer.

1.3. Compliance Monitoring and Enforcement Program
As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

1.4. Additional Compliance Information

Periodic Data Submittal: The applicable Transmission Owner and applicable Generator Owner will submit a quarterly report to its Regional Entity, or the Regional Entity's designee, identifying all Sustained Outages of applicable lines operated within their Rating and all Rated Electrical Operating Conditions as determined by the applicable Transmission Owner or applicable Generator Owner to have been caused by vegetation, except as excluded in footnote 4, and including as a minimum the following:

- The name of the circuit(s), the date, time and duration of the outage; the voltage of the circuit; a description of the cause of the outage; the category associated with the Sustained Outage; other pertinent comments; and any countermeasures taken by the applicable Transmission Owner or applicable Generator Owner.

  A Sustained Outage is to be categorized as one of the following:

- Category 1A — Grow-ins: Sustained Outages caused by vegetation growing into applicable lines, that are identified by the Planning Coordinator, per its Planning Assessment of the Near-Term Transmission Planning Horizon as a Facility that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation that adversely impacts the reliability of the Bulk Electric System by vegetation inside and/or outside of the ROW;
- Category 1B — Grow-ins: Sustained Outages caused by vegetation growing into applicable lines, but are not identified by the Planning Coordinator, per its Planning Assessment of the Near-Term Transmission Planning Horizon as a Facility that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation that adversely impacts the reliability of the Bulk Electric System for a planning event by vegetation inside and/or outside of the ROW;
- Category 2A — Fall-ins: Sustained Outages caused by vegetation falling into applicable lines that are identified by the Planning Coordinator, per its Planning Assessment of the Near-Term Transmission Planning Horizon as Facility that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation that adversely impacts the reliability of the Bulk Electric System for a planning event from within the ROW;
- Category 2B — Fall-ins: Sustained Outages caused by vegetation falling into applicable lines, but are not identified by the Planning Coordinator, per its Planning Assessment of the Near-Term Transmission Planning Horizon as Facilities that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation that adversely impacts the reliability of the Bulk Electric System for a planning event ,from within the ROW;

- Category 3 — Fall-ins: Sustained Outages caused by vegetation falling into applicable lines from outside the ROW;
- Category 4A — Blowing together: Sustained Outages caused by vegetation and applicable lines that are identified by the Planning Coordinator, per its Planning Assessment of the Near-Term Transmission Planning Horizon as a Facility that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation that adversely impacts the reliability of the Bulk Electric System for a planning event blowing together from within the ROW;
- Category 4B — Blowing together: Sustained Outages caused by vegetation and applicable lines, but are not identified by the Planning Coordinator, per its Planning Assessment of the Near-Term Transmission Planning Horizon as a Facility that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation that adversely impacts the reliability of the Bulk Electric System for a planning event , blowing together from within the ROW.

The Regional Entity will report the outage information provided by applicable Transmission Owners and applicable Generator Owners, as per the above, quarterly to NERC, as well as any actions taken by the Regional Entity as a result of any of the reported Sustained Outages.

Violation Severity Levels (Table 1)

R #	Table 1: Violation Severity Levels (VSL)			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1.			The responsible entity failed to manage vegetation to prevent encroachment into the MVCD of a line identified in the Applicability section 4.2 and 4.3 and encroachment into the MVCD as identified in FAC-003-5-Table 2 was observed in real time absent a Sustained Outage.	The responsible entity failed to manage vegetation to prevent encroachment into the MVCD of a line identified in the Applicability section 4.2 and 4.3 and a vegetation-related Sustained Outage was caused by one of the following: • *A fall-in from inside the active transmission line ROW* • *Blowing together of applicable lines and vegetation located inside the active transmission line ROW* • *A grow-in*
R2. Reserved for				•

future use				
R3.		The responsible entity has maintenance strategies or documented procedures or processes or specifications but has not accounted for the inter-relationships between vegetation growth rates, vegetation control methods, and inspection frequency, for the responsible entity's applicable lines. (Requirement R3, Part 3.2.)	The responsible entity has maintenance strategies or documented procedures or processes or specifications but has not accounted for the movement of transmission line conductors under their Rating and all Rated Electrical Operating Conditions, for the responsible entity's applicable lines. (Requirement R3, Part 3.1.)	The responsible entity does not have any maintenance strategies or documented procedures or processes or specifications used to prevent the encroachment of vegetation into the MVCD, for the responsible entity's applicable lines.
R4.			The responsible entity experienced a confirmed vegetation threat and notified the control center holding switching authority for that applicable line, but there was intentional delay in that notification.	The responsible entity experienced a confirmed vegetation threat and did not notify the control center holding switching authority for that applicable line.
R5.				The responsible entity did not take corrective action when it was constrained from performing planned

				vegetation work where an applicable line was put at potential risk.
R6.	The responsible entity failed to inspect 5% or less of its applicable lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.)	The responsible entity failed to inspect more than 5% up to and including 10% of its applicable lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.).	The responsible entity failed to inspect more than 10% up to and including 15% of its applicable lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.).	The responsible entity failed to inspect more than 15% of its applicable lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.).
R7.	The responsible entity failed to complete 5% or less of its annual vegetation work plan for its applicable lines (as finally modified).	The responsible entity failed to complete more than 5% and up to and including 10% of its annual vegetation work plan for its applicable lines (as finally modified).	The responsible entity failed to complete more than 10% and up to and including 15% of its annual vegetation work plan for its applicable lines (as finally modified).	The responsible entity failed to complete more than 15% of its annual vegetation work plan for its applicable lines (as finally modified).

D. Regional Variances

None.

- FAC-003-4 Implementation Plan

Version History

Version	Date	Action	Change Tracking
1	January 20, 2006	1. Added “Standard Development Roadmap.” 2. Changed “60” to “Sixty” in section A, 5.2. 3. Added “Proposed Effective Date: April 7, 2006” to footer. 4. Added “Draft 3: November 17, 2005” to footer.	New
1	April 4, 2007	Regulatory Approval - Effective Date	New
2	November 3, 2011	Adopted by the NERC Board of Trustees	New
2	March 21, 2013	FERC Order issued approving FAC-003-2 (Order No. 777) FERC Order No. 777 was issued on March 21, 2013 directing NERC to “conduct or contract testing to obtain empirical data and submit a report to the Commission providing the results of the testing.”[11]	Revisions
2	May 9, 2013	Board of Trustees adopted the modification of the VRF for Requirement R2 of FAC-003-2 by raising the VRF from “Medium” to “High.”	Revisions
3	May 9, 2013	FAC-003-3 adopted by Board of Trustees	Revisions
3	September 19, 2013	A FERC order was issued on September 19, 2013, approving FAC-003-3. This standard became enforceable on July 1, 2014 for Transmission Owners. For Generator Owners, R3 became enforceable on January 1, 2015 and all other requirements (R1, R2, R4, R5, R6, and R7) became enforceable on January 1, 2016.	Revisions
3	November 22, 2013	Updated the VRF for R2 from “Medium” to “High” per a Final Rule issued by FERC	Revisions
3	July 30, 2014	Transferred the effective dates section from FAC-003-2 (for Transmission Owners) into FAC-003-3, per the FAC-003-3 implementation plan	Revisions

[11] *Revisions to Reliability Standard for Transmission Vegetation Management, Order No. 777,* 142 FERC ¶ 61,208 (2013)

4	February 11, 2016	Adopted by Board of Trustees. Adjusted MVCD values in Table 2 for alternating current systems, consistent with findings reported in report filed on August 12, 2015 in Docket No. RM12-4-002 consistent with FERC's directive in Order No. 777, and based on empirical testing results for flashover distances between conductors and vegetation.	Revisions
4	March 9, 2016	Corrected subpart 7.10 to M7, corrected value of .07 to .7	Errata
4	April 26, 2016	FERC Letter Order approving FAC-003-4. Docket No. RD16-4-000.	
5	TBD	Approved by Board of Trustees	Revisions

FAC-003 — TABLE 2 — Minimum Vegetation Clearance Distances (MVCD)[12]

For **Alternating Current** Voltages (feet)

* Such lines are applicable to this standard only if PC has determined such per FAC-014 (refer to the Applicability Section above)

[12] The distances in this Table are the minimums required to prevent Flash-over; however prudent vegetation maintenance practices dictate that substantially greater distances will be achieved at time of vegetation maintenance.

[13] Where applicable lines are operated at nominal voltages other than those listed, the applicable Transmission Owner or applicable Generator Owner should use the maximum system voltage to determine the appropriate clearance for that line.

[14] The change in transient overvoltage factors in the calculations are the driver in the decrease in MVCDs for voltages of 345 kV and above. Refer to pp.29-31 in the Supplemental Materials for additional information.

+ Table 2 – Table of MVCD values at a 1.0 gap factor (in U.S. customary units), which is located in the EPRI report filed with FERC on August 12, 2015. (The 14000-15000 foot values were subsequently provided by EPRI in an updated Table 2 on December 1, 2015, filed with the FAC-003-4 Petition at FERC)

[18] The distances in this Table are the minimums required to prevent Flash-over; however prudent vegetation maintenance practices dictate that substantially greater distances will be achieved at time of vegetation maintenance.

Guideline and Technical Basis

Effective dates:

The Compliance section is standard language used in most NERC standards to cover the general effective date and covers the vast majority of situations. A special case covers effective dates for (1) lines initially becoming subject to the Standard, (2) lines changing in applicability within the standard.

The special case is needed because the Planning Coordinators or Transmission Planners may designate lines below 200 kV, per its Planning Assessment of the Near-Term Transmission Planning Horizon or its Transfer Capability Assessment as Facilities that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation that adversely impacts the reliability of the Bulk Electric System for a planning event in a future Planning Year (PY). For example, studies by the Planning Coordinator in 2015 may identify a line to have that designation beginning in PY 2025, ten years after the planning study is performed. It is not intended for the Standard to be immediately applicable to, or in effect for, that line until that future PY begins. The effective date provision for such lines ensures that the line will become subject to the standard on January 1 of the PY specified with an allowance of at least 12 months for the applicable Transmission Owner or applicable Generator Owner to make the necessary preparations to achieve compliance on that line. A line operating below 200kV designated by the Planning Coordinator or Transmission Planner, per its Planning Assessment of the Near-Term Transmission Planning Horizon or its Transfer Capability Assessment (Planning Coordinator only) as Facilities that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation that adversely impacts the reliability of the Bulk Electric System for a planning event may be removed from that designation due to system improvements, changes in generation, changes in loads or changes in studies and analysis of the network.

Date that Planning Study is completed	PY the line will become an identified element	Date 1	Date 2	Effective Date The later of Date 1 or Date 2
05/15/2011	2012	05/15/2012	01/01/2012	05/15/2012
05/15/2011	2013	05/15/2012	01/01/2013	01/01/2013
05/15/2011	2014	05/15/2012	01/01/2014	01/01/2014
05/15/2011	2021	05/15/2012	01/01/2021	01/01/2021

Defined Terms:

Explanation for revising the definition of ROW:

The current NERC glossary definition of Right of Way has been modified to include Generator Owners and to address the matter set forth in Paragraph 734 of FERC Order 693. The Order pointed out that Transmission Owners may in some cases own more property or rights than are needed to reliably operate transmission lines. This definition represents a slight but significant departure from the strict legal definition of "right of way" in that this definition is based on engineering and construction considerations that establish the width of a corridor from a technical basis. The pre-2007 maintenance records are included in the current definition to allow the use of such vegetation widths if there were no engineering or construction standards that referenced the width of right of way to be maintained for vegetation on a particular line but the evidence exists in maintenance records for a width that was in fact maintained prior to this standard becoming mandatory. Such widths may be the only information available for lines that had limited or no vegetation easement rights and were typically maintained primarily to ensure public safety. This standard does not require additional easement rights to be purchased to satisfy a minimum right of way width that did not exist prior to this standard becoming mandatory.

Explanation for revising the definition of Vegetation Inspection:
The current glossary definition of this NERC term was modified to include Generator Owners and to allow both maintenance inspections and vegetation inspections to be performed concurrently. This allows potential efficiencies, especially for those lines with minimal vegetation and/or slow vegetation growth rates.

Explanation of the derivation of the MVCD:
The MVCD is a calculated minimum distance that is derived from the Gallet equation. This is a method of calculating a flash over distance that has been used in the design of high voltage transmission lines. Keeping vegetation away from high voltage conductors by this distance will prevent voltage flash-over to the vegetation. See the explanatory text below for Requirement R3 and associated Figure 1. Table 2 of the standard provides MVCD values for various voltages and altitudes. The table is based on empirical testing data from EPRI as requested by FERC in Order No. 777.

Project 2010-07.1 Adjusted MVCDs per EPRI Testing:
In Order No. 777, FERC directed NERC to undertake testing to gather empirical data validating the appropriate gap factor used in the Gallet equation to calculate MVCDs, specifically the gap factor for the flash-over distances between conductors and vegetation. See, Order No. 777, at P 60. NERC engaged industry through a collaborative research project and contracted EPRI to complete the scope of work. In January 2014, NERC formed an advisory group to assist with developing the scope of work for the project. This team provided subject matter expertise for developing the test plan, monitoring testing, and vetting the analysis and conclusions to be submitted in a final report. The advisory team was comprised of NERC staff, arborists, and industry members with wide-ranging expertise in transmission engineering, insulation coordination, and vegetation management. The testing project commenced in April 2014 and continued through October 2014 with the final set of testing completed in May 2015. Based on these testing results conducted by EPRI, and consistent with the report filed in FERC Docket No.

RM12-4-000, the gap factor used in the Gallet equation required adjustment from 1.3 to 1.0. This resulted in increased MVCD values for all alternating current system voltages identified. The adjusted MVCD values, reflecting the 1.0 gap factor, are included in Table 2 of version 4 of FAC-003.

The air gap testing completed by EPRI per FERC Order No. 777 established that trees with large spreading canopies growing directly below energized high voltage conductors create the greatest likelihood of an air gap flash over incident and was a key driver in changing the gap factor to a more conservative value of 1.0 in version 4 of this standard.

Requirements R1:
R1 is a performance-based requirements. The reliability objective or outcome to be achieved is the management of vegetation such that there are no vegetation encroachments within a minimum distance of transmission lines R1 requires each applicable Transmission Owner or applicable Generator Owner to manage vegetation to prevent encroachment within the MVCD of transmission lines. R1 is applicable to lines that are identified as an element in the Applicability section 4.2 and 4.3.

Requirements R1 states that if inadequate vegetation management allows vegetation to encroach within the MVCD distance as shown in Table 2, it is a violation of the standard. Table 2 distances are the minimum clearances that will prevent spark-over based on the Gallet equations. These requirements assume that transmission lines and their conductors are operating within their Rating. If a line conductor is intentionally or inadvertently operated beyond its Rating and Rated Electrical Operating Condition (potentially in violation of other standards), the occurrence of a clearance encroachment may occur solely due to that condition. For example, emergency actions taken by an applicable Transmission Owner or applicable Generator Owner or Reliability Coordinator to protect an Interconnection may cause excessive sagging and an outage. Another example would be ice loading beyond the line's Rating and Rated Electrical Operating Condition. Such vegetation-related encroachments and outages are not violations of this standard.

Evidence of failures to adequately manage vegetation include real-time observation of a vegetation encroachment into the MVCD (absent a Sustained Outage), or a vegetation-related encroachment resulting in a Sustained Outage due to a fall-in from inside the ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to the blowing together of the lines and vegetation located inside the ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to a grow-in. Faults which do not cause a Sustained outage and which are confirmed to have been caused by vegetation encroachment within the MVCD are considered the equivalent of a Real-time observation for violation severity levels.

With this approach, the VSLs for R1 are structured such that they directly correlate to the severity of a failure of an applicable Transmission Owner or applicable Generator Owner to manage vegetation and to the corresponding performance level of the Transmission Owner's vegetation program's ability to meet the objective of "preventing the risk of those vegetation related outages that could lead to Cascading." Thus violation severity increases with an applicable

Transmission Owner's or applicable Generator Owner's inability to meet this goal and its potential of leading to a Cascading event. The additional benefits of such a combination are that it simplifies the standard and clearly defines performance for compliance. A performance-based requirement of this nature will promote high quality, cost effective vegetation management programs that will deliver the overall end result of improved reliability to the system.

Multiple Sustained Outages on an individual line can be caused by the same vegetation. For example initial investigations and corrective actions may not identify and remove the actual outage cause then another outage occurs after the line is re-energized and previous high conductor temperatures return. Such events are considered to be a single vegetation-related Sustained Outage under the standard where the Sustained Outages occur within a 24 hour period.

If the applicable Transmission Owner or applicable Generator Owner has applicable lines operated at nominal voltage levels not listed in Table 2, then the applicable TO or applicable GO should use the next largest clearance distance based on the next highest nominal voltage in the table to determine an acceptable distance.

Requirement R3:
R3 is a competency based requirement concerned with the maintenance strategies, procedures, processes, or specifications, an applicable Transmission Owner or applicable Generator Owner uses for vegetation management.

An adequate transmission vegetation management program formally establishes the approach the applicable Transmission Owner or applicable Generator Owner uses to plan and perform vegetation work to prevent transmission Sustained Outages and minimize risk to the transmission system. The approach provides the basis for evaluating the intent, allocation of appropriate resources, and the competency of the applicable Transmission Owner or applicable Generator Owner in managing vegetation. There are many acceptable approaches to manage vegetation and avoid Sustained Outages. However, the applicable Transmission Owner or applicable Generator Owner must be able to show the documentation of its approach and how it conducts work to maintain clearances.

An example of one approach commonly used by industry is ANSI Standard A300, part 7. However, regardless of the approach a utility uses to manage vegetation, any approach an applicable Transmission Owner or applicable Generator Owner chooses to use will generally contain the following elements:

1. *the maintenance strategy used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that MVCD clearances are never violated*
2. *the work methods that the applicable Transmission Owner or applicable Generator Owner uses to control vegetation*
3. *a stated Vegetation Inspection frequency*

4. *an annual work plan*

The conductor's position in space at any point in time is continuously changing in reaction to a number of different loading variables. Changes in vertical and horizontal conductor positioning are the result of thermal and physical loads applied to the line. Thermal loading is a function of line current and the combination of numerous variables influencing ambient heat dissipation including wind velocity/direction, ambient air temperature and precipitation. Physical loading applied to the conductor affects sag and sway by combining physical factors such as ice and wind loading. The movement of the transmission line conductor and the MVCD is illustrated in Figure 1 below.

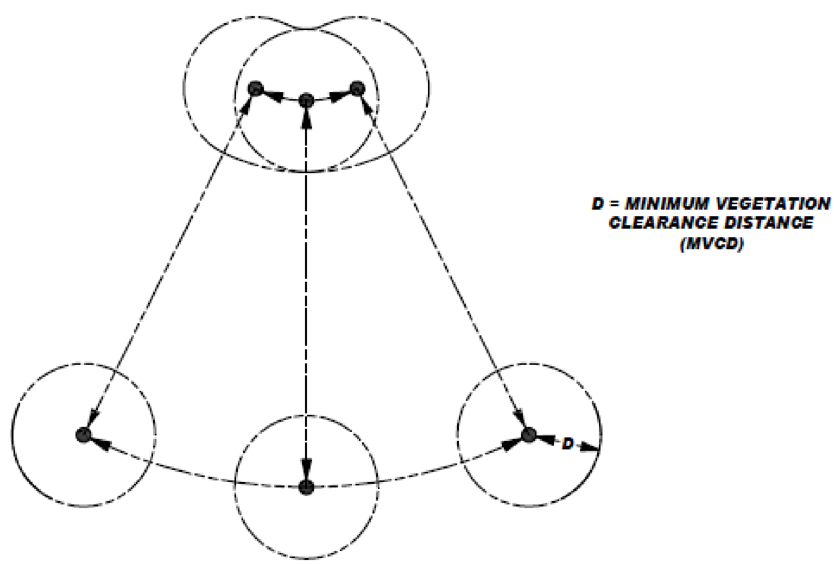

Figure 1

A cross-section view of a single conductor at a given point along the span is shown with six possible conductor positions due to movement resulting from thermal and mechanical loading.

Requirement R4:

R4 is a risk-based requirement. It focuses on preventative actions to be taken by the applicable Transmission Owner or applicable Generator Owner for the mitigation of Fault risk when a vegetation threat is confirmed. R4 involves the notification of potentially threatening vegetation conditions, without any intentional delay, to the control center holding switching authority for that specific transmission line. Examples of acceptable unintentional delays may include communication system problems (for example, cellular service or two-way radio disabled), crews located in remote field locations with no communication access, delays due to severe weather, etc.

Confirmation is key that a threat actually exists due to vegetation. This confirmation could be in the form of an applicable Transmission Owner or applicable Generator Owner employee who personally identifies such a threat in the field. Confirmation could also be made by sending out an employee to evaluate a situation reported by a landowner.

Vegetation-related conditions that warrant a response include vegetation that is near or encroaching into the MVCD (a grow-in issue) or vegetation that could fall into the transmission conductor (a fall-in issue). A knowledgeable verification of the risk would include an assessment of the possible sag or movement of the conductor while operating between no-load conditions and its rating.

The applicable Transmission Owner or applicable Generator Owner has the responsibility to ensure the proper communication between field personnel and the control center to allow the control center to take the appropriate action until or as the vegetation threat is relieved. Appropriate actions may include a temporary reduction in the line loading, switching the line out of service, or other preparatory actions in recognition of the increased risk of outage on that circuit. The notification of the threat should be communicated in terms of minutes or hours as opposed to a longer time frame for corrective action plans (see R5).

All potential grow-in or fall-in vegetation-related conditions will not necessarily cause a Fault at any moment. For example, some applicable Transmission Owners or applicable Generator Owners may have a danger tree identification program that identifies trees for removal with the potential to fall near the line. These trees would not require notification to the control center unless they pose an immediate fall-in threat.

Requirement R5:

R5 is a risk-based requirement. It focuses upon preventative actions to be taken by the applicable Transmission Owner or applicable Generator Owner for the mitigation of Sustained Outage risk when temporarily constrained from performing vegetation maintenance. The intent of this requirement is to deal with situations that prevent the applicable Transmission Owner or applicable Generator Owner from performing planned vegetation management work and, as a result, have the potential to put the transmission line at risk. Constraints to performing vegetation maintenance work as planned could result from legal injunctions filed by property owners, the discovery of easement stipulations which limit the applicable Transmission Owner's or applicable Generator Owner's rights, or other circumstances.

This requirement is not intended to address situations where the transmission line is not at potential risk and the work event can be rescheduled or re-planned using an alternate work methodology. For example, a land owner may prevent the planned use of herbicides to control incompatible vegetation outside of the MVCD, but agree to the use of mechanical clearing. In this case the applicable Transmission Owner or applicable Generator Owner is not under any immediate time constraint for achieving the management objective, can easily reschedule work using an alternate approach, and therefore does not need to take interim corrective action.

However, in situations where transmission line reliability is potentially at risk due to a constraint, the applicable Transmission Owner or applicable Generator Owner is required to take an interim corrective action to mitigate the potential risk to the transmission line. A wide range of actions can be taken to address various situations. General considerations include:

- Identifying locations where the applicable Transmission Owner or applicable Generator Owner is constrained from performing planned vegetation maintenance work which potentially leaves the transmission line at risk.
- Developing the specific action to mitigate any potential risk associated with not performing the vegetation maintenance work as planned.
- Documenting and tracking the specific action taken for the location.
- In developing the specific action to mitigate the potential risk to the transmission line the applicable Transmission Owner or applicable Generator Owner could consider location specific measures such as modifying the inspection and/or maintenance intervals. Where a legal constraint would not allow any vegetation work, the interim corrective action could include limiting the loading on the transmission line.
- The applicable Transmission Owner or applicable Generator Owner should document and track the specific corrective action taken at each location. This location may be indicated as one span, one tree or a combination of spans on one property where the constraint is considered to be temporary.

Requirement R6:
R6 is a risk-based requirement. This requirement sets a minimum time period for completing Vegetation Inspections. The provision that Vegetation Inspections can be performed in conjunction with general line inspections facilitates a Transmission Owner’s ability to meet this requirement. However, the applicable Transmission Owner or applicable Generator Owner may determine that more frequent vegetation specific inspections are needed to maintain reliability levels, based on factors such as anticipated growth rates of the local vegetation, length of the local growing season, limited ROW width, and local rainfall. Therefore it is expected that some transmission lines may be designated with a higher frequency of inspections.

The VSLs for Requirement R6 have levels ranked by the failure to inspect a percentage of the applicable lines to be inspected. To calculate the appropriate VSL the applicable Transmission Owner or applicable Generator Owner may choose units such as: circuit, pole line, line miles or kilometers, etc.

For example, when an applicable Transmission Owner or applicable Generator Owner operates 2,000 miles of applicable transmission lines this applicable Transmission Owner or applicable Generator Owner will be responsible for inspecting all the 2,000 miles of lines at least once during the calendar year. If one of the included lines was 100 miles long, and if it was not inspected during the year, then the amount failed to inspect would be 100/2000 = 0.05 or 5%. The "Low VSL" for R6 would apply in this example.

Requirement R7:
R7 is a risk-based requirement. The applicable Transmission Owner or applicable Generator Owner is required to complete its annual work plan for vegetation management to accomplish the purpose of this standard. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made and documented provided they do not put the transmission system at risk. The annual work plan requirement is not intended to necessarily require a "span-by-span", or even a "line-by-line" detailed description of all work to be performed. It is only intended to require that the applicable Transmission Owner or applicable Generator Owner provide evidence of annual planning and execution of a vegetation management maintenance approach which successfully prevents encroachment of vegetation into the MVCD.

When an applicable Transmission Owner or applicable Generator Owner identifies 1,000 miles of applicable transmission lines to be completed in the applicable Transmission Owner's or applicable Generator Owner's annual plan, the applicable Transmission Owner or applicable Generator Owner will be responsible completing those identified miles. If an applicable Transmission Owner or applicable Generator Owner makes a modification to the annual plan that does not put the transmission system at risk of an encroachment the annual plan may be modified. If 100 miles of the annual plan is deferred until next year the calculation to determine what percentage was completed for the current year would be: 1000 – 100 (deferred miles) = 900 modified annual plan, or 900 / 900 = 100% completed annual miles. If an applicable Transmission Owner or applicable Generator Owner only completed 875 of the total 1000 miles with no acceptable documentation for modification of the annual plan the calculation for failure to complete the annual plan would be: 1000 – 875 = 125 miles failed to complete then, 125 miles (not completed) / 1000 total annual plan miles = 12.5% failed to complete.

The ability to modify the work plan allows the applicable Transmission Owner or applicable Generator Owner to change priorities or treatment methodologies during the year as conditions or situations dictate. For example recent line inspections may identify unanticipated high priority work, weather conditions (drought) could make herbicide application ineffective during the plan year, or a major storm could require redirecting local resources away from planned maintenance. This situation may also include complying with mutual assistance agreements by moving resources off the applicable Transmission Owner's or applicable Generator Owner's system to work on another system. Any of these examples could result in acceptable deferrals or additions to the annual work plan provided that they do not put the transmission system at risk of a vegetation encroachment.
In general, the vegetation management maintenance approach should use the full extent of the applicable Transmission Owner's or applicable Generator Owner's easement, fee simple and other legal rights allowed. A comprehensive approach that exercises the full extent of legal rights on the ROW is superior to incremental management because in the long term it reduces

the overall potential for encroachments, and it ensures that future planned work and future planned inspection cycles are sufficient.

When developing the annual work plan the applicable Transmission Owner or applicable Generator Owner should allow time for procedural requirements to obtain permits to work on federal, state, provincial, public, tribal lands. In some cases the lead time for obtaining permits may necessitate preparing work plans more than a year prior to work start dates. Applicable Transmission Owners or applicable Generator Owners may also need to consider those special landowner requirements as documented in easement instruments.

This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. Therefore, deferrals or relevant changes to the annual plan shall be documented. Depending on the planning and documentation format used by the applicable Transmission Owner or applicable Generator Owner, evidence of successful annual work plan execution could consist of signed-off work orders, signed contracts, printouts from work management systems, spreadsheets of planned versus completed work, timesheets, work inspection reports, or paid invoices. Other evidence may include photographs, and walk-through reports.

Notes:

The SDT determined that the use of IEEE 516-2003 in version 1 of FAC-003 was a misapplication. The SDT consulted specialists who advised that the Gallet equation would be a technically justified method. The explanation of why the Gallet approach is more appropriate is explained in the paragraphs below.

The drafting team sought a method of establishing minimum clearance distances that uses realistic weather conditions and realistic maximum transient over-voltages factors for in-service transmission lines.

The SDT considered several factors when looking at changes to the minimum vegetation to conductor distances in FAC-003-1:

- avoid the problem associated with referring to tables in another standard (IEEE-516-2003)
- transmission lines operate in non-laboratory environments (wet conditions)
- transient over-voltage factors are lower for in-service transmission lines than for inadvertently re-energized transmission lines with trapped charges.

FAC-003-1 used the minimum air insulation distance (MAID) without tools formula provided in IEEE 516-2003 to determine the minimum distance between a transmission line conductor and vegetation. The equations and methods provided in IEEE 516 were developed by an IEEE Task Force in 1968 from test data provided by thirteen independent laboratories. The distances provided in IEEE 516 Tables 5 and 7 are based on the withstand voltage of a dry rod-rod air gap, or in other words, dry laboratory conditions. Consequently, the validity of using these distances in an outside environment application has been questioned.

FAC-003-1 allowed Transmission Owners to use either Table 5 or Table 7 to establish the minimum clearance distances. Table 7 could be used if the Transmission Owner knew the maximum transient over-voltage factor for its system. Otherwise, Table 5 would have to be used. Table 5 represented minimum air insulation distances under the worst possible case for transient over-voltage factors. These worst case transient over-voltage factors were as follows: 3.5 for voltages up to 362 kV phase to phase; 3.0 for 500 - 550 kV phase to phase; and 2.5 for 765 to 800 kV phase to phase. These worst case over-voltage factors were also a cause for concern in this particular application of the distances.

In general, the worst case transient over-voltages occur on a transmission line that is inadvertently re-energized immediately after the line is de-energized and a trapped charge is still present. The intent of FAC-003 is to keep a transmission line that is in service from becoming de-energized (i.e. tripped out) due to spark-over from the line conductor to nearby vegetation. Thus, the worst case transient overvoltage assumptions are not appropriate for this application. Rather, the appropriate over voltage values are those that occur only while the line is energized.

Typical values of transient over-voltages of in-service lines are not readily available in the literature because they are negligible compared with the maximums. A conservative value for the maximum transient over-voltage that can occur anywhere along the length of an in-service ac line was approximately 2.0 per unit. This value was a conservative estimate of the transient over-voltage that is created at the point of application (e.g. a substation) by switching a capacitor bank without pre-insertion devices (e.g. closing resistors). At voltage levels where capacitor banks are not very common (e.g. Maximum System Voltage of 362 kV), the maximum transient over-voltage of an in-service ac line are created by fault initiation on adjacent ac lines and shunt reactor bank switching. These transient voltages are usually 1.5 per unit or less.

Even though these transient over-voltages will not be experienced at locations remote from the bus at which they are created, in order to be conservative, it is assumed that all nearby ac lines are subjected to this same level of over-voltage. Thus, a maximum transient over-voltage factor of 2.0 per unit for transmission lines operated at 302 kV and below was considered to be a realistic maximum in this application. Likewise, for ac transmission lines operated at Maximum System Voltages of 362 kV and above a transient over-voltage factor of 1.4 per unit was considered a realistic maximum.

The Gallet equations are an accepted method for insulation coordination in tower design. These equations are used for computing the required strike distances for proper transmission line insulation coordination. They were developed for both wet and dry applications and can be used with any value of transient over-voltage factor. The Gallet equation also can take into account various air gap geometries. This approach was used to design the first 500 kV and 765 kV lines in North America.

If one compares the MAID using the IEEE 516-2003 Table 7 (table D.5 for English values) with the critical spark-over distances computed using the Gallet wet equations, for each of the nominal voltage classes and identical transient over-voltage factors, the Gallet equations yield a more conservative (larger) minimum distance value.

Distances calculated from either the IEEE 516 (dry) formulas or the Gallet “wet” formulas are not vastly different when the same transient overvoltage factors are used; the “wet” equations will consistently produce slightly larger distances than the IEEE 516 equations when the same transient overvoltage is used. While the IEEE 516 equations were only developed for dry conditions the Gallet equations have provisions to calculate spark-over distances for both wet and dry conditions.

Since no empirical data for spark over distances to live vegetation existed at the time version 3 was developed, the SDT chose a proven method that has been used in other EHV applications. The Gallet equations relevance to wet conditions and the selection of a Transient Overvoltage Factor that is consistent with the absence of trapped charges on an in-service transmission line make this methodology a better choice.

The following table is an example of the comparison of distances derived from IEEE 516 and the Gallet equations.

Comparison of spark-over distances computed using Gallet wet equations vs.

IEEE 516-2003 MAID distances

(AC) **Nom System** **Voltage (kV)**	**(AC)** **Max System** **Voltage (kV)**	**Transient** **Over-voltage** **Factor (T)**	**Clearance (ft.)** **Gallet (wet)** **@ Alt. 3000 feet**	Table 7 (Table D.5 for feet) **IEEE 516-2003** **MAID (ft)** **@ Alt. 3000 feet**
765	800	2.0	14.36	13.95
500	550	2.4	11.0	10.07
345	362	3.0	8.55	7.47
230	242	3.0	5.28	4.2
115	121	3.0	2.46	2.1

Rationale:
During development of this standard, text boxes were embedded within the standard to explain the rationale for various parts of the standard. Upon BOT approval, the text from the rationale text boxes was moved to this section.
Rationale for Applicability (section 4.2.4):
The areas excluded in 4.2.4 were excluded based on comments from industry for reasons summarized as follows:

1) There is a very low risk from vegetation in this area. Based on an informal survey, no TOs reported such an event.
2) Substations, switchyards, and stations have many inspection and maintenance activities that are necessary for reliability. Those existing process manage the threat. As such, the formal steps in this standard are not well suited for this environment.
3) Specifically addressing the areas where the standard does and does not apply makes the standard clearer.

Rationale for Applicability (section 4.3):
Within the text of NERC Reliability Standard FAC-003-3, "transmission line(s)" and "applicable line(s)" can also refer to the generation Facilities as referenced in 4.3 and its subsections.

Rationale for R1:
Lines with the highest significance to reliability are covered in R1; all other lines are covered in R2.

Rationale for the types of failure to manage vegetation which are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of an applicable Transmission Owner's or applicable Generator Owner's vegetation maintenance program:

1. This management failure is found by routine inspection or Fault event investigation, and is normally symptomatic of unusual conditions in an otherwise sound program.
2. This management failure occurs when the height and location of a side tree within the ROW is not adequately addressed by the program.
3. This management failure occurs when side growth is not adequately addressed and may be indicative of an unsound program.
4. This management failure is usually indicative of a program that is not addressing the most fundamental dynamic of vegetation management, (i.e. a grow-in under the line). If this type of failure is pervasive on multiple lines, it provides a mechanism for a Cascade.

Rationale for R3:
The documentation provides a basis for evaluating the competency of the applicable Transmission Owner's or applicable Generator Owner's vegetation program. There may be many acceptable approaches to maintain clearances. Any approach must demonstrate that the

applicable Transmission Owner or applicable Generator Owner avoids vegetation-to-wire conflicts under all Ratings and all Rated Electrical Operating Conditions.

Rationale for R4:

This is to ensure expeditious communication between the applicable Transmission Owner or applicable Generator Owner and the control center when a critical situation is confirmed.

Rationale for R5:

Legal actions and other events may occur which result in constraints that prevent the applicable Transmission Owner or applicable Generator Owner from performing planned vegetation maintenance work.

In cases where the transmission line is put at potential risk due to constraints, the intent is for the applicable Transmission Owner and applicable Generator Owner to put interim measures in place, rather than do nothing.

The corrective action process is not intended to address situations where a planned work methodology cannot be performed but an alternate work methodology can be used.

Rationale for R6:

Inspections are used by applicable Transmission Owners and applicable Generator Owners to assess the condition of the entire ROW. The information from the assessment can be used to determine risk, determine future work and evaluate recently-completed work. This requirement sets a minimum Vegetation Inspection frequency of once per calendar year but with no more than 18 months between inspections on the same ROW. Based upon average growth rates across North America and on common utility practice, this minimum frequency is reasonable. Transmission Owners should consider local and environmental factors that could warrant more frequent inspections.

Rationale for R7:

This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. It allows modifications to the planned work for changing conditions, taking into consideration anticipated growth of vegetation and all other environmental factors, provided that those modifications do not put the transmission system at risk of a vegetation encroachment.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	08/19/15
SAR posted for comment	08/20/15 – 09/21/15
45-day formal comment period with initial ballot	08/24/18-10/17/18

Anticipated Actions	Date
45-day formal comment period with initial ballot	June 2020
10-day final ballot	August 2020
NERC Board adoption	November 2020

A. Introduction

1. **Title:** Transmission Vegetation Management
2. **Number:** FAC-003-5
3. **Purpose:** To maintain a reliable electric transmission system by using a defense-in-depth strategy to manage vegetation located on transmission rights of way (ROW) and minimize encroachments from vegetation located adjacent to the ROW, thus preventing the risk of those vegetation-related outages that could lead to Cascading.
4. **Applicability:**

4.1. Functional Entities:

4.1.1. Applicable Transmission Owners

4.1.1.1. Transmission Owners that own Transmission Facilities defined in 4.2.

4.1.2. Applicable Generator Owners

4.1.2.1. Generator Owners that own generation Facilities defined in 4.3.

4.2. Transmission Facilities: Defined below (referred to as "applicable lines"), including but not limited to those that cross lands owned by federal[1], state, provincial, public, private, or tribal entities:

4.2.1. Each overhead transmission line operated at 200kV or higher.

4.2.2. Each overhead transmission line operated below 200kV, identified by the Planning Coordinator or Transmission Planner, per its Planning Assessment of the Near-Term Transmission Planning Horizon ~~or its Transfer Capability Assessment (Planning Coordinator only)~~ as a Facility that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation that adversely impacts the reliability of the Bulk Electric System for a planning event.

4.2.3. Each overhead transmission line operated below 200 kV identified as an element of a Major Western Electricity Coordinating Council (WECC) Transfer Path in the Bulk Electric System by WECC.

4.2.4. Each overhead transmission line identified above (4.2.1. through 4.2.3.) located outside the fenced area of the switchyard, station or substation and any portion of the span of the transmission line that is crossing the substation fence.

[1] EPAct 2005 section 1211c: *"Access approvals by Federal agencies."*

4.3. Generation Facilities: Defined below (referred to as "applicable lines"), including but not limited to those that cross lands owned by federal[2], state, provincial, public, private, or tribal entities:

4.3.1. Overhead transmission lines that (1) extend greater than one mile or 1.609 kilometers beyond the fenced area of the generating station switchyard to the point of interconnection with a Transmission Owner's Facility or (2) do not have a clear line of sight[3] from the generating station switchyard fence to the point of interconnection with a Transmission Owner's Facility and are:

4.3.1.1. Operated at 200kV or higher; or

4.3.1.2. Operated below 200kV and are identified by the Planning Coordinator or Transmission Planner, per its Planning Assessment of the Near-Term Transmission Planning Horizon ~~or its Transfer Capability Assessment (Planning Coordinator only)~~ as a Facility that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation that adversely impacts the reliability of the Bulk Electric System for a planning event; or

4.3.1.3. Operated below 200 kV identified as an element of a Major WECC Transfer Path in the Bulk Electric System by WECC.

5. **Effective Date:** See Implementation Plan

6. **Background:** This standard uses three types of requirements to provide layers of protection to prevent vegetation related outages that could lead to Cascading:

a) Performance-based defines a particular reliability objective or outcome to be achieved. In its simplest form, a results-based requirement has four components: *who, under what conditions (if any), shall perform what action, to achieve what particular bulk power system performance result or outcome?*

b) Risk-based preventive requirements to reduce the risks of failure to acceptable tolerance levels. A risk-based reliability requirement should be framed as: *who, under what conditions (if any), shall perform what action, to achieve what particular result or outcome that reduces a stated risk to the reliability of the bulk power system?*

c) Competency-based defines a minimum set of capabilities an entity needs to have to demonstrate it is able to perform its designated reliability functions. A competency-based reliability requirement should be framed as: *who, under what*

---

[2] *Id.*

[3] "Clear line of sight" means the distance that can be seen by the average person without special instrumentation (e.g., binoculars, telescope, spyglasses, etc.) on a clear day.

> *conditions (if any), shall have what capability, to achieve what particular result or outcome to perform an action to achieve a result or outcome or to reduce a risk to the reliability of the bulk power system?*

The defense-in-depth strategy for Reliability Standards development recognizes that each requirement in a NERC Reliability Standard has a role in preventing system failures, and that these roles are complementary and reinforcing. Reliability Standards should not be viewed as a body of unrelated requirements, but rather should be viewed as part of a portfolio of requirements designed to achieve an overall defense-in-depth strategy and comport with the quality objectives of a Reliability Standard.

This standard uses a defense-in-depth approach to improve the reliability of the electric Transmission system by:

- Requiring that vegetation be managed to prevent vegetation encroachment inside the flash-over clearance (R1 and R2);
- Requiring documentation of the maintenance strategies, procedures, processes and specifications used to manage vegetation to prevent potential flash-over conditions including consideration of 1) conductor dynamics and 2) the interrelationships between vegetation growth rates, control methods and the inspection frequency (R3);
- Requiring timely notification to the appropriate control center of vegetation conditions that could cause a flash-over at any moment (R4);
- Requiring corrective actions to ensure that flash-over distances will not be violated due to work constrains such as legal injunctions (R5);
- Requiring inspections of vegetation conditions to be performed annually (R6); and
- Requiring that the annual work needed to prevent flash-over is completed (R7).

For this standard, the requirements have been developed as follows:

- Performance-based: Requirements 1 and 2
- Competency-based: Requirement 3
- Risk-based: Requirements 4, 5, 6 and 7

Requirement R3 serves as the first line of defense by ensuring that entities understand the problem they are trying to manage and have fully developed strategies and plans to manage the problem. Requirements R1, R2, and R7 serve as the second line of defense by requiring that entities carry out their plans and manage vegetation. Requirement R6, which requires inspections, may be either a part of the first line of defense (as input into the strategies and plans) or as a third line of defense (as a check of the first and second lines of defense). Requirement R4 serves as the final line of defense, as it addresses cases in which all the other lines of defense have failed.

Major outages and operational problems have resulted from interference between overgrown vegetation and transmission lines located on many types of lands and ownership situations. Adherence to the standard requirements for applicable lines on any kind of land or easement, whether they are Federal Lands, state or provincial lands, public or private lands, franchises, easements or lands owned in fee, will reduce and manage this risk. For the purpose of the standard the term “public lands” includes municipal lands, village lands, city lands, and a host of other governmental entities.

This standard addresses vegetation management along applicable overhead lines and does not apply to underground lines, submarine lines or to line sections inside an electric station boundary.

This standard focuses on transmission lines to prevent those vegetation related outages that could lead to Cascading. It is not intended to prevent customer outages due to tree contact with lower voltage distribution system lines. For example, localized customer service might be disrupted if vegetation were to make contact with a 69kV transmission line supplying power to a 12kV distribution station. However, this standard is not written to address such isolated situations which have little impact on the overall electric transmission system.

Since vegetation growth is constant and always present, unmanaged vegetation poses an increased outage risk, especially when numerous transmission lines are operating at or near their Rating. This can present a significant risk of consecutive line failures when lines are experiencing large sags thereby leading to Cascading. Once the first line fails the shift of the current to the other lines and/or the increasing system loads will lead to the second and subsequent line failures as contact to the vegetation under those lines occurs. Conversely, most other outage causes (such as trees falling into lines, lightning, animals, motor vehicles, etc.) are not an interrelated function of the shift of currents or the increasing system loading. These events are not any more likely to occur during heavy system loads than any other time. There is no cause-effect relationship which creates the probability of simultaneous occurrence of other such events. Therefore these types of events are highly unlikely to cause large-scale grid failures. Thus, this standard places the highest priority on the management of vegetation to prevent vegetation grow-ins.

B. Requirements and Measures

R1. Each applicable Transmission Owner and applicable Generator Owner shall manage vegetation to prevent encroachments into the Minimum Vegetation Clearance Distance (MVCD) of its applicable line(s), operating within their Rating and all Rated

Electrical Operating Conditions of the types shown below[4] *[Violation Risk Factor: High] [Time Horizon: Real-time]*:

1.1. An encroachment into the MVCD as shown in FAC-003-Table 2, observed in Real-time, absent a Sustained Outage,[5]

1.2. An encroachment due to a fall-in from inside the ROW that caused a vegetation-related Sustained Outage,[6]

1.3. An encroachment due to the blowing together of applicable lines and vegetation located inside the ROW that caused a vegetation-related Sustained Outage[7],

1.4. An encroachment due to vegetation growth into the MVCD that caused a vegetation-related Sustained Outage.[8]

M1. Each applicable Transmission Owner and applicable Generator Owner has evidence that it managed vegetation to prevent encroachment into the MVCD as described in R1. Examples of acceptable forms of evidence may include dated attestations, dated reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-time observations of any MVCD encroachments. (R1)

R2. [Reserved for future use]

~~**2.0.**~~

~~**M3.**~~**M2.** [Reserved for future use]

R3. Each applicable Transmission Owner and applicable Generator Owner shall have documented maintenance strategies or procedures or processes or specifications it uses to prevent the encroachment of vegetation into the MVCD of its applicable lines that accounts for the following: *[Violation Risk Factor: Lower] [Time Horizon: Long Term Planning]:*

3.1. Movement of applicable line conductors under their Rating and all Rated Electrical Operating Conditions;

---

[4] This requirement does not apply to circumstances that are beyond the control of an applicable Transmission Owner or applicable Generator Owner subject to this R~~r~~eliability S~~s~~tandard, including natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the applicable Transmission Owner or applicable Generator Owner or an applicable regulatory body, ice storms, and floods; human or animal activity such as logging, animal severing tree, vehicle contact with tree, or installation, removal, or digging of vegetation. Nothing in this footnote should be construed to limit the Transmission Owner's or applicable Generator Owner's right to exercise its full legal rights on the ROW.

[5] If a later confirmation of a Fault by the applicable Transmission Owner or applicable Generator Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the equivalent of a Real-time observation.

[6] Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period.

[7] *Id.*

[8] *Id.*

3.2. Inter-relationships between vegetation growth rates, vegetation control methods, and inspection frequency.

~~M4.~~M3. The maintenance strategies or procedures or processes or specifications provided demonstrate that the applicable Transmission Owner and applicable Generator Owner can prevent encroachment into the MVCD considering the factors identified in the requirement. (R3)

R4. Each applicable Transmission Owner and applicable Generator Owner, without any intentional time delay, shall notify the control center holding switching authority for the associated applicable line when the applicable Transmission Owner and applicable Generator Owner has confirmed the existence of a vegetation condition that is likely to cause a Fault at any moment *[Violation Risk Factor: Medium] [Time Horizon: Real-time].*

~~M5.~~M4. Each applicable Transmission Owner and applicable Generator Owner that has a confirmed vegetation condition likely to cause a Fault at any moment will have evidence that it notified the control center holding switching authority for the associated transmission line without any intentional time delay. Examples of evidence may include control center logs, voice recordings, switching orders, clearance orders and subsequent work orders. (R4)

R5. When an applicable Transmission Owner and an applicable Generator Owner are constrained from performing vegetation work on an applicable line operating within its Rating and all Rated Electrical Operating Conditions, and the constraint may lead to a vegetation encroachment into the MVCD prior to the implementation of the next annual work plan, then the applicable Transmission Owner or applicable Generator Owner shall take corrective action to ensure continued vegetation management to prevent encroachments [*Violation Risk Factor: Medium*] [*Time Horizon: Operations Planning*].

~~M6.~~M5. Each applicable Transmission Owner and applicable Generator Owner has evidence of the corrective action taken for each constraint where an applicable transmission line was put at potential risk. Examples of acceptable forms of evidence may include initially-planned work orders, documentation of constraints from landowners, court orders, inspection records of increased monitoring, documentation of the de-rating of lines, revised work orders, invoices, or evidence that the line was de-energized. (R5)

R6. Each applicable Transmission Owner and applicable Generator Owner shall perform a Vegetation Inspection of 100% of its applicable transmission lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.) at least once per calendar

year and with no more than 18 calendar months between inspections on the same ROW[9] [*Violation Risk Factor: Medium*] [*Time Horizon: Operations Planning*].

~~M7.~~M6. Each applicable Transmission Owner and applicable Generator Owner has evidence that it conducted Vegetation Inspections of the transmission line ROW for all applicable lines at least once per calendar year but with no more than 18 calendar months between inspections on the same ROW. Examples of acceptable forms of evidence may include completed and dated work orders, dated invoices, or dated inspection records. (R6)

R7. Each applicable Transmission Owner and applicable Generator Owner shall complete 100% of its annual vegetation work plan of applicable lines to ensure no vegetation encroachments occur within the MVCD. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made (provided they do not allow encroachment of vegetation into the MVCD) and must be documented. The percent completed calculation is based on the number of units actually completed divided by the number of units in the final amended plan (measured in units of choice - circuit, pole line, line miles or kilometers, etc.). Examples of reasons for modification to annual plan may include [*Violation Risk Factor: Medium*] [*Time Horizon: Operations Planning*]:

7.1. Change in expected growth rate/environmental factors

7.2. Circumstances that are beyond the control of an applicable Transmission Owner or applicable Generator Owner[10]

7.3. Rescheduling work between growing seasons

7.4. Crew or contractor availability/Mutual assistance agreements

7.5. Identified unanticipated high priority work

7.6. Weather conditions/Accessibility

7.7. Permitting delays

7.8. Land ownership changes/Change in land use by the landowner

7.9. Emerging technologies

~~M8.~~M7. Each applicable Transmission Owner and applicable Generator Owner has evidence that it completed its annual vegetation work plan for its applicable lines. Examples of acceptable forms of evidence may include a copy of the completed

[9] When the applicable Transmission Owner or applicable Generator Owner is prevented from performing a Vegetation Inspection within the timeframe in R6 due to a natural disaster, the TO or GO is granted a time extension that is equivalent to the duration of the time the TO or GO was prevented from performing the Vegetation Inspection.

[10] Circumstances that are beyond the control of an applicable Transmission Owner or applicable Generator Owner include but are not limited to natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, ice storms, floods, or major storms as defined either by the TO or GO or an applicable regulatory body.

annual work plan (as finally modified), dated work orders, dated invoices, or dated inspection records. (R7)

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority:
"Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention:
The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

- The applicable Transmission Owner and applicable Generator Owner retains data or evidence to show compliance with Requirements R1, ~~R2,~~ R3, R5, R6 and R7, for three calendar years.
- The applicable Transmission Owner and applicable Generator Owner retains data or evidence to show compliance with Requirement R4, Measure M4 for most recent 12 months of operator logs or most recent 3 months of voice recordings or transcripts of voice recordings, unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.
- If an applicable Transmission Owner or applicable Generator Owner is found non-compliant, it shall keep information related to the non-compliance until found compliant or for the time period specified above, whichever is longer.

1.3. Compliance Monitoring and Enforcement Program
As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

1.4. Additional Compliance Information

Periodic Data Submittal: The applicable Transmission Owner and applicable Generator Owner will submit a quarterly report to its Regional Entity, or the Regional Entity's designee, identifying all Sustained Outages of applicable lines operated within their Rating and all Rated Electrical Operating Conditions as determined by the applicable Transmission Owner or applicable Generator Owner to have been caused by vegetation, except as excluded in footnote ~~2~~4, and including as a minimum the following:

- The name of the circuit(s), the date, time and duration of the outage; the voltage of the circuit; a description of the cause of the outage; the category associated with the Sustained Outage; other pertinent comments; and any countermeasures taken by the applicable Transmission Owner or applicable Generator Owner.

  A Sustained Outage is to be categorized as one of the following:

- Category 1A — Grow-ins: Sustained Outages caused by vegetation growing into applicable lines, that are identified by the Planning Coordinator, per its Planning Assessment of the Near-Term Transmission Planning Horizon ~~or its Transfer Capability Assessment (Planning Coordinator only),~~ as a Facilit~~y~~ies that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation that adversely impacts the reliability of the Bulk Electric System ~~as an element of an IROL or Major WECC Transfer Path,~~ by vegetation inside and/or outside of the ROW;
- Category 1B — Grow-ins: Sustained Outages caused by vegetation growing into applicable lines, but are not identified by the Planning Coordinator, per its Planning Assessment of the Near-Term Transmission Planning Horizon ~~or its Transfer Capability Assessment (Planning Coordinator only)~~ as a Facility~~ies~~ that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation that adversely impacts the reliability of the Bulk Electric System for a planning event ~~as an element of an IROL or Major WECC Transfer Path,~~ by vegetation inside and/or outside of the ROW;
- Category 2A — Fall-ins: Sustained Outages caused by vegetation falling into applicable lines that are identified by the Planning Coordinator, per its Planning Assessment of the Near-Term Transmission Planning Horizon ~~or its Transfer Capability Assessment (Planning Coordinator only)~~ as Facility~~ies~~ that if lost or degraded are ~~epected~~expected to result in instances of instability, Cascading, or uncontrolled separation that adversely impacts the reliability of the Bulk Electric System for a planning event ~~as an element of an IROL or Major WECC Transfer Path,~~ from within the ROW;
- Category 2B — Fall-ins: Sustained Outages caused by vegetation falling into applicable lines, but are not identified by the Planning Coordinator, per its Planning Assessment of the Near-Term Transmission Planning Horizon ~~or its~~

~~Transfer Capability Assessment (Planning Coordinator only)~~ as Facilities that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation that adversely impacts the reliability of the Bulk Electric System for a planning event ~~as an element of an IROL or Major WECC Transfer Path~~, from within the ROW;

- Category 3 — Fall-ins: Sustained Outages caused by vegetation falling into applicable lines from outside the ROW;
- Category 4A — Blowing together: Sustained Outages caused by vegetation and applicable lines that are identified by the Planning Coordinator, per its Planning Assessment of the Near-Term Transmission Planning Horizon ~~or its Transfer Capability Assessment (Planning Coordinator only)~~ as a Facility~~ies~~ that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation that adversely impacts the reliability of the Bulk Electric System for a planning event ~~as an element of an IROL or Major WECC Transfer Path,~~ blowing together from within the ROW;
- Category 4B — Blowing together: Sustained Outages caused by vegetation and applicable lines, but are not identified by the Planning Coordinator, per its Planning Assessment of the Near-Term Transmission Planning Horizon ~~or its Transfer Capability Assessment (Planning Coordinator only)~~ as a Facility~~ies~~ that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation that adversely impacts the reliability of the Bulk Electric System for a planning event ~~as an element of an IROL or Major WECC Transfer Path~~, blowing together from within the ROW.

The Regional Entity will report the outage information provided by applicable Transmission Owners and applicable Generator Owners, as per the above, quarterly to NERC, as well as any actions taken by the Regional Entity as a result of any of the reported Sustained Outages.

Violation Severity Levels (Table 1)

R #	Table 1: Violation Severity Levels (VSL)			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1.			The responsible entity failed to manage vegetation to prevent encroachment into the MVCD of a line identified in the Applicability section 4.2 and 4.3 and encroachment into the MVCD as identified in FAC-003-5-Table 2 was observed in real time absent a Sustained Outage.	The responsible entity failed to manage vegetation to prevent encroachment into the MVCD of a line identified in the Applicability section 4.2 and 4.3 and a vegetation-related Sustained Outage was caused by one of the following: • *A fall-in from inside the active transmission line ROW* • *Blowing together of applicable lines and vegetation located inside the active transmission line ROW* • *A grow-in*
R2. Reserved for				•

future use				
R3.		The responsible entity has maintenance strategies or documented procedures or processes or specifications but has not accounted for the inter-relationships between vegetation growth rates, vegetation control methods, and inspection frequency, for the responsible entity's applicable lines. (Requirement R3, Part 3.2.)	The responsible entity has maintenance strategies or documented procedures or processes or specifications but has not accounted for the movement of transmission line conductors under their Rating and all Rated Electrical Operating Conditions, for the responsible entity's applicable lines. (Requirement R3, Part 3.1.)	The responsible entity does not have any maintenance strategies or documented procedures or processes or specifications used to prevent the encroachment of vegetation into the MVCD, for the responsible entity's applicable lines.
R4.			The responsible entity experienced a confirmed vegetation threat and notified the control center holding switching authority for that applicable line, but there was intentional delay in that notification.	The responsible entity experienced a confirmed vegetation threat and did not notify the control center holding switching authority for that applicable line.
R5.				The responsible entity did not take corrective action when it was constrained from performing planned

				vegetation work where an applicable line was put at potential risk.
R6.	The responsible entity failed to inspect 5% or less of its applicable lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.)	The responsible entity failed to inspect more than 5% up to and including 10% of its applicable lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.).	The responsible entity failed to inspect more than 10% up to and including 15% of its applicable lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.).	The responsible entity failed to inspect more than 15% of its applicable lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.).
R7.	The responsible entity failed to complete 5% or less of its annual vegetation work plan for its applicable lines (as finally modified).	The responsible entity failed to complete more than 5% and up to and including 10% of its annual vegetation work plan for its applicable lines (as finally modified).	The responsible entity failed to complete more than 10% and up to and including 15% of its annual vegetation work plan for its applicable lines (as finally modified).	The responsible entity failed to complete more than 15% of its annual vegetation work plan for its applicable lines (as finally modified).

- FAC-003-4 Implementation Plan

Version History

Version	Date	Action	Change Tracking
1	January 20, 2006	1. Added “Standard Development Roadmap.” 2. Changed “60” to “Sixty” in section A, 5.2. 3. Added “Proposed Effective Date: April 7, 2006” to footer. 4. Added “Draft 3: November 17, 2005” to footer.	New
1	April 4, 2007	Regulatory Approval - Effective Date	New
2	November 3, 2011	Adopted by the NERC Board of Trustees	New
2	March 21, 2013	FERC Order issued approving FAC-003-2 (Order No. 777) FERC Order No. 777 was issued on March 21, 2013 directing NERC to “conduct or contract testing to obtain empirical data and submit a report to the Commission providing the results of the testing.”[11]	Revisions
2	May 9, 2013	Board of Trustees adopted the modification of the VRF for Requirement R2 of FAC-003-2 by raising the VRF from “Medium” to “High.”	Revisions
3	May 9, 2013	FAC-003-3 adopted by Board of Trustees	Revisions
3	September 19, 2013	A FERC order was issued on September 19, 2013, approving FAC-003-3. This standard became enforceable on July 1, 2014 for Transmission Owners. For Generator Owners, R3 became enforceable on January 1, 2015 and all other requirements (R1, R2, R4, R5, R6, and R7) became enforceable on January 1, 2016.	Revisions
3	November 22, 2013	Updated the VRF for R2 from “Medium” to “High” per a Final Rule issued by FERC	Revisions
3	July 30, 2014	Transferred the effective dates section from FAC-003-2 (for Transmission Owners) into FAC-003-3, per the FAC-003-3 implementation plan	Revisions

[11] *Revisions to Reliability Standard for Transmission Vegetation Management, Order No. 777,* 142 FERC ¶ 61,208 (2013)

4	February 11, 2016	Adopted by Board of Trustees. Adjusted MVCD values in Table 2 for alternating current systems, consistent with findings reported in report filed on August 12, 2015 in Docket No. RM12-4-002 consistent with FERC's directive in Order No. 777, and based on empirical testing results for flashover distances between conductors and vegetation.	Revisions
4	March 9, 2016	Corrected subpart 7.10 to M7, corrected value of .07 to .7	Errata
4	April 26, 2016	FERC Letter Order approving FAC-003-4. Docket No. RD16-4-000.	
5	TBD	Approved by Board of Trustees	Revisions

FAC-003 — TABLE 2 — Minimum Vegetation Clearance Distances (MVCD)[12]

For **Alternating Current** Voltages (feet)

(AC) Nominal System Voltage (KV)[+]	(AC) Maximum System Voltage (kV)[13]	MVCD (feet) Over sea level up to 500 ft	MVCD feet Over 500 ft up to 1000 ft	MVCD feet Over 1000 ft up to 2000 ft	MVCD feet Over 2000 ft up to 3000 ft	MVCD feet Over 3000 ft up to 4000 ft	MVCD feet Over 4000 ft up to 5000 ft	MVCD feet Over 5000 ft up to 6000 ft	MVCD feet Over 6000 ft up to 7000 ft	MVCD feet Over 7000 ft up to 8000 ft	MVCD feet Over 8000 ft up to 9000 ft	MVCD feet Over 9000 ft up to 10000 ft	MVCD feet Over 10000 ft up to 11000 ft	MVCD feet Over 11000 ft up to 12000 ft	MVCD feet Over 12000 ft up to 13000 ft	MVCD feet Over 13000 ft up to 14000 ft	MVCD feet Over 14000 ft up to 15000 ft

287	302	5.2ft	5.3ft	5.4ft	5.5ft	5.6ft	5.7ft	5.8ft	5.9ft	6.1ft	6.2ft	6.3ft	6.4ft	6.5ft	6.6ft	6.8ft	6.9ft
230	242	4.0ft	4.1ft	4.2ft	4.3ft	4.3ft	4.4ft	4.5ft	4.6ft	4.7ft	4.8ft	4.9ft	5.0ft	5.1ft	5.2ft	5.3ft	5.4ft
161*	169	2.7ft	2.7ft	2.8ft	2.9ft	2.9ft	3.0ft	3.0ft	3.1ft	3.2ft	3.3ft	3.3ft	3.4ft	3.5ft	3.6ft	3.7ft	3.8ft
138*	145	2.3ft	2.3ft	2.4ft	2.4ft	2.5ft	2.5ft	2.6ft	2.7ft	2.7ft	2.8ft	2.8ft	2.9ft	3.0ft	3.0ft	3.1ft	3.2ft
115*	121	1.9ft	1.9ft	1.9ft	2.0ft	2.0ft	2.1ft	2.1ft	2.2ft	2.2ft	2.3ft	2.3ft	2.4ft	2.5ft	2.5ft	2.6ft	2.7ft
88*	100	1.5ft	1.5ft	1.6ft	1.6ft	1.7ft	1.7ft	1.8ft	1.8ft	1.8ft	1.9ft	1.9ft	2.0ft	2.0ft	2.1ft	2.2ft	2.2ft
69*	72	1.1ft	1.1ft	1.1ft	1.2ft	1.2ft	1.2ft	1.2ft	1.3ft	1.3ft	1.3ft	1.4ft	1.4ft	1.4ft	1.5ft	1.6ft	1.6ft

* Such lines are applicable to this standard only if PC has determined such per FAC-014 (refer to the Applicability Section above)

[12] The distances in this Table are the minimums required to prevent Flash-over; however prudent vegetation maintenance practices dictate that substantially greater distances will be achieved at time of vegetation maintenance.

[13] Where applicable lines are operated at nominal voltages other than those listed, the applicable Transmission Owner or applicable Generator Owner should use the maximum system voltage to determine the appropriate clearance for that line.

[14] The change in transient overvoltage factors in the calculations are the driver in the decrease in MVCDs for voltages of 345 kV and above. Refer to pp.29-31 in the Supplemental Materials for additional information.

+ Table 2 – Table of MVCD values at a 1.0 gap factor (in U.S. customary units), which is located in the EPRI report filed with FERC on August 12, 2015. (The 14000-15000 foot values were subsequently provided by EPRI in an updated Table 2 on December 1, 2015, filed with the FAC-003-4 Petition at FERC)

[18] The distances in this Table are the minimums required to prevent Flash-over; however prudent vegetation maintenance practices dictate that substantially greater distances will be achieved at time of vegetation maintenance.

Guideline and Technical Basis

Effective dates:

The Compliance section is standard language used in most NERC standards to cover the general effective date and covers the vast majority of situations. A special case covers effective dates for (1) lines initially becoming subject to the Standard, (2) lines changing in applicability within the standard.

The special case is needed because the Planning Coordinators or Transmission Planners may designate lines below 200 kV-, per its Planning Assessment of the Near-Term Transmission Planning Horizon or its Transfer Capability Assessment as Facilities that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation that adversely impacts the reliability of the Bulk Electric System for a planning event in a future Planning Year (PY). For example, studies by the Planning Coordinator in 2015 may identify a line to have that designation beginning in PY 2025, ten years after the planning study is performed. It is not intended for the Standard to be immediately applicable to, or in effect for, that line until that future PY begins. The effective date provision for such lines ensures that the line will become subject to the standard on January 1 of the PY specified with an allowance of at least 12 months for the applicable Transmission Owner or applicable Generator Owner to make the necessary preparations to achieve compliance on that line. A line operating below 200kV designated by the Planning Coordinator or Transmission Planner, per its Planning Assessment of the Near-Term Transmission Planning Horizon or its Transfer Capability Assessment (Planning Coordinator only) as Facilities that if lost or degraded are expected to result in instances of instability, Cascading, or uncontrolled separation that adversely impacts the reliability of the Bulk Electric System for a planning event may be removed from that designation due to system improvements, changes in generation, changes in loads or changes in studies and analysis of the network.

Date that Planning Study is completed	PY the line will become an identified element	Date 1	Date 2	Effective Date The later of Date 1 or Date 2
05/15/2011	2012	05/15/2012	01/01/2012	05/15/2012
05/15/2011	2013	05/15/2012	01/01/2013	01/01/2013
05/15/2011	2014	05/15/2012	01/01/2014	01/01/2014
05/15/2011	2021	05/15/2012	01/01/2021	01/01/2021

Defined Terms:

Explanation for revising the definition of ROW:

The current NERC glossary definition of Right of Way has been modified to include Generator Owners and to address the matter set forth in Paragraph 734 of FERC Order 693. The Order pointed out that Transmission Owners may in some cases own more property or rights than are needed to reliably operate transmission lines. This definition represents a slight but significant departure from the strict legal definition of "right of way" in that this definition is based on engineering and construction considerations that establish the width of a corridor from a technical basis. The pre-2007 maintenance records are included in the current definition to allow the use of such vegetation widths if there were no engineering or construction standards that referenced the width of right of way to be maintained for vegetation on a particular line but the evidence exists in maintenance records for a width that was in fact maintained prior to this standard becoming mandatory. Such widths may be the only information available for lines that had limited or no vegetation easement rights and were typically maintained primarily to ensure public safety. This standard does not require additional easement rights to be purchased to satisfy a minimum right of way width that did not exist prior to this standard becoming mandatory.

Explanation for revising the definition of Vegetation Inspection:

The current glossary definition of this NERC term was modified to include Generator Owners and to allow both maintenance inspections and vegetation inspections to be performed concurrently. This allows potential efficiencies, especially for those lines with minimal vegetation and/or slow vegetation growth rates.

Explanation of the derivation of the MVCD:

The MVCD is a calculated minimum distance that is derived from the Gallet equation. This is a method of calculating a flash over distance that has been used in the design of high voltage transmission lines. Keeping vegetation away from high voltage conductors by this distance will prevent voltage flash-over to the vegetation. See the explanatory text below for Requirement R3 and associated Figure 1. Table 2 of the standard provides MVCD values for various voltages and altitudes. The table is based on empirical testing data from EPRI as requested by FERC in Order No. 777.

Project 2010-07.1 Adjusted MVCDs per EPRI Testing:

In Order No. 777, FERC directed NERC to undertake testing to gather empirical data validating the appropriate gap factor used in the Gallet equation to calculate MVCDs, specifically the gap factor for the flash-over distances between conductors and vegetation. See, Order No. 777, at P 60. NERC engaged industry through a collaborative research project and contracted EPRI to complete the scope of work. In January 2014, NERC formed an advisory group to assist with developing the scope of work for the project. This team provided subject matter expertise for developing the test plan, monitoring testing, and vetting the analysis and conclusions to be submitted in a final report. The advisory team was comprised of NERC staff, arborists, and industry members with wide-ranging expertise in transmission engineering, insulation coordination, and vegetation management. The testing project commenced in April 2014 and continued through October 2014 with the final set of testing completed in May 2015. Based on these testing results conducted by EPRI, and consistent with the report filed in FERC Docket No.

RM12-4-000, the gap factor used in the Gallet equation required adjustment from 1.3 to 1.0. This resulted in increased MVCD values for all alternating current system voltages identified. The adjusted MVCD values, reflecting the 1.0 gap factor, are included in Table 2 of version 4 of FAC-003.

The air gap testing completed by EPRI per FERC Order No. 777 established that trees with large spreading canopies growing directly below energized high voltage conductors create the greatest likelihood of an air gap flash over incident and was a key driver in changing the gap factor to a more conservative value of 1.0 in version 4 of this standard.

Requirements R1:
R1 is a performance-based requirements. The reliability objective or outcome to be achieved is the management of vegetation such that there are no vegetation encroachments within a minimum distance of transmission lines R1 requires each applicable Transmission Owner or applicable Generator Owner to manage vegetation to prevent encroachment within the MVCD of transmission lines. R1 is applicable to lines that are identified as an element in the Applicability section 4.2 and 4.3.

Requirements R1 states that if inadequate vegetation management allows vegetation to encroach within the MVCD distance as shown in Table 2, it is a violation of the standard. Table 2 distances are the minimum clearances that will prevent spark-over based on the Gallet equations. These requirements assume that transmission lines and their conductors are operating within their Rating. If a line conductor is intentionally or inadvertently operated beyond its Rating and Rated Electrical Operating Condition (potentially in violation of other standards), the occurrence of a clearance encroachment may occur solely due to that condition. For example, emergency actions taken by an applicable Transmission Owner or applicable Generator Owner or Reliability Coordinator to protect an Interconnection may cause excessive sagging and an outage. Another example would be ice loading beyond the line's Rating and Rated Electrical Operating Condition. Such vegetation-related encroachments and outages are not violations of this standard.

Evidence of failures to adequately manage vegetation include real-time observation of a vegetation encroachment into the MVCD (absent a Sustained Outage), or a vegetation-related encroachment resulting in a Sustained Outage due to a fall-in from inside the ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to the blowing together of the lines and vegetation located inside the ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to a grow-in. Faults which do not cause a Sustained outage and which are confirmed to have been caused by vegetation encroachment within the MVCD are considered the equivalent of a Real-time observation for violation severity levels.

With this approach, the VSLs for R1 are structured such that they directly correlate to the severity of a failure of an applicable Transmission Owner or applicable Generator Owner to manage vegetation and to the corresponding performance level of the Transmission Owner's vegetation program's ability to meet the objective of "preventing the risk of those vegetation related outages that could lead to Cascading." Thus violation severity increases with an applicable Transmission Owner's or applicable Generator Owner's inability to meet this goal and its potential of leading to a Cascading event. The additional benefits of such a combination are that it simplifies the standard and clearly defines performance for compliance. A performance-based requirement of this nature will promote high quality, cost effective vegetation management programs that will deliver the overall end result of improved reliability to the system.

Multiple Sustained Outages on an individual line can be caused by the same vegetation. For example initial investigations and corrective actions may not identify and remove the actual outage cause then another outage occurs after the line is re-energized and previous high conductor temperatures return. Such events are considered to be a single vegetation-related Sustained Outage under the standard where the Sustained Outages occur within a 24 hour period.

If the applicable Transmission Owner or applicable Generator Owner has applicable lines operated at nominal voltage levels not listed in Table 2, then the applicable TO or applicable GO should use the next largest clearance distance based on the next highest nominal voltage in the table to determine an acceptable distance.

Requirement R3:
R3 is a competency based requirement concerned with the maintenance strategies, procedures, processes, or specifications, an applicable Transmission Owner or applicable Generator Owner uses for vegetation management.

An adequate transmission vegetation management program formally establishes the approach the applicable Transmission Owner or applicable Generator Owner uses to plan and perform vegetation work to prevent transmission Sustained Outages and minimize risk to the transmission system. The approach provides the basis for evaluating the intent, allocation of appropriate resources, and the competency of the applicable Transmission Owner or applicable Generator Owner in managing vegetation. There are many acceptable approaches to manage vegetation and avoid Sustained Outages. However, the applicable Transmission Owner or applicable Generator Owner must be able to show the documentation of its approach and how it conducts work to maintain clearances.

An example of one approach commonly used by industry is ANSI Standard A300, part 7. However, regardless of the approach a utility uses to manage vegetation, any approach an applicable Transmission Owner or applicable Generator Owner chooses to use will generally contain the following elements:

1. *the maintenance strategy used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that MVCD clearances are never violated*
2. *the work methods that the applicable Transmission Owner or applicable Generator Owner uses to control vegetation*

3. *a stated Vegetation Inspection frequency*
4. *an annual work plan*

The conductor's position in space at any point in time is continuously changing in reaction to a number of different loading variables. Changes in vertical and horizontal conductor positioning are the result of thermal and physical loads applied to the line. Thermal loading is a function of line current and the combination of numerous variables influencing ambient heat dissipation including wind velocity/direction, ambient air temperature and precipitation. Physical loading applied to the conductor affects sag and sway by combining physical factors such as ice and wind loading. The movement of the transmission line conductor and the MVCD is illustrated in Figure 1 below.

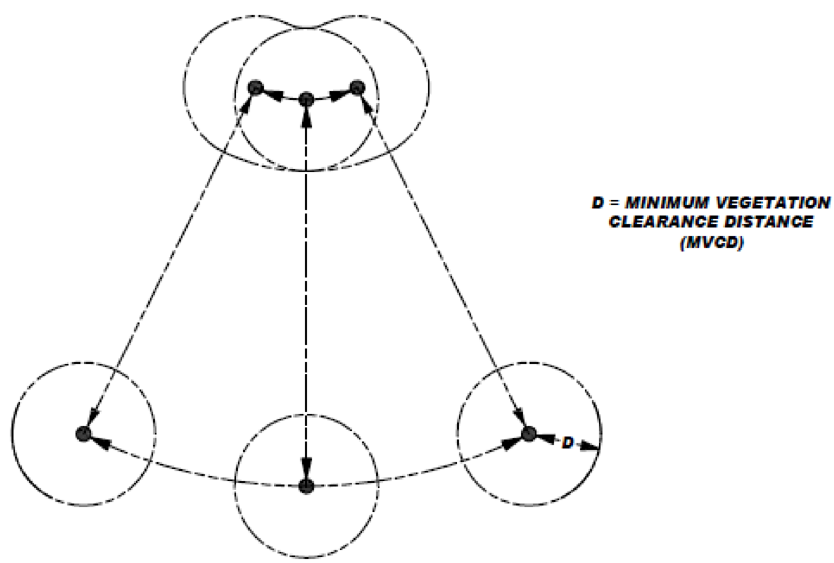

Figure 1

A cross-section view of a single conductor at a given point along the span is shown with six possible conductor positions due to movement resulting from thermal and mechanical loading.

Requirement R4:

R4 is a risk-based requirement. It focuses on preventative actions to be taken by the applicable Transmission Owner or applicable Generator Owner for the mitigation of Fault risk when a vegetation threat is confirmed. R4 involves the notification of potentially threatening vegetation conditions, without any intentional delay, to the control center holding switching authority for that specific transmission line. Examples of acceptable unintentional delays may include communication system problems (for example, cellular service or two-way radio disabled), crews located in remote field locations with no communication access, delays due to severe weather, etc.

Confirmation is key that a threat actually exists due to vegetation. This confirmation could be in the form of an applicable Transmission Owner or applicable Generator Owner employee who personally identifies such a threat in the field. Confirmation could also be made by sending out an employee to evaluate a situation reported by a landowner.

Vegetation-related conditions that warrant a response include vegetation that is near or encroaching into the MVCD (a grow-in issue) or vegetation that could fall into the transmission conductor (a fall-in issue). A knowledgeable verification of the risk would include an assessment of the possible sag or movement of the conductor while operating between no-load conditions and its rating.

The applicable Transmission Owner or applicable Generator Owner has the responsibility to ensure the proper communication between field personnel and the control center to allow the control center to take the appropriate action until or as the vegetation threat is relieved. Appropriate actions may include a temporary reduction in the line loading, switching the line out of service, or other preparatory actions in recognition of the increased risk of outage on that circuit. The notification of the threat should be communicated in terms of minutes or hours as opposed to a longer time frame for corrective action plans (see R5).

All potential grow-in or fall-in vegetation-related conditions will not necessarily cause a Fault at any moment. For example, some applicable Transmission Owners or applicable Generator Owners may have a danger tree identification program that identifies trees for removal with the potential to fall near the line. These trees would not require notification to the control center unless they pose an immediate fall-in threat.

Requirement R5:

R5 is a risk-based requirement. It focuses upon preventative actions to be taken by the applicable Transmission Owner or applicable Generator Owner for the mitigation of Sustained Outage risk when temporarily constrained from performing vegetation maintenance. The intent of this requirement is to deal with situations that prevent the applicable Transmission Owner or applicable Generator Owner from performing planned vegetation management work and, as a result, have the potential to put the transmission line at risk. Constraints to performing vegetation maintenance work as planned could result from legal injunctions filed by property owners, the discovery of easement stipulations which limit the applicable Transmission Owner's or applicable Generator Owner's rights, or other circumstances.

This requirement is not intended to address situations where the transmission line is not at potential risk and the work event can be rescheduled or re-planned using an alternate work methodology. For example, a land owner may prevent the planned use of herbicides to control incompatible vegetation outside of the MVCD, but agree to the use of mechanical clearing. In this case the applicable Transmission Owner or applicable Generator Owner is not under any immediate time constraint for achieving the management objective, can easily reschedule work using an alternate approach, and therefore does not need to take interim corrective action.

However, in situations where transmission line reliability is potentially at risk due to a constraint, the applicable Transmission Owner or applicable Generator Owner is required to take an interim corrective action to mitigate the potential risk to the transmission line. A wide range of actions can be taken to address various situations. General considerations include:

- Identifying locations where the applicable Transmission Owner or applicable Generator Owner is constrained from performing planned vegetation maintenance work which potentially leaves the transmission line at risk.
- Developing the specific action to mitigate any potential risk associated with not performing the vegetation maintenance work as planned.
- Documenting and tracking the specific action taken for the location.
- In developing the specific action to mitigate the potential risk to the transmission line the applicable Transmission Owner or applicable Generator Owner could consider location specific measures such as modifying the inspection and/or maintenance intervals. Where a legal constraint would not allow any vegetation work, the interim corrective action could include limiting the loading on the transmission line.
- The applicable Transmission Owner or applicable Generator Owner should document and track the specific corrective action taken at each location. This location may be indicated as one span, one tree or a combination of spans on one property where the constraint is considered to be temporary.

Requirement R6:
R6 is a risk-based requirement. This requirement sets a minimum time period for completing Vegetation Inspections. The provision that Vegetation Inspections can be performed in conjunction with general line inspections facilitates a Transmission Owner's ability to meet this requirement. However, the applicable Transmission Owner or applicable Generator Owner may determine that more frequent vegetation specific inspections are needed to maintain reliability levels, based on factors such as anticipated growth rates of the local vegetation, length of the local growing season, limited ROW width, and local rainfall. Therefore it is expected that some transmission lines may be designated with a higher frequency of inspections.

The VSLs for Requirement R6 have levels ranked by the failure to inspect a percentage of the applicable lines to be inspected. To calculate the appropriate VSL the applicable Transmission Owner or applicable Generator Owner may choose units such as: circuit, pole line, line miles or kilometers, etc.

For example, when an applicable Transmission Owner or applicable Generator Owner operates 2,000 miles of applicable transmission lines this applicable Transmission Owner or applicable Generator Owner will be responsible for inspecting all the 2,000 miles of lines at least once during the calendar year. If one of the included lines was 100 miles long, and if it was not inspected during the year, then the amount failed to inspect would be 100/2000 = 0.05 or 5%. The "Low VSL" for R6 would apply in this example.

Requirement R7:
R7 is a risk-based requirement. The applicable Transmission Owner or applicable Generator Owner is required to complete its annual work plan for vegetation management to accomplish the purpose of this standard. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made and documented provided they do not put the transmission system at risk. The annual work plan requirement is not intended to necessarily require a "span-by-span", or even a "line-by-line" detailed description of all work to be performed. It is only intended to require that the applicable Transmission Owner or applicable Generator Owner provide evidence of annual planning and execution of a vegetation management maintenance approach which successfully prevents encroachment of vegetation into the MVCD.

When an applicable Transmission Owner or applicable Generator Owner identifies 1,000 miles of applicable transmission lines to be completed in the applicable Transmission Owner's or applicable Generator Owner's annual plan, the applicable Transmission Owner or applicable Generator Owner will be responsible completing those identified miles. If an applicable Transmission Owner or applicable Generator Owner makes a modification to the annual plan that does not put the transmission system at risk of an encroachment the annual plan may be modified. If 100 miles of the annual plan is deferred until next year the calculation to determine what percentage was completed for the current year would be: 1000 – 100 (deferred miles) = 900 modified annual plan, or 900 / 900 = 100% completed annual miles. If an applicable Transmission Owner or applicable Generator Owner only completed 875 of the total 1000 miles with no acceptable documentation for modification of the annual plan the calculation for failure to complete the annual plan would be: 1000 – 875 = 125 miles failed to complete then, 125 miles (not completed) / 1000 total annual plan miles = 12.5% failed to complete.

The ability to modify the work plan allows the applicable Transmission Owner or applicable Generator Owner to change priorities or treatment methodologies during the year as conditions or situations dictate. For example recent line inspections may identify unanticipated high priority work, weather conditions (drought) could make herbicide application ineffective during the plan year, or a major storm could require redirecting local resources away from planned maintenance. This situation may also include complying with mutual assistance agreements by moving resources off the applicable Transmission Owner's or applicable Generator Owner's system to work on another system. Any of these examples could result in acceptable deferrals or additions to the annual work plan provided that they do not put the transmission system at risk of a vegetation encroachment.
In general, the vegetation management maintenance approach should use the full extent of the applicable Transmission Owner's or applicable Generator Owner's easement, fee simple and other legal rights allowed. A comprehensive approach that exercises the full extent of legal

rights on the ROW is superior to incremental management because in the long term it reduces the overall potential for encroachments, and it ensures that future planned work and future planned inspection cycles are sufficient.

When developing the annual work plan the applicable Transmission Owner or applicable Generator Owner should allow time for procedural requirements to obtain permits to work on federal, state, provincial, public, tribal lands. In some cases the lead time for obtaining permits may necessitate preparing work plans more than a year prior to work start dates. Applicable Transmission Owners or applicable Generator Owners may also need to consider those special landowner requirements as documented in easement instruments.

This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. Therefore, deferrals or relevant changes to the annual plan shall be documented. Depending on the planning and documentation format used by the applicable Transmission Owner or applicable Generator Owner, evidence of successful annual work plan execution could consist of signed-off work orders, signed contracts, printouts from work management systems, spreadsheets of planned versus completed work, timesheets, work inspection reports, or paid invoices. Other evidence may include photographs, and walk-through reports.

Notes:

The SDT determined that the use of IEEE 516-2003 in version 1 of FAC-003 was a misapplication. The SDT consulted specialists who advised that the Gallet equation would be a technically justified method. The explanation of why the Gallet approach is more appropriate is explained in the paragraphs below.

The drafting team sought a method of establishing minimum clearance distances that uses realistic weather conditions and realistic maximum transient over-voltages factors for in-service transmission lines.

The SDT considered several factors when looking at changes to the minimum vegetation to conductor distances in FAC-003-1:

- avoid the problem associated with referring to tables in another standard (IEEE-516-2003)
- transmission lines operate in non-laboratory environments (wet conditions)
- transient over-voltage factors are lower for in-service transmission lines than for inadvertently re-energized transmission lines with trapped charges.

FAC-003-1 used the minimum air insulation distance (MAID) without tools formula provided in IEEE 516-2003 to determine the minimum distance between a transmission line conductor and vegetation. The equations and methods provided in IEEE 516 were developed by an IEEE Task Force in 1968 from test data provided by thirteen independent laboratories. The distances provided in IEEE 516 Tables 5 and 7 are based on the withstand voltage of a dry rod-rod air gap, or in other words, dry laboratory conditions. Consequently, the validity of using these distances in an outside environment application has been questioned.

FAC-003-1 allowed Transmission Owners to use either Table 5 or Table 7 to establish the minimum clearance distances. Table 7 could be used if the Transmission Owner knew the maximum transient over-voltage factor for its system. Otherwise, Table 5 would have to be used. Table 5 represented minimum air insulation distances under the worst possible case for transient over-voltage factors. These worst case transient over-voltage factors were as follows: 3.5 for voltages up to 362 kV phase to phase; 3.0 for 500 - 550 kV phase to phase; and 2.5 for 765 to 800 kV phase to phase. These worst case over-voltage factors were also a cause for concern in this particular application of the distances.

In general, the worst case transient over-voltages occur on a transmission line that is inadvertently re-energized immediately after the line is de-energized and a trapped charge is still present. The intent of FAC-003 is to keep a transmission line that is in service from becoming de-energized (i.e. tripped out) due to spark-over from the line conductor to nearby vegetation. Thus, the worst case transient overvoltage assumptions are not appropriate for this application. Rather, the appropriate over voltage values are those that occur only while the line is energized.

Typical values of transient over-voltages of in-service lines are not readily available in the literature because they are negligible compared with the maximums. A conservative value for the maximum transient over-voltage that can occur anywhere along the length of an in-service ac line was approximately 2.0 per unit. This value was a conservative estimate of the transient over-voltage that is created at the point of application (e.g. a substation) by switching a capacitor bank without pre-insertion devices (e.g. closing resistors). At voltage levels where capacitor banks are not very common (e.g. Maximum System Voltage of 362 kV), the maximum transient over-voltage of an in-service ac line are created by fault initiation on adjacent ac lines and shunt reactor bank switching. These transient voltages are usually 1.5 per unit or less.

Even though these transient over-voltages will not be experienced at locations remote from the bus at which they are created, in order to be conservative, it is assumed that all nearby ac lines are subjected to this same level of over-voltage. Thus, a maximum transient over-voltage factor of 2.0 per unit for transmission lines operated at 302 kV and below was considered to be a realistic maximum in this application. Likewise, for ac transmission lines operated at Maximum System Voltages of 362 kV and above a transient over-voltage factor of 1.4 per unit was considered a realistic maximum.

The Gallet equations are an accepted method for insulation coordination in tower design. These equations are used for computing the required strike distances for proper transmission line insulation coordination. They were developed for both wet and dry applications and can be used with any value of transient over-voltage factor. The Gallet equation also can take into account various air gap geometries. This approach was used to design the first 500 kV and 765 kV lines in North America.

If one compares the MAID using the IEEE 516-2003 Table 7 (table D.5 for English values) with the critical spark-over distances computed using the Gallet wet equations, for each of the nominal voltage classes and identical transient over-voltage factors, the Gallet equations yield a more conservative (larger) minimum distance value.

Distances calculated from either the IEEE 516 (dry) formulas or the Gallet "wet" formulas are not vastly different when the same transient overvoltage factors are used; the "wet" equations will consistently produce slightly larger distances than the IEEE 516 equations when the same transient overvoltage is used. While the IEEE 516 equations were only developed for dry conditions the Gallet equations have provisions to calculate spark-over distances for both wet and dry conditions.

Since no empirical data for spark over distances to live vegetation existed at the time version 3 was developed, the SDT chose a proven method that has been used in other EHV applications. The Gallet equations relevance to wet conditions and the selection of a Transient Overvoltage Factor that is consistent with the absence of trapped charges on an in-service transmission line make this methodology a better choice.

The following table is an example of the comparison of distances derived from IEEE 516 and the Gallet equations.

Comparison of spark-over distances computed using Gallet wet equations vs. IEEE 516-2003 MAID distances

(AC) **Nom System** **Voltage (kV)**	**(AC)** **Max System** **Voltage (kV)**	**Transient** **Over-voltage** **Factor (T)**	**Clearance (ft.)** **Gallet (wet)** **@ Alt. 3000 feet**	Table 7 (Table D.5 for feet) **IEEE 516-2003** **MAID (ft)** **@ Alt. 3000 feet**
765	800	2.0	14.36	13.95
500	550	2.4	11.0	10.07
345	362	3.0	8.55	7.47
230	242	3.0	5.28	4.2
115	121	3.0	2.46	2.1

Rationale:
During development of this standard, text boxes were embedded within the standard to explain the rationale for various parts of the standard. Upon BOT approval, the text from the rationale text boxes was moved to this section.
Rationale for Applicability (section 4.2.4):
The areas excluded in 4.2.4 were excluded based on comments from industry for reasons summarized as follows:

1) There is a very low risk from vegetation in this area. Based on an informal survey, no TOs reported such an event.
2) Substations, switchyards, and stations have many inspection and maintenance activities that are necessary for reliability. Those existing process manage the threat. As such, the formal steps in this standard are not well suited for this environment.
3) Specifically addressing the areas where the standard does and does not apply makes the standard clearer.

Rationale for Applicability (section 4.3):
Within the text of NERC Reliability Standard FAC-003-3, "transmission line(s)" and "applicable line(s)" can also refer to the generation Facilities as referenced in 4.3 and its subsections.

Rationale for R1:
Lines with the highest significance to reliability are covered in R1; all other lines are covered in R2.

Rationale for the types of failure to manage vegetation which are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of an applicable Transmission Owner's or applicable Generator Owner's vegetation maintenance program:

1. This management failure is found by routine inspection or Fault event investigation, and is normally symptomatic of unusual conditions in an otherwise sound program.
2. This management failure occurs when the height and location of a side tree within the ROW is not adequately addressed by the program.
3. This management failure occurs when side growth is not adequately addressed and may be indicative of an unsound program.
4. This management failure is usually indicative of a program that is not addressing the most fundamental dynamic of vegetation management, (i.e. a grow-in under the line). If this type of failure is pervasive on multiple lines, it provides a mechanism for a Cascade.

Rationale for R3:
The documentation provides a basis for evaluating the competency of the applicable Transmission Owner's or applicable Generator Owner's vegetation program. There may be many acceptable approaches to maintain clearances. Any approach must demonstrate that the

applicable Transmission Owner or applicable Generator Owner avoids vegetation-to-wire conflicts under all Ratings and all Rated Electrical Operating Conditions.

Rationale for R4:

This is to ensure expeditious communication between the applicable Transmission Owner or applicable Generator Owner and the control center when a critical situation is confirmed.

Rationale for R5:

Legal actions and other events may occur which result in constraints that prevent the applicable Transmission Owner or applicable Generator Owner from performing planned vegetation maintenance work.

In cases where the transmission line is put at potential risk due to constraints, the intent is for the applicable Transmission Owner and applicable Generator Owner to put interim measures in place, rather than do nothing.

The corrective action process is not intended to address situations where a planned work methodology cannot be performed but an alternate work methodology can be used.

Rationale for R6:

Inspections are used by applicable Transmission Owners and applicable Generator Owners to assess the condition of the entire ROW. The information from the assessment can be used to determine risk, determine future work and evaluate recently-completed work. This requirement sets a minimum Vegetation Inspection frequency of once per calendar year but with no more than 18 months between inspections on the same ROW. Based upon average growth rates across North America and on common utility practice, this minimum frequency is reasonable. Transmission Owners should consider local and environmental factors that could warrant more frequent inspections.

Rationale for R7:

This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. It allows modifications to the planned work for changing conditions, taking into consideration anticipated growth of vegetation and all other environmental factors, provided that those modifications do not put the transmission system at risk of a vegetation encroachment.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	08/19/15
SAR posted for comment	08/20/15 – 09/21/15
45-day formal comment period with initial ballot	08/27/18-10/17/18

Anticipated Actions	Date
45-day formal comment period with additional ballot	June 2020
10-day final ballot	August 2020
NERC Board adoption	November 2020

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s):

None

Upon Board adoption, the rationale boxes will be moved to the Supplemental Material Section.

A. Introduction

1. **Title:** Assessment of Transfer Capability for the Near-Term Transmission Planning Horizon
2. **Number:** FAC-013-3
3. **Purpose:** To ensure that Planning Coordinators have a methodology for, and perform an annual assessment to identify potential future Transmission System weaknesses and limiting Facilities that could impact the Bulk Electric System's (BES) ability to reliably transfer energy in the Near-Term Transmission Planning Horizon.
4. **Applicability:**
   4.1. Planning Coordinators
5. **Effective Date:** See Implementation Plan

B. Requirements and Measures

R1. Each Planning Coordinator shall have a documented methodology it uses to perform an annual assessment of Transfer Capability in the Near-Term Transmission Planning Horizon (Transfer Capability methodology). The Transfer Capability methodology shall include, at a minimum, the following information: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

1.1. Criteria for the selection of the transfers to be assessed.

1.2. Reserved for future use.

1.3. A statement that the assumptions and criteria used to perform the assessment are consistent with the Planning Coordinator's Planning Assessments.

1.4. A description of how each of the following assumptions and criteria used in performing the assessment are addressed:

1.4.1. Generation dispatch, including but not limited to long term planned outages, additions and retirements.

1.4.2. Transmission system topology, including but not limited to long term planned Transmission outages, additions, and retirements.

1.4.3. System demand.

1.4.4. Current approved and projected Transmission uses.

1.4.5. Parallel path (loop flow) adjustments.

1.4.6. Contingencies

1.4.7. Monitored Facilities.

1.5. A description of how simulations of transfers are performed through the adjustment of generation, Load or both.

M1. Each Planning Coordinator shall have a Transfer Capability methodology that includes the information specified in Requirement R1.

R2. Each Planning Coordinator shall issue its Transfer Capability methodology, and any revisions to the Transfer Capability methodology, to the following entities subject to the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

2.1. Distribute to the following prior to the effectiveness of such revisions:

2.1.1. Each Planning Coordinator adjacent to the Planning Coordinator's Planning Coordinator area or overlapping the Planning Coordinator's area.

2.1.2. Each Transmission Planner within the Planning Coordinator's Planning Coordinator area.

2.2. Distribute to each functional entity that has a reliability-related need for the Transfer Capability methodology and submits a request for that methodology within 30 calendar days of receiving that written request.

M2. Each Planning Coordinator shall have evidence such as dated e-mail or dated transmittal letters that it provided the new or revised Transfer Capability methodology in accordance with Requirement R2

R3. Reserved for Future use

M3. Reserved for Future use

R4. During each calendar year, each Planning Coordinator shall conduct simulations and document an assessment based on those simulations in accordance with its Transfer Capability methodology for at least one year in the Near-Term Transmission Planning Horizon. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

M4. Each Planning Coordinator shall have evidence such as dated assessment results, that it conducted and documented a Transfer Capability assessment in accordance with Requirement R4.

R5. Each Planning Coordinator shall make the documented Transfer Capability assessment results available within 45 calendar days of the completion of the assessment to the recipients of its Transfer Capability methodology pursuant to Requirement R2, Parts 2.1 and Part 2.2. However, if a functional entity that has a reliability related need for the results of the annual assessment of the Transfer Capabilities makes a written request for such an assessment after the completion of the assessment, the Planning Coordinator shall make the documented Transfer Capability assessment results available to that entity within 45 calendar days of receipt of the request *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

M5. Each Planning Coordinator shall have evidence, such as dated copies of e-mails or transmittal letters, that it made its documented Transfer Capability assessment available to the entities in accordance with Requirement R5

R6. If a recipient of a documented Transfer Capability assessment requests data to support the assessment results, the Planning Coordinator shall provide such data to that entity within 45 calendar days of receipt of the request. The provision of such data shall be subject to the legal and regulatory obligations of the Planning Coordinator's area regarding the disclosure of confidential and/or sensitive information. *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

M6. Each Planning Coordinator shall have evidence, such as dated copies of e-mails or transmittal letters, that it made its documented Transfer Capability assessment data available in accordance with Requirement R6.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority:
"Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention: The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

The Planning Coordinator shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

- The Planning Coordinator shall have its current Transfer Capability methodology and any prior versions of the Transfer Capability methodology that were in force since the last compliance audit to show compliance with Requirement R1.
- The Planning Coordinator shall retain evidence since its last compliance audit to show compliance with Requirement R2.
- The Planning Coordinator shall retain evidence to show compliance with Requirements R4, R5 and R6 for the most recent assessment.

- If a Planning Coordinator is found non-compliant, it shall keep information related to the non-compliance until found compliant or for the time periods specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Enforcement Program: As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s):

None

Upon Board adoption, the rationale boxes will be moved to the Supplemental Material Section.

A. Introduction

1. **Title:** Assessment of Transfer Capability for the Near-Term Transmission Planning Horizon
2. **Number:** FAC-013-3
3. **Purpose:** To ensure that Planning Coordinators have a methodology for, and perform an annual assessment to identify potential future Transmission System weaknesses and limiting Facilities that could impact the Bulk Electric System's (BES) ability to reliably transfer energy in the Near-Term Transmission Planning Horizon.
4. **Applicability:**
    4.1. Planning Coordinators
5. **Effective Date:** See Implementation Plan ~~for FAC-013-3.~~

B. Requirements and Measures

R1. Each Planning Coordinator shall have a documented methodology it uses to perform an annual assessment of Transfer Capability in the Near-Term Transmission Planning Horizon (Transfer Capability methodology). The Transfer Capability methodology shall include, at a minimum, the following information: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

1.1. Criteria for the selection of the transfers to be assessed.

1.2. Reserved for future use.

1.3. A statement that the assumptions and criteria used to perform the assessment are consistent with the Planning Coordinator's Planning Assessments.

1.4. A description of how each of the following assumptions and criteria used in performing the assessment are addressed:

1.4.1. Generation dispatch, including but not limited to long term planned outages, additions and retirements.

1.4.2. Transmission system topology, including but not limited to long term planned Transmission outages, additions, and retirements.

1.4.3. System demand.

1.4.4. Current approved and projected Transmission uses.

1.4.5. Parallel path (loop flow) adjustments.

1.4.6. Contingencies

1.4.7. Monitored Facilities.

1.5. A description of how simulations of transfers are performed through the adjustment of generation, Load or both.

~~M2.~~M1. Each Planning Coordinator shall have a Transfer Capability methodology that includes the information specified in Requirement R1.

~~R3.~~R2. Each Planning Coordinator shall issue its Transfer Capability methodology, and any revisions to the Transfer Capability methodology, to the following entities subject to the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

~~3.1.~~2.1. Distribute to the following prior to the effectiveness of such revisions:

~~3.1.1.~~2.1.1. Each Planning Coordinator adjacent to the Planning Coordinator's Planning Coordinator area or overlapping the Planning Coordinator's area.

~~3.1.2.~~2.1.2. Each Transmission Planner within the Planning Coordinator's Planning Coordinator area.

~~3.2.~~2.2. Distribute to each functional entity that has a reliability-related need for the Transfer Capability methodology and submits a request for that methodology within 30 calendar days of receiving that written request.

~~M3.~~M2. Each Planning Coordinator shall have evidence such as dated e-mail or dated transmittal letters that it provided the new or revised Transfer Capability methodology in accordance with Requirement R2

~~R5.~~R3. Reserved for Future use ~~If a recipient of the Transfer Capability methodology provides documented concerns with the methodology, the Planning Coordinator shall provide a documented response to that recipient within 45 calendar days of receipt of those comments. The response shall indicate whether a change will be made to the Transfer Capability methodology and, if no change will be made to that Transfer Capability methodology, the reason why. *[Violation Risk Factor: Lower][Time Horizon: Long-term Planning]* (Retirement approved by FERC effective January 21, 2014.)~~

~~M4.~~M3. ~~Each Planning Coordinator shall have evidence, such as dated e-mail or dated transmittal letters, that the Planning Coordinator provided a written response to that commenter in accordance with Requirement R3. (Retirement approved by FERC effective January 21, 2014.)~~Reserved for Future use

~~R7.~~R4. During each calendar year, each Planning Coordinator shall conduct simulations and document an assessment based on those simulations in accordance with its Transfer Capability methodology for at least one year in the Near-Term Transmission Planning Horizon. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

~~M5.~~M4. Each Planning Coordinator shall have evidence such as dated assessment results, that it conducted and documented a Transfer Capability assessment in accordance with Requirement R4.

~~R8.~~R5. Each Planning Coordinator shall make the documented Transfer Capability assessment results available within 45 calendar days of the completion of the assessment to the recipients of its Transfer Capability methodology pursuant to Requirement R2, Parts 2.1 and Part 2.2. However, if a functional entity that has a reliability related need for the results of the annual assessment of the Transfer Capabilities makes a written request for such an assessment after the completion of the assessment, the Planning Coordinator shall make the documented Transfer Capability assessment results available to that entity within 45 calendar days of receipt of the request *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

~~M6.~~M5. Each Planning Coordinator shall have evidence, such as dated copies of e-mails or transmittal letters, that it made its documented Transfer Capability assessment available to the entities in accordance with Requirement R5

~~R9.~~R6. If a recipient of a documented Transfer Capability assessment requests data to support the assessment results, the Planning Coordinator shall provide such data to that entity within 45 calendar days of receipt of the request. The provision of such data shall be subject to the legal and regulatory obligations of the Planning Coordinator's area regarding the disclosure of confidential and/or sensitive information. *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

~~M7.~~M6. Each Planning Coordinator shall have evidence, such as dated copies of e-mails or transmittal letters, that it made its documented Transfer Capability assessment data available in accordance with Requirement R6.

C. Compliance

1. **Compliance Monitoring Process**

   1.1. **Compliance Enforcement Authority:**
   "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

   1.2. **Evidence Retention:** The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

The Planning Coordinator shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

- The Planning Coordinator shall have its current Transfer Capability methodology and any prior versions of the Transfer Capability methodology that were in force since the last compliance audit to show compliance with Requirement R1.
- The Planning Coordinator shall retain evidence since its last compliance audit to show compliance with Requirement R2.
- The Planning Coordinator shall retain evidence to show compliance with Requirements~~ R3,~~ R4, R5 and R6 for the most recent assessment. ~~(R3 retired-Retirement approved by FERC effective January 21, 2014.)~~
- If a Planning Coordinator is found non-compliant, it shall keep information related to the non-compliance until found compliant or for the time periods specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Enforcement Program: As defined in the NERC Rules of Procedure, “Compliance Monitoring and Enforcement Program” refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

Anticipated Actions	Date
45-day formal comment period with initial ballot	June 2020
10-day final ballot	August 2020
NERC Board adoption	November 2020

A. Introduction

1. **Title:** Disturbance Monitoring and Reporting Requirements
2. **Number:** PRC-002-3
3. **Purpose:** To have adequate data available to facilitate analysis of Bulk Electric System (BES) Disturbances.
4. **Applicability:**

   Functional Entities:

   4.1 Reliability Coordinator

   4.2 Transmission Owner

   4.3 Generator Owner

5. **Effective Date:** See Implementation Plan

B. Requirements and Measures

R1. Each Transmission Owner shall: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

1.1. Identify BES buses for which sequence of events recording (SER) and fault recording (FR) data is required by using the methodology in PRC-002-3, Attachment 1.

1.2. Notify other owners of BES Elements connected to those BES buses, if any, within 90-calendar days of completion of Part 1.1, that those BES Elements require SER data and/or FR data.

1.3. Re-evaluate all BES buses at least once every five calendar years in accordance with Part 1.1 and notify other owners, if any, in accordance with Part 1.2, and implement the re-evaluated list of BES buses as per the Implementation Plan.

M1. The Transmission Owner has a dated (electronic or hard copy) list of BES buses for which SER and FR data is required, identified in accordance with PRC-002-3, Attachment 1, and evidence that all BES buses have been re-evaluated within the required intervals under Requirement R1. The Transmission Owner will also have dated (electronic or hard copy) evidence that it notified other owners in accordance with Requirement R1.

R2. Each Transmission Owner and Generator Owner shall have SER data for circuit breaker position (open/close) for each circuit breaker it owns connected directly to the BES buses identified in Requirement R1 and associated with the BES Elements at those BES buses. *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

M2. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) of SER data for circuit breaker position as specified in Requirement R2. Evidence may include, but is not limited to: (1) documents describing the device interconnections and configurations which may include a single design standard as representative for common installations; or (2) actual data recordings; or (3) station drawings.

R3. Each Transmission Owner and Generator Owner shall have FR data to determine the following electrical quantities for each triggered FR for the BES Elements it owns connected to the BES buses identified in Requirement R1: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

3.1 Phase-to-neutral voltage for each phase of each specified BES bus.

3.2 Each phase current and the residual or neutral current for the following BES Elements:

3.2.1 Transformers that have a low-side operating voltage of 100kV or above.

3.2.2 Transmission Lines.

M3. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) of FR data that is sufficient to determine electrical quantities as specified in Requirement R3. Evidence may include, but is not limited to: (1) documents describing the device specifications and configurations which may include a single design standard as representative for common installations; or (2) actual data recordings or derivations; or (3) station drawings.

R4. Each Transmission Owner and Generator Owner shall have FR data as specified in Requirement R3 that meets the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

4.1 A single record or multiple records that include:

- A pre-trigger record length of at least two cycles and a total record length of at least 30-cycles for the same trigger point, or
- At least two cycles of the pre-trigger data, the first three cycles of the post-trigger data, and the final cycle of the fault as seen by the fault recorder.

4.2 A minimum recording rate of 16 samples per cycle.

4.3 Trigger settings for at least the following:

4.3.1 Neutral (residual) overcurrent.

4.3.2 Phase undervoltage or overcurrent.

M4. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) that FR data meets Requirement R4. Evidence may include, but is not limited to: (1) documents describing the device specification (R4, Part 4.2) and device configuration or settings (R4, Parts 4.1 and 4.3), or (2) actual data recordings or derivations.

R5. Each Reliability Coordinator shall: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

5.1 Identify BES Elements for which dynamic Disturbance recording (DDR) data is required, including the following:

5.1.1 Generating resource(s) with:

5.1.1.1 Gross individual nameplate rating greater than or equal to 500 MVA.

5.1.1.2 Gross individual nameplate rating greater than or equal to 300 MVA where the gross plant/facility aggregate nameplate rating is greater than or equal to 1,000 MVA.

5.1.2 Any one BES Element that is part of a stability (angular or voltage) related System Operating Limit (SOL).

5.1.3 Each terminal of a high voltage direct current (HVDC) circuit with a nameplate rating greater than or equal to 300 MVA, on the alternating current (AC) portion of the converter.

5.1.4 One or more BES Elements that are part of an Interconnection Reliability Operating Limit (IROL).

5.1.5 Any one BES Element within a major voltage sensitive area as defined by an area with an in-service undervoltage load shedding (UVLS) program.

5.2 Identify a minimum DDR coverage, inclusive of those BES Elements identified in Part 5.1, of at least:

5.2.1 One BES Element; and

5.2.2 One BES Element per 3,000 MW of the Reliability Coordinator's historical simultaneous peak System Demand.

5.3 Notify all owners of identified BES Elements, within 90-calendar days of completion of Part 5.1, that their respective BES Elements require DDR data when requested.

5.4 Re-evaluate all BES Elements at least once every five calendar years in accordance with Parts 5.1 and 5.2, and notify owners in accordance with Part 5.3 to implement the re-evaluated list of BES Elements as per the Implementation Plan.

M5. The Reliability Coordinator has a dated (electronic or hard copy) list of BES Elements for which DDR data is required, developed in accordance with Requirement R5, Part 5.1 and Part 5.2; and re-evaluated in accordance with Part 5.4. The Reliability Coordinator has dated evidence (electronic or hard copy) that each Transmission Owner or Generator Owner has been notified in accordance with Requirement 5, Part 5.3. Evidence may include, but is not limited to: letters, emails, electronic files, or hard copy records demonstrating transmittal of information.

R6. Each Transmission Owner shall have DDR data to determine the following electrical quantities for each BES Element it owns for which it received notification as identified in Requirement R5: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

6.1 One phase-to-neutral or positive sequence voltage.

6.2 The phase current for the same phase at the same voltage corresponding to the voltage in Requirement R6, Part 6.1, or the positive sequence current.

6.3 Real Power and Reactive Power flows expressed on a three phase basis corresponding to all circuits where current measurements are required.

6.4 Frequency of any one of the voltage(s) in Requirement R6, Part 6.1.

M6. The Transmission Owner has evidence (electronic or hard copy) of DDR data to determine electrical quantities as specified in Requirement R6. Evidence may include, but is not limited to: (1) documents describing the device specifications and configurations, which may include a single design standard as representative for common installations; or (2) actual data recordings or derivations; or (3) station drawings.

R7. Each Generator Owner shall have DDR data to determine the following electrical quantities for each BES Element it owns for which it received notification as identified in Requirement R5: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

7.1 One phase-to-neutral, phase-to-phase, or positive sequence voltage at either the generator step-up transformer (GSU) high-side or low-side voltage level.

7.2 The phase current for the same phase at the same voltage corresponding to the voltage in Requirement R7, Part 7.1, phase current(s) for any phase-to-phase voltages, or positive sequence current.

7.3 Real Power and Reactive Power flows expressed on a three phase basis corresponding to all circuits where current measurements are required.

7.4 Frequency of at least one of the voltages in Requirement R7, Part 7.1.

M7. The Generator Owner has evidence (electronic or hard copy) of DDR data to determine electrical quantities as specified in Requirement R7. Evidence may include, but is not limited to: (1) documents describing the device specifications and configurations, which may include a single design standard as representative for common installations; or (2) actual data recordings or derivations; or (3) station drawings.

R8. Each Transmission Owner and Generator Owner responsible for DDR data for the BES Elements identified in Requirement R5 shall have continuous data recording and storage. If the equipment was installed prior to the effective date of this standard and is not capable of continuous recording, triggered records must meet the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

8.1 Triggered record lengths of at least three minutes.

8.2 At least one of the following three triggers:

- Off nominal frequency trigger set at:

	Low	High
Eastern Interconnection	<59.75 Hz	>61.0 Hz
Western Interconnection	<59.55 Hz	>61.0 Hz
ERCOT Interconnection	<59.35 Hz	>61.0 Hz
Hydro-Quebec Interconnection	<58.55 Hz	>61.5 Hz

- Rate of change of frequency trigger set at:

Eastern Interconnection	< -0.03125 Hz/sec	> 0.125 Hz/sec
Western Interconnection	< -0.05625 Hz/sec	> 0.125 Hz/sec
ERCOT Interconnection	< -0.08125 Hz/sec	> 0.125 Hz/sec
Hydro-Quebec Interconnection	< -0.18125 Hz/sec	> 0.1875 Hz/sec

- Undervoltage trigger set no lower than 85 percent of normal operating voltage for a duration of 5 seconds.

M8. Each Transmission Owner and Generator Owner has dated evidence (electronic or hard copy) of data recordings and storage in accordance with Requirement R8. Evidence may include, but is not limited to: (1) documents describing the device specifications and configurations, which may include a single design standard as representative for common installations; or (2) actual data recordings.

R9. Each Transmission Owner and Generator Owner responsible for DDR data for the BES Elements identified in Requirement R5 shall have DDR data that meet the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

9.1 Input sampling rate of at least 960 samples per second.

9.2 Output recording rate of electrical quantities of at least 30 times per second.

M9. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) that DDR data meets Requirement R9. Evidence may include, but is not limited to: (1) documents describing the device specification, device configuration, or settings (R9, Part 9.1; R9, Part 9.2); or (2) actual data recordings (R9, Part 9.2).

R10. Each Transmission Owner and Generator Owner shall time synchronize all SER and FR data for the BES buses identified in Requirement R1 and DDR data for the BES Elements identified in Requirement R5 to meet the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

10.1 Synchronization to Coordinated Universal Time (UTC) with or without a local time offset.

10.2 Synchronized device clock accuracy within ± 2 milliseconds of UTC.

M10. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) of time synchronization described in Requirement R10. Evidence may include, but is not limited to: (1) documents describing the device specification, configuration, or setting; (2) time synchronization indication or status; or 3) station drawings.

R11. Each Transmission Owner and Generator Owner shall provide, upon request, all SER and FR data for the BES buses identified in Requirement R1 and DDR data for the BES Elements identified in Requirement R5 to the Reliability Coordinator, Regional Entity, or NERC in accordance with the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

11.1 Data will be retrievable for the period of 10-calendar days, inclusive of the day the data was recorded.

11.2 Data subject to Part 11.1 will be provided within 30-calendar days of a request unless an extension is granted by the requestor.

11.3 SER data will be provided in ASCII Comma Separated Value (CSV) format following Attachment 2.

11.4 FR and DDR data will be provided in electronic files that are formatted in conformance with C37.111, (IEEE Standard for Common Format for Transient Data Exchange (COMTRADE), revision C37.111-1999 or later.

11.5 Data files will be named in conformance with C37.232, IEEE Standard for Common Format for Naming Time Sequence Data Files (COMNAME), revision C37.232-2011 or later.

M11. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) that data was submitted upon request in accordance with Requirement R11. Evidence may include, but is not limited to: (1) dated transmittals to the requesting entity with formatted records; (2) documents describing data storage capability, device specification, configuration or settings; or (3) actual data recordings.

R12. Each Transmission Owner and Generator Owner shall, within 90-calendar days of the discovery of a failure of the recording capability for the SER, FR or DDR data, either: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

- Restore the recording capability, or
- Submit a Corrective Action Plan (CAP) to the Regional Entity and implement it.

M12. The Transmission Owner or Generator Owner has dated evidence (electronic or hard copy) that meets Requirement R12. Evidence may include, but is not limited to: (1) dated reports of discovery of a failure, (2) documentation noting the date the data recording was restored, (3) SCADA records, or (4) dated CAP transmittals to the Regional Entity and evidence that it implemented the CAP.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

As defined in the NERC Rules of Procedure, "Compliance Enforcement Authority" (CEA) means NERC or the Regional Entity in their respective roles of monitoring and enforcing compliance with the NERC Reliability Standards.

1.2. Evidence Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Transmission Owner, Generator Owner, and Reliability Coordinator shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

The Transmission Owner shall retain evidence of Requirement R1, Measure M1 for five calendar years.

The Transmission Owner shall retain evidence of Requirement R6, Measure M6 for three calendar years.

The Generator Owner shall retain evidence of Requirement R7, Measure M7 for three calendar years.

The Transmission Owner and Generator Owner shall retain evidence of requested data provided as per Requirements R2, R3, R4, R8, R9, R10, R11, and R12, Measures M2, M3, M4, M8, M9, M10, M11, and M12 for three calendar years.

The Reliability Coordinator shall retain evidence of Requirement R5, Measure M5 for five calendar years.

If a Transmission Owner, Generator Owner, or Reliability Coordinator is found non-compliant, it shall keep information related to the non-compliance until mitigation is completed and approved or for the time specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes:

Compliance Audit

Self-Certification

Spot Checking

Compliance Violation Investigation

Self-Reporting

Complaints

1.4. Additional Compliance Information

None

Table of Compliance Elements

R #	Time Horizon	VRF	Violation Severity Levels			
			Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	Long-term Planning	Lower	The Transmission Owner identified the BES buses as directed by Requirement R1, Part 1.1 or Part 1.3 for more than 80 percent but less than 100 percent of the required BES buses that they own. OR The Transmission Owner evaluated the BES buses as directed by Requirement R1, Part 1.1 or Part 1.3 but was late by 30-calendar days or less. Methodology for Selecting Buses for Capturing Sequence of Events Recording (SER) and Fault Recording (FR) Data

(Requirement R1)

To identify monitored BES buses for sequence of events recording (SER) and Fault recording (FR) data required by Requirement 1, each Transmission Owner shall follow sequentially, unless otherwise noted, the steps listed below:

Step 1. Determine a complete list of BES buses that it owns.

For the purposes of this standard, a single BES bus includes physical buses with breakers connected at the same voltage level within the same physical location sharing a common ground grid. These buses may be modeled or represented by a single node in fault studies. For example, ring bus or breaker-and-a-half bus configurations are considered to be a single bus.

Step 2. Reduce the list to those BES buses that have a maximum available calculated three phase short circuit MVA of 1,500 MVA or greater. If there are no buses on the resulting list, proceed to Step 7.

Step 3. Determine the 11 BES buses on the list with the highest maximum available calculated three phase short circuit MVA level. If the list has 11 or fewer buses, proceed to Step 7.

Step 4. Calculate the median MVA level of the 11 BES buses determined in Step 3.

Step 5. Multiply the median MVA level determined in Step 4 by 20 percent.

Step 6. Reduce the BES buses on the list to only those that have a maximum available calculated three phase short circuit MVA higher than the greater of:

- 1,500 MVA or
- 20 percent of median MVA level determined in Step 5.

Step 7. If there are no BES buses on the list: the procedure is complete and no FR and SER data will be required. Proceed to Step 9.

If the list has 1 or more but less than or equal to 11 BES buses: FR and SER data is required at the BES bus with the highest maximum available calculated three phase short circuit MVA as determined in Step 3. Proceed to Step 9.

If the list has more than 11 BES buses: SER and FR data is required on at least the 10 percent of the BES buses determined in Step 6 with the highest maximum available calculated three phase short circuit MVA. Proceed to Step 8.

Step 8. SER and FR data is required at additional BES buses on the list determined in Step 6. The aggregate of the number of BES buses determined in Step 7 and this Step will be at least 20 percent of the BES buses determined in Step 6.

The additional BES buses are selected, at the Transmission Owner's discretion, to provide maximum wide-area coverage for SER and FR data. The following BES bus locations are recommended:

- Electrically distant buses or electrically distant from other DME devices.
- Voltage sensitive areas.
- Cohesive load and generation zones.
- BES buses with a relatively high number of incident Transmission circuits.
- BES buses with reactive power devices.
- Major Facilities interconnecting outside the Transmission Owner's area.

Step 9. The list of monitored BES buses for SER and FR data for Requirement R1 is the aggregate of the BES buses determined in Steps 7 and 8.

Attachment 2

Sequence of Events Recording (SER) Data Format

(Requirement R11, Part 11.3)

Date, Time, Local Time Code, Substation, Device, State[1]

R12	TO | GO			X

Rationale:

During development of this standard, text boxes were embedded within the standard to explain the rationale for various parts of the standard. Upon BOT approval, the text from the rationale text boxes was moved to this section.

Rationale for Functional Entities:

Because the Reliability Coordinator has the best wide-area view of the BES, the Reliability Coordinator is most suited to be responsible for determining the BES Elements for which dynamic Disturbance recording (DDR) data is required. The Transmission Owners and Generator Owners will have the responsibility for ensuring that adequate data is available for those BES Elements selected.

BES buses where sequence of events recording (SER) and fault recording (FR) data is required are best selected by Transmission Owners because they have the required tools, information, and working knowledge of their Systems to determine those buses. The Transmission Owners and Generator Owners that own BES Elements on those BES buses will have the responsibility for ensuring that adequate data is available.

Rationale for R1:

Analysis and reconstruction of BES events requires SER and FR data from key BES buses. Attachment 1 provides a uniform methodology to identify those BES buses. Repeated testing of the Attachment 1 methodology has demonstrated the proper distribution of SER and FR data collection. Review of actual BES short circuit data received from the industry in response to the DMSDT's data request (June 5, 2013 through July 5, 2013) illuminated a strong correlation between the available short circuit MVA at a Transmission bus and its relative size and importance to the BES based on (i) its voltage level, (ii) the number of Transmission Lines and other BES Elements connected to the BES bus, and (iii) the number and size of generating units connected to the bus. BES buses with a large short circuit MVA level are BES Elements that have a significant effect on System reliability and performance. Conversely, BES buses with very low short circuit MVA levels seldom cause wide-area or cascading System events, so SER and FR data from those BES Elements are not as significant. After analyzing and reviewing the collected data submittals from across the continent, the threshold MVA values were chosen to provide sufficient data for event analysis using engineering and operational judgment.

Concerns have existed that the defined methodology for bus selection will overly concentrate data to selected BES buses. For the purpose of PRC-002-3, there are a minimum number of BES buses for which SER and FR data is required based on the short circuit level. With these concepts and the objective being sufficient recording coverage for event analysis, the DMSDT developed the procedure in Attachment 1 that utilizes the maximum available calculated three phase short circuit MVA. This methodology ensures comparable and sufficient coverage for SER and FR data regardless of variations in the size and System topology of Transmission Owners across all Interconnections. Additionally, this methodology provides a degree of flexibility for the use of judgment in the selection process to ensure sufficient distribution.

BES buses where SER and FR data is required are best selected by Transmission Owners because they have the required tools, information, and working knowledge of their Systems to determine those buses.

Each Transmission Owner must re-evaluate the list of BES buses at least every five calendar years to address System changes since the previous evaluation. Changes to the BES do not mandate immediate inclusion of BES buses into the currently enforced list, but the list of BES buses will be re-evaluated at least every five calendar years to address System changes since the previous evaluation.

Since there may be multiple owners of equipment that comprise a BES bus, the notification required in R1 is necessary to ensure all owners are notified.

A 90-calendar day notification deadline provides adequate time for the Transmission Owner to make the appropriate determination and notification.

Rationale for R2:
The intent is to capture SER data for the status (open/close) of the circuit breakers that can interrupt the current flow through each BES Element connected to a BES bus. Change of state of circuit breaker position, time stamped according to Requirement R10 to a time synchronized clock, provides the basis for assembling the detailed sequence of events timeline of a power System Disturbance. Other status monitoring nomenclature can be used for devices other than circuit breakers.

Rationale for R3:
The required electrical quantities may either be directly measured or determinable if sufficient FR data is captured (e.g. residual or neutral current if the phase currents are directly measured). In order to cover all possible fault types, all BES bus phase-to-neutral voltages are required to be determinable for each BES bus identified in Requirement R1. BES bus voltage data is adequate for System Disturbance analysis. Phase current and residual current are required to distinguish between phase faults and ground faults. It also facilitates determination of the fault location and cause of relay operation. For transformers (Part 3.2.1), the data may be from either the high-side or the low-side of the transformer. Generator step-up transformers (GSUs) and leads that connect the GSU transformer(s) to the Transmission System that are used exclusively to export energy directly from a BES generating unit or generating plant are excluded from Requirement R3 because the fault current contribution from a generator to a fault on the Transmission System will be captured by FR data on the Transmission System, and Transmission System FR will capture faults on the generator interconnection.

Generator Owners may install this capability or, where the Transmission Owners already have suitable FR data, contract with the Transmission Owner. However, when required, the Generator Owner is still responsible for the provision of this data.

Rationale for R4:

Time stamped pre- and post-trigger fault data aid in the analysis of power System operations and determination if operations were as intended. System faults generally persist for a short time period, thus a 30-cycle total minimum record length is adequate. Multiple records allow for legacy microprocessor relays which, when time-synchronized, are capable of providing adequate fault data but not capable of providing fault data in a single record with 30-contiguous cycles total.

A minimum recording rate of 16 samples per cycle (960 Hz) is required to get sufficient point on wave data for recreating accurate fault conditions.

Rationale for R5:

DDR is used for capturing the BES transient and post-transient response following Disturbances, and the data is used for event analysis and validating System performance. DDR plays a critical role in wide-area Disturbance analysis, and Requirement R5 ensures there is adequate wide-area coverage of DDR data for specific BES Elements to facilitate accurate and efficient event analysis. The Reliability Coordinator has the best wide-area view of the System and needs to ensure that there are sufficient BES Elements identified for DDR data capture. The identification of BES Elements requiring DDR data as per Requirement R5 is based upon industry experience with wide-area Disturbance analysis and the need for adequate data to facilitate event analysis. Ensuring data is captured for these BES Elements will significantly improve the accuracy of analysis and understanding of why an event occurred, not simply what occurred.

From its experience with changes to the Bulk Electric System that would affect DDR, the DMSDT decided that the five calendar year re-evaluation of the list is a reasonable interval for this review. Changes to the BES do not mandate immediate inclusion of BES Elements into the in force list, but the list of BES Elements will be re-evaluated at least every five calendar years to address System changes since the previous evaluation. However, this standard does not preclude the Reliability Coordinator from performing this re-evaluation more frequently to capture updated BES Elements.

The Reliability Coordinator must notify all owners of the selected BES Elements that DDR data is required for this standard. The Reliability Coordinator is only required to share the list of selected BES Elements that each Transmission Owner and Generator Owner respectively owns, not the entire list. This communication of selected BES Elements is required to ensure that the owners of the respective BES Elements are aware of their responsibilities under this standard.

Implementation of the monitoring equipment is the responsibility of the respective Transmission Owners and Generator Owners, the timeline for installing this capability is outlined in the Implementation Plan, and starts from notification of the list from the Reliability Coordinator. Data for each BES Element as defined by the Reliability Coordinator must be provided; however, this data can be either directly measured or accurately calculated. With the exception of HVDC circuits, DDR data is only required for one end or terminal of the BES Elements selected. For example, DDR data must be provided for at least one terminal of a

Transmission Line or generator step-up (GSU) transformer, but not both terminals. For an interconnection between two Reliability Coordinators, each Reliability Coordinator will consider this interconnection independently, and are expected to work cooperatively to determine how to monitor the BES Elements that require DDR data. For an interconnection between two TO's, or a TO and a GO, the Reliability Coordinator will determine which entity will provide the data. The Reliability Coordinator will notify the owners that their BES Elements require DDR data.

Refer to the Guidelines and Technical Basis Section for more detail on the rationale and technical reasoning for each identified BES Element in Requirement R5, Part 5.1; monitoring these BES Elements with DDR will facilitate thorough and informative event analysis of wide-area Disturbances on the BES. Part 5.2 is included to ensure wide-area coverage across all Reliability Coordinators. It is intended that each Reliability Coordinator will have DDR data for one BES Element and at least one additional BES Element per 3,000 MW of its historical simultaneous peak System Demand.

Rationale for R6:
DDR is used to measure transient response to System Disturbances during a relatively balanced post-fault condition. Therefore, it is sufficient to provide a phase-to-neutral voltage or positive sequence voltage. The electrical quantities can be determined (calculated, derived, etc.).

Because all of the BES buses within a location are at the same frequency, one frequency measurement is adequate.

The data requirements for PRC-002-3 are based on a System configuration assuming all normally closed circuit breakers on a BES bus are closed.

Rationale for R7:
A crucial part of wide-area Disturbance analysis is understanding the dynamic response of generating resources. Therefore, it is necessary for Generator Owners to have DDR at either the high- or low-side of the generator step-up transformer (GSU) measuring the specified electrical quantities to adequately capture generator response. This standard defines the 'what' of DDR, not the 'how'. Generator Owners may install this capability or, where the Transmission Owners already have suitable DDR data, contract with the Transmission Owner. However, the Generator Owner is still responsible for the provision of this data.

Rationale for R8:
Large scale System outages generally are an evolving sequence of events that occur over an extended period of time, making DDR data essential for event analysis. Data available pre- and post-contingency helps identify the causes and effects of each event leading to outages. Therefore, continuous recording and storage are necessary to ensure sufficient data is available for the entire event.
Existing DDR data recording across the BES may not record continuously. To accommodate its use for the purposes of this standard, triggered records are acceptable if the equipment was installed prior to the effective date of this standard. The frequency triggers are defined based on the dynamic response associated with each Interconnection. The undervoltage trigger is

defined to capture possible delayed undervoltage conditions such as Fault Induced Delayed Voltage Recovery (FIDVR).

Rationale for R9:

An input sampling rate of at least 960 samples per second, which corresponds to 16 samples per cycle on the input side of the DDR equipment, ensures adequate accuracy for calculation of recorded measurements such as complex voltage and frequency.
An output recording rate of electrical quantities of at least 30 times per second refers to the recording and measurement calculation rate of the device. Recorded measurements of at least 30 times per second provide adequate recording speed to monitor the low frequency oscillations typically of interest during power System Disturbances.

Rationale for R10:

Time synchronization of Disturbance monitoring data is essential for time alignment of large volumes of geographically dispersed records from diverse recording sources. Coordinated Universal Time (UTC) is a recognized time standard that utilizes atomic clocks for generating precision time measurements. All data must be provided in UTC formatted time either with or without the local time offset, expressed as a negative number (the difference between UTC and the local time zone where the measurements are recorded).
Accuracy of time synchronization applies only to the clock used for synchronizing the monitoring equipment. The equipment used to measure the electrical quantities must be time synchronized to ± 2 ms accuracy; however, accuracy of the application of this time stamp and therefore the accuracy of the data itself is not mandated. This is because of inherent delays associated with measuring the electrical quantities and events such as breaker closing, measurement transport delays, algorithm and measurement calculation techniques, etc. Ensuring that the monitoring devices internal clocks are within ± 2 ms accuracy will suffice with respect to providing time synchronized data.

Rationale for R11:

Wide-area Disturbance analysis includes data recording from many devices and entities. Standardized formatting and naming conventions of these files significantly improves timely analysis.

Providing the data within 30-calendar days (or the granted extension time), subject to Part 11.1, allows for reasonable time to collect the data and perform any necessary computations or formatting.

Data is required to be retrievable for 10-calendar days inclusive of the day the data was recorded, i.e. a 10-calendar day rolling window of available data. Data hold requests are usually initiated the same or next day following a major event for which data is requested. A 10-calendar day time frame provides a practical limit on the duration of data required to be stored and informs the requesting entities as to how long the data will be available. The requestor of data has to be aware of the Part 11.1 10-calendar day retrievability because requiring data retention for a longer period of time is expensive and unnecessary.

SER data shall be provided in a simple ASCII .CSV format as outlined in Attachment 2. Either equipment can provide the data or a simple conversion program can be used to convert files into this format. This will significantly improve the data format for event records, enabling the use of software tools for analyzing the SER data.

Part 11.4 specifies FR and DDR data files be provided in conformance with IEEE C37.111, IEEE Standard for Common Format for Transient Exchange (COMTRADE), revision 1999 or later. The use of IEEE C37.111-1999 or later is well established in the industry. C37.111-2013 is a version of COMTRADE that includes an annex describing the application of the COMTRADE standard to synchrophasor data; however, version C37.111-1999 is commonly used in the industry today.

Part 11.5 uses a standardized naming format, C37.232-2011, IEEE Standard for Common Format for Naming Time Sequence Data Files (COMNAME), for providing Disturbance monitoring data. This file format allows a streamlined analysis of large Disturbances, and includes critical records such as local time offset associated with the synchronization of the data.

Rationale for R12:

Each Transmission Owner and Generator Owner who owns equipment used for collecting the data required for this standard must repair any failures within 90-calendar days to ensure that adequate data is available for event analysis. If the Disturbance monitoring capability cannot be restored within 90-calendar days (e.g. budget cycle, service crews, vendors, needed outages, etc.), the entity must develop a Corrective Action Plan (CAP) for restoring the data recording capability. The timeline required for the CAP depends on the entity and the type of data required. It is treated as a failure if the recording capability is out of service for maintenance and/or testing for greater than 90-calendar days. An outage of the monitored BES Element does not constitute a failure of the Disturbance monitoring capability.

Guidelines and Technical Basis Section

Introduction

The emphasis of PRC-002-3 is not on how Disturbance monitoring data is captured, but what Bulk Electric System data is captured. There are a variety of ways to capture the data PRC-002-3 addresses, and existing and currently available equipment can meet the requirements of this standard. PRC-002-3 also addresses the importance of addressing the availability of Disturbance monitoring capability to ensure the completeness of BES data capture.

The data requirements for PRC-002-3 are based on a System configuration assuming all normally closed circuit breakers on a bus are closed.

PRC-002-3 addresses “what” data is recorded, not “how” it is recorded.

Guideline for Requirement R1:

Sequence of events and fault recording for the analysis, reconstruction, and reporting of System Disturbances is important. However, SER and FR data is not required at every BES bus on the BES to conduct adequate or thorough analysis of a Disturbance. As major tools of event analysis, the time synchronized time stamp for a breaker change of state and the recorded waveforms of voltage and current for individual circuits allows the precise reconstruction of events of both localized and wide-area Disturbances.

More quality information is always better than less when performing event analysis. However, 100 percent coverage of all BES Elements is not practical nor required for effective analysis of wide-area Disturbances. Therefore, selectivity of required BES buses to monitor is important for the following reasons:

1. Identify key BES buses with breakers where crucial information is available when required.
2. Avoid excessive overlap of coverage.
3. Avoid gaps in critical coverage.
4. Provide coverage of BES Elements that could propagate a Disturbance.
5. Avoid mandates to cover BES Elements that are more likely to be a casualty of a Disturbance rather than a cause.
6. Establish selection criteria to provide effective coverage in different regions of the continent.

The major characteristics available to determine the selection process are:

1. System voltage level;
2. The number of Transmission Lines into a substation or switchyard;
3. The number and size of connected generating units;
4. The available short circuit levels.

Although it is straightforward to establish criteria for the application of identified BES buses, analysis was required to establish a sound technical basis to fulfill the required objectives.

To answer these questions and establish criteria for BES buses of SER and FR, the DMSDT established a sub-team referred to as the Monitored Value Analysis Team (MVA Team). The MVA Team collected information from a wide variety of Transmission Systems throughout the continent to analyze Transmission buses by the characteristics previously identified for the selection process.

The MVA Team learned that the development of criteria is not possible for adequate SER and FR coverage, based solely upon simple, bright line characteristics, such as the number of lines into a substation or switchyard at a particular voltage level or at a set level of short circuit current. To provide the appropriate coverage, a relatively simple but effective Methodology for Selecting Buses for Capturing Sequence of Events Recording (SER) and Fault Recording (FR) Data was developed. This Procedure, included as Attachment 1, assists entities in fulfilling Requirement R1 of the standard.

The Methodology for Selecting Buses for Capturing Sequence of Events Recording (SER) and Fault Recording (FR) Data is weighted to buses with higher short circuit levels. This is chosen for the following reasons:

1. The method is voltage level independent.
2. It is likely to select buses near large generation centers.
3. It is likely to select buses where delayed clearing can cause Cascading.
4. Selected buses directly correlate to the Universal Power Transfer equation: Lower Impedance – increased power flows – greater System impact.

To perform the calculations of Attachment 1, the following information below is required and the following steps (provided in summary form) are required for Systems with more than 11 BES buses with three phase short circuit levels above 1,500 MVA.

1. Total number of BES buses in the Transmission System under evaluation.
   a. Only tangible substation or switchyard buses are included.
   b. Pseudo buses created for analysis purposes in System models are excluded.
2. Determine the three phase short circuit MVA for each BES bus.
3. Exclude BES buses from the list with short circuit levels below 1,500 MVA.
4. Determine the median short circuit for the top 11 BES buses on the list (position number 6).
5. Multiply median short circuit level by 20 percent.
6. Reduce the list of BES buses to those with short circuit levels higher than 20 percent of the median.
7. Apply SER and FR at BES buses with short circuit levels in the top 10 percent of the list (from 6).

8. Apply SER and FR at BES buses at an additional 10 percent of the list using engineering judgment, and allowing flexibility to factor in the following considerations:
   - Electrically distant BES buses or electrically distant from other DME devices
   - Voltage sensitive areas
   - Cohesive load and generation zones
   - BES buses with a relatively high number of incident Transmission circuits
   - BES buses with reactive power devices
   - Major facilities interconnecting outside the Transmission Owner's area.

For event analysis purposes, more valuable information is attained about generators and their response to System events pre- and post-contingency through DDR data versus SER or FR records. SER data of the opening of the primary generator output interrupting devices (e.g. synchronizing breaker) may not reliably indicate the actual time that a generator tripped; for instance, when it trips on reverse power after loss of its prime mover (e.g. combustion or steam turbine). As a result, this standard only requires DDR data.

The re-evaluation interval of five years was chosen based on the experience of the DMSDT to address changing System configurations while creating balance in the frequency of re-evaluations.

Guideline for Requirement R2:

Analyses of wide-area Disturbances often begin by evaluation of SERs to help determine the initiating event(s) and follow the Disturbance propagation. Recording of breaker operations help determine the interruption of line flows while generator loading is best determined by DDR data, since generator loading can be essentially zero regardless of breaker position. However, generator breakers directly connected to an identified BES bus are required to have SER data captured. It is important in event analysis to know when a BES bus is cleared regardless of a generator's loading.

Generator Owners are included in this requirement because a Generator Owner may, in some instances, own breakers directly connected to the Transmission Owner's BES bus.

Guideline for Requirement R3:

The BES buses for which FR data is required are determined based on the methodology described in Attachment 1 of the standard. The BES Elements connected to those BES buses for which FR data is required include:

- Transformers with a low-side operating voltage of 100kV or above
- Transmission Lines

Only those BES Elements that are identified as BES as defined in the latest in effect NERC definition are to be monitored. For example, radial lines or transformers with low-side voltage less than 100kV are not included.

FR data must be determinable from each terminal of a BES Element connected to applicable BES buses.

Generator step-up transformers (GSU) are excluded from the above based on the following:

- Current contribution from a generator in case of fault on the Transmission System will be captured by FR data on the Transmission System.
- For faults on the interconnection to generating facilities it is sufficient to have fault current data from the Transmission station end of the interconnection. Current contribution from a generator can be readily calculated if needed.

The DMSDT, after consulting with NERC's Event Analysis group, determined that DDR data from selected generator locations was more important for event analysis than FR data.

<u>Recording of Electrical Quantities</u>
For effective fault analysis it is necessary to know values of all phase and neutral currents and all phase-to-neutral voltages. Based on such FR data it is possible to determine all fault types. FR data also augments SERs in evaluating circuit breaker operation.

<u>Current Recordings</u>
The required electrical quantities are normally directly measured. Certain quantities can be derived if sufficient data is measured, for example residual or neutral currents.
Since a Transmission System is generally well balanced, with phase currents having essentially similar magnitudes and phase angle differences of 120°, during normal conditions there is negligible neutral (residual) current. In case of a ground fault the resulting phase current imbalance produces residual current that can be either measured or calculated.

Neutral current, also known as ground or residual current $\mathbf{I}_{r,}$ is calculated as a sum of vectors of three phase currents:
$\mathbf{I}_r = 3 \bullet \mathbf{I}_0 = \mathbf{I}_A + \mathbf{I}_B + \mathbf{I}_C$

$\mathbf{I}_0$ - Zero-sequence current

$\mathbf{I}_A$, $\mathbf{I}_B$, $\mathbf{I}_C$ - Phase current (vectors)

Another example of how required electrical quantities can be derived is based on Kirchhoff's Law. Fault currents for one of the BES Elements connected to a particular BES bus can be derived as a vectorial sum of fault currents recorded at the other BES Elements connected to that BES bus.

<u>Voltage Recordings</u>
Voltages are to be recorded or accurately determined at applicable BES buses.

Guideline for Requirement R4:

Pre- and post-trigger fault data along with the SER breaker data, all time stamped to a common clock at millisecond accuracy, aid in the analysis of protection System operations after a fault to determine if a protection System operated as designed. Generally speaking, BES faults persist for a very short time period, approximately 1 to 30 cycles, thus a 30-cycle record length provides adequate data. Multiple records allow for legacy microprocessor relays which, when time synchronized to a common clock, are capable of providing adequate fault data but not capable of providing fault data in a single record with 30-contiguous cycles total.

A minimum recording rate of 16 samples per cycle is required to get accurate waveforms and to get 1 millisecond resolution for any digital input which may be used for FR.

FR triggers can be set so that when the monitored value on the recording device goes above or below the trigger value, data is recorded. Requirement R4, sub-Part 4.3.1 specifies a neutral (residual) overcurrent trigger for ground faults. Requirement R4, sub-Part 4.3.2 specifies a phase undervoltage or overcurrent trigger for phase-to-phase faults.

Guideline for Requirement R5:

DDR data is used for wide-area Disturbance monitoring to determine the System's electromechanical transient and post-transient response and validate System model performance. DDR is typically located based on strategic studies which include angular, frequency, voltage, and oscillation stability. However, for adequately monitoring the System's dynamic response and ensuring sufficient coverage to determine System performance, DDR is required for key BES Elements in addition to a minimum requirement of DDR coverage.

Each Reliability Coordinator is required to identify sufficient DDR data capture for, at a minimum, one BES Element and then one additional BES Element per 3,000 MW of historical simultaneous peak System Demand. This DDR data is included to provide adequate System wide coverage across an Interconnection. To clarify, if any of the key BES Elements requiring DDR monitoring are within the Reliability Coordinator Area, DDR data capability is required. If a Reliability Coordinator does not meet the requirements of Part 5.1, additional coverage had to be specified.

Loss of large generating resources poses a frequency and angular stability risk for all Interconnections across North America. Data capturing the dynamic response of these machines during a Disturbance helps the analysis of large Disturbances. Having data regarding generator dynamic response to Disturbances greatly improves understanding of ***why*** an event occurs rather than what occurred. To determine and provide the basis for unit size criteria, the DMSDT acquired specific generating unit data from NERC's Generating Availability Data System (GADS) program. The data contained generating unit size information for each generating unit in North America which was reported in 2013 to the NERC GADS program. The DMSDT analyzed the spreadsheet data to determine: (i) how many units were above or below selected size thresholds; and (ii) the aggregate sum of the ratings of the units within the boundaries of those thresholds. Statistical information about this data was then produced, i.e. averages, means and percentages. The DMSDT determined the following basic information about the generating units of interest (current North America fleet, i.e. units reporting in 2013) included in the spreadsheet:

- The number of individual generating units in total included in the spreadsheet.
- The number of individual generating units rated at 20 MW or larger included in the spreadsheet. These units would generally require that their owners be registered as GOs in the NERC CMEP.
- The total number of units within selected size boundaries.
- The aggregate sum of ratings, in MWs, of the units within the boundaries of those thresholds.

The information in the spreadsheet does not provide information by which the plant information location of each unit can be determined, i.e. the DMSDT could not use the information to determine which units were located together at a given generation site or facility.

From this information, the DMSDT was able to reasonably speculate the generating unit size thresholds proposed in Requirement R5, sub-Part 5.1.1 of the standard. Generating resources intended for DDR data recording are those individual units with gross nameplate ratings "greater than or equal to 500 MVA". The 500 MVA individual unit size threshold was selected because this number roughly accounts for 47 percent of the generating capacity in NERC footprint while only requiring DDR coverage on about 12.5 percent of the generating units. As mentioned, there was no data pertaining to unit location for aggregating plant/facility sizes. However, Requirement R5, sub-Part 5.1.1 is included to capture larger units located at large generating plants which could pose a stability risk to the System if multiple large units were lost due to electrical or non-electrical contingencies. For generating plants, each individual generator at the plant/facility with a gross nameplate rating greater than or equal to 300 MVA must have DDR where the gross nameplate rating of the plant/facility is greater than or equal to 1,000 MVA. The 300 MVA threshold was chosen based on the DMSDT's judgment and experience. The incremental impact to the number of units requiring monitoring is expected to be relatively low. For combined cycle plants where only one generator has a rating greater than or equal to 300MVA, that is the only generator that would need DDR.

Permanent System Operating Limits (SOLs) are used to operate the System within reliable and secure limits. In particular, SOLs related to angular or voltage stability have a significant impact on BES reliability and performance. Therefore, at least one BES Element of an SOL should be monitored.

The draft standard requires "One or more BES Elements that are part of an Interconnection Reliability Operating Limits (IROLs)." Interconnection Reliability Operating Limits (IROLs) are included because the risk of violating these limits poses a risk to System stability and the potential for cascading outages. IROLs may be defined by a single or multiple monitored BES Element(s) and contingent BES Element(s). The standard does not dictate selection of the contingent and/or monitored BES Elements. Rather the Drafting Team believes this

determination is best made by the Reliability Coordinator for each IROL considered based on the severity of violating this IROL.

Locations where an undervoltage load shedding (UVLS) program is deployed are prone to voltage instability since they are generally areas of significant Demand. The Reliability Coordinator will identify these areas where a UVLS is in service and identify a useful and effective BES Element to monitor for DDR such that action of the UVLS or voltage instability on the BES could be captured. For example, a major 500kV or 230kV substation on the EHV System close to the load pocket where the UVLS is deployed would likely be a valuable electrical location for DDR coverage and would aid in post-Disturbance analysis of the load area's response to large System excursions (voltage, frequency, etc.).

Guideline for Requirement R6:

DDR data shows transient response to System Disturbances after a fault is cleared (post-fault), under a relatively balanced operating condition. Therefore, it is sufficient to provide a single phase-to-neutral voltage or positive sequence voltage. Recording of all three phases of a circuit is not required, although this may be used to compute and record the positive sequence voltage.

The bus where a voltage measurement is required is based on the list of BES Elements defined by the Reliability Coordinator in Requirement R5. The intent of the standard is not to require a separate voltage measurement of each BES Element where a common bus voltage measurement is available. For example, a breaker-and-a-half or double-bus configuration with a North (or East) Bus and South (or West) Bus, would require both buses to have voltage recording because either can be taken out of service indefinitely with the targeted BES Element remaining in service. This may be accomplished either by recording both bus voltages separately, or by providing a selector switch to connect either of the bus voltage sources to a single recording input of the DDR device. This component of the requirement is therefore included to mitigate the potential of failed frequency, phase angle, real power, and reactive power calculations due to voltage measurements removed from service while sufficient voltage measurement is actually available during these operating conditions.

It must be emphasized that the data requirements for PRC-002-3 are based on a System configuration assuming all normally closed circuit breakers on a bus are closed.

When current recording is required, it should be on the same phase as the voltage recording taken at the location if a single phase-to-neutral voltage is provided. Positive sequence current recording is also acceptable.

For all circuits where current recording is required, Real and Reactive Power will be recorded on a three phase basis. These recordings may be derived either from phase quantities or from positive sequence quantities.

Guideline for Requirement R7:

All Guidelines specified for Requirement R6 apply to Requirement R7. Since either the high- or low-side windings of the generator step-up transformer (GSU) may be connected in delta, phase-to-phase voltage recording is an acceptable voltage recording. As was explained in the Guideline for Requirement R6, the BES is operating under a relatively balanced operating condition and, if needed, phase-to-neutral quantities can be derived from phase-to-phase quantities.

Again it must be emphasized that the data requirements for PRC-002-3are based on a System configuration assuming all normally closed circuit breakers on a bus are closed.

Guideline for Requirement R8:

Wide-area System outages are generally an evolving sequence of events that occur over an extended period of time, making DDR data essential for event analysis. Pre- and post-contingency data helps identify the causes and effects of each event leading to the outages. This drives a need for continuous recording and storage to ensure sufficient data is available for the entire Disturbance.

Transmission Owners and Generator Owners are required to have continuous DDR for the BES Elements identified in Requirement R6. However, this requirement recognizes that legacy equipment may exist for some BES Elements that do not have continuous data recording capabilities. For equipment that was installed prior to the effective date of the standard, triggered DDR records of three minutes are acceptable using at least one of the trigger types specified in Requirement R8, Part 8.2:

- Off nominal frequency triggers are used to capture high- or low-frequency excursions of significant size based on the Interconnection size and inertia.
- Rate of change of frequency triggers are used to capture major changes in System frequency which could be caused by large changes in generation or load, or possibly changes in System impedance.
- The undervoltage trigger specified in this standard is provided to capture possible sustained undervoltage conditions such as Fault Induced Delayed Voltage Recovery (FIDVR) events. A sustained voltage of 85 percent is outside normal schedule operating voltages and is sufficiently low to capture abnormal voltage conditions on the BES.

Guideline for Requirement R9:

DDR data contains the dynamic response of a power System to a Disturbance and is used for analyzing complex power System events. This recording is typically used to capture short-term and long-term Disturbances, such as a power swing. Since the data of interest is changing over time, DDR data is normally stored in the form of RMS values or phasor values, as opposed to directly sampled data as found in FR data.

The issue of the sampling rate used in a recording instrument is quite important for at least two reasons: the anti-aliasing filter selection and accuracy of signal representation. The anti-aliasing

filter selection is associated with the requirement of a sampling rate at least twice the highest frequency of a sampled signal. At the same time, the accuracy of signal representation is also dependent on the selection of the sampling rate. In general, the higher the sampling rate, the better the representation. In the abnormal conditions of interest (e.g. faults or other Disturbances); the input signal may contain frequencies in the range of 0-400 Hz. Hence, the rate of 960 samples per second (16 samples/cycle) is considered an adequate sampling rate that satisfies the input signal requirements.

In general, dynamic events of interest are: inter-area oscillations, local generator oscillations, wind turbine generator torsional modes, HVDC control modes, exciter control modes, and steam turbine torsional modes. Their frequencies range from 0.1-20 Hz. In order to reconstruct these dynamic events, a minimum recording time of 30 times per second is required.

Guideline for Requirement R10:

Time synchronization of Disturbance monitoring data allows for the time alignment of large volumes of geographically dispersed data records from diverse recording sources. A universally recognized time standard is necessary to provide the foundation for this alignment. Coordinated Universal Time (UTC) is the foundation used for the time alignment of records. It is an international time standard utilizing atomic clocks for generating precision time measurements at fractions of a second levels. The local time offset, expressed as a negative number, is the difference between UTC and the local time zone where the measurements are recorded.

Accuracy of time synchronization applies only to the clock used for synchronizing the monitoring equipment.

Time synchronization accuracy is specified in response to Recommendation 12b in the NERC August, 2003, Blackout Final NERC Report Section V Conclusions and Recommendations:

“Recommendation 12b: Facilities owners shall, in accordance with regional criteria, upgrade existing dynamic recorders to include GPS time synchronization…”

Also, from the U.S.-Canada Power System Outage Task Force Interim Report: Causes of the August 14th Blackout, November 2003, in the United States and Canada, page 103:

“Establishing a precise and accurate sequence of outage-related events was a critical building block for the other parts of the investigation. One of the key problems in developing this sequence was that although much of the data pertinent to an event was time-stamped, there was some variance from source to source in how the time-stamping was done, and not all of the time-stamps were synchronized…”

From NPCC’s SP6 Report Synchronized Event Data Reporting, revised March 31, 2005, the investigation by the authoring working group revealed that existing GPS receivers can be expected to provide a time code output which has an uncertainty on the order of 1 millisecond, uncertainty being a quantitative descriptor.

Guideline for Requirement R11:

This requirement directs the applicable entities, upon requests from the Reliability Coordinator, Regional Entity or NERC, to provide SER and FR data for BES buses determined in Requirement R1 and DDR data for BES Elements determined as per Requirement R5. To facilitate the analysis of BES Disturbances, it is important that the data is provided to the requestor within a reasonable period of time.

Requirement R11, Part 11.1 specifies the maximum time frame of 30-calendar days to provide the data. Thirty calendar days is a reasonable time frame to allow for the collection of data, and submission to the requestor. An entity may request an extension of the 30-day submission requirement. If granted by the requestor, the entity must submit the data within the approved extended time.

Requirement R11, Part 11.2 specifies that the minimum time period of 10-calendar days inclusive of the day the data was recorded for which the data will be retrievable. With the equipment in use that has the capability of recording data, having the data retrievable for the 10-calendar days is realistic and doable. It is important to note that applicable entities should account for any expected delays in retrieving data and this may require devices to have data available for more than 10 days. To clarify the 10-calendar day time frame, an incident occurs on Day 1. If a request for data is made on Day 6, then that data has to be provided to the requestor within 30-calendar days after a request or a granted time extension. However, if a request for the data is made on Day 11, that is outside the 10-calendar days specified in the requirement, and an entity would not be out of compliance if it did not have the data.

Requirement R11, Part 11.3 specifies a Comma Separated Value (CSV) format according to Attachment 2 for the SER data. It is necessary to establish a standard format as it will be incorporated with other submitted data to provide a detailed sequence of events timeline of a power System Disturbance.

Requirement R11, Part 11.4 specifies the IEEE C37.111 COMTRADE format for the FR and DDR data. The IEEE C37.111 is the Standard for Common Format for Transient Data Exchange and is well established in the industry. It is necessary to specify a standard format as multiple submissions of data from many sources will be incorporated to provide a detailed analysis of a power System Disturbance. The latest revision of COMTRADE (C37.111-2013) includes an annex describing the application of the COMTRADE standard to synchophasor data.

Requirement R11, Part 11.5 specifies the IEEE C37.232 COMNAME format for naming the data files of the SER, FR and DDR. The IEEE C37.232 is the Standard for Common Format for Naming Time Sequence Data Files. The first version was approved in 2007. From the August 14, 2003 blackout there were thousands of Fault Recording data files collected. The collected data files did not have a common naming convention and it was therefore difficult to discern which files came from which utilities and which ones were captured by which devices. The lack of a common naming practice seriously hindered the investigation process. Subsequently, and in its initial report on the blackout, NERC stressed the need for having a common naming practice and listed it as one of its top ten recommendations.

Guideline for Requirement R12:

This requirement directs the respective owners of Transmission and Generator equipment to be alert to the proper functioning of equipment used for SER, FR, and DDR data capabilities for the BES buses and BES Elements, which were established in Requirements R1 and R5. The owners are to restore the capability within 90-calendar days of discovery of a failure. This requirement is structured to recognize that the existence of a “reasonable” amount of capability out-of-service does not result in lack of sufficient data for coverage of the System. Furthermore, 90-calendar days is typically sufficient time for repair or maintenance to be performed. However, in recognition of the fact that there may be occasions for which it is not possible to restore the capability within 90-calendar days, the requirement further provides that, for such cases, the entity submit a Corrective Action Plan (CAP) to the Regional Entity and implement it. These actions are considered to be appropriate to provide for robust and adequate data availability.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the Board of Trustees.

Description of Current Draft

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	08/19/15
SAR posted for comment	08/20/15 – 09/21/15
45-day formal comment period with initial ballot	08/24/18-10/17/18

Anticipated Actions	Date
45-day formal comment period with initial ballot	June 2020
10-day final ballot	August 2020
NERC Board adoption	November 2020

A. Introduction

1. **Title:** Disturbance Monitoring and Reporting Requirements
2. **Number:** PRC-002-3
3. **Purpose:** To have adequate data available to facilitate analysis of Bulk Electric System (BES) Disturbances.
4. **Applicability:**

   Functional Entities:

   4.1 Reliability Coordinator

   4.2 Transmission Owner

   4.3 Generator Owner

5. **Effective Date~~s~~:** See Implementation Plan

B. Requirements and Measures

R1. Each Transmission Owner shall: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

1.1. Identify BES buses for which sequence of events recording (SER) and fault recording (FR) data is required by using the methodology in PRC-002-~~2~~3, Attachment 1.

1.2. Notify other owners of BES Elements connected to those BES buses, if any, within 90-calendar days of completion of Part 1.1, that those BES Elements require SER data and/or FR data.

1.3. Re-evaluate all BES buses at least once every five calendar years in accordance with Part 1.1 and notify other owners, if any, in accordance with Part 1.2, and implement the re-evaluated list of BES buses as per the Implementation Plan.

M1. The Transmission Owner has a dated (electronic or hard copy) list of BES buses for which SER and FR data is required, identified in accordance with PRC-002-~~2~~3, Attachment 1, and evidence that all BES buses have been re-evaluated within the required intervals under Requirement R1. The Transmission Owner will also have dated (electronic or hard copy) evidence that it notified other owners in accordance with Requirement R1.

R2. Each Transmission Owner and Generator Owner shall have SER data for circuit breaker position (open/close) for each circuit breaker it owns connected directly to the BES buses identified in Requirement R1 and associated with the BES Elements at those BES buses. *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

M2. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) of SER data for circuit breaker position as specified in Requirement R2. Evidence may include, but is not limited to: (1) documents describing the device interconnections and configurations which may include a single design standard as representative for common installations; or (2) actual data recordings; or (3) station drawings.

R3. Each Transmission Owner and Generator Owner shall have FR data to determine the following electrical quantities for each triggered FR for the BES Elements it owns connected to the BES buses identified in Requirement R1: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

3.1 Phase-to-neutral voltage for each phase of each specified BES bus.

3.2 Each phase current and the residual or neutral current for the following BES Elements:

3.2.1 Transformers that have a low-side operating voltage of 100kV or above.

3.2.2 Transmission Lines.

M3. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) of FR data that is sufficient to determine electrical quantities as specified in Requirement R3. Evidence may include, but is not limited to: (1) documents describing the device specifications and configurations which may include a single design standard as representative for common installations; or (2) actual data recordings or derivations; or (3) station drawings.

R4. Each Transmission Owner and Generator Owner shall have FR data as specified in Requirement R3 that meets the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

4.1 A single record or multiple records that include:

- A pre-trigger record length of at least two cycles and a total record length of at least 30-cycles for the same trigger point, or
- At least two cycles of the pre-trigger data, the first three cycles of the post-trigger data, and the final cycle of the fault as seen by the fault recorder.

4.2 A minimum recording rate of 16 samples per cycle.

4.3 Trigger settings for at least the following:

4.3.1 Neutral (residual) overcurrent.

4.3.2 Phase undervoltage or overcurrent.

M4. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) that FR data meets Requirement R4. Evidence may include, but is not limited to: (1) documents describing the device specification (R4, Part 4.2) and device configuration or settings (R4, Parts 4.1 and 4.3), or (2) actual data recordings or derivations.

R5. Each Reliability Coordinator shall: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

5.1 Identify BES Elements for which dynamic Disturbance recording (DDR) data is required, including the following:

5.1.1 Generating resource(s) with:

5.1.1.1 Gross individual nameplate rating greater than or equal to 500 MVA.

5.1.1.2 Gross individual nameplate rating greater than or equal to 300 MVA where the gross plant/facility aggregate nameplate rating is greater than or equal to 1,000 MVA.

5.1.2 Any one BES Element that is part of a stability (angular or voltage) related System Operating Limit (SOL).

5.1.3 Each terminal of a high voltage direct current (HVDC) circuit with a nameplate rating greater than or equal to 300 MVA, on the alternating current (AC) portion of the converter.

5.1.4 One or more BES Elements that are part of an Interconnection Reliability Operating Limit (IROL).

5.1.5 Any one BES Element within a major voltage sensitive area as defined by an area with an in-service undervoltage load shedding (UVLS) program.

5.2 Identify a minimum DDR coverage, inclusive of those BES Elements identified in Part 5.1, of at least:

5.2.1 One BES Element; and

5.2.2 One BES Element per 3,000 MW of the Reliability Coordinator's historical simultaneous peak System Demand.

5.3 Notify all owners of identified BES Elements, within 90-calendar days of completion of Part 5.1, that their respective BES Elements require DDR data when requested.

5.4 Re-evaluate all BES Elements at least once every five calendar years in accordance with Parts 5.1 and 5.2, and notify owners in accordance with Part 5.3 to implement the re-evaluated list of BES Elements as per the Implementation Plan.

M5. The Reliability Coordinator has a dated (electronic or hard copy) list of BES Elements for which DDR data is required, developed in accordance with Requirement R5, Part 5.1 and Part 5.2; and re-evaluated in accordance with Part 5.4. The Reliability Coordinator has dated evidence (electronic or hard copy) that each Transmission Owner or Generator Owner has been notified in accordance with Requirement 5, Part 5.3. Evidence may include, but is not limited to: letters, emails, electronic files, or hard copy records demonstrating transmittal of information.

R6. Each Transmission Owner shall have DDR data to determine the following electrical quantities for each BES Element it owns for which it received notification as identified in Requirement R5: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

6.1 One phase-to-neutral or positive sequence voltage.

6.2 The phase current for the same phase at the same voltage corresponding to the voltage in Requirement R6, Part 6.1, or the positive sequence current.

6.3 Real Power and Reactive Power flows expressed on a three phase basis corresponding to all circuits where current measurements are required.

6.4 Frequency of any one of the voltage(s) in Requirement R6, Part 6.1.

M6. The Transmission Owner has evidence (electronic or hard copy) of DDR data to determine electrical quantities as specified in Requirement R6. Evidence may include, but is not limited to: (1) documents describing the device specifications and configurations, which may include a single design standard as representative for common installations; or (2) actual data recordings or derivations; or (3) station drawings.

R7. Each Generator Owner shall have DDR data to determine the following electrical quantities for each BES Element it owns for which it received notification as identified in Requirement R5: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

7.1 One phase-to-neutral, phase-to-phase, or positive sequence voltage at either the generator step-up transformer (GSU) high-side or low-side voltage level.

7.2 The phase current for the same phase at the same voltage corresponding to the voltage in Requirement R7, Part 7.1, phase current(s) for any phase-to-phase voltages, or positive sequence current.

7.3 Real Power and Reactive Power flows expressed on a three phase basis corresponding to all circuits where current measurements are required.

7.4 Frequency of at least one of the voltages in Requirement R7, Part 7.1.

M7. The Generator Owner has evidence (electronic or hard copy) of DDR data to determine electrical quantities as specified in Requirement R7. Evidence may include, but is not limited to: (1) documents describing the device specifications and configurations, which may include a single design standard as representative for common installations; or (2) actual data recordings or derivations; or (3) station drawings.

R8. Each Transmission Owner and Generator Owner responsible for DDR data for the BES Elements identified in Requirement R5 shall have continuous data recording and storage. If the equipment was installed prior to the effective date of this standard and is not capable of continuous recording, triggered records must meet the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

8.1 Triggered record lengths of at least three minutes.

8.2 At least one of the following three triggers:

- Off nominal frequency trigger set at:

	Low	High
Eastern Interconnection	<59.75 Hz	>61.0 Hz
Western Interconnection	<59.55 Hz	>61.0 Hz
ERCOT Interconnection	<59.35 Hz	>61.0 Hz
Hydro-Quebec Interconnection	<58.55 Hz	>61.5 Hz

- Rate of change of frequency trigger set at:

Eastern Interconnection	< -0.03125 Hz/sec	> 0.125 Hz/sec
Western Interconnection	< -0.05625 Hz/sec	> 0.125 Hz/sec
ERCOT Interconnection	< -0.08125 Hz/sec	> 0.125 Hz/sec
Hydro-Quebec Interconnection	< -0.18125 Hz/sec	> 0.1875 Hz/sec

- Undervoltage trigger set no lower than 85 percent of normal operating voltage for a duration of 5 seconds.

M8. Each Transmission Owner and Generator Owner has dated evidence (electronic or hard copy) of data recordings and storage in accordance with Requirement R8. Evidence may include, but is not limited to: (1) documents describing the device specifications and configurations, which may include a single design standard as representative for common installations; or (2) actual data recordings.

R9. Each Transmission Owner and Generator Owner responsible for DDR data for the BES Elements identified in Requirement R5 shall have DDR data that meet the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

9.1 Input sampling rate of at least 960 samples per second.

9.2 Output recording rate of electrical quantities of at least 30 times per second.

M9. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) that DDR data meets Requirement R9. Evidence may include, but is not limited to: (1) documents describing the device specification, device configuration, or settings (R9, Part 9.1; R9, Part 9.2); or (2) actual data recordings (R9, Part 9.2).

R10. Each Transmission Owner and Generator Owner shall time synchronize all SER and FR data for the BES buses identified in Requirement R1 and DDR data for the BES Elements identified in Requirement R5 to meet the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

10.1 Synchronization to Coordinated Universal Time (UTC) with or without a local time offset.

10.2 Synchronized device clock accuracy within ± 2 milliseconds of UTC.

M10. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) of time synchronization described in Requirement R10. Evidence may include, but is not limited to: (1) documents describing the device specification, configuration, or setting; (2) time synchronization indication or status; or 3) station drawings.

R11. Each Transmission Owner and Generator Owner shall provide, upon request, all SER and FR data for the BES buses identified in Requirement R1 and DDR data for the BES Elements identified in Requirement R5 to the Reliability Coordinator, Regional Entity, or NERC in accordance with the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

11.1 Data will be retrievable for the period of 10-calendar days, inclusive of the day the data was recorded.

11.2 Data subject to Part 11.1 will be provided within 30-calendar days of a request unless an extension is granted by the requestor.

11.3 SER data will be provided in ASCII Comma Separated Value (CSV) format following Attachment 2.

11.4 FR and DDR data will be provided in electronic files that are formatted in conformance with C37.111, (IEEE Standard for Common Format for Transient Data Exchange (COMTRADE), revision C37.111-1999 or later.

11.5 Data files will be named in conformance with C37.232, IEEE Standard for Common Format for Naming Time Sequence Data Files (COMNAME), revision C37.232-2011 or later.

M11. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) that data was submitted upon request in accordance with Requirement R11. Evidence may include, but is not limited to: (1) dated transmittals to the requesting entity with formatted records; (2) documents describing data storage capability, device specification, configuration or settings; or (3) actual data recordings.

R12. Each Transmission Owner and Generator Owner shall, within 90-calendar days of the discovery of a failure of the recording capability for the SER, FR or DDR data, either: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

- Restore the recording capability, or
- Submit a Corrective Action Plan (CAP) to the Regional Entity and implement it.

M12. The Transmission Owner or Generator Owner has dated evidence (electronic or hard copy) that meets Requirement R12. Evidence may include, but is not limited to: (1) dated reports of discovery of a failure, (2) documentation noting the date the data recording was restored, (3) SCADA records, or (4) dated CAP transmittals to the Regional Entity and evidence that it implemented the CAP.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

As defined in the NERC Rules of Procedure, "Compliance Enforcement Authority" (CEA) means NERC or the Regional Entity in their respective roles of monitoring and enforcing compliance with the NERC Reliability Standards.

1.2. Evidence Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Transmission Owner, Generator Owner, and Reliability Coordinator shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

The Transmission Owner shall retain evidence of Requirement R1, Measure M1 for five calendar years.

The Transmission Owner shall retain evidence of Requirement R6, Measure M6 for three calendar years.

The Generator Owner shall retain evidence of Requirement R7, Measure M7 for three calendar years.

The Transmission Owner and Generator Owner shall retain evidence of requested data provided as per Requirements R2, R3, R4, R8, R9, R10, R11, and R12, Measures M2, M3, M4, M8, M9, M10, M11, and M12 for three calendar years.

The Reliability Coordinator shall retain evidence of Requirement R5, Measure M5 for five calendar years.

If a Transmission Owner, Generator Owner, or Reliability Coordinator is found non-compliant, it shall keep information related to the non-compliance until mitigation is completed and approved or for the time specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes:

Compliance Audit

Self-Certification

Spot Checking

Compliance Violation Investigation

Self-Reporting

Complaints

1.4. Additional Compliance Information

None

Table of Compliance Elements

R #	Time Horizon	VRF	Violation Severity Levels			
			Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	Long-term Planning	Lower	The Transmission Owner identified the BES buses as directed by Requirement R1, Part 1.1 or Part 1.3 for more than 80 percent but less than 100 percent of the required BES buses that they own. OR The Transmission Owner evaluated the BES buses as directed by Requirement R1, Part 1.1 or Part 1.3 but was late by 30-calendar days or less. OR The Transmission Owner as directed by Requirement R1, Part 1.2 was late in notifying the other	The Transmission Owner identified the BES buses as directed by Requirement R1, Part 1.1 or Part 1.3 for more than 70 percent but less than or equal to 80 percent of the required BES buses that they own. OR The Transmission Owner evaluated the BES buses as directed by Requirement R1, Part 1.1 or Part 1.3 but was late by greater than 30-calendar days and less than or equal to 60-calendar days. Methodology for Selecting Buses for Capturing Sequence of Events Recording (SER) and Fault Recording (FR) Data

(Requirement R1)

To identify monitored BES buses for sequence of events recording (SER) and Fault recording (FR) data required by Requirement 1, each Transmission Owner shall follow sequentially, unless otherwise noted, the steps listed below:

Step 1. Determine a complete list of BES buses that it owns.

For the purposes of this standard, a single BES bus includes physical buses with breakers connected at the same voltage level within the same physical location sharing a common ground grid. These buses may be modeled or represented by a single node in fault studies. For example, ring bus or breaker-and-a-half bus configurations are considered to be a single bus.

Step 2. Reduce the list to those BES buses that have a maximum available calculated three phase short circuit MVA of 1,500 MVA or greater. If there are no buses on the resulting list, proceed to Step 7.

Step 3. Determine the 11 BES buses on the list with the highest maximum available calculated three phase short circuit MVA level. If the list has 11 or fewer buses, proceed to Step 7.

Step 4. Calculate the median MVA level of the 11 BES buses determined in Step 3.

Step 5. Multiply the median MVA level determined in Step 4 by 20 percent.

Step 6. Reduce the BES buses on the list to only those that have a maximum available calculated three phase short circuit MVA higher than the greater of:

- 1,500 MVA or
- 20 percent of median MVA level determined in Step 5.

Step 7. <u>If there are no BES buses on the list:</u> the procedure is complete and no FR and SER data will be required. Proceed to Step 9.

<u>If the list has 1 or more but less than or equal to 11 BES buses:</u> FR and SER data is required at the BES bus with the highest maximum available calculated three phase short circuit MVA as determined in Step 3. Proceed to Step 9.

If the list has more than 11 BES buses: SER and FR data is required on at least the 10 percent of the BES buses determined in Step 6 with the highest maximum available calculated three phase short circuit MVA. Proceed to Step 8.

Step 8. SER and FR data is required at additional BES buses on the list determined in Step 6. The aggregate of the number of BES buses determined in Step 7 and this Step will be at least 20 percent of the BES buses determined in Step 6.

The additional BES buses are selected, at the Transmission Owner's discretion, to provide maximum wide-area coverage for SER and FR data. The following BES bus locations are recommended:

- Electrically distant buses or electrically distant from other DME devices.
- Voltage sensitive areas.
- Cohesive load and generation zones.
- BES buses with a relatively high number of incident Transmission circuits.
- BES buses with reactive power devices.
- Major Facilities interconnecting outside the Transmission Owner's area.

Step 9. The list of monitored BES buses for SER and FR data for Requirement R1 is the aggregate of the BES buses determined in Steps 7 and 8.

Rationale:

During development of this standard, text boxes were embedded within the standard to explain the rationale for various parts of the standard. Upon BOT approval, the text from the rationale text boxes was moved to this section.

Rationale for Functional Entities:

Because the Reliability Coordinator has the best wide-area view of the BES, the Reliability Coordinator is most suited to be responsible for determining the BES Elements for which dynamic Disturbance recording (DDR) data is required. The Transmission Owners and Generator Owners will have the responsibility for ensuring that adequate data is available for those BES Elements selected.

BES buses where sequence of events recording (SER) and fault recording (FR) data is required are best selected by Transmission Owners because they have the required tools, information, and working knowledge of their Systems to determine those buses. The Transmission Owners and Generator Owners that own BES Elements on those BES buses will have the responsibility for ensuring that adequate data is available.

Rationale for R1:

Analysis and reconstruction of BES events requires SER and FR data from key BES buses. Attachment 1 provides a uniform methodology to identify those BES buses. Repeated testing of the Attachment 1 methodology has demonstrated the proper distribution of SER and FR data collection. Review of actual BES short circuit data received from the industry in response to the DMSDT's data request (June 5, 2013 through July 5, 2013) illuminated a strong correlation between the available short circuit MVA at a Transmission bus and its relative size and importance to the BES based on (i) its voltage level, (ii) the number of Transmission Lines and other BES Elements connected to the BES bus, and (iii) the number and size of generating units connected to the bus. BES buses with a large short circuit MVA level are BES Elements that have a significant effect on System reliability and performance. Conversely, BES buses with very low short circuit MVA levels seldom cause wide-area or cascading System events, so SER and FR data from those BES Elements are not as significant. After analyzing and reviewing the collected data submittals from across the continent, the threshold MVA values were chosen to provide sufficient data for event analysis using engineering and operational judgment.

Concerns have existed that the defined methodology for bus selection will overly concentrate data to selected BES buses. For the purpose of PRC-002-~~2~~3, there are a minimum number of BES buses for which SER and FR data is required based on the short circuit level. With these concepts and the objective being sufficient recording coverage for event analysis, the DMSDT developed the procedure in Attachment 1 that utilizes the maximum available calculated three phase short circuit MVA. This methodology ensures comparable and sufficient coverage for SER and FR data regardless of variations in the size and System topology of Transmission Owners across all Interconnections. Additionally, this methodology provides a degree of flexibility for the use of judgment in the selection process to ensure sufficient distribution.

BES buses where SER and FR data is required are best selected by Transmission Owners because they have the required tools, information, and working knowledge of their Systems to determine those buses.

Each Transmission Owner must re-evaluate the list of BES buses at least every five calendar years to address System changes since the previous evaluation. Changes to the BES do not mandate immediate inclusion of BES buses into the currently enforced list, but the list of BES buses will be re-evaluated at least every five calendar years to address System changes since the previous evaluation.

Since there may be multiple owners of equipment that comprise a BES bus, the notification required in R1 is necessary to ensure all owners are notified.

A 90-calendar day notification deadline provides adequate time for the Transmission Owner to make the appropriate determination and notification.

Rationale for R2:
The intent is to capture SER data for the status (open/close) of the circuit breakers that can interrupt the current flow through each BES Element connected to a BES bus. Change of state of circuit breaker position, time stamped according to Requirement R10 to a time synchronized clock, provides the basis for assembling the detailed sequence of events timeline of a power System Disturbance. Other status monitoring nomenclature can be used for devices other than circuit breakers.

Rationale for R3:
The required electrical quantities may either be directly measured or determinable if sufficient FR data is captured (e.g. residual or neutral current if the phase currents are directly measured). In order to cover all possible fault types, all BES bus phase-to-neutral voltages are required to be determinable for each BES bus identified in Requirement R1. BES bus voltage data is adequate for System Disturbance analysis. Phase current and residual current are required to distinguish between phase faults and ground faults. It also facilitates determination of the fault location and cause of relay operation. For transformers (Part 3.2.1), the data may be from either the high-side or the low-side of the transformer. Generator step-up transformers (GSUs) and leads that connect the GSU transformer(s) to the Transmission System that are used exclusively to export energy directly from a BES generating unit or generating plant are excluded from Requirement R3 because the fault current contribution from a generator to a fault on the Transmission System will be captured by FR data on the Transmission System, and Transmission System FR will capture faults on the generator interconnection.

Generator Owners may install this capability or, where the Transmission Owners already have suitable FR data, contract with the Transmission Owner. However, when required, the Generator Owner is still responsible for the provision of this data.

Rationale for R4:

Time stamped pre- and post-trigger fault data aid in the analysis of power System operations and determination if operations were as intended. System faults generally persist for a short time period, thus a 30-cycle total minimum record length is adequate. Multiple records allow for legacy microprocessor relays which, when time-synchronized, are capable of providing adequate fault data but not capable of providing fault data in a single record with 30-contiguous cycles total.

A minimum recording rate of 16 samples per cycle (960 Hz) is required to get sufficient point on wave data for recreating accurate fault conditions.

Rationale for R5:

DDR is used for capturing the BES transient and post-transient response following Disturbances, and the data is used for event analysis and validating System performance. DDR plays a critical role in wide-area Disturbance analysis, and Requirement R5 ensures there is adequate wide-area coverage of DDR data for specific BES Elements to facilitate accurate and efficient event analysis. The Reliability Coordinator has the best wide-area view of the System and needs to ensure that there are sufficient BES Elements identified for DDR data capture. The identification of BES Elements requiring DDR data as per Requirement R5 is based upon industry experience with wide-area Disturbance analysis and the need for adequate data to facilitate event analysis. Ensuring data is captured for these BES Elements will significantly improve the accuracy of analysis and understanding of why an event occurred, not simply what occurred.

From its experience with changes to the Bulk Electric System that would affect DDR, the DMSDT decided that the five calendar year re-evaluation of the list is a reasonable interval for this review. Changes to the BES do not mandate immediate inclusion of BES Elements into the in force list, but the list of BES Elements will be re-evaluated at least every five calendar years to address System changes since the previous evaluation. However, this standard does not preclude the Reliability Coordinator from performing this re-evaluation more frequently to capture updated BES Elements.

The Reliability Coordinator must notify all owners of the selected BES Elements that DDR data is required for this standard. The Reliability Coordinator is only required to share the list of selected BES Elements that each Transmission Owner and Generator Owner respectively owns, not the entire list. This communication of selected BES Elements is required to ensure that the owners of the respective BES Elements are aware of their responsibilities under this standard.

Implementation of the monitoring equipment is the responsibility of the respective Transmission Owners and Generator Owners, the timeline for installing this capability is outlined in the Implementation Plan, and starts from notification of the list from the Reliability Coordinator. Data for each BES Element as defined by the Reliability Coordinator must be provided; however, this data can be either directly measured or accurately calculated. With the exception of HVDC circuits, DDR data is only required for one end or terminal of the BES Elements selected. For example, DDR data must be provided for at least one terminal of a

Transmission Line or generator step-up (GSU) transformer, but not both terminals. For an interconnection between two Reliability Coordinators, each Reliability Coordinator will consider this interconnection independently, and are expected to work cooperatively to determine how to monitor the BES Elements that require DDR data. For an interconnection between two TO's, or a TO and a GO, the Reliability Coordinator will determine which entity will provide the data. The Reliability Coordinator will notify the owners that their BES Elements require DDR data.

Refer to the Guidelines and Technical Basis Section for more detail on the rationale and technical reasoning for each identified BES Element in Requirement R5, Part 5.1; monitoring these BES Elements with DDR will facilitate thorough and informative event analysis of wide-area Disturbances on the BES. Part 5.2 is included to ensure wide-area coverage across all Reliability Coordinators. It is intended that each Reliability Coordinator will have DDR data for one BES Element and at least one additional BES Element per 3,000 MW of its historical simultaneous peak System Demand.

Rationale for R6:
DDR is used to measure transient response to System Disturbances during a relatively balanced post-fault condition. Therefore, it is sufficient to provide a phase-to-neutral voltage or positive sequence voltage. The electrical quantities can be determined (calculated, derived, etc.).

Because all of the BES buses within a location are at the same frequency, one frequency measurement is adequate.

The data requirements for PRC-002-~~2~~ 3 are based on a System configuration assuming all normally closed circuit breakers on a BES bus are closed.

Rationale for R7:
A crucial part of wide-area Disturbance analysis is understanding the dynamic response of generating resources. Therefore, it is necessary for Generator Owners to have DDR at either the high- or low-side of the generator step-up transformer (GSU) measuring the specified electrical quantities to adequately capture generator response. This standard defines the 'what' of DDR, not the 'how'. Generator Owners may install this capability or, where the Transmission Owners already have suitable DDR data, contract with the Transmission Owner. However, the Generator Owner is still responsible for the provision of this data.

Rationale for R8:
Large scale System outages generally are an evolving sequence of events that occur over an extended period of time, making DDR data essential for event analysis. Data available pre- and post-contingency helps identify the causes and effects of each event leading to outages. Therefore, continuous recording and storage are necessary to ensure sufficient data is available for the entire event.
Existing DDR data recording across the BES may not record continuously. To accommodate its use for the purposes of this standard, triggered records are acceptable if the equipment was installed prior to the effective date of this standard. The frequency triggers are defined based on the dynamic response associated with each Interconnection. The undervoltage trigger is

defined to capture possible delayed undervoltage conditions such as Fault Induced Delayed Voltage Recovery (FIDVR).

Rationale for R9:
An input sampling rate of at least 960 samples per second, which corresponds to 16 samples per cycle on the input side of the DDR equipment, ensures adequate accuracy for calculation of recorded measurements such as complex voltage and frequency.
An output recording rate of electrical quantities of at least 30 times per second refers to the recording and measurement calculation rate of the device. Recorded measurements of at least 30 times per second provide adequate recording speed to monitor the low frequency oscillations typically of interest during power System Disturbances.

Rationale for R10:
Time synchronization of Disturbance monitoring data is essential for time alignment of large volumes of geographically dispersed records from diverse recording sources. Coordinated Universal Time (UTC) is a recognized time standard that utilizes atomic clocks for generating precision time measurements. All data must be provided in UTC formatted time either with or without the local time offset, expressed as a negative number (the difference between UTC and the local time zone where the measurements are recorded).
Accuracy of time synchronization applies only to the clock used for synchronizing the monitoring equipment. The equipment used to measure the electrical quantities must be time synchronized to ± 2 ms accuracy; however, accuracy of the application of this time stamp and therefore the accuracy of the data itself is not mandated. This is because of inherent delays associated with measuring the electrical quantities and events such as breaker closing, measurement transport delays, algorithm and measurement calculation techniques, etc. Ensuring that the monitoring devices internal clocks are within ± 2 ms accuracy will suffice with respect to providing time synchronized data.

Rationale for R11:
Wide-area Disturbance analysis includes data recording from many devices and entities. Standardized formatting and naming conventions of these files significantly improves timely analysis.

Providing the data within 30-calendar days (or the granted extension time), subject to Part 11.1, allows for reasonable time to collect the data and perform any necessary computations or formatting.

Data is required to be retrievable for 10-calendar days inclusive of the day the data was recorded, i.e. a -10-calendar day rolling window of available data. Data hold requests are usually initiated the same or next day following a major event for which data is requested. A 10-calendar day time frame provides a practical limit on the duration of data required to be stored and informs the requesting entities as to how long the data will be available. The requestor of data has to be aware of the Part 11.1 10-calendar day retrievability because requiring data retention for a longer period of time is expensive and unnecessary.

SER data shall be provided in a simple ASCII .CSV format as outlined in Attachment 2. Either equipment can provide the data or a simple conversion program can be used to convert files into this format. This will significantly improve the data format for event records, enabling the use of software tools for analyzing the SER data.

Part 11.4 specifies FR and DDR data files be provided in conformance with IEEE C37.111, IEEE Standard for Common Format for Transient Exchange (COMTRADE), revision 1999 or later. The use of IEEE C37.111-1999 or later is well established in the industry. C37.111-2013 is a version of COMTRADE that includes an annex describing the application of the COMTRADE standard to synchrophasor data; however, version C37.111-1999 is commonly used in the industry today.

Part 11.5 uses a standardized naming format, C37.232-2011, IEEE Standard for Common Format for Naming Time Sequence Data Files (COMNAME), for providing Disturbance monitoring data. This file format allows a streamlined analysis of large Disturbances, and includes critical records such as local time offset associated with the synchronization of the data.

Rationale for R12:

Each Transmission Owner and Generator Owner who owns equipment used for collecting the data required for this standard must repair any failures within 90-calendar days to ensure that adequate data is available for event analysis. If the Disturbance monitoring capability cannot be restored within 90-calendar days (e.g. budget cycle, service crews, vendors, needed outages, etc.), the entity must develop a Corrective Action Plan (CAP) for restoring the data recording capability. The timeline required for the CAP depends on the entity and the type of data required. It is treated as a failure if the recording capability is out of service for maintenance and/or testing for greater than 90-calendar days. An outage of the monitored BES Element does not constitute a failure of the Disturbance monitoring capability.

Guidelines and Technical Basis Section

Introduction

The emphasis of PRC-002-~~2~~ 3 is not on how Disturbance monitoring data is captured, but what Bulk Electric System data is captured. There are a variety of ways to capture the data PRC-002-~~2~~ 3 addresses, and existing and currently available equipment can meet the requirements of this standard. PRC-002-~~2~~ 3 also addresses the importance of addressing the availability of Disturbance monitoring capability to ensure the completeness of BES data capture.

The data requirements for PRC-002-~~2~~ 3 are based on a System configuration assuming all normally closed circuit breakers on a bus are closed.

PRC-002-~~2~~ 3 addresses "what" data is recorded, not "how" it is recorded.

Guideline for Requirement R1:

Sequence of events and fault recording for the analysis, reconstruction, and reporting of System Disturbances is important. However, SER and FR data is not required at every BES bus on the BES to conduct adequate or thorough analysis of a Disturbance. As major tools of event analysis, the time synchronized time stamp for a breaker change of state and the recorded waveforms of voltage and current for individual circuits allows the precise reconstruction of events of both localized and wide-area Disturbances.

More quality information is always better than less when performing event analysis. However, 100 percent coverage of all BES Elements is not practical nor required for effective analysis of wide-area Disturbances. Therefore, selectivity of required BES buses to monitor is important for the following reasons:

1. Identify key BES buses with breakers where crucial information is available when required.
2. Avoid excessive overlap of coverage.
3. Avoid gaps in critical coverage.
4. Provide coverage of BES Elements that could propagate a Disturbance.
5. Avoid mandates to cover BES Elements that are more likely to be a casualty of a Disturbance rather than a cause.
6. Establish selection criteria to provide effective coverage in different regions of the continent.

The major characteristics available to determine the selection process are:

1. System voltage level;
2. The number of Transmission Lines into a substation or switchyard;
3. The number and size of connected generating units;
4. The available short circuit levels.

Although it is straightforward to establish criteria for the application of identified BES buses, analysis was required to establish a sound technical basis to fulfill the required objectives.

To answer these questions and establish criteria for BES buses of SER and FR, the DMSDT established a sub-team referred to as the Monitored Value Analysis Team (MVA Team). The MVA Team collected information from a wide variety of Transmission Systems throughout the continent to analyze Transmission buses by the characteristics previously identified for the selection process.

The MVA Team learned that the development of criteria is not possible for adequate SER and FR coverage, based solely upon simple, bright line characteristics, such as the number of lines into a substation or switchyard at a particular voltage level or at a set level of short circuit current. To provide the appropriate coverage, a relatively simple but effective Methodology for Selecting Buses for Capturing Sequence of Events Recording (SER) and Fault Recording (FR) Data was developed. This Procedure, included as Attachment 1, assists entities in fulfilling Requirement R1 of the standard.

The Methodology for Selecting Buses for Capturing Sequence of Events Recording (SER) and Fault Recording (FR) Data is weighted to buses with higher short circuit levels. This is chosen for the following reasons:

1. The method is voltage level independent.
2. It is likely to select buses near large generation centers.
3. It is likely to select buses where delayed clearing can cause Cascading.
4. Selected buses directly correlate to the Universal Power Transfer equation: Lower Impedance – increased power flows – greater System impact.

To perform the calculations of Attachment 1, the following information below is required and the following steps (provided in summary form) are required for Systems with more than 11 BES buses with three phase short circuit levels above 1,500 MVA.

1. Total number of BES buses in the Transmission System under evaluation.
   a. Only tangible substation or switchyard buses are included.
   b. Pseudo buses created for analysis purposes in System models are excluded.
2. Determine the three phase short circuit MVA for each BES bus.
3. Exclude BES buses from the list with short circuit levels below 1,500 MVA.
4. Determine the median short circuit for the top 11 BES buses on the list (position number 6).
5. Multiply median short circuit level by 20 percent.
6. Reduce the list of BES buses to those with short circuit levels higher than 20 percent of the median.
7. Apply SER and FR at BES buses with short circuit levels in the top 10 percent of the list (from 6).

8. Apply SER and FR at BES buses at an additional 10 percent of the list using engineering judgment, and allowing flexibility to factor in the following considerations:
   - Electrically distant BES buses or electrically distant from other DME devices
   - Voltage sensitive areas
   - Cohesive load and generation zones
   - BES buses with a relatively high number of incident Transmission circuits
   - BES buses with reactive power devices
   - Major facilities interconnecting outside the Transmission Owner's area.

For event analysis purposes, more valuable information is attained about generators and their response to System events pre- and post-contingency through DDR data versus SER or FR records. SER data of the opening of the primary generator output interrupting devices (e.g. synchronizing breaker) may not reliably indicate the actual time that a generator tripped; for instance, when it trips on reverse power after loss of its prime mover (e.g. combustion or steam turbine). As a result, this standard only requires DDR data.

The re-evaluation interval of five years was chosen based on the experience of the DMSDT to address changing System configurations while creating balance in the frequency of re-evaluations.

Guideline for Requirement R2:

Analyses of wide-area Disturbances often begin by evaluation of SERs to help determine the initiating event(s) and follow the Disturbance propagation. Recording of breaker operations help determine the interruption of line flows while generator loading is best determined by DDR data, since generator loading can be essentially zero regardless of breaker position. However, generator breakers directly connected to an identified BES bus are required to have SER data captured. It is important in event analysis to know when a BES bus is cleared regardless of a generator's loading.

Generator Owners are included in this requirement because a Generator Owner may, in some instances, own breakers directly connected to the Transmission Owner's BES bus.

Guideline for Requirement R3:

The BES buses for which FR data is required are determined based on the methodology described in Attachment 1 of the standard. The BES Elements connected to those BES buses for which FR data is required include:

- Transformers with a low-side operating voltage of 100kV or above
- Transmission Lines

Only those BES Elements that are identified as BES as defined in the latest in effect NERC definition are to be monitored. For example, radial lines or transformers with low-side voltage less than 100kV are not included.

FR data must be determinable from each terminal of a BES Element connected to applicable BES buses.

Generator step-up transformers (GSU) are excluded from the above based on the following:

- Current contribution from a generator in case of fault on the Transmission System will be captured by FR data on the Transmission System.
- For faults on the interconnection to generating facilities it is sufficient to have fault current data from the Transmission station end of the interconnection. Current contribution from a generator can be readily calculated if needed.

The DMSDT, after consulting with NERC's Event Analysis group, determined that DDR data from selected generator locations was more important for event analysis than FR data.

<u>Recording of Electrical Quantities</u>
For effective fault analysis it is necessary to know values of all phase and neutral currents and all phase-to-neutral voltages. Based on such FR data it is possible to determine all fault types. FR data also augments SERs in evaluating circuit breaker operation.

<u>Current Recordings</u>
The required electrical quantities are normally directly measured. Certain quantities can be derived if sufficient data is measured, for example residual or neutral currents.
Since a Transmission System is generally well balanced, with phase currents having essentially similar magnitudes and phase angle differences of 120°, during normal conditions there is negligible neutral (residual) current. In case of a ground fault the resulting phase current imbalance produces residual current that can be either measured or calculated.

Neutral current, also known as ground or residual current $\mathbf{I}_{r,}$ is calculated as a sum of vectors of three phase currents:
$\mathbf{I}_r = 3 \bullet \mathbf{I}_0 = \mathbf{I}_A + \mathbf{I}_B + \mathbf{I}_C$

$\mathbf{I}_0$ - Zero-sequence current

$\mathbf{I}_A$, $\mathbf{I}_B$, $\mathbf{I}_C$ - Phase current (vectors)

Another example of how required electrical quantities can be derived is based on Kirchhoff's Law. Fault currents for one of the BES Elements connected to a particular BES bus can be derived as a vectorial sum of fault currents recorded at the other BES Elements connected to that BES bus.

<u>Voltage Recordings</u>
Voltages are to be recorded or accurately determined at applicable BES buses.

Guideline for Requirement R4:

Pre- and post-trigger fault data along with the SER breaker data, all time stamped to a common clock at millisecond accuracy, aid in the analysis of protection System operations after a fault to determine if a protection System operated as designed. Generally speaking, BES faults persist for a very short time period, approximately 1 to 30 cycles, thus a 30-cycle record length provides adequate data. Multiple records allow for legacy microprocessor relays which, when time synchronized to a common clock, are capable of providing adequate fault data but not capable of providing fault data in a single record with 30-contiguous cycles total.

A minimum recording rate of 16 samples per cycle is required to get accurate waveforms and to get 1 millisecond resolution for any digital input which may be used for FR.

FR triggers can be set so that when the monitored value on the recording device goes above or below the trigger value, data is recorded. Requirement R4, sub-Part 4.3.1 specifies a neutral (residual) overcurrent trigger for ground faults. Requirement R4, sub-Part 4.3.2 specifies a phase undervoltage or overcurrent trigger for phase-to-phase faults.

Guideline for Requirement R5:

DDR data is used for wide-area Disturbance monitoring to determine the System's electromechanical transient and post-transient response and validate System model performance. DDR is typically located based on strategic studies which include angular, frequency, voltage, and oscillation stability. However, for adequately monitoring the System's dynamic response and ensuring sufficient coverage to determine System performance, DDR is required for key BES Elements in addition to a minimum requirement of DDR coverage.

Each Reliability Coordinator is required to identify sufficient DDR data capture for, at a minimum, one BES Element and then one additional BES Element per 3,000 MW of historical simultaneous peak System Demand. This DDR data is included to provide adequate System wide coverage across an Interconnection. To clarify, if any of the key BES Elements requiring DDR monitoring are within the Reliability Coordinator Area, DDR data capability is required. If a Reliability Coordinator does not meet the requirements of Part 5.1, additional coverage had to be specified.

Loss of large generating resources poses a frequency and angular stability risk for all Interconnections across North America. Data capturing the dynamic response of these machines during a Disturbance helps the analysis of large Disturbances. Having data regarding generator dynamic response to Disturbances greatly improves understanding of ***why*** an event occurs rather than what occurred. To determine and provide the basis for unit size criteria, the DMSDT acquired specific generating unit data from NERC's Generating Availability Data System (GADS) program. The data contained generating unit size information for each generating unit in North America which was reported in 2013 to the NERC GADS program. The DMSDT analyzed the spreadsheet data to determine: (i) how many units were above or below selected size thresholds; and (ii) the aggregate sum of the ratings of the units within the boundaries of those thresholds. Statistical information about this data was then produced, i.e. averages, means and percentages. The DMSDT determined the following basic information about the generating units of interest (current North America fleet, i.e. units reporting in 2013) included in the spreadsheet:

- The number of individual generating units in total included in the spreadsheet.
- The number of individual generating units rated at 20 MW or larger included in the spreadsheet. These units would generally require that their owners be registered as GOs in the NERC CMEP.
- The total number of units within selected size boundaries.
- The aggregate sum of ratings, in MWs, of the units within the boundaries of those thresholds.

The information in the spreadsheet does not provide information by which the plant information location of each unit can be determined, i.e. the DMSDT could not use the information to determine which units were located together at a given generation site or facility.

From this information, the DMSDT was able to reasonably speculate the generating unit size thresholds proposed in Requirement R5, sub-Part 5.1.1 of the standard. Generating resources intended for DDR data recording are those individual units with gross nameplate ratings “greater than or equal to 500 MVA”. The 500 MVA individual unit size threshold was selected because this number roughly accounts for 47 percent of the generating capacity in NERC footprint while only requiring DDR coverage on about 12.5 percent of the generating units. As mentioned, there was no data pertaining to unit location for aggregating plant/facility sizes. However, Requirement R5, sub-Part 5.1.1 is included to capture larger units located at large generating plants which could pose a stability risk to the System if multiple large units were lost due to electrical or non-electrical contingencies. For generating plants, each individual generator at the plant/facility with a gross nameplate rating greater than or equal to 300 MVA must have DDR where the gross nameplate rating of the plant/facility is greater than or equal to 1,000 MVA. The 300 MVA threshold was chosen based on the DMSDT’s judgment and experience. The incremental impact to the number of units requiring monitoring is expected to be relatively low. For combined cycle plants where only one generator has a rating greater than or equal to 300MVA, that is the only generator that would need DDR.

Permanent System Operating Limits (SOLs) are used to operate the System within reliable and secure limits. In particular, SOLs related to angular or voltage stability have a significant impact on BES reliability and performance. Therefore, at least one BES Element of an SOL should be monitored.

The draft standard requires “One or more BES Elements that are part of an Interconnection Reliability Operating Limits (IROLs).” Interconnection Reliability Operating Limits (IROLs) are included because the risk of violating these limits poses a risk to System stability and the potential for cascading outages. IROLs may be defined by a single or multiple monitored BES Element(s) and contingent BES Element(s). The standard does not dictate selection of the contingent and/or monitored BES Elements. Rather the Drafting Team believes this

determination is best made by the Reliability Coordinator for each IROL considered based on the severity of violating this IROL.

Locations where an undervoltage load shedding (UVLS) program is deployed are prone to voltage instability since they are generally areas of significant Demand. The Reliability Coordinator will identify these areas where a UVLS is in service and identify a useful and effective BES Element to monitor for DDR such that action of the UVLS or voltage instability on the BES could be captured. For example, a major 500kV or 230kV substation on the EHV System close to the load pocket where the UVLS is deployed would likely be a valuable electrical location for DDR coverage and would aid in post-Disturbance analysis of the load area's response to large System excursions (voltage, frequency, etc.).

Guideline for Requirement R6:

DDR data shows transient response to System Disturbances after a fault is cleared (post-fault), under a relatively balanced operating condition. Therefore, it is sufficient to provide a single phase-to-neutral voltage or positive sequence voltage. Recording of all three phases of a circuit is not required, although this may be used to compute and record the positive sequence voltage.

The bus where a voltage measurement is required is based on the list of BES Elements defined by the Reliability Coordinator in Requirement R5. The intent of the standard is not to require a separate voltage measurement of each BES Element where a common bus voltage measurement is available. For example, a breaker-and-a-half or double-bus configuration with a North (or East) Bus and South (or West) Bus, would require both buses to have voltage recording because either can be taken out of service indefinitely with the targeted BES Element remaining in service. This may be accomplished either by recording both bus voltages separately, or by providing a selector switch to connect either of the bus voltage sources to a single recording input of the DDR device. This component of the requirement is therefore included to mitigate the potential of failed frequency, phase angle, real power, and reactive power calculations due to voltage measurements removed from service while sufficient voltage measurement is actually available during these operating conditions.

It must be emphasized that the data requirements for PRC-002-~~2~~ 3 are based on a System configuration assuming all normally closed circuit breakers on a bus are closed.

When current recording is required, it should be on the same phase as the voltage recording taken at the location if a single phase-to-neutral voltage is provided. Positive sequence current recording is also acceptable.

For all circuits where current recording is required, Real and Reactive Power will be recorded on a three phase basis. These recordings may be derived either from phase quantities or from positive sequence quantities.

Guideline for Requirement R7:

All Guidelines specified for Requirement R6 apply to Requirement R7. Since either the high- or low-side windings of the generator step-up transformer (GSU) may be connected in delta, phase-to-phase voltage recording is an acceptable voltage recording. As was explained in the Guideline for Requirement R6, the BES is operating under a relatively balanced operating condition and, if needed, phase-to-neutral quantities can be derived from phase-to-phase quantities.

Again it must be emphasized that the data requirements for PRC-002-~~2~~ 3are based on a System configuration assuming all normally closed circuit breakers on a bus are closed.

Guideline for Requirement R8:

Wide-area System outages are generally an evolving sequence of events that occur over an extended period of time, making DDR data essential for event analysis. Pre- and post-contingency data helps identify the causes and effects of each event leading to the outages. This drives a need for continuous recording and storage to ensure sufficient data is available for the entire Disturbance.

Transmission Owners and Generator Owners are required to have continuous DDR for the BES Elements identified in Requirement R6. However, this requirement recognizes that legacy equipment may exist for some BES Elements that do not have continuous data recording capabilities. For equipment that was installed prior to the effective date of the standard, triggered DDR records of three minutes are acceptable using at least one of the trigger types specified in Requirement R8, Part 8.2:

- Off nominal frequency triggers are used to capture high- or low-frequency excursions of significant size based on the Interconnection size and inertia.
- Rate of change of frequency triggers are used to capture major changes in System frequency which could be caused by large changes in generation or load, or possibly changes in System impedance.
- The undervoltage trigger specified in this standard is provided to capture possible sustained undervoltage conditions such as Fault Induced Delayed Voltage Recovery (FIDVR) events. A sustained voltage of 85 percent is outside normal schedule operating voltages and is sufficiently low to capture abnormal voltage conditions on the BES.

Guideline for Requirement R9:

DDR data contains the dynamic response of a power System to a Disturbance and is used for analyzing complex power System events. This recording is typically used to capture short-term and long-term Disturbances, such as a power swing. Since the data of interest is changing over time, DDR data is normally stored in the form of RMS values or phasor values, as opposed to directly sampled data as found in FR data.

The issue of the sampling rate used in a recording instrument is quite important for at least two reasons: the anti-aliasing filter selection and accuracy of signal representation. The anti-aliasing

filter selection is associated with the requirement of a sampling rate at least twice the highest frequency of a sampled signal. At the same time, the accuracy of signal representation is also dependent on the selection of the sampling rate. In general, the higher the sampling rate, the better the representation. In the abnormal conditions of interest (e.g. faults or other Disturbances); the input signal may contain frequencies in the range of 0-400 Hz. Hence, the rate of 960 samples per second (16 samples/cycle) is considered an adequate sampling rate that satisfies the input signal requirements.

In general, dynamic events of interest are: inter-area oscillations, local generator oscillations, wind turbine generator torsional modes, HVDC control modes, exciter control modes, and steam turbine torsional modes. Their frequencies range from 0.1-20 Hz. In order to reconstruct these dynamic events, a minimum recording time of 30 times per second is required.

Guideline for Requirement R10:

Time synchronization of Disturbance monitoring data allows for the time alignment of large volumes of geographically dispersed data records from diverse recording sources. A universally recognized time standard is necessary to provide the foundation for this alignment. Coordinated Universal Time (UTC) is the foundation used for the time alignment of records. It is an international time standard utilizing atomic clocks for generating precision time measurements at fractions of a second levels. The local time offset, expressed as a negative number, is the difference between UTC and the local time zone where the measurements are recorded.

Accuracy of time synchronization applies only to the clock used for synchronizing the monitoring equipment.

Time synchronization accuracy is specified in response to Recommendation 12b in the NERC August, 2003, Blackout Final NERC Report Section V Conclusions and Recommendations:

“Recommendation 12b: Facilities owners shall, in accordance with regional criteria, upgrade existing dynamic recorders to include GPS time synchronization…”

Also, from the U.S.-Canada Power System Outage Task Force Interim Report: Causes of the August 14th Blackout, November 2003, in the United States and Canada, page 103:

“Establishing a precise and accurate sequence of outage-related events was a critical building block for the other parts of the investigation. One of the key problems in developing this sequence was that although much of the data pertinent to an event was time-stamped, there was some variance from source to source in how the time-stamping was done, and not all of the time-stamps were synchronized…”

From NPCC’s SP6 Report Synchronized Event Data Reporting, revised March 31, 2005, the investigation by the authoring working group revealed that existing GPS receivers can be expected to provide a time code output which has an uncertainty on the order of 1 millisecond, uncertainty being a quantitative descriptor.

Guideline for Requirement R11:

This requirement directs the applicable entities, upon requests from the Reliability Coordinator, Regional Entity or NERC, to provide SER and FR data for BES buses determined in Requirement R1 and DDR data for BES Elements determined as per Requirement R5. To facilitate the analysis of BES Disturbances, it is important that the data is provided to the requestor within a reasonable period of time.

Requirement R11, Part 11.1 specifies the maximum time frame of 30-calendar days to provide the data. Thirty calendar days is a reasonable time frame to allow for the collection of data, and submission to the requestor. An entity may request an extension of the 30-day submission requirement. If granted by the requestor, the entity must submit the data within the approved extended time.

Requirement R11, Part 11.2 specifies that the minimum time period of 10-calendar days inclusive of the day the data was recorded for which the data will be retrievable. With the equipment in use that has the capability of recording data, having the data retrievable for the 10-calendar days is realistic and doable. It is important to note that applicable entities should account for any expected delays in retrieving data and this may require devices to have data available for more than 10 days. To clarify the 10-calendar day time frame, an incident occurs on Day 1. If a request for data is made on Day 6, then that data has to be provided to the requestor within 30-calendar days after a request or a granted time extension. However, if a request for the data is made on Day 11, that is outside the 10-calendar days specified in the requirement, and an entity would not be out of compliance if it did not have the data.

Requirement R11, Part 11.3 specifies a Comma Separated Value (CSV) format according to Attachment 2 for the SER data. It is necessary to establish a standard format as it will be incorporated with other submitted data to provide a detailed sequence of events timeline of a power System Disturbance.

Requirement R11, Part 11.4 specifies the IEEE C37.111 COMTRADE format for the FR and DDR data. The IEEE C37.111 is the Standard for Common Format for Transient Data Exchange and is well established in the industry. It is necessary to specify a standard format as multiple submissions of data from many sources will be incorporated to provide a detailed analysis of a power System Disturbance. The latest revision of COMTRADE (C37.111-2013) includes an annex describing the application of the COMTRADE standard to synchophasor data.

Requirement R11, Part 11.5 specifies the IEEE C37.232 COMNAME format for naming the data files of the SER, FR and DDR. The IEEE C37.232 is the Standard for Common Format for Naming Time Sequence Data Files. The first version was approved in 2007. From the August 14, 2003 blackout there were thousands of Fault Recording data files collected. The collected data files did not have a common naming convention and it was therefore difficult to discern which files came from which utilities and which ones were captured by which devices. The lack of a common naming practice seriously hindered the investigation process. Subsequently, and in its initial report on the blackout, NERC stressed the need for having a common naming practice and listed it as one of its top ten recommendations.

Guideline for Requirement R12:

This requirement directs the respective owners of Transmission and Generator equipment to be alert to the proper functioning of equipment used for SER, FR, and DDR data capabilities for the BES buses and BES Elements, which were established in Requirements R1 and R5. The owners are to restore the capability within 90-calendar days of discovery of a failure. This requirement is structured to recognize that the existence of a "reasonable" amount of capability out-of-service does not result in lack of sufficient data for coverage of the System. Furthermore, 90-calendar days is typically sufficient time for repair or maintenance to be performed. However, in recognition of the fact that there may be occasions for which it is not possible to restore the capability within 90-calendar days, the requirement further provides that, for such cases, the entity submit a Corrective Action Plan (CAP) to the Regional Entity and implement it. These actions are considered to be appropriate to provide for robust and adequate data availability.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the Board of Trustees.

Description of Current Draft

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	08/19/15
SAR posted for comment	08/20/15 – 09/21/15
45-day formal comment period with initial ballot	08/27/18-10/17/18

Anticipated Actions	Date
45-day formal comment period with initial ballot	June 2020
10-day final ballot	August 2020
NERC Board adoption	November 2020

A. Introduction

1. **Title:** **Transmission Relay Loadability**
2. **Number:** PRC-023-5
3. **Purpose:** Protective relay settings shall not limit transmission loadability; not interfere with system operators' ability to take remedial action to protect system reliability and; be set to reliably detect all fault conditions and protect the electrical network from these faults.
4. **Applicability:**

4.1. Functional Entity:

4.1.1 Transmission Owner with load-responsive phase protection systems as described in PRC-023-5 - Attachment A, applied at the terminals of the circuits defined in 4.2.1 *(Circuits Subject to Requirements R1 – R5)*.

4.1.2 Generator Owner with load-responsive phase protection systems as described in PRC-023-5 - Attachment A, applied at the terminals of the circuits defined in 4.2.1 *(Circuits Subject to Requirements R1 – R5)*.

4.1.3 Distribution Provider with load-responsive phase protection systems as described in PRC-023-5 - Attachment A, applied at the terminals of the circuits defined in 4.2.1 *(Circuits Subject to Requirements R1 – R5)*, provided those circuits have bi-directional flow capabilities.

4.1.4 Planning Coordinator

4.2. Circuits:

4.2.1 Circuits Subject to Requirements R1 – R5:

4.2.1.1 Transmission lines operated at 200 kV and above, except Elements that connect the GSU transformer(s) to the Transmission system that are used exclusively to export energy directly from a BES generating unit or generating plant. Elements may also supply generating plant loads.

4.2.1.2 Transmission lines operated at 100 kV to 200 kV selected by the Planning Coordinator in accordance with Requirement R6.

4.2.1.3 Transmission lines operated below 100 kV that are part of the BES and selected by the Planning Coordinator in accordance with Requirement R6.

4.2.1.4 Transformers with low voltage terminals connected at 200 kV and above.

4.2.1.5 Transformers with low voltage terminals connected at 100 kV to 200 kV selected by the Planning Coordinator in accordance with Requirement R6.

4.2.1.6 Transformers with low voltage terminals connected below 100 kV that are part of the BES and selected by the Planning Coordinator in accordance with Requirement R6.

4.2.2 Circuits Subject to Requirement R6:

4.2.2.1 Transmission lines operated at 100 kV to 200 kV and transformers with low voltage terminals connected at 100 kV to 200 kV, except Elements that connect the GSU transformer(s) to the Transmission system that are used exclusively to export energy directly from a BES generating unit or generating plant. Elements may also supply generating plant loads.

4.2.2.2 Transmission lines operated below 100 kV and transformers with low voltage terminals connected below 100 kV that are part of the BES, except Elements that connect the GSU transformer(s) to the Transmission system that are used exclusively to export energy directly from a BES generating unit or generating plant. Elements may also supply generating plant loads.

5. Effective Dates: See Implementation.

B. Requirements

R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall use any one of the following criteria (Requirement R1, criteria 1 through 13) for any specific circuit terminal to prevent its phase protective relay settings from limiting transmission system loadability while maintaining reliable protection of the BES for all fault conditions. Each Transmission Owner, Generator Owner, and Distribution Provider shall evaluate relay loadability at 0.85 per unit voltage and a power factor angle of 30 degrees. *[Violation Risk Factor: High] [Time Horizon: Long Term Planning].*

Criteria:

1. Set transmission line relays so they do not operate at or below 150% of the highest seasonal Facility Rating of a circuit, for the available defined loading duration nearest 4 hours (expressed in amperes).
2. Set transmission line relays so they do not operate at or below 115% of the highest seasonal 15-minute Facility Rating[1] of a circuit (expressed in amperes).

[1] When a 15-minute rating has been calculated and published for use in real-time operations, the 15-minute rating can be used to establish the loadability requirement for the protective relays.

3. Set transmission line relays so they do not operate at or below 115% of the maximum theoretical power transfer capability (using a 90-degree angle between the sending-end and receiving-end voltages and either reactance or complex impedance) of the circuit (expressed in amperes) using one of the following to perform the power transfer calculation:
   - An infinite source (zero source impedance) with a 1.00 per unit bus voltage at each end of the line.
   - An impedance at each end of the line, which reflects the actual system source impedance with a 1.05 per unit voltage behind each source impedance.
4. Set transmission line relays on series compensated transmission lines so they do not operate at or below the maximum power transfer capability of the line, determined as the greater of:
   - 115% of the highest emergency rating of the series capacitor.
   - 115% of the maximum power transfer capability of the circuit (expressed in amperes), calculated in accordance with Requirement R1, criterion 3, using the full line inductive reactance.
5. Set transmission line relays on weak source systems so they do not operate at or below 170% of the maximum end-of-line three-phase fault magnitude (expressed in amperes).
6. Not used.
7. Set transmission line relays applied at the load center terminal, remote from generation stations, so they do not operate at or below 115% of the maximum current flow from the load to the generation source under any system configuration.
8. Set transmission line relays applied on the bulk system-end of transmission lines that serve load remote to the system so they do not operate at or below 115% of the maximum current flow from the system to the load under any system configuration.
9. Set transmission line relays applied on the load-end of transmission lines that serve load remote to the bulk system so they do not operate at or below 115% of the maximum current flow from the load to the system under any system configuration.
10. Set transformer fault protection relays and transmission line relays on transmission lines terminated only with a transformer so that the relays do not operate at or below the greater of:
    - 150% of the applicable maximum transformer nameplate rating (expressed in amperes), including the forced cooled ratings corresponding to all installed supplemental cooling equipment.
    - 115% of the highest operator established emergency transformer rating.

10.1 Set load-responsive transformer fault protection relays, if used, such that the protection settings do not expose the transformer to a fault level and duration that exceeds the transformer's mechanical withstand capability[2].

11. For transformer overload protection relays that do not comply with the loadability component of Requirement R1, criterion 10 set the relays according to one of the following:

- Set the relays to allow the transformer to be operated at an overload level of at least 150% of the maximum applicable nameplate rating, or 115% of the highest operator established emergency transformer rating, whichever is greater, for at least 15 minutes to provide time for the operator to take controlled action to relieve the overload.
- Install supervision for the relays using either a top oil or simulated winding hot spot temperature element set no less than 100° C for the top oil temperature or no less than 140° C for the winding hot spot temperature[3].

12. When the desired transmission line capability is limited by the requirement to adequately protect the transmission line, set the transmission line distance relays to a maximum of 125% of the apparent impedance (at the impedance angle of the transmission line) subject to the following constraints:

a. Set the maximum torque angle (MTA) to 90 degrees or the highest supported by the manufacturer.

b. Evaluate the relay loadability in amperes at the relay trip point at 0.85 per unit voltage and a power factor angle of 30 degrees.

c. Include a relay setting component of 87% of the current calculated in Requirement R1, criterion 12 in the Facility Rating determination for the circuit.

13. Where other situations present practical limitations on circuit capability, set the phase protection relays so they do not operate at or below 115% of such limitations.

R2. Each Transmission Owner, Generator Owner, and Distribution Provider shall set its out-of-step blocking elements to allow tripping of phase protective relays for faults that occur during the loading conditions used to verify transmission line relay loadability per Requirement R1. *[Violation Risk Factor: High] [Time Horizon: Long Term Planning]*

R3. Each Transmission Owner, Generator Owner, and Distribution Provider that uses a circuit capability with the practical limitations described in Requirement R1, criterion 7, 8, 9, 12, or 13 shall use the calculated circuit capability as the Facility Rating of the circuit and shall obtain the agreement of the Planning Coordinator, Transmission

[2] As illustrated by the "dotted line" in IEEE C57.109-1993 - *IEEE Guide for Liquid-Immersed Transformer Through-Fault-Current Duration*, Clause 4.4, Figure 4.

[3] IEEE standard C57.91, Tables 7 and 8, specify that transformers are to be designed to withstand a winding hot spot temperature of 180 degrees C, and Annex A cautions that bubble formation may occur above 140 degrees C.

Operator, and Reliability Coordinator with the calculated circuit capability. *[Violation Risk Factor: Medium] [Time Horizon: Long Term Planning]*

R4. Each Transmission Owner, Generator Owner, and Distribution Provider that chooses to use Requirement R1 criterion 2 as the basis for verifying transmission line relay loadability shall provide its Planning Coordinator, Transmission Operator, and Reliability Coordinator with an updated list of circuits associated with those transmission line relays at least once each calendar year, with no more than 15 months between reports. *[Violation Risk Factor: Lower] [Time Horizon: Long Term Planning]*

R5. Each Transmission Owner, Generator Owner, and Distribution Provider that sets transmission line relays according to Requirement R1 criterion 12 shall provide an updated list of the circuits associated with those relays to its Regional Entity at least once each calendar year, with no more than 15 months between reports, to allow the ERO to compile a list of all circuits that have protective relay settings that limit circuit capability. *[Violation Risk Factor: Lower] [Time Horizon: Long Term Planning]*

R6. Each Planning Coordinator shall conduct an assessment at least once each calendar year, with no more than 15 months between assessments, by applying the criteria in PRC-023-4, Attachment B to determine the circuits in its Planning Coordinator area for which Transmission Owners, Generator Owners, and Distribution Providers must comply with Requirements R1 through R5. The Planning Coordinator shall: *[Violation Risk Factor: High] [Time Horizon: Long Term Planning]*

6.1 Maintain a list of circuits subject to PRC-023-4 per application of Attachment B, including identification of the first calendar year in which any criterion in PRC-023-4, Attachment B applies.

6.2 Provide the list of circuits to all Regional Entities, Reliability Coordinators, Transmission Owners, Generator Owners, and Distribution Providers within its Planning Coordinator area within 30 calendar days of the establishment of the initial list and within 30 calendar days of any changes to that list.

C. Measures

M1. Each Transmission Owner, Generator Owner, and Distribution Provider shall have evidence such as spreadsheets or summaries of calculations to show that each of its transmission relays is set according to one of the criteria in Requirement R1, criterion 1 through 13 and shall have evidence such as coordination curves or summaries of calculations that show that relays set per criterion 10 do not expose the transformer to fault levels and durations beyond those indicated in the standard. (R1)

M2. Each Transmission Owner, Generator Owner, and Distribution Provider shall have evidence such as spreadsheets or summaries of calculations to show that each of its out-of-step blocking elements is set to allow tripping of phase protective relays for faults that occur during the loading conditions used to verify transmission line relay loadability per Requirement R1. (R2)

M3. Each Transmission Owner, Generator Owner, and Distribution Provider with transmission relays set according to Requirement R1, criterion 7, 8, 9, 12, or 13 shall have evidence such as Facility Rating spreadsheets or Facility Rating database to show that it used the calculated circuit capability as the Facility Rating of the circuit and evidence such as dated correspondence that the resulting Facility Rating was agreed to by its associated Planning Coordinator, Transmission Operator, and Reliability Coordinator. (R3)

M4. Each Transmission Owner, Generator Owner, or Distribution Provider that sets transmission line relays according to Requirement R1, criterion 2 shall have evidence such as dated correspondence to show that it provided its Planning Coordinator, Transmission Operator, and Reliability Coordinator with an updated list of circuits associated with those transmission line relays within the required timeframe. The updated list may either be a full list, a list of incremental changes to the previous list, or a statement that there are no changes to the previous list. (R4)

M5. Each Transmission Owner, Generator Owner, or Distribution Provider that sets transmission line relays according to Requirement R1, criterion 12 shall have evidence such as dated correspondence that it provided an updated list of the circuits associated with those relays to its Regional Entity within the required timeframe. The updated list may either be a full list, a list of incremental changes to the previous list, or a statement that there are no changes to the previous list. (R5)

M6. Each Planning Coordinator shall have evidence such as power flow results, calculation summaries, or study reports that it used the criteria established within PRC-023-4, Attachment B to determine the circuits in its Planning Coordinator area for which applicable entities must comply with the standard as described in Requirement R6. The Planning Coordinator shall have a dated list of such circuits and shall have evidence such as dated correspondence that it provided the list to the Regional Entities, Reliability Coordinators, Transmission Owners, Generator Owners, and Distribution Providers within its Planning Coordinator area within the required timeframe. (R6)

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

As defined in the NERC Rules of Procedure, “Compliance Enforcement Authority” means NERC or the Regional Entity in their respective roles of monitoring and enforcing compliance with the NERC Reliability Standards.

1.2. Data Retention

The Transmission Owner, Generator Owner, Distribution Provider and Planning Coordinator shall keep data or evidence to show compliance as identified below

unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

The Transmission Owner, Generator Owner, and Distribution Provider shall each retain documentation to demonstrate compliance with Requirements R1 through R5 for three calendar years.

The Planning Coordinator shall retain documentation of the most recent review process required in Requirement R6. The Planning Coordinator shall retain the most recent list of circuits in its Planning Coordinator area for which applicable entities must comply with the standard, as determined per Requirement R6.

If a Transmission Owner, Generator Owner, Distribution Provider, or Planning Coordinator is found non-compliant, it shall keep information related to the non-compliance until found compliant or for the time specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit record and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes

- Compliance Audit
- Self-Certification
- Spot Checking
- Compliance Violation Investigation
- Self-Reporting
- Complaint

1.4. Additional Compliance Information

None.

2. Violation Severity Levels:

Requirement	Lower	Moderate	High	Severe
R1	N/A	N/A	N/A	The responsible entity did not use any one of the following criteria (Requirement R1 criterion 1 through 13) for any specific circuit terminal to prevent its phase protective relay settings from limiting transmission system loadability while maintaining reliable protection of the BES for all fault conditions. OR The responsible entity did not evaluate relay loadability at 0.85 per unit voltage and a power factor angle of 30 degrees.
R2	N/A	N/A	N/A	The responsible entity failed to ensure that its out-of-step blocking elements allowed tripping of phase protective relays for faults that occur during the

PRC-023-5 — Attachment A

1. This standard includes any protective functions which could trip with or without time delay, on load current, including but not limited to:

1.1. Phase distance.

1.2. Out-of-step tripping.

1.3. Switch-on-to-fault.

1.4. Overcurrent relays.

1.5. Communications aided protection schemes including but not limited to:

1.5.1 Permissive overreach transfer trip (POTT).

1.5.2 Permissive under-reach transfer trip (PUTT).

1.5.3 Directional comparison blocking (DCB).

1.5.4 Directional comparison unblocking (DCUB).

1.6. Phase overcurrent supervisory elements (i.e., phase fault detectors) associated with current-based, communication-assisted schemes (i.e., pilot wire, phase comparison, and line current differential) where the scheme is capable of tripping for loss of communications.

2. The following protection systems are excluded from requirements of this standard:

2.1. Relay elements that are only enabled when other relays or associated systems fail. For example:

- Overcurrent elements that are only enabled during loss of potential conditions.
- Elements that are only enabled during a loss of communications except as noted in section 1.6.

2.2. Protection systems intended for the detection of ground fault conditions.

2.3. Protection systems intended for protection during stable power swings.

2.4. Not used.

2.5. Relay elements used only for Remedial Action Schemes applied and approved in accordance with NERC Reliability Standards PRC-012 through PRC-017 or their successors.

2.6. Protection systems that are designed only to respond in time periods which allow 15 minutes or greater to respond to overload conditions.

2.7. Thermal emulation relays which are used in conjunction with dynamic Facility Ratings.

2.8. Relay elements associated with dc lines.

2.9. Relay elements associated with dc converter transformers.

PRC-023-5 — Attachment B

Circuits to Evaluate

- Transmission lines operated at 100 kV to 200 kV and transformers with low voltage terminals connected at 100 kV to 200 kV.
- Transmission lines operated below 100 kV and transformers with low voltage terminals connected below 100 kV that are part of the Bulk Electric System.

Criteria

If any of the following criteria apply to a circuit, the applicable entity must comply with the standard for that circuit.

B1. The circuit is a monitored Facility of a permanent flowgate in the Eastern Interconnection, a major transfer path within the Western Interconnection as defined by the Regional Entity, or a comparable monitored Facility in the Québec Interconnection, that has been included to address reliability concerns for loading of that circuit, as confirmed by the applicable Planning Coordinator.

B2. The circuit is selected by the Planning Coordinator or Transmission Planner based on Planning Assessments of the Near-Term Transmission Planning Horizon that identify instances of instability, Cascading, or uncontrolled separation, that adversely impact the reliability of the Bulk Electric System for planning events.

B3. The circuit forms a path (as agreed to by the Generator Operator and the transmission entity) to supply off-site power to a nuclear plant as established in the Nuclear Plant Interface Requirements (NPIRs) pursuant to NUC-001.

B4. The circuit is identified through the following sequence of power flow analyses[4] performed by the Planning Coordinator for the one-to-five-year planning horizon:

a. Simulate double contingency combinations selected by engineering judgment, without manual system adjustments in between the two contingencies (reflects a situation where a System Operator may not have time between the two contingencies to make appropriate system adjustments).

b. For circuits operated between 100 kV and 200 kV evaluate the post-contingency loading, in consultation with the Facility owner, against a threshold based on the

[4] Past analyses may be used to support the assessment if no material changes to the system have occurred since the last assessment

Facility Rating assigned for that circuit and used in the power flow case by the Planning Coordinator.

c. When more than one Facility Rating for that circuit is available in the power flow case, the threshold for selection will be based on the Facility Rating for the loading duration nearest four hours.

d. The threshold for selection of the circuit will vary based on the loading duration assumed in the development of the Facility Rating.

    i. If the Facility Rating is based on a loading duration of up to and including four hours, the circuit must comply with the standard if the loading exceeds 115% of the Facility Rating.

    ii. If the Facility Rating is based on a loading duration greater than four and up to and including eight hours, the circuit must comply with the standard if the loading exceeds 120% of the Facility Rating.

    iii. If the Facility Rating is based on a loading duration of greater than eight hours, the circuit must comply with the standard if the loading exceeds 130% of the Facility Rating.

e. Radially operated circuits serving only load are excluded.

B5. The circuit is selected by the Planning Coordinator based on technical studies or assessments, other than those specified in criteria B1 through B4, in consultation with the Facility owner.

B6. The circuit is mutually agreed upon for inclusion by the Planning Coordinator and the Facility owner.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the Board of Trustees.

Description of Current Draft

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	08/19/15
SAR posted for comment	08/20/15 – 09/21/15

Anticipated Actions	Date
45-day formal comment period with initial ballot	June 2020
10-day final ballot	August 2020
NERC Board adoption	November 2020

A. Introduction

1. **Title:** **Transmission Relay Loadability**
2. **Number:** PRC-023-5
3. **Purpose:** Protective relay settings shall not limit transmission loadability; not interfere with system operators' ability to take remedial action to protect system reliability and; be set to reliably detect all fault conditions and protect the electrical network from these faults.
4. **Applicability:**

   4.1. Functional Entity:

   4.1.1 Transmission Owner with load-responsive phase protection systems as described in PRC-023-~~4~~ 5 - Attachment A, applied at the terminals of the circuits defined in 4.2.1 *(Circuits Subject to Requirements R1 – R5)*.

   4.1.2 Generator Owner with load-responsive phase protection systems as described in PRC-023-~~4~~ 5 - Attachment A, applied at the terminals of the circuits defined in 4.2.1 *(Circuits Subject to Requirements R1 – R5)*.

   4.1.3 Distribution Provider with load-responsive phase protection systems as described in PRC-023-~~4~~ 5 - Attachment A, applied at the terminals of the circuits defined in 4.2.1 *(Circuits Subject to Requirements R1 – R5)*, provided those circuits have bi-directional flow capabilities.

   4.1.4 Planning Coordinator

   4.2. Circuits:

   4.2.1 Circuits Subject to Requirements R1 – R5:

   4.2.1.1 Transmission lines operated at 200 kV and above, except Elements that connect the GSU transformer(s) to the Transmission system that are used exclusively to export energy directly from a BES generating unit or generating plant. Elements may also supply generating plant loads.

   4.2.1.2 Transmission lines operated at 100 kV to 200 kV selected by the Planning Coordinator in accordance with Requirement R6.

   4.2.1.3 Transmission lines operated below 100 kV that are part of the BES and selected by the Planning Coordinator in accordance with Requirement R6.

   4.2.1.4 Transformers with low voltage terminals connected at 200 kV and above.

4.2.1.5 Transformers with low voltage terminals connected at 100 kV to 200 kV selected by the Planning Coordinator in accordance with Requirement R6.

4.2.1.6 Transformers with low voltage terminals connected below 100 kV that are part of the BES and selected by the Planning Coordinator in accordance with Requirement R6.

4.2.2 Circuits Subject to Requirement R6:

4.2.2.1 Transmission lines operated at 100 kV to 200 kV and transformers with low voltage terminals connected at 100 kV to 200 kV, except Elements that connect the GSU transformer(s) to the Transmission system that are used exclusively to export energy directly from a BES generating unit or generating plant. Elements may also supply generating plant loads.

4.2.2.2 Transmission lines operated below 100 kV and transformers with low voltage terminals connected below 100 kV that are part of the BES, except Elements that connect the GSU transformer(s) to the Transmission system that are used exclusively to export energy directly from a BES generating unit or generating plant. Elements may also supply generating plant loads.

5. **Effective Dates:** See Implementation~~ Plan for the Revised Definition of "Remedial Action Scheme"~~.

B. Requirements

R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall use any one of the following criteria (Requirement R1, criteria 1 through 13) for any specific circuit terminal to prevent its phase protective relay settings from limiting transmission system loadability while maintaining reliable protection of the BES for all fault conditions. Each Transmission Owner, Generator Owner, and Distribution Provider shall evaluate relay loadability at 0.85 per unit voltage and a power factor angle of 30 degrees. *[Violation Risk Factor: High] [Time Horizon: Long Term Planning].*

Criteria:

1. Set transmission line relays so they do not operate at or below 150% of the highest seasonal Facility Rating of a circuit, for the available defined loading duration nearest 4 hours (expressed in amperes).
2. Set transmission line relays so they do not operate at or below 115% of the highest seasonal 15-minute Facility Rating[1] of a circuit (expressed in amperes).

[1] When a 15-minute rating has been calculated and published for use in real-time operations, the 15-minute rating can be used to establish the loadability requirement for the protective relays.

3. Set transmission line relays so they do not operate at or below 115% of the maximum theoretical power transfer capability (using a 90-degree angle between the sending-end and receiving-end voltages and either reactance or complex impedance) of the circuit (expressed in amperes) using one of the following to perform the power transfer calculation:
    - An infinite source (zero source impedance) with a 1.00 per unit bus voltage at each end of the line.
    - An impedance at each end of the line, which reflects the actual system source impedance with a 1.05 per unit voltage behind each source impedance.
4. Set transmission line relays on series compensated transmission lines so they do not operate at or below the maximum power transfer capability of the line, determined as the greater of:
    - 115% of the highest emergency rating of the series capacitor.
    - 115% of the maximum power transfer capability of the circuit (expressed in amperes), calculated in accordance with Requirement R1, criterion 3, using the full line inductive reactance.
5. Set transmission line relays on weak source systems so they do not operate at or below 170% of the maximum end-of-line three-phase fault magnitude (expressed in amperes).
6. Not used.
7. Set transmission line relays applied at the load center terminal, remote from generation stations, so they do not operate at or below 115% of the maximum current flow from the load to the generation source under any system configuration.
8. Set transmission line relays applied on the bulk system-end of transmission lines that serve load remote to the system so they do not operate at or below 115% of the maximum current flow from the system to the load under any system configuration.
9. Set transmission line relays applied on the load-end of transmission lines that serve load remote to the bulk system so they do not operate at or below 115% of the maximum current flow from the load to the system under any system configuration.
10. Set transformer fault protection relays and transmission line relays on transmission lines terminated only with a transformer so that the relays do not operate at or below the greater of:
    - 150% of the applicable maximum transformer nameplate rating (expressed in amperes), including the forced cooled ratings corresponding to all installed supplemental cooling equipment.
    - 115% of the highest operator established emergency transformer rating.

10.1 Set load-responsive transformer fault protection relays, if used, such that the protection settings do not expose the transformer to a fault level and duration that exceeds the transformer's mechanical withstand capability[2].

11. For transformer overload protection relays that do not comply with the loadability component of Requirement R1, criterion 10 set the relays according to one of the following:

- Set the relays to allow the transformer to be operated at an overload level of at least 150% of the maximum applicable nameplate rating, or 115% of the highest operator established emergency transformer rating, whichever is greater, for at least 15 minutes to provide time for the operator to take controlled action to relieve the overload.
- Install supervision for the relays using either a top oil or simulated winding hot spot temperature element set no less than 100° C for the top oil temperature or no less than 140° C for the winding hot spot temperature[3].

12. When the desired transmission line capability is limited by the requirement to adequately protect the transmission line, set the transmission line distance relays to a maximum of 125% of the apparent impedance (at the impedance angle of the transmission line) subject to the following constraints:

a. Set the maximum torque angle (MTA) to 90 degrees or the highest supported by the manufacturer.

b. Evaluate the relay loadability in amperes at the relay trip point at 0.85 per unit voltage and a power factor angle of 30 degrees.

c. Include a relay setting component of 87% of the current calculated in Requirement R1, criterion 12 in the Facility Rating determination for the circuit.

13. Where other situations present practical limitations on circuit capability, set the phase protection relays so they do not operate at or below 115% of such limitations.

R2. Each Transmission Owner, Generator Owner, and Distribution Provider shall set its out-of-step blocking elements to allow tripping of phase protective relays for faults that occur during the loading conditions used to verify transmission line relay loadability per Requirement R1. *[Violation Risk Factor: High] [Time Horizon: Long Term Planning]*

R3. Each Transmission Owner, Generator Owner, and Distribution Provider that uses a circuit capability with the practical limitations described in Requirement R1, criterion 7, 8, 9, 12, or 13 shall use the calculated circuit capability as the Facility Rating of the circuit and shall obtain the agreement of the Planning Coordinator, Transmission

---

[2] As illustrated by the "dotted line" in IEEE C57.109-1993 - *IEEE Guide for Liquid-Immersed Transformer Through-Fault-Current Duration*, Clause 4.4, Figure 4.

[3] IEEE standard C57.91, Tables 7 and 8, specify that transformers are to be designed to withstand a winding hot spot temperature of 180 degrees C, and Annex A cautions that bubble formation may occur above 140 degrees C.

Operator, and Reliability Coordinator with the calculated circuit capability. *[Violation Risk Factor: Medium] [Time Horizon: Long Term Planning]*

R4. Each Transmission Owner, Generator Owner, and Distribution Provider that chooses to use Requirement R1 criterion 2 as the basis for verifying transmission line relay loadability shall provide its Planning Coordinator, Transmission Operator, and Reliability Coordinator with an updated list of circuits associated with those transmission line relays at least once each calendar year, with no more than 15 months between reports. *[Violation Risk Factor: Lower] [Time Horizon: Long Term Planning]*

R5. Each Transmission Owner, Generator Owner, and Distribution Provider that sets transmission line relays according to Requirement R1 criterion 12 shall provide an updated list of the circuits associated with those relays to its Regional Entity at least once each calendar year, with no more than 15 months between reports, to allow the ERO to compile a list of all circuits that have protective relay settings that limit circuit capability. *[Violation Risk Factor: Lower] [Time Horizon: Long Term Planning]*

R6. Each Planning Coordinator shall conduct an assessment at least once each calendar year, with no more than 15 months between assessments, by applying the criteria in PRC-023-4, Attachment B to determine the circuits in its Planning Coordinator area for which Transmission Owners, Generator Owners, and Distribution Providers must comply with Requirements R1 through R5. The Planning Coordinator shall: *[Violation Risk Factor: High] [Time Horizon: Long Term Planning]*

6.1 Maintain a list of circuits subject to PRC-023-4 per application of Attachment B, including identification of the first calendar year in which any criterion in PRC-023-4, Attachment B applies.

6.2 Provide the list of circuits to all Regional Entities, Reliability Coordinators, Transmission Owners, Generator Owners, and Distribution Providers within its Planning Coordinator area within 30 calendar days of the establishment of the initial list and within 30 calendar days of any changes to that list.

C. Measures

M1. Each Transmission Owner, Generator Owner, and Distribution Provider shall have evidence such as spreadsheets or summaries of calculations to show that each of its transmission relays is set according to one of the criteria in Requirement R1, criterion 1 through 13 and shall have evidence such as coordination curves or summaries of calculations that show that relays set per criterion 10 do not expose the transformer to fault levels and durations beyond those indicated in the standard. (R1)

M2. Each Transmission Owner, Generator Owner, and Distribution Provider shall have evidence such as spreadsheets or summaries of calculations to show that each of its out-of-step blocking elements is set to allow tripping of phase protective relays for faults that occur during the loading conditions used to verify transmission line relay loadability per Requirement R1. (R2)

M3. Each Transmission Owner, Generator Owner, and Distribution Provider with transmission relays set according to Requirement R1, criterion 7, 8, 9, 12, or 13 shall have evidence such as Facility Rating spreadsheets or Facility Rating database to show that it used the calculated circuit capability as the Facility Rating of the circuit and evidence such as dated correspondence that the resulting Facility Rating was agreed to by its associated Planning Coordinator, Transmission Operator, and Reliability Coordinator. (R3)

M4. Each Transmission Owner, Generator Owner, or Distribution Provider that sets transmission line relays according to Requirement R1, criterion 2 shall have evidence such as dated correspondence to show that it provided its Planning Coordinator, Transmission Operator, and Reliability Coordinator with an updated list of circuits associated with those transmission line relays within the required timeframe. The updated list may either be a full list, a list of incremental changes to the previous list, or a statement that there are no changes to the previous list. (R4)

M5. Each Transmission Owner, Generator Owner, or Distribution Provider that sets transmission line relays according to Requirement R1, criterion 12 shall have evidence such as dated correspondence that it provided an updated list of the circuits associated with those relays to its Regional Entity within the required timeframe. The updated list may either be a full list, a list of incremental changes to the previous list, or a statement that there are no changes to the previous list. (R5)

M6. Each Planning Coordinator shall have evidence such as power flow results, calculation summaries, or study reports that it used the criteria established within PRC-023-4, Attachment B to determine the circuits in its Planning Coordinator area for which applicable entities must comply with the standard as described in Requirement R6. The Planning Coordinator shall have a dated list of such circuits and shall have evidence such as dated correspondence that it provided the list to the Regional Entities, Reliability Coordinators, Transmission Owners, Generator Owners, and Distribution Providers within its Planning Coordinator area within the required timeframe. (R6)

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

As defined in the NERC Rules of Procedure, “Compliance Enforcement Authority” means NERC or the Regional Entity in their respective roles of monitoring and enforcing compliance with the NERC Reliability Standards.

1.2. Data Retention

The Transmission Owner, Generator Owner, Distribution Provider and Planning Coordinator shall keep data or evidence to show compliance as identified below

unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

The Transmission Owner, Generator Owner, and Distribution Provider shall each retain documentation to demonstrate compliance with Requirements R1 through R5 for three calendar years.

The Planning Coordinator shall retain documentation of the most recent review process required in Requirement R6. The Planning Coordinator shall retain the most recent list of circuits in its Planning Coordinator area for which applicable entities must comply with the standard, as determined per Requirement R6.

If a Transmission Owner, Generator Owner, Distribution Provider, or Planning Coordinator is found non-compliant, it shall keep information related to the non-compliance until found compliant or for the time specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit record and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes

- Compliance Audit
- Self-Certification
- Spot Checking
- Compliance Violation Investigation
- Self-Reporting
- Complaint

1.4. Additional Compliance Information

None.

2. Violation Severity Levels:

Requirement	Lower	Moderate	High	Severe
R1	N/A	N/A	N/A	The responsible entity did not use any one of the following criteria (Requirement R1 criterion 1 through 13) for any specific circuit terminal to prevent its phase protective relay settings from limiting transmission system loadability while maintaining reliable protection of the BES for all fault conditions. OR The responsible entity did not evaluate relay loadability at 0.85 per unit voltage and a power factor angle of 30 degrees.
R2	N/A	N/A	N/A	The responsible entity failed to ensure that its out-of-step blocking elements allowed tripping of phase protective relays for faults that occur during the

Requirement	Lower	Moderate	High	Severe
				loading conditions used to verify transmission line relay loadability per Requirement R1.
R3	N/A	N/A	N/A	The responsible entity that uses a circuit capability with the practical limitations described in Requirement R1 criterion 7, 8, 9, 12, or 13 did not use the calculated circuit capability as the Facility Rating of the circuit. OR The responsible entity did not obtain the agreement of the Planning Coordinator, Transmission Operator, and Reliability Coordinator with the calculated circuit capability.
R4	N/A	N/A	N/A	The responsible entity did not provide its Planning Coordinator, Transmission Operator, and Reliability Coordinator with an updated list of circuits that have transmission line

Requirement	Lower	Moderate	High	Severe
		months lapsed between assessments. OR The Planning Coordinator used the criteria established within Attachment B at least once each calendar year, with no more than 15 months between assessments to determine the circuits in its Planning Coordinator area for which applicable entities must comply with the standard and met 6.1 and 6.2 but failed to include the calendar year in which any criterion in Attachment B first applies. OR The Planning Coordinator used the criteria established within Attachment B at least once each calendar year, with no more than 15 months between assessments to determine the circuits in its Planning	more lapsed between assessments. OR The Planning Coordinator used the criteria established within Attachment B at least once each calendar year, with no more than 15 months between assessments to determine the circuits in its Planning Coordinator area for which applicable entities must comply with the standard and met 6.1 and 6.2 but provided the list of circuits to the Reliability Coordinators, Transmission Coordinators, Transmission Owners, Generator Owners, and Distribution Providers within its Planning Coordinator area between 46 days and 60 days after list was established or updated. (part 6.2)	The Planning Coordinator used the criteria established within Attachment B, at least once each calendar year, with no more than 15 months between assessments to determine the circuits in its Planning Coordinator area for which applicable entities must comply with the standard but failed to meet parts 6.1 and 6.2. OR The Planning Coordinator used the criteria established within Attachment B at least once each calendar year, with no more than 15 months between assessments to determine the circuits in its Planning Coordinator area for which applicable entities must comply with the standard but failed to maintain the list of circuits determined according to the process

Requirement	Lower	Moderate	High	Severe
		Coordinator area for which applicable entities must comply with the standard and met 6.1 and 6.2 but provided the list of circuits to the Reliability Coordinators, Transmission Owners, Generator Owners, and Distribution Providers within its Planning Coordinator area between 31 days and 45 days after the list was established or updated. (part 6.2)		described in Requirement R6. (part 6.1) OR The Planning Coordinator used the criteria established within Attachment B at least once each calendar year, with no more than 15 months between assessments to determine the circuits in its Planning Coordinator area for which applicable entities must comply with the standard and met 6.1 but failed to provide the list of circuits to the Reliability Coordinators, Transmission Owners, Generator Owners, and Distribution Providers within its Planning Coordinator area or provided the list more than 60 days after the list was established or updated. (part 6.2) OR

Requirement	Lower	Moderate	High	Severe
				The Planning Coordinator failed to determine the circuits in its Planning Coordinator area for which applicable entities must comply with the standard.

E. Regional Differences

None.

F. Supplemental Technical Reference Document

1. The following document is an explanatory supplement to the standard. It provides the technical rationale underlying the requirements in this standard. The reference document contains methodology examples for illustration purposes it does not preclude other technically comparable methodologies.

"Determination and Application of Practical Relaying Loadability Ratings," Version 1.0, June 2008, prepared by the System Protection and Control Task Force of the NERC Planning Committee, available at: http://www.nerc.com/fileUploads/File/Standards/Relay_Loadability_Reference_Doc_Clean_Final_2008July3.pdf

Version History

Version	Date	Action	Change Tracking
1	February 12, 2008	Approved by Board of Trustees	New
1	March 19, 2008	Corrected typo in last sentence of Severe VSL for Requirement 3 — "then" should be "than."	Errata
1	March 18, 2010	Approved by FERC	
1	Filed for approval April 19, 2010	Changed VRF for R3 from Medium to High; changed VSLs for R1, R2, R3 to binary Severe to comply with Order 733	Revision
2	March 10, 2011 approved by Board of Trustees	Revised to address initial set of directives from Order 733	Revision (Project 2010-13)
2	March 15, 2012	FERC order issued approving PRC-023-2 (approval becomes effective May 7, 2012)	

Version	Date	Action	Change Tracking
3	November 7, 2013	Adopted by NERC Board of Trustees	Supplemental SAR to Clarify applicability for consistency with PRC-025-1 and other minor corrections.
4	November 13, 2014	Adopted by the NERC Board of Trustees	Replaced references to Special Protection System and SPS with Remedial Action Scheme and RAS
4	November 19, 2015	FERC Order issued approving PRC-023-4. Docket No. RM15-13-000.	
5	TBD	Adopted by the NERC Board of Trustees	

PRC-023-~~4~~5 — Attachment A

1. This standard includes any protective functions which could trip with or without time delay, on load current, including but not limited to:

1.1. Phase distance.

1.2. Out-of-step tripping.

1.3. Switch-on-to-fault.

1.4. Overcurrent relays.

1.5. Communications aided protection schemes including but not limited to:

1.5.1 Permissive overreach transfer trip (POTT).

1.5.2 Permissive under-reach transfer trip (PUTT).

1.5.3 Directional comparison blocking (DCB).

1.5.4 Directional comparison unblocking (DCUB).

1.6. Phase overcurrent supervisory elements (i.e., phase fault detectors) associated with current-based, communication-assisted schemes (i.e., pilot wire, phase comparison, and line current differential) where the scheme is capable of tripping for loss of communications.

2. The following protection systems are excluded from requirements of this standard:

2.1. Relay elements that are only enabled when other relays or associated systems fail. For example:

- Overcurrent elements that are only enabled during loss of potential conditions.
- Elements that are only enabled during a loss of communications except as noted in section 1.6.

2.2. Protection systems intended for the detection of ground fault conditions.

2.3. Protection systems intended for protection during stable power swings.

2.4. Not used.

2.5. Relay elements used only for Remedial Action Schemes applied and approved in accordance with NERC Reliability Standards PRC-012 through PRC-017 or their successors.

2.6. Protection systems that are designed only to respond in time periods which allow 15 minutes or greater to respond to overload conditions.

2.7. Thermal emulation relays which are used in conjunction with dynamic Facility Ratings.

2.8. Relay elements associated with dc lines.

2.9. Relay elements associated with dc converter transformers.

PRC-023-45 — Attachment B

Circuits to Evaluate

- Transmission lines operated at 100 kV to 200 kV and transformers with low voltage terminals connected at 100 kV to 200 kV.
- Transmission lines operated below 100 kV and transformers with low voltage terminals connected below 100 kV that are part of the Bulk Electric System.

Criteria

If any of the following criteria apply to a circuit, the applicable entity must comply with the standard for that circuit.

B1. The circuit is a monitored Facility of a permanent flowgate in the Eastern Interconnection, a major transfer path within the Western Interconnection as defined by the Regional Entity, or a comparable monitored Facility in the Québec Interconnection, that has been included to address reliability concerns for loading of that circuit, as confirmed by the applicable Planning Coordinator.

B2. The circuit is selected by the Planning Coordinator or Transmission Planner based on Planning Assessments of the Near-Term Transmission Planning Horizon that identify instances of instability, Cascading, or uncontrolled separation, that adversely impact the reliability of the Bulk Electric System for planning events.

B3. The circuit forms a path (as agreed to by the Generator Operator and the transmission entity) to supply off-site power to a nuclear plant as established in the Nuclear Plant Interface Requirements (NPIRs) pursuant to NUC-001.

B4. The circuit is identified through the following sequence of power flow analyses[4] performed by the Planning Coordinator for the one-to-five-year planning horizon:

a. Simulate double contingency combinations selected by engineering judgment, without manual system adjustments in between the two contingencies (reflects a situation where a System Operator may not have time between the two contingencies to make appropriate system adjustments).

b. For circuits operated between 100 kV and 200 kV evaluate the post-contingency loading, in consultation with the Facility owner, against a threshold based on the

[4] Past analyses may be used to support the assessment if no material changes to the system have occurred since the last assessment

Facility Rating assigned for that circuit and used in the power flow case by the Planning Coordinator.

c. When more than one Facility Rating for that circuit is available in the power flow case, the threshold for selection will be based on the Facility Rating for the loading duration nearest four hours.

d. The threshold for selection of the circuit will vary based on the loading duration assumed in the development of the Facility Rating.

    i. If the Facility Rating is based on a loading duration of up to and including four hours, the circuit must comply with the standard if the loading exceeds 115% of the Facility Rating.

    ii. If the Facility Rating is based on a loading duration greater than four and up to and including eight hours, the circuit must comply with the standard if the loading exceeds 120% of the Facility Rating.

    iii. If the Facility Rating is based on a loading duration of greater than eight hours, the circuit must comply with the standard if the loading exceeds 130% of the Facility Rating.

e. Radially operated circuits serving only load are excluded.

B5. The circuit is selected by the Planning Coordinator based on technical studies or assessments, other than those specified in criteria B1 through B4, in consultation with the Facility owner.

B6. The circuit is mutually agreed upon for inclusion by the Planning Coordinator and the Facility owner.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the Board of Trustees.

Description of Current Draft

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	08/19/15
SAR posted for comment	08/20/15 – 09/21/15
45-day formal comment period with initial ballot	08/24/18-10/17/18

Anticipated Actions	Date
45-day formal comment period with initial ballot	June 2020
10-day final ballot	August 2020
NERC Board adoption	November 2020

A. Introduction

1. **Title:** **Relay Performance During Stable Power Swings**
2. **Number:** **PRC-026-2**
3. **Purpose:** To ensure that load-responsive protective relays are expected to not trip in response to stable power swings during non-Fault conditions.
4. **Applicability:**

   4.1. Functional Entities:

   4.1.1 Generator Owner that applies load-responsive protective relays as described in PRC-026-2 – Attachment A at the terminals of the Elements listed in Section 4.2, Facilities.

   4.1.2 Planning Coordinator.

   4.1.3 Transmission Owner that applies load-responsive protective relays as described in PRC-026-2 – Attachment A at the terminals of the Elements listed in Section 4.2, Facilities.

   4.2. Facilities: The following Elements that are part of the Bulk Electric System (BES):

   4.2.1 Generators.

   4.2.2 Transformers.

   4.2.3 Transmission lines.

5. **Background:**

This is the third phase of a three-phased standard development project that focused on developing this new Reliability Standard to address protective relay operations due to stable power swings. The March 18, 2010, Federal Energy Regulatory Commission (FERC) Order No. 733 approved Reliability Standard PRC-023-1 – Transmission Relay Loadability. In that Order, FERC directed NERC to address three areas of relay loadability that include modifications to the approved PRC-023-1, development of a new Reliability Standard to address generator protective relay loadability, and a new Reliability Standard to address the operation of protective relays due to stable power swings. This project's SAR addresses these directives with a three-phased approach to standard development.

Phase 1 focused on making the specific modifications from FERC Order No. 733 to PRC-023-1. Reliability Standard PRC-023-2, which incorporated these modifications, became mandatory on July 1, 2012.

Phase 2 focused on developing a new Reliability Standard, PRC-025-1 – Generator Relay Loadability, to address generator protective relay loadability. PRC-025-1 became mandatory on October 1, 2014, along with PRC-023-3, which was modified to harmonize PRC-023-2 with PRC-025-1.

Phase 3 focuses on preventing protective relays from tripping unnecessarily due to stable power swings by requiring identification of Elements on which a stable or unstable power

swing may affect Protection System operation, assessment of the security of load-responsive protective relays to tripping in response to only a stable power swing, and implementation of Corrective Action Plans (CAP), where necessary. Phase 3 improves security of load-responsive protective relays for stable power swings so they are expected to not trip in response to stable power swings during non-Fault conditions while maintaining dependable fault detection and dependable out-of-step tripping.

6. **Effective Dates: See Implementation Plan**

B. Requirements and Measures

R1. Each Planning Coordinator shall, at least once each calendar year, provide notification of each generator, transformer, and transmission line BES Element in its area that meets one or more of the following criteria, if any, to the respective Generator Owner and Transmission Owner: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

Criteria:

1. Generator(s) where an angular stability constraint, identified in Planning Assessments of the Near-Term Planning Horizon for a planning event, that is addressed by limiting the output of a generator or a Remedial Action Scheme (RAS), and those Elements terminating at the Transmission station associated with the generator(s).
2. Elements associated with angular instability identified in Planning Assessments of the Near-Term Planning Horizon for a planning event.
3. An Element that forms the boundary of an island in the most recent underfrequency load shedding (UFLS) design assessment based on application of the Planning Coordinator's criteria for identifying islands, only if the island is formed by tripping the Element due to angular instability.
4. An Element identified in the most recent annual Planning Assessment of the Near-Term Planning Horizon where relay tripping occurs due to a stable or unstable[1] power swing during a simulated disturbance for a planning event.

M1. Each Planning Coordinator shall have dated evidence that demonstrates notification of the generator, transformer, and transmission line BES Element(s) that meet one or more of the criteria in Requirement R1, if any, to the respective Generator Owner and Transmission Owner. Evidence may include, but is not limited to, the following documentation: emails, facsimiles, records, reports, transmittals, lists, or spreadsheets.

[1] An example of an unstable power swing is provided in the Guidelines and Technical Basis section, "Justification for Including Unstable Power Swings in the Requirements section of the Guidelines and Technical Basis."

R2. Each Generator Owner and Transmission Owner shall: [Violation Risk Factor: High] [Time Horizon: Operations Planning]

2.1 Within 12 full calendar months of notification of a BES Element pursuant to Requirement R1, determine whether its load-responsive protective relay(s) applied to that BES Element meets the criteria in PRC-026-2 – Attachment B where an evaluation of that Element's load-responsive protective relay(s) based on PRC-026-2 – Attachment B criteria has not been performed in the last five calendar years.

2.2 Within 12 full calendar months of becoming aware[2] of a generator, transformer, or transmission line BES Element that tripped in response to a stable or unstable[3] power swing due to the operation of its protective relay(s), determine whether its load-responsive protective relay(s) applied to that BES Element meets the criteria in PRC-026-2 – Attachment B.

M2. Each Generator Owner and Transmission Owner shall have dated evidence that demonstrates the evaluation was performed according to Requirement R2. Evidence may include, but is not limited to, the following documentation: apparent impedance characteristic plots, email, design drawings, facsimiles, R-X plots, software output, records, reports, transmittals, lists, settings sheets, or spreadsheets.

R3. Each Generator Owner and Transmission Owner shall, within six full calendar months of determining a load-responsive protective relay does not meet the PRC-026-2 – Attachment B criteria pursuant to Requirement R2, develop a Corrective Action Plan (CAP) to meet one of the following: *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

- The Protection System meets the PRC-026-2 – Attachment B criteria, while maintaining dependable fault detection and dependable out-of-step tripping (if out-of-step tripping is applied at the terminal of the BES Element); or
- The Protection System is excluded under the PRC-026-2 – Attachment A criteria (e.g., modifying the Protection System so that relay functions are supervised by power swing blocking or using relay systems that are immune to power swings), while maintaining dependable fault detection and dependable out-of-step tripping (if out-of-step tripping is applied at the terminal of the BES Element).

M3. The Generator Owner and Transmission Owner shall have dated evidence that demonstrates the development of a CAP in accordance with Requirement R3. Evidence may include, but is not limited to, the following documentation: corrective action plans, maintenance records, settings sheets, project or work management program records, or work orders.

R4. Each Generator Owner and Transmission Owner shall implement each CAP developed pursuant to Requirement R3 and update each CAP if actions or timetables change until all actions are complete. *[Violation Risk Factor: Medium][Time Horizon: Long-Term Planning]*

M4. The Generator Owner and Transmission Owner shall have dated evidence that demonstrates implementation of each CAP according to Requirement R4, including updates to the CAP when actions or timetables change. Evidence may include, but is not limited to, the following documentation: corrective action plans, maintenance records, settings sheets, project or work management program records, or work orders.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

As defined in the NERC Rules of Procedure, “Compliance Enforcement Authority” (CEA) means NERC or the Regional Entity in their respective roles of monitoring and enforcing compliance with the NERC Reliability Standards.

1.2. Evidence Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the CEA may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Generator Owner, Planning Coordinator, and Transmission Owner shall keep data or evidence to show compliance as identified below unless directed by its CEA to retain specific evidence for a longer period of time as part of an investigation.

- The Planning Coordinator shall retain evidence of Requirement R1 for a minimum of one calendar year following the completion of the Requirement.
- The Generator Owner and Transmission Owner shall retain evidence of Requirement R2 evaluation for a minimum of 12 calendar months following completion of each evaluation where a CAP is not developed.
- The Generator Owner and Transmission Owner shall retain evidence of Requirements R2, R3, and R4 for a minimum of 12 calendar months following completion of each CAP.

If a Generator Owner, Planning Coordinator, or Transmission Owner is found non-compliant, it shall keep information related to the non-compliance until mitigation is complete and approved, or for the time specified above, whichever is longer.

---

[2] Some examples of the ways an entity may become aware of a power swing are provided in the Guidelines and Technical Basis section, “Becoming Aware of an Element That Tripped in Response to a Power Swing.”

[3] An example of an unstable power swing is provided in the Guidelines and Technical Basis section, “Justification for Including Unstable Power Swings in the Requirements section of the Guidelines and Technical Basis.”

The CEA shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes:

As defined in the NERC Rules of Procedure; "Compliance Monitoring and Assessment Processes" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated reliability standard.

1.4. Additional Compliance Information

None.

Table of Compliance Elements

R#	Time Horizon	VRF	Violation Severity Levels			
			Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	Long-term Planning	Medium	The Planning Coordinator provided notification of the BES Element(s) in accordance with Requirement R1, but was less than or equal to 30 calendar days late.	The Planning Coordinator provided notification of the BES Element(s) in accordance with Requirement R1, but was more than 30 calendar days and less than or equal to 60 calendar days late.	The Planning Coordinator provided notification of the BES Element(s) in accordance with Requirement R1, but was more than 60 calendar days and less than or equal to 90 calendar days late.	The Planning Coordinator provided notification of the BES Element(s) in accordance with Requirement R1, but was more than 90 calendar days late. OR The Planning Coordinator failed to provide notification of the BES Element(s) in accordance with Requirement R1.

R#	Time Horizon	VRF	Violation Severity Levels			
			Lower VSL	Moderate VSL	High VSL	Severe VSL
R2	Operations Planning	High	The Generator Owner or Transmission Owner evaluated its load-responsive protective relay(s) in accordance with Requirement R2, but was less than or equal to 30 calendar days late.	The Generator Owner or Transmission Owner evaluated its load-responsive protective relay(s) in accordance with Requirement R2, but was more than 30 calendar days and less than or equal to 60 calendar days late.	The Generator Owner or Transmission Owner evaluated its load-responsive protective relay(s) in accordance with Requirement R2, but was more than 60 calendar days and less than or equal to 90 calendar days late.	The Generator Owner or Transmission Owner evaluated its load-responsive protective relay(s) in accordance with Requirement R2, but was more than 90 calendar days late. OR The Generator Owner or Transmission Owner failed to evaluate its load-responsive protective relay(s) in accordance with Requirement R2.

R#	Time Horizon	VRF	Violation Severity Levels			
			Lower VSL	Moderate VSL	High VSL	Severe VSL
R3	Long-term Planning	Medium	The Generator Owner or Transmission Owner developed a Corrective Action Plan (CAP) in accordance with Requirement R3, but in more than six calendar months and less than or equal to seven calendar months.	The Generator Owner or Transmission Owner developed a Corrective Action Plan (CAP) in accordance with Requirement R3, but in more than seven calendar months and less than or equal to eight calendar months.	The Generator Owner or Transmission Owner developed a Corrective Action Plan (CAP) in accordance with Requirement R3, but in more than eight calendar months and less than or equal to nine calendar months.	The Generator Owner or Transmission Owner developed a Corrective Action Plan (CAP) in accordance with Requirement R3, but in more than nine calendar months. OR The Generator Owner or Transmission Owner failed to develop a CAP in accordance with Requirement R3.
R4	Long-term Planning	Medium	The Generator Owner or Transmission Owner implemented a Corrective Action Plan (CAP), but failed to update a CAP when actions or timetables changed, in accordance with Requirement R4.	N/A	N/A	The Generator Owner or Transmission Owner failed to implement a Corrective Action Plan (CAP) in accordance with Requirement R4.

PRC-026-2 – Attachment A

This standard applies to any protective functions which could trip instantaneously or with a time delay of less than 15 cycles on load current (i.e., "load-responsive") including, but not limited to:

- Phase distance
- Phase overcurrent
- Out-of-step tripping
- Loss-of-field

The following protection functions are excluded from Requirements of this standard:

- Relay elements supervised by power swing blocking
- Relay elements that are only enabled when other relays or associated systems fail. For example:
  - Overcurrent elements that are only enabled during loss of potential conditions.
  - Relay elements that are only enabled during a loss of communications
- Thermal emulation relays which are used in conjunction with dynamic Facility Ratings
- Relay elements associated with direct current (dc) lines
- Relay elements associated with dc converter transformers
- Phase fault detector relay elements employed to supervise other load-responsive phase distance elements (i.e., in order to prevent false operation in the event of a loss of potential)
- Relay elements associated with switch-onto-fault schemes
- Reverse power relay on the generator
- Generator relay elements that are armed only when the generator is disconnected from the system, (e.g., non-directional overcurrent elements used in conjunction with inadvertent energization schemes, and open breaker flashover schemes)
- Current differential relay, pilot wire relay, and phase comparison relay
- Voltage-restrained or voltage-controlled overcurrent relays

PRC-026-2 – Attachment B

Criterion A:

An impedance-based relay used for tripping is expected to not trip for a stable power swing, when the relay characteristic is completely contained within the unstable power swing region.[4] The unstable power swing region is formed by the union of three shapes in the impedance (R-X) plane; (1) a lower loss-of-synchronism circle based on a ratio of the sending-end to receiving-end voltages of 0.7; (2) an upper loss-of-synchronism circle based on a ratio of the sending-end to receiving-end voltages of 1.43; (3) a lens that connects the endpoints of the total system impedance (with the parallel transfer impedance removed) bounded by varying the sending-end and receiving-end voltages from 0.0 to 1.0 per unit, while maintaining a constant system separation angle across the total system impedance where:

1. The system separation angle is:
    - At least 120 degrees, or
    - An angle less than 120 degrees where a documented transient stability analysis demonstrates that the expected maximum stable separation angle is less than 120 degrees.
2. All generation is in service and all transmission BES Elements are in their normal operating state when calculating the system impedance.
3. Saturated (transient or sub-transient) reactance is used for all machines.

[4] Guidelines and Technical Basis, Figures 1 and 2.

PRC-026-2 – Attachment B

Criterion B:

The pickup of an overcurrent relay element used for tripping, that is above the calculated current value (with the parallel transfer impedance removed) for the conditions below:

1. The system separation angle is:
   - At least 120 degrees, or
   - An angle less than 120 degrees where a documented transient stability analysis demonstrates that the expected maximum stable separation angle is less than 120 degrees.
2. All generation is in service and all transmission BES Elements are in their normal operating state when calculating the system impedance.
3. Saturated (transient or sub-transient) reactance is used for all machines.
4. Both the sending-end and receiving-end voltages at 1.05 per unit.

Guidelines and Technical Basis

Introduction

The NERC System Protection and Control Subcommittee technical document, *Protection System Response to Power Swings*, August 2013,[5] ("PSRPS Report" or "report") was specifically prepared to support the development of this NERC Reliability Standard. The report provided a historical perspective on power swings as early as 1965 up through the approval of the report by the NERC Planning Committee. The report also addresses reliability issues regarding trade-offs between security and dependability of Protection Systems, considerations for this NERC Reliability Standard, and a collection of technical information about power swing characteristics and varying issues with practical applications and approaches to power swings. Of these topics, the report suggests an approach for this NERC Reliability Standard ("standard" or "PRC-026-2") which is consistent with addressing three regulatory directives in the FERC Order No. 733. The first directive concerns the need for "…protective relay systems that differentiate between faults and stable power swings and, when necessary, phases out protective relay systems that cannot meet this requirement."[6] Second, is "…to develop a Reliability Standard addressing undesirable relay operation due to stable power swings."[7] The third directive "…to consider "islanding" strategies that achieve the fundamental performance for all islands in developing the new Reliability Standard addressing stable power swings"[8] was considered during development of the standard.

The development of this standard implements the majority of the approaches suggested by the report. However, it is noted that the Reliability Coordinator and Transmission Planner have not been included in the standard's Applicability section (as suggested by the PSRPS Report). This is so that a single entity, the Planning Coordinator, may be the single source for identifying Elements according to Requirement R1. A single source will insure that multiple entities will not identify Elements in duplicate, nor will one entity fail to provide an Element because it believes the Element is being provided by another entity. The Planning Coordinator has, or has access to, the wide-area model and can correctly identify the Elements that may be susceptible to a stable or unstable power swing. Additionally, not including the Reliability Coordinator and Transmission Planner is consistent with the applicability of other relay loadability NERC Reliability Standards (e.g., PRC-023 and PRC-025). It is also consistent with the NERC Functional Model.

The phrase, "while maintaining dependable fault detection and dependable out-of-step tripping" in Requirement R3, describes that the Generator Owner and Transmission Owner are to comply with this standard while achieving its desired protection goals. Load-responsive protective relays, as addressed within this standard, may be intended to provide a variety of backup protection functions, both within the generating unit or generating plant and on the transmission system, and

[8] Ibid. P.162.

this standard is not intended to result in the loss of these protection functions. Instead, the Generator Owner and Transmission Owner must consider both the Requirements within this standard and its desired protection goals and perform modifications to its protective relays or protection philosophies as necessary to achieve both.

Power Swings

The IEEE Power System Relaying Committee WG D6 developed a technical document called *Power Swing and Out-of-Step Considerations on Transmission Lines* (July 2005) that provides background on power swings. The following are general definitions from that document:[9]

> Power Swing: a variation in three phase power flow which occurs when the generator rotor angles are advancing or retarding relative to each other in response to changes in load magnitude and direction, line switching, loss of generation, faults, and other system disturbances.
>
> Pole Slip: a condition whereby a generator, or group of generators, terminal voltage angles (or phases) go past 180 degrees with respect to the rest of the connected power system.
>
> Stable Power Swing: a power swing is considered stable if the generators do not slip poles and the system reaches a new state of equilibrium, i.e. an acceptable operating condition.
>
> Unstable Power Swing: a power swing that will result in a generator or group of generators experiencing pole slipping for which some corrective action must be taken.
>
> Out-of-Step Condition: Same as an unstable power swing.
>
> Electrical System Center or Voltage Zero: it is the point or points in the system where the voltage becomes zero during an unstable power swing.

Burden to Entities

The PSRPS Report provides a technical basis and approach for focusing on Protection Systems, which are susceptible to power swings, while achieving the purpose of the standard. The approach reduces the number of relays to which the PRC-026-2 Requirements would apply by first identifying the BES Element(s) on which load-responsive protective relays must be evaluated. The first step uses criteria to identify the Elements on which a Protection System is expected to be challenged by power swings. Of those Elements, the second step is to evaluate each load-responsive protective relay that is applied on each identified Element. Rather than requiring the Planning Coordinator or Transmission Planner to perform simulations to obtain information for each identified Element, the Generator Owner and Transmission Owner will reduce the need for simulation by comparing the load-responsive protective relay characteristic to specific criteria in PRC-026-2 – Attachment B.

[9] http://www.pes-psrc.org/Reports/Power%20Swing%20and%20OOS%20Considerations%20on%20Transmission%20Lines%20F..pdf.

Applicability

The standard is applicable to the Generator Owner, Planning Coordinator, and Transmission Owner entities. More specifically, the Generator Owner and Transmission Owner entities are applicable when applying load-responsive protective relays at the terminals of the applicable BES Elements. The standard is applicable to the following BES Elements: generators, transformers, and transmission lines. The Distribution Provider was considered for inclusion in the standard; however, it is not subject to the standard because this entity, by functional registration, would not own generators, transmission lines, or transformers other than load serving.

Load-responsive protective relays include any protective functions which could trip with or without time delay, on load current.

Requirement R1

The Planning Coordinator has a wide-area view and is in the position to identify what, if any, Elements meet the criteria. The criterion-based approach is consistent with the NERC System Protection and Control Subcommittee (SPCS) technical document, *Protection System Response to Power Swings (*August 2013),[10] which recommends a focused approach to determine an at-risk Element. Identification of Elements comes from the annual Planning Assessments pursuant to the transmission planning (i.e., "TPL") and other NERC Reliability Standards (e.g., PRC-006), and the standard is not requiring any other assessments to be performed by the Planning Coordinator. The required notification on a calendar year basis to the respective Generator Owner and Transmission Owner is sufficient because it is expected that the Planning Coordinator will make its notifications following the completion of its annual Planning Assessments. The Planning Coordinator will continue to provide notification of Elements on a calendar year basis even if a study is performed less frequently (e.g., PRC-006 – Automatic Underfrequency Load Shedding, which is five years) and has not changed. It is possible that a Planning Coordinator could utilize studies from a prior year in determining the necessary notifications pursuant to Requirement R1.

Criterion 1

The first criterion involves generator(s) where an angular stability constraint exists that is addressed by limiting the output of a generator or a Remedial Action Scheme (RAS) and those Elements terminating at the Transmission station associated with the generator(s). For example, a scheme to remove generation for specific conditions is implemented for a four-unit generating plant (1,100 MW). Two of the units are 500 MW each; one is connected to the 345 kV system and one is connected to the 230 kV system. The Transmission Owner has two 230 kV transmission lines and one 345 kV transmission line all terminating at the generating facility as well as a 345/230 kV autotransformer. The remaining 100 MW consists of two 50 MW combustion turbine (CT) units connected to four 66 kV transmission lines. The 66 kV transmission lines are not electrically joined to the 345 kV and 230 kV transmission lines at the plant site and are not subject to any generating output limitation or RAS. A stability constraint limits the output of the portion of the

[10] http://www.nerc.com/comm/PC/System%20Protection%20and%20Control%20Subcommittee%20SPCS%20 20/SPCS%20Power%20Swing%20Report_Final_20131015.pdf)

plant affected by the RAS to 700 MW for an outage of the 345 kV transmission line. The RAS trips one of the 500 MW units to maintain stability for a loss of the 345 kV transmission line when the total output from both 500 MW units is above 700 MW. For this example, both 500 MW generating units and the associated generator step-up (GSU) transformers would be identified as Elements meeting this criterion. The 345/230 kV autotransformer, the 345 kV transmission line, and the two 230 kV transmission lines would also be identified as Elements meeting this criterion. The 50 MW combustion turbines and 66 kV transmission lines would not be identified pursuant to Criterion 1 because these Elements are not subject to any generating output limitation or RAS and do not terminate at the Transmission station associated with the generators that are subject to any generating output limitation or RAS.

Criterion 2

The second criterion involves Elements associated with angular instability identified in the Planning Assessments. For example, if Planning Assessments have identified that an angular instability could limit transfer capability on two long parallel 500 kV transmission lines to a maximum of 1,200 MW, and this limitation is based on angular instability resulting from a fault and subsequent loss of one of the two lines, then both lines would be identified as Elements meeting the criterion.

Criterion 3

The third criterion involves Elements that form the boundary of an island within an underfrequency load shedding (UFLS) design assessment. The criterion applies to islands identified based on application of the Planning Coordinator's criteria for identifying islands, where the island is formed by tripping the Elements based on angular instability. The criterion applies if the angular instability is modeled in the UFLS design assessment, or if the boundary is identified "off-line" (i.e., the Elements are selected based on angular instability considerations, but the Elements are tripped in the UFLS design assessment without modeling the initiating angular instability). In cases where an out-of-step condition is detected and tripping is initiated at an alternate location, the criterion applies to the Element on which the power swing is detected. The criterion does not apply to islands identified based on other considerations that do not involve angular instability, such as excessive loading, Planning Coordinator area boundary tie lines, or Balancing Authority boundary tie lines.

Criterion 4

The fourth criterion involves Elements identified in the most recent annual Planning Assessment where relay tripping occurs due to a stable or unstable[11] power swing during a simulated disturbance. The intent is for the Planning Coordinator to include any Element(s) where relay tripping was observed during simulations performed for the most recent annual Planning Assessment associated with the transmission planning TPL-001-4 Reliability Standard. Note that

[11] Refer to the "Justification for Including Unstable Power Swings in the Requirements" section.

relay tripping must be assessed within those annual Planning Assessments per TPL-001-4, R4, Part 4.3.1.3, which indicates that analysis shall include the “Tripping of Transmission lines and transformers where transient swings cause Protection System operation based on generic or actual relay models.” Identifying such Elements according to Criterion 4 and notifying the respective Generator Owner and Transmission Owner will require that the owners of any load-responsive protective relay applied at the terminals of the identified Element evaluate the relay’s susceptibility to tripping in response to a stable power swing.

Planning Coordinators have the discretion to determine whether the observed tripping for a power swing in its Planning Assessments occurs for valid contingencies and system conditions. The Planning Coordinator will address tripping that is observed in transient analyses on an individual basis; therefore, the Planning Coordinator is responsible for identifying the Elements based only on simulation results that are determined to be valid.

Due to the nature of how a Planning Assessment is performed, there may be cases where a previously-identified Element is not identified in the most recent annual Planning Assessment. If so, this is acceptable because the Generator Owner and Transmission Owner would have taken action upon the initial notification of the previously identified Element. When an Element is not identified in later Planning Assessments, the risk of load-responsive protective relays tripping in response to a stable power swing during non-Fault conditions would have already been assessed under Requirement R2 and mitigated according to Requirements R3 and R4 where the relays did not meet the PRC-026-2 – Attachment B criteria. According to Requirement R2, the Generator Owner and Transmission Owner are only required to re-evaluate each load-responsive protective relay for an identified Element where the evaluation has not been performed in the last five calendar years.

Although Requirement R1 requires the Planning Coordinator to notify the respective Generator Owner and Transmission Owner of any Elements meeting one or more of the four criteria, it does not preclude the Planning Coordinator from providing additional information, such as apparent impedance characteristics, in advance or upon request, that may be useful in evaluating protective relays. Generator Owners and Transmission Owners are able to complete protective relay evaluations and perform the required actions without additional information. The standard does not include any requirement for the entities to provide information that is already being shared or exchanged between entities for operating needs. While a Requirement has not been included for the exchange of information, entities should recognize that relay performance needs to be measured against the most current information.

Requirement R2

Requirement R2 requires the Generator Owner and Transmission Owner to evaluate its load-responsive protective relays to ensure that they are expected to not trip in response to stable power swings.

The PRC-026-2 – Attachment A lists the applicable load-responsive relays that must be evaluated which include phase distance, phase overcurrent, out-of-step tripping, and loss-of-field relay functions. Phase distance relays could include, but are not limited to, the following:

- Zone elements with instantaneous tripping or intentional time delays of less than 15 cycles
- Phase distance elements used in high-speed communication-aided tripping schemes including:
  - Directional Comparison Blocking (DCB) schemes
  - Directional Comparison Un-Blocking (DCUB) schemes
  - Permissive Overreach Transfer Trip (POTT) schemes
  - Permissive Underreach Transfer Trip (PUTT) schemes

A method is provided within the standard to support consistent evaluation by Generator Owners and Transmission Owners based on specified conditions. Once a Generator Owner or Transmission Owner is notified of Elements pursuant to Requirement R1, it has 12 full calendar months to determine if each Element's load-responsive protective relays meet the PRC-026-2 – Attachment B criteria, if the determination has not been performed in the last five calendar years. Additionally, each Generator Owner and Transmission Owner, that becomes aware of a generator, transformer, or transmission line BES Element that tripped in response to a stable or unstable power swing due to the operation of its protective relays pursuant to Requirement R2, Part 2.2, must perform the same PRC-026-2 – Attachment B criteria determination within 12 full calendar months.

Becoming Aware of an Element That Tripped in Response to a Power Swing

Part 2.2 in Requirement R2 is intended to initiate action by the Generator Owner and Transmission Owner when there is a known stable or unstable power swing and it resulted in the entity's Element tripping. The criterion starts with becoming aware of the event (i.e., power swing) and then any connection with the entity's Element tripping. By doing so, the focus is removed from the entity having to demonstrate that it made a determination whether a power swing was present for every Element trip. The basis for structuring the criterion in this manner is driven by the available ways that a Generator Owner and Transmission Owner could become aware of an Element that tripped in response to a stable or unstable power swing due to the operation of its protective relay(s).

Element trips caused by stable or unstable power swings, though infrequent, would be more common in a larger event. The identification of power swings will be revealed during an analysis of the event. Event analysis where an entity may become aware of a stable or unstable power swing could include internal analysis conducted by the entity, the entity's Protection System review following a trip, or a larger scale analysis by other entities. Event analysis could include involvement by the entity's Regional Entity, and in some cases NERC.

Information Common to Both Generation and Transmission Elements

The PRC-026-2 – Attachment A lists the load-responsive protective relays that are subject to this standard. Generator Owners and Transmission Owners may own load-responsive protective relays (e.g., distance relays) that directly affect generation or transmission BES Elements and will require analysis as a result of Elements being identified by the Planning Coordinator in Requirement R1

or the Generator Owner or Transmission Owner in Requirement R2. For example, distance relays owned by the Transmission Owner may be installed at the high-voltage side of the generator step-up (GSU) transformer (directional toward the generator) providing backup to generation protection. Generator Owners may have distance relays applied to backup transmission protection or backup protection to the GSU transformer. The Generator Owner may have relays installed at the generator terminals or the high-voltage side of the GSU transformer.

Exclusion of Time Based Load-Responsive Protective Relays

The purpose of the standard is "[t]o ensure that load-responsive protective relays are expected to not trip in response to stable power swings during non-Fault conditions." Load-responsive, high-speed tripping protective relays pose the highest risk of operating during a power swing. Because of this, high-speed tripping protective relays and relays with a time delay of less than 15 cycles are included in the standard; whereas other relays (i.e., Zones 2 and 3) with a time delay of 15 cycles or greater are excluded. The time delay used for exclusion on some load-responsive protective relays is based on the maximum expected time that load-responsive protective relays would be exposed to a stable power swing with a slow slip rate frequency.

In order to establish a time delay that distinguishes a high-risk load-responsive protective relay from one that has a time delay for tripping (lower-risk), a sample of swing rates were calculated based on a stable power swing entering and leaving the impedance characteristic as shown in Table 1. For a relay impedance characteristic that has a power swing entering and leaving, beginning at 90 degrees with a termination at 120 degrees before exiting the zone, the zone timer must be greater than the calculated time the stable power swing is inside the relay's operating zone to not trip in response to the stable power swing.

Eq. (1) $$Zone\ timer > 2 \times \left(\frac{(120° - Angle\ of\ entry\ into\ the\ relay\ characteristic) \times 60}{(360 \times Slip\ Rate)}\right)$$

Table 1: Swing Rates	
Zone Timer (Cycles)	**Slip Rate (Hz)**
10	1.00
15	0.67
20	0.50
30	0.33

With a minimum zone timer of 15 cycles, the corresponding slip rate of the system is 0.67 Hz. This represents an approximation of a slow slip rate during a system Disturbance. Longer time delays allow for slower slip rates.

Application to Transmission Elements

Criterion A in PRC-026-2 – Attachment B describes an unstable power swing region that is formed by the union of three shapes in the impedance (R-X) plane. The first shape is a lower loss-of-synchronism circle based on a ratio of the sending-end to receiving-end voltages of 0.7 (i.e., E_S / E_R = 0.7 / 1.0 = 0.7). The second shape is an upper loss-of-synchronism circle based on a ratio of the sending-end to receiving-end voltages of 1.43 (i.e., E_S / E_R = 1.0 / 0.7 = 1.43). The third shape is a lens that connects the endpoints of the total system impedance together by varying the sending-end and receiving-end system voltages from 0.0 to 1.0 per unit, while maintaining a constant system separation angle across the total system impedance (with the parallel transfer impedance removed—see Figures 1 through 5). The total system impedance is derived from a two-bus equivalent network and is determined by summing the sending-end source impedance, the line impedance (excluding the Thévenin equivalent transfer impedance), and the receiving-end source impedance as shown in Figures 6 and 7. Establishing the total system impedance provides a conservative condition that will maximize the security of the relay against various system conditions. The smallest total system impedance represents a condition where the size of the lens characteristic in the R-X plane is smallest and is a conservative operating point from the standpoint of ensuring a load-responsive protective relay is expected to not trip given a predetermined angular displacement between the sending-end and receiving-end voltages. The smallest total system impedance results when all generation is in service and all transmission BES Elements are modeled in their "normal" system configuration (PRC-026-2 – Attachment B, Criterion A). The parallel transfer impedance is removed to represent a likely condition where parallel Elements may be lost during the disturbance, and the loss of these Elements magnifies the sensitivity of the load-responsive relays on the parallel line by removing the "infeed effect" (i.e., the apparent impedance sensed by the relay is decreased as a result of the loss of the transfer impedance, thus making the relay more likely to trip for a stable power swing—See Figures 13 and 14).

The sending-end and receiving-end source voltages are varied from 0.7 to 1.0 per unit to form the lower and upper loss-of-synchronism circles. The ratio of these two voltages is used in the calculation of the loss-of-synchronism circles, and result in a ratio range from 0.7 to 1.43.

Eq. (2) $$\frac{E_S}{E_R} = \frac{0.7}{1.0} = 0.7$$

Eq. (3): $$\frac{E_S}{E_R} = \frac{1.0}{0.7} = 1.43$$

The internal generator voltage during severe power swings or transmission system fault conditions will be greater than zero due to voltage regulator support. The voltage ratio of 0.7 to 1.43 is chosen to be more conservative than the PRC-023[12] and PRC-025[13] NERC Reliability Standards where a lower bound voltage of 0.85 per unit voltage is used. A ±15% internal generator voltage range was chosen as a conservative voltage range for calculation of the voltage ratio used to calculate the loss-of-synchronism circles. For example, the voltage ratio using these voltages would result in a ratio range from 0.739 to 1.353.

[12] Transmission Relay Loadability

[13] Generator Relay Loadability

Eq. (4) $$\frac{E_S}{E_R}=\frac{0.85}{1.15}=0.739$$ Eq. (5): $$\frac{E_S}{E_R}=\frac{1.15}{0.85}=1.353$$

The lower ratio is rounded down to 0.7 to be more conservative, allowing a voltage range of 0.7 to 1.0 per unit to be used for the calculation of the loss-of-synchronism circles.[14]

When the parallel transfer impedance is included in the model, the division of current through the parallel transfer impedance path results in actual measured relay impedances that are larger than those measured when the parallel transfer impedance is removed (i.e., infeed effect), which would make it more likely for an impedance relay element to be completely contained within the unstable power swing region as shown in Figure 11. If the transfer impedance is included in the evaluation, a distance relay element could be deemed as meeting PRC-026-2 – Attachment B criteria and, in fact would be secure, assuming all Elements were in their normal state. In this case, the distance relay element could trip in response to a stable power swing during an actual event if the system was weakened (i.e., a higher transfer impedance) by the loss of a subset of lines that make up the parallel transfer impedance as shown in Figure 10. This could happen because the subset of lines that make up the parallel transfer impedance tripped on unstable swings, contained the initiating fault, and/or were lost due to operation of breaker failure or remote back-up protection schemes.

Table 10 shows the percent size increase of the lens shape as seen by the relay under evaluation when the parallel transfer impedance is included. The parallel transfer impedance has minimal effect on the apparent size of the lens shape as long as the parallel transfer impedance is at least 10 multiples of the parallel line impedance (less than 5% lens shape expansion), therefore, its removal has minimal impact, but results in a slightly more conservative, smaller lens shape. Parallel transfer impedances of 5 multiples of the parallel line impedance or less result in an apparent lens shape size of 10% or greater as seen by the relay. If two parallel lines and a parallel transfer impedance tie the sending-end and receiving-end buses together, the total parallel transfer impedance will be one or less multiples of the parallel line impedance, resulting in an apparent lens shape size of 45% or greater. It is a realistic contingency that the parallel line could be out-of-service, leaving the parallel transfer impedance making up the rest of the system in parallel with the line impedance. Since it is not known exactly which lines making up the parallel transfer impedance will be out of service during a major system disturbance, it is most conservative to assume that all of them are out, leaving just the line under evaluation in service.

Either the saturated transient or sub-transient direct axis reactance may be used for machines in the evaluation because they are smaller than the un-saturated reactances. Since saturated sub-transient generator reactances are smaller than the transient or synchronous reactances, the use of sub-transient reactances will result in a smaller source impedance and a smaller unstable power swing region in the graphical analysis as shown in Figures 8 and 9. Because power swings occur in a time frame where generator transient reactances will be prevalent, it is acceptable to use saturated transient reactances instead of saturated sub-transient reactances. Because some short-

[14] *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*, April 2004, Section 6 (The Cascade Stage of the Blackout), p. 94 under "Why the Generators Tripped Off," states, "Some generator undervoltage relays were set to trip at or above 90% voltage. However, a motor stalls out at about 70% voltage and a motor starter contactor drops out around 75%, so if there is a compelling need to protect the turbine from the system the under-voltage trigger point should be no higher than 80%."

circuit models may not include transient reactances, the use of sub-transient reactances is also acceptable because it produces more conservative results. For this reason, either value is acceptable when determining the system source impedances (PRC-026-2 – Attachment B, Criterion A and B, No. 3).

Saturated reactances are used in short-circuit programs that produce the system impedance mentioned above. Planning and stability software generally use un-saturated reactances. Generator models used in transient stability analyses recognize that the extent of the saturation effect depends upon both rotor (field) and stator currents. Accordingly, they derive the effective saturated parameters of the machine at each instant by internal calculation from the specified (constant) unsaturated values of machine reactances and the instantaneous internal flux level. The specific assumptions regarding which inductances are affected by saturation, and the relative effect of that saturation, are different for the various generator models used. Thus, unsaturated values of all machine reactances are used in setting up planning and stability software data, and the appropriate set of open-circuit magnetization curve data is provided for each machine.

Saturated reactance values are smaller than unsaturated reactance values and are used in short-circuit programs owned by the Generator and Transmission Owners. Because of this, saturated reactance values are to be used in the development of the system source impedances.

The source or system equivalent impedances can be obtained by a number of different methods using commercially available short-circuit calculation tools.[15] Most short-circuit tools have a network reduction feature that allows the user to select the local and remote terminal buses to retain. The first method reduces the system to one that contains two buses, an equivalent generator at each bus (representing the source impedances at the sending-end and receiving-end), and two parallel lines; one being the line impedance of the protected line with relays being analyzed, the other being the parallel transfer impedance representing all other combinations of lines that connect the two buses together as shown in Figure 6. Another conservative method is to open both ends of the line being evaluated, and apply a three-phase bolted fault at each bus to determine the Thévenin equivalent impedance at each bus. The source impedances are set equal to the Thévenin equivalent impedances and will be less than or equal to the actual source impedances calculated by the network reduction method. Either method can be used to develop the system source impedances at both ends.

The two bullets of PRC-026-2 – Attachment B, Criterion A, No. 1, identify the system separation angles used to identify the size of the power swing stability boundary for evaluating load-responsive protective relay impedance elements. The first bullet of PRC-026-2 – Attachment B, Criterion A, No. 1 evaluates a system separation angle of at least 120 degrees that is held constant while varying the sending-end and receiving-end source voltages from 0.7 to 1.0 per unit, thus creating an unstable power swing region about the total system impedance in Figure 1. This unstable power swing region is compared to the tripping portion of the distance relay characteristic; that is, the portion that is not supervised by load encroachment, blinders, or some other form of supervision as shown in Figure 12 that restricts the distance element from tripping

[15] Demetrios A. Tziouvaras and Daqing Hou, Appendix in *Out-Of-Step Protection Fundamentals and Advancements,* April 17, 2014: https://www.selinc.com.

for heavy, balanced load conditions. If the tripping portion of the impedance characteristics are completely contained within the unstable power swing region, the relay impedance element meets Criterion A in PRC-026-2 – Attachment B. A system separation angle of 120 degrees was chosen for the evaluation because it is generally accepted in the industry that recovery for a swing beyond this angle is unlikely to occur.[16]

The second bullet of PRC-026-2 – Attachment B, Criterion A, No. 1 evaluates impedance relay elements at a system separation angle of less than 120 degrees, similar to the first bullet described above. An angle less than 120 degrees may be used if a documented stability analysis demonstrates that the power swing becomes unstable at a system separation angle of less than 120 degrees.

The exclusion of relay elements supervised by Power Swing Blocking (PSB) in PRC-026-2 – Attachment A allows the Generator Owner or Transmission Owner to exclude protective relay elements if they are blocked from tripping by PSB relays. A PSB relay applied and set according to industry accepted practices prevent supervised load-responsive protective relays from tripping in response to power swings. Further, PSB relays are set to allow dependable tripping of supervised elements. The criteria in PRC-026-2 – Attachment B specifically applies to unsupervised elements that could trip for stable power swings. Therefore, load-responsive protective relay elements supervised by PSB can be excluded from the Requirements of this standard.

[16] "The critical angle for maintaining stability will vary depending on the contingency and the system condition at the time the contingency occurs; however, the likelihood of recovering from a swing that exceeds 120 degrees is marginal and 120 degrees is generally accepted as an appropriate basis for setting out-of-step protection. Given the importance of separating unstable systems, defining 120 degrees as the critical angle is appropriate to achieve a proper balance between dependable tripping for unstable power swings and secure operation for stable power swings." NERC System Protection and Control Subcommittee, *Protection System Response to Power Swings*, August 2013: http://www.nerc.com/comm/PC/System%20Protection%20and%20Control%20Subcommittee%20SPCS%2020/SPCS%20Power%20Swing%20Report_Final_20131015.pdf), p. 28.

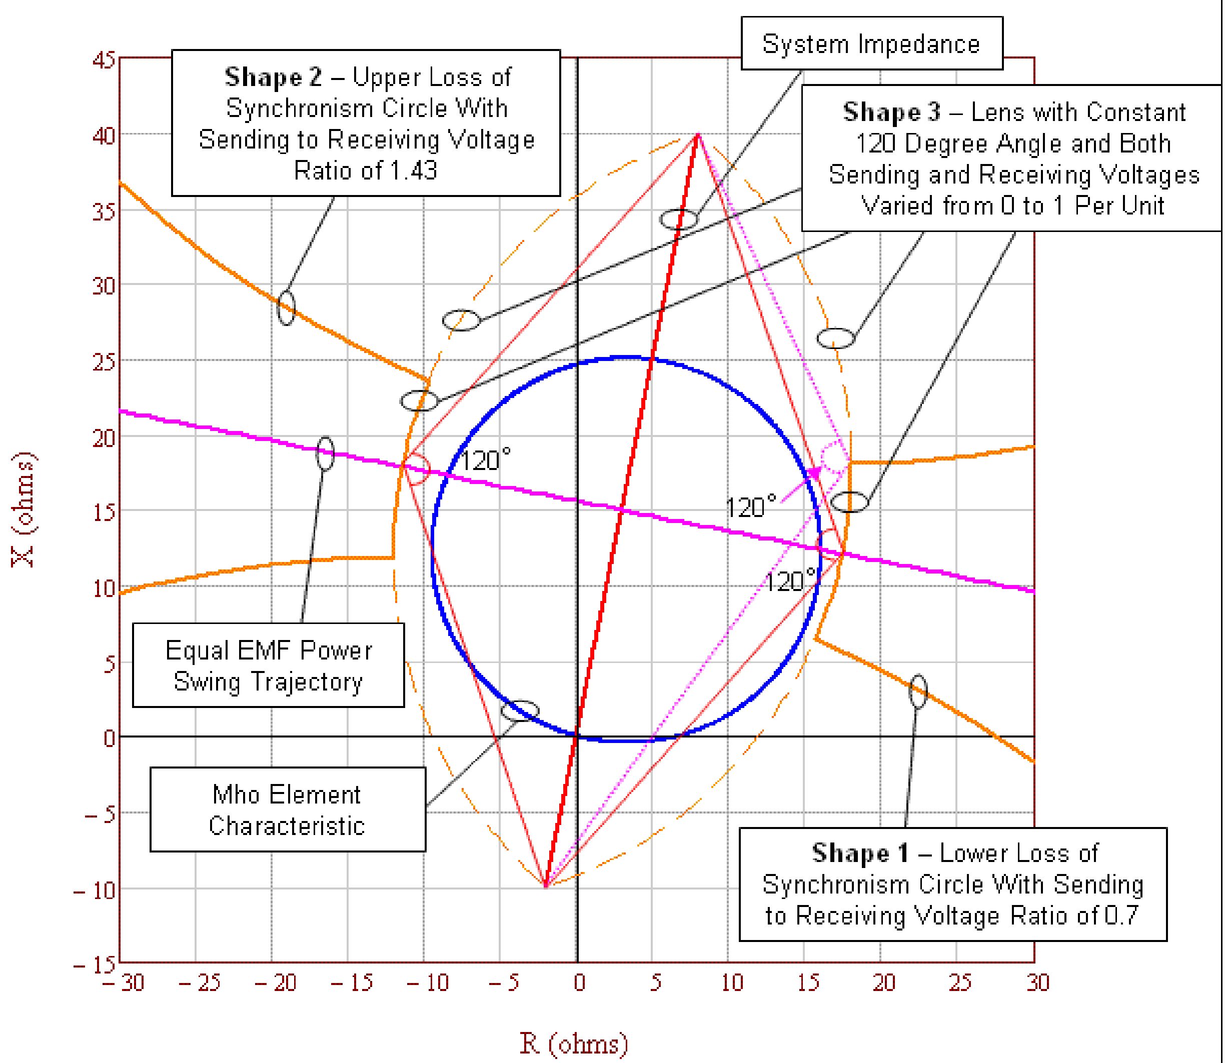

Figure 1: An enlarged graphic illustrating the unstable power swing region formed by the union of three shapes in the impedance (R-X) plane: Shape 1) Lower loss-of-synchronism circle, Shape 2) Upper loss-of-synchronism circle, and Shape 3) Lens. The mho element characteristic is completely contained within the unstable power swing region (i.e., it does not intersect any portion of the unstable power swing region), therefore it meets PRC-026-2 – Attachment B, Criterion A, No. 1.

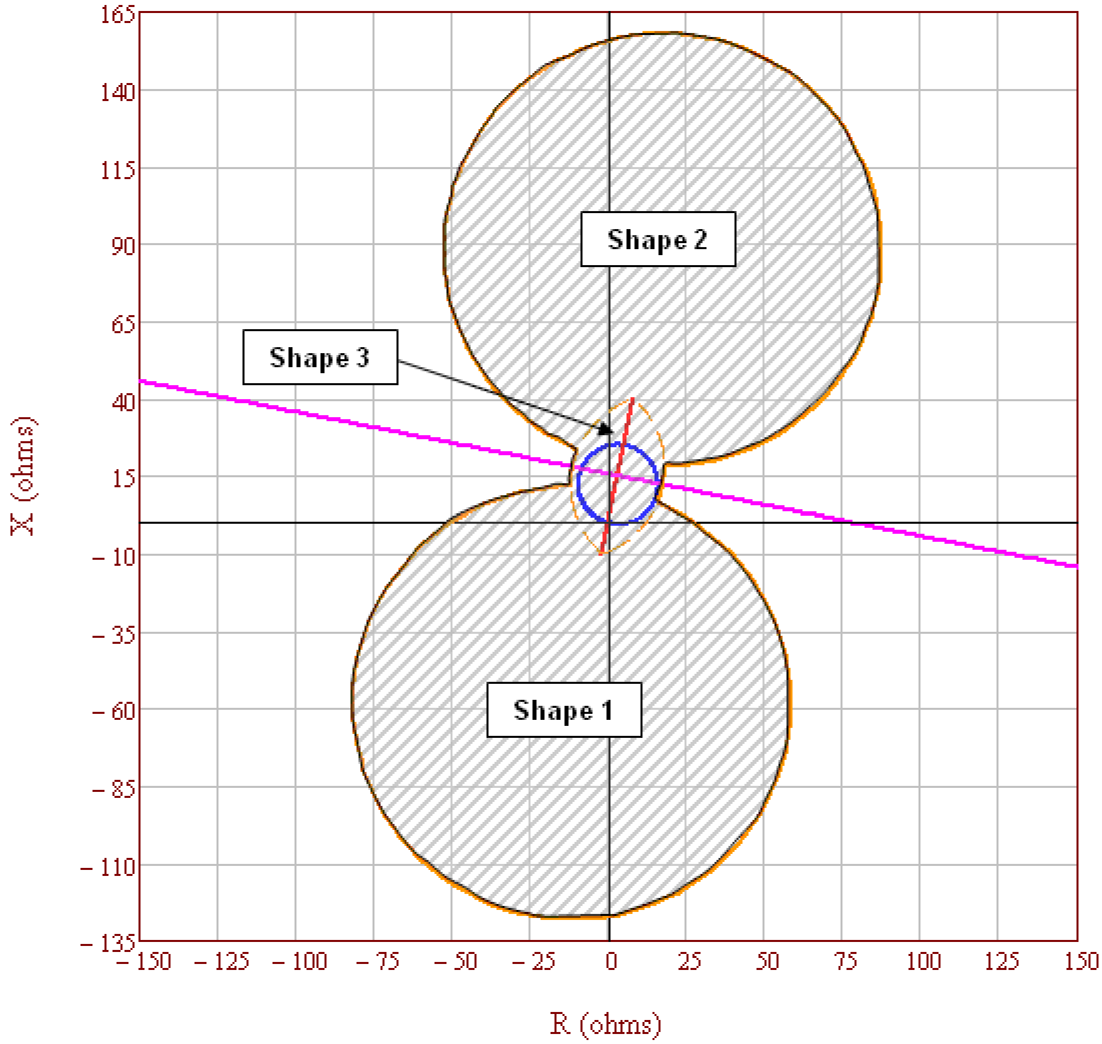

Figure 2: Full graphic of the unstable power swing region formed by the union of the three shapes in the impedance (R-X) plane: Shape 1) Lower loss-of-synchronism circle, Shape 2) Upper loss-of-synchronism circle, and Shape 3) Lens. The mho element characteristic is completely contained within the unstable power swing region, therefore it meets PRC-026-2 – Attachment B, Criterion A, No.1.

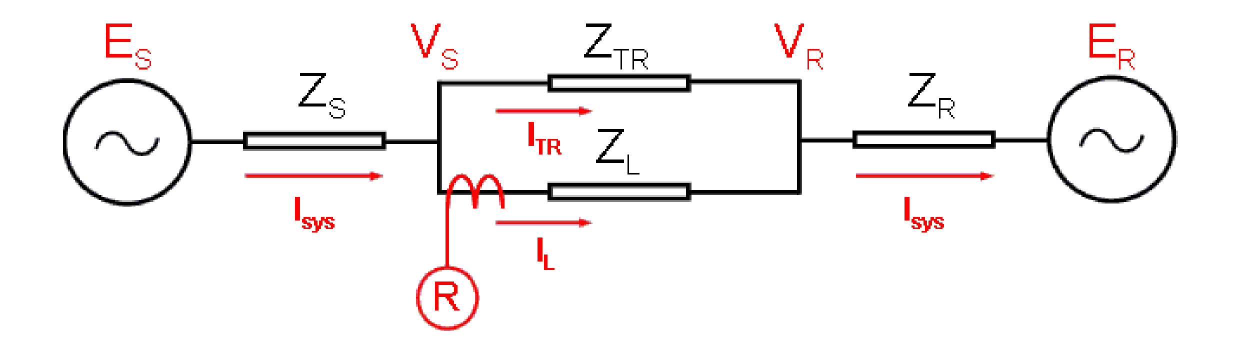

Figure 3: System impedances as seen by Relay R (voltage connections are not shown).

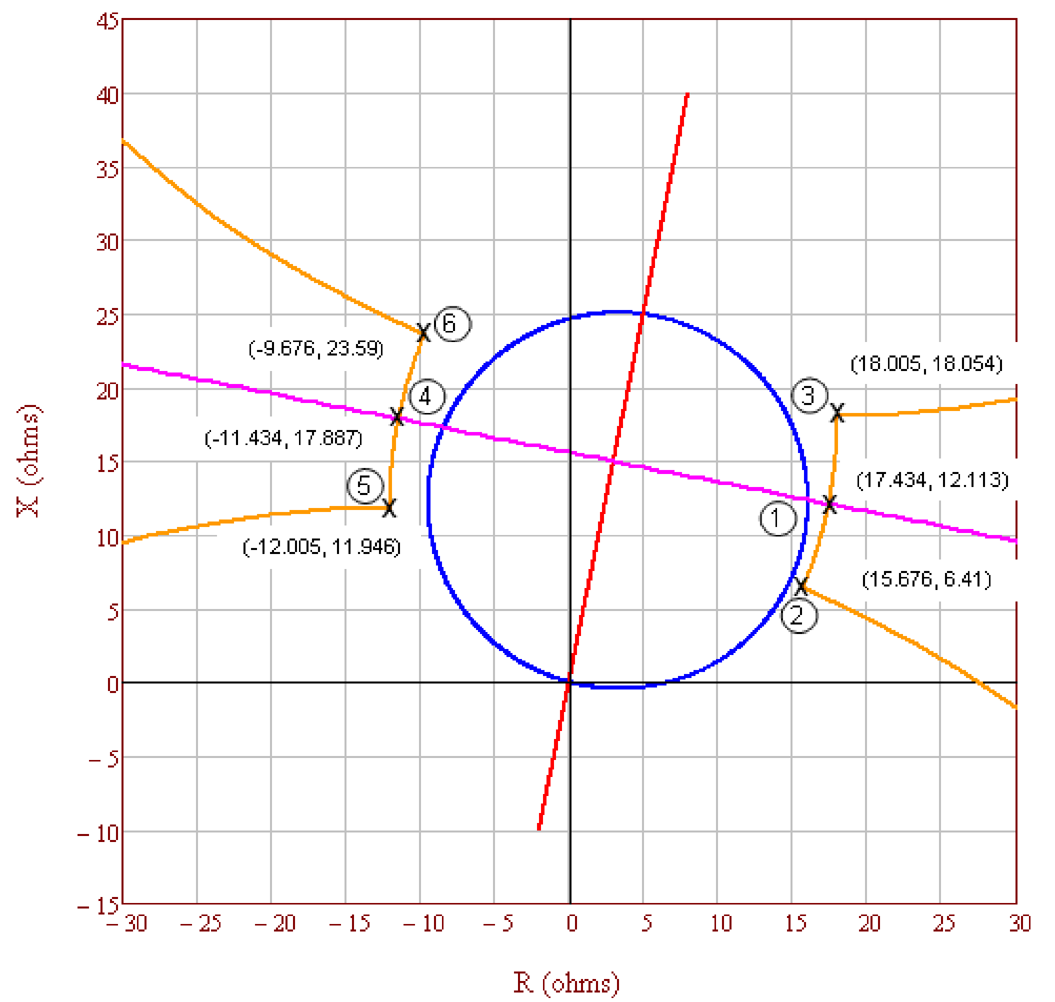

Figure 4: The defining unstable power swing region points where the lens shape intersects the lower and upper loss-of-synchronism circle shapes and where the lens intersects the equal EMF (electromotive force) power swing.

Figure 5: Full table of 31 detailed lens shape point calculations. The bold highlighted rows correspond to the detailed calculations in Tables 2-7.

Table 2: Example Calculation (Lens Point 1)	
This example is for calculating the impedance the first point of the lens characteristic. Equal source voltages are used for the 230 kV (base) line with the sending-end voltage (E_S) leading the receiving-end voltage (E_R) by 120 degrees. See Figures 3 and 4.	
Eq. (6)	$E_S = \frac{V_{LL}\angle 120°}{\sqrt{3}}$

Table 2: Example Calculation (Lens Point 1)			
	$E_S = \dfrac{230{,}000\angle 120°\,V}{\sqrt{3}}$		
	$E_S = 132{,}791\angle 120°\,V$		
Eq. (7)	$E_R = \dfrac{V_{LL}\angle 0°}{\sqrt{3}}$		
	$E_R = \dfrac{230{,}000\angle 0°\,V}{\sqrt{3}}$		
	$E_R = 132{,}791\angle 0°\,V$		
Positive sequence impedance data (with transfer impedance Z_{TR} set to a large value).			
Given:	$Z_S = 2 + j10\,\Omega$	$Z_L = 4 + j20\,\Omega$	$Z_R = 4 + j20\,\Omega$
Given:	$Z_{TR} = Z_L \times 10^{10}\,\Omega$		
Total impedance between the generators.			
Eq. (8)	$Z_{total} = \dfrac{(Z_L \times Z_{TR})}{(Z_L + Z_{TR})}$		
	$Z_{total} = \dfrac{\left((4+j20)\,\Omega \times (4+j20) \times 10^{10}\,\Omega\right)}{\left((4+j20)\,\Omega + (4+j20) \times 10^{10}\,\Omega\right)}$		
	$Z_{total} = 4 + j20\,\Omega$		
Total system impedance.			
Eq. (9)	$Z_{sys} = Z_S + Z_{total} + Z_R$		
	$Z_{sys} = (2+j10)\,\Omega + (4+j20)\,\Omega + (4+j20)\,\Omega$		
	$Z_{sys} = 10 + j50\,\Omega$		
Total system current from sending-end source.			
Eq. (10)	$I_{sys} = \dfrac{E_S - E_R}{Z_{sys}}$		
	$I_{sys} = \dfrac{132{,}791\angle 120°\,V - 132{,}791\angle 0°\,V}{(10 + j50\,)\Omega}$		
	$I_{sys} = 4{,}511\angle 71.3°\,A$		
The current, as measured by the relay on Z_L (Figure 3), is only the current flowing through that line as determined by using the current divider equation.			
Eq. (11)	$I_L = I_{sys} \times \dfrac{Z_{TR}}{Z_L + Z_{TR}}$		

Table 2: Example Calculation (Lens Point 1)	
	$I_L = 4{,}511\angle 71.3°\ A \times \frac{(4+j20)\times 10^{10}\ \Omega}{(4+j20)\ \Omega + (4+j20)\times 10^{10}\ \Omega}$
	$I_L = 4{,}511\angle 71.3°\ A$
The voltage, as measured by the relay on Z_L (Figure 3), is the voltage drop from the sending-end source through the sending-end source impedance.	
Eq. (12)	$V_S = E_S - \left(Z_S \times I_{sys}\right)$
	$V_S = 132{,}791\angle 120°\ V - [(2+j10)\ \Omega \times 4{,}511\angle 71.3°\ A]$
	$V_S = 95{,}757\angle 106.1°\ V$
The impedance seen by the relay on Z_L.	
Eq. (13)	$Z_{L-Relay} = \frac{V_S}{I_L}$
	$Z_{L-Relay} = \frac{95{,}757\angle 106.1°\ V}{4{,}511\angle 71.3°\ A}$
	$Z_{L-Relay} = 17.434 + j12.113\ \Omega$

Table 3: Example Calculation (Lens Point 2)			
This example is for calculating the impedance second point of the lens characteristic. Unequal source voltages are used for the 230 kV (base) line with the sending-end voltage (E_S) at 70% of the receiving-end voltage (E_R) and leading the receiving-end voltage by 120 degrees. See Figures 3 and 4.			
Eq. (14)	$E_S = \frac{V_{LL}\angle 120°}{\sqrt{3}} \times 70\%$		
	$E_S = \frac{230{,}000\angle 120°\ V}{\sqrt{3}} \times 0.70$		
	$E_S = 92{,}953.7\angle 120°\ V$		
Eq. (15)	$E_R = \frac{V_{LL}\angle 0°}{\sqrt{3}}$		
	$E_R = \frac{230{,}000\angle 0°\ V}{\sqrt{3}}$		
	$E_R = 132{,}791\angle 0°\ V$		
Positive sequence impedance data (with transfer impedance Z_{TR} set to a large value).			
Given:	$Z_S = 2 + j10\ \Omega$	$Z_L = 4 + j20\ \Omega$	$Z_R = 4 + j20\ \Omega$
Given:	$Z_{TR} = Z_L \times 10^{10}\ \Omega$		

Table 3: Example Calculation (Lens Point 2)	
Total impedance between the generators.	
Eq. (16)	$Z_{total} = \frac{(Z_L \times Z_{TR})}{(Z_L + Z_{TR})}$
	$Z_{total} = \frac{\left((4 + j20)\ \Omega \times (4 + j20) \times 10^{10}\ \Omega\right)}{\left((4 + j20)\ \Omega + (4 + j20) \times 10^{10}\ \Omega\right)}$
	$Z_{total} = 4 + j20\ \Omega$
Total system impedance.	
Eq. (17)	$Z_{sys} = Z_S + Z_{total} + Z_R$
	$Z_{sys} = (2 + j10)\ \Omega + (4 + j20)\ \Omega + (4 + j20)\ \Omega$
	$Z_{sys} = 10 + j50\ \Omega$
Total system current from sending-end source.	
Eq. (18)	$I_{sys} = \frac{E_S - E_R}{Z_{sys}}$
	$I_{sys} = \frac{92{,}953.7\angle 120°\ V - 132{,}791\angle 0°\ V}{(10 + j50)\ \Omega}$
	$I_{sys} = 3{,}854\angle 77°\ A$
The current, as measured by the relay on Z_L (Figure 3), is only the current flowing through that line as determined by using the current divider equation.	
Eq. (19)	$I_L = I_{sys} \times \frac{Z_{TR}}{Z_L + Z_{TR}}$
	$I_L = 3{,}854\angle 77°\ A \times \frac{(4 + j20) \times 10^{10}\ \Omega}{(4 + j20)\ \Omega + (4 + j20) \times 10^{10}\ \Omega}$
	$I_L = 3{,}854\angle 77°\ A$
The voltage, as measured by the relay on Z_L (Figure 3), is the voltage drop from the sending-end source through the sending-end source impedance.	
Eq. (20)	$V_S = E_S - \left(Z_S \times I_{sys}\right)$
	$V_S = 92{,}953\angle 120°\ V - [(2 + j10\ )\Omega \times 3{,}854\angle 77°\ A]$
	$V_S = 65{,}271\angle 99°\ V$
The impedance seen by the relay on Z_L.	
Eq. (21)	$Z_{L-Relay} = \frac{V_S}{I_L}$

Table 3: Example Calculation (Lens Point 2)	
	$Z_{L-Relay} = \frac{65{,}271\angle 99°\ V}{3{,}854\angle 77°\ A}$
	$Z_{L-Relay} = 15.676 + j6.41\ \Omega$

Table 4: Example Calculation (Lens Point 3)			
This example is for calculating the impedance third point of the lens characteristic. Unequal source voltages are used for the 230 kV (base) line with the receiving-end voltage (E_R) at 70% of the sending-end voltage (E_S) and the sending-end voltage leading the receiving-end voltage by 120 degrees. See Figures 3 and 4.			
Eq. (22)	$E_S = \frac{V_{LL}\angle 120°}{\sqrt{3}}$		
	$E_S = \frac{230{,}000\angle 120°\ V}{\sqrt{3}}$		
	$E_S = 132{,}791\angle 120°\ V$		
Eq. (23)	$E_R = \frac{V_{LL}\angle 0°}{\sqrt{3}} \times 70\%$		
	$E_R = \frac{230{,}000\angle 0°\ V}{\sqrt{3}} \times 0.70$		
	$E_R = 92{,}953.7\angle 0°\ V$		
Positive sequence impedance data (with transfer impedance Z_{TR} set to a large value).			
Given:	$Z_S = 2 + j10\ \Omega$	$Z_L = 4 + j20\ \Omega$	$Z_R = 4 + j20\ \Omega$
Given:	$Z_{TR} = Z_L \times 10^{10}\ \Omega$		
Total impedance between the generators.			
Eq. (24)	$Z_{total} = \frac{(Z_L \times Z_{TR})}{(Z_L + Z_{TR})}$		
	$Z_{total} = \frac{\left((4 + j20)\ \Omega \times (4 + j20) \times 10^{10}\ \Omega\right)}{\left((4 + j20)\ \Omega + (4 + j20) \times 10^{10}\ \Omega\right)}$		
	$Z_{total} = 4 + j20\ \Omega$		
Total system impedance.			
Eq. (25)	$Z_{sys} = Z_S + Z_{total} + Z_R$		
	$Z_{sys} = (2 + j10)\ \Omega + (4 + j20)\ \Omega + (4 + j20)\ \Omega$		
	$Z_{sys} = 10 + j50\ \Omega$		

Table 4: Example Calculation (Lens Point 3)	
Total system current from sending-end source.	
Eq. (26)	$I_{sys} = \dfrac{E_S - E_R}{Z_{sys}}$
	$I_{sys} = \dfrac{132{,}791\angle 120°\ V - 92{,}953.7\angle 0°\ V}{(10 + j50)\ \Omega}$
	$I_{sys} = 3{,}854\angle 65.5°\ A$
The current, as measured by the relay on Z_L (Figure 3), is only the current flowing through that line as determined by using the current divider equation.	
Eq. (27)	$I_L = I_{sys} \times \dfrac{Z_{TR}}{Z_L + Z_{TR}}$
	$I_L = 3{,}854\angle 65.5°\ A \times \dfrac{(4 + j20) \times 10^{10}\ \Omega}{(4 + j20)\ \Omega + (4 + j20) \times 10^{10}\ \Omega}$
	$I_L = 3{,}854\angle 65.5°\ A$
The voltage, as measured by the relay on Z_L (Figure 3), is the voltage drop from the sending-end source through the sending-end source impedance.	
Eq. (28)	$V_S = E_S - (Z_S \times I_L)$
	$V_S = 132{,}791\angle 120°\ V - [(2 + j10)\ \Omega \times 3{,}854\angle 65.5°\ A]$
	$V_S = 98{,}265\angle 110.6°\ V$
The impedance seen by the relay on Z_L.	
Eq. (29)	$Z_{L-Relay} = \dfrac{V_S}{I_L}$
	$Z_{L-Relay} = \dfrac{98{,}265\angle 110.6°\ V}{3{,}854\angle 65.5°\ A}$
	$Z_{L-Relay} = 18.005 + j18.054\ \Omega$

Table 5: Example Calculation (Lens Point 4)	
This example is for calculating the impedance fourth point of the lens characteristic. Equal source voltages are used for the 230 kV (base) line with the sending-end voltage (E_S) leading the receiving-end voltage (E_R) by 240 degrees. See Figures 3 and 4.	
Eq. (30)	$E_S = \dfrac{V_{LL}\angle 240°}{\sqrt{3}}$
	$E_S = \dfrac{230{,}000\angle 240°\ V}{\sqrt{3}}$

Table 5: Example Calculation (Lens Point 4)			
	$E_S = 132{,}791\angle 240°\ V$		
Eq. (31)	$E_R = \dfrac{V_{LL}\angle 0°}{\sqrt{3}}$		
	$E_R = \dfrac{230{,}000\angle 0°\ V}{\sqrt{3}}$		
	$E_R = 132{,}791\angle 0°\ V$		
Positive sequence impedance data (with transfer impedance Z_{TR} set to a large value).			
Given:	$Z_S = 2 + j10\ \Omega$	$Z_L = 4 + j20\ \Omega$	$Z_R = 4 + j20\ \Omega$
Given:	$Z_{TR} = Z_L \times 10^{10}\ \Omega$		
Total impedance between the generators.			
Eq. (32)	$Z_{total} = \dfrac{(Z_L \times Z_{TR})}{(Z_L + Z_{TR})}$		
	$Z_{total} = \dfrac{\big((4 + j20)\ \Omega \times (4 + j20) \times 10^{10}\ \Omega\big)}{\big((4 + j20)\ \Omega + (4 + j20) \times 10^{10}\ \Omega\big)}$		
	$Z_{total} = 4 + j20\ \Omega$		
Total system impedance.			
Eq. (33)	$Z_{sys} = Z_S + Z_{total} + Z_R$		
	$Z_{sys} = (2 + j10)\ \Omega + (4 + j20)\ \Omega + (4 + j20)\ \Omega$		
	$Z_{sys} = 10 + j50\ \Omega$		
Total system current from sending-end source.			
Eq. (34)	$I_{sys} = \dfrac{E_S - E_R}{Z_{sys}}$		
	$I_{sys} = \dfrac{132{,}791\angle 240°\ V - 132{,}791\angle 0°\ V}{(10 + j50\ )\Omega}$		
	$I_{sys} = 4{,}511\angle 131.3°\ A$		
The current, as measured by the relay on Z_L (Figure 3), is only the current flowing through that line as determined by using the current divider equation.			
Eq. (35)	$I_L = I_{sys} \times \dfrac{Z_{TR}}{Z_L + Z_{TR}}$		
	$I_L = 4{,}511\angle 131.1°\ A \times \dfrac{(4 + j20) \times 10^{10}\ \Omega}{(4 + j20)\ \Omega + (4 + j20) \times 10^{10}\ \Omega}$		
	$I_L = 4{,}511\angle 131.1°\ A$		

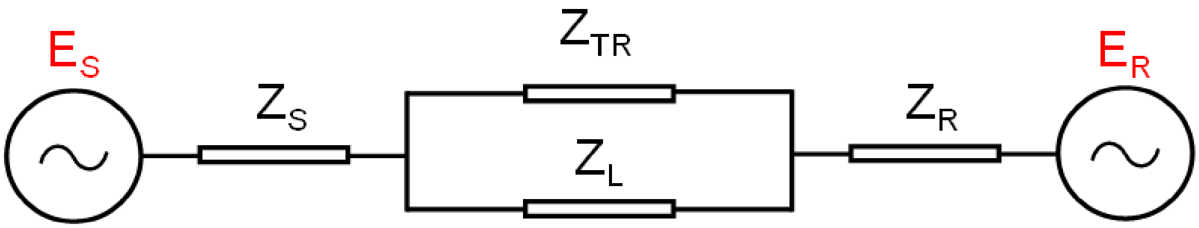
Table 5: Example Calculation (Lens Point 4)	
The voltage, as measured by the relay on Z_L (Figure 3), is the voltage drop from the sending-end source through the sending-end source impedance.	
Eq. (36)	$V_S = E_S - (Z_S \times I_L)$
	$V_S = 132{,}791\angle 240°\,V - [(2 + j10\,)\,\Omega \times 4{,}511\angle 131.1°\,A]$
	$V_S = 95{,}756\angle - 106.1°\,V$
The impedance seen by the relay on Z_L.	
Eq. (37)	$Z_{L-Relay} = \dfrac{V_S}{I_L}$
	$Z_{L-Relay} = \dfrac{95{,}756\angle - 106.1°\,V}{4{,}511\angle 131.1°\,A}$
	$Z_{L-Relay} = -11.434 + j17.887\,\Omega$

Table 6: Example Calculation (Lens Point 5)			
This example is for calculating the impedance fifth point of the lens characteristic. Unequal source voltages are used for the 230 kV (base) line with the sending-end voltage (E_S) at 70% of the receiving-end voltage (E_R) and leading the receiving-end voltage by 240 degrees. See Figures 3 and 4.			
Eq. (38)	$E_S = \dfrac{V_{LL}\angle 240°}{\sqrt{3}} \times 70\%$		
	$E_S = \dfrac{230{,}000\angle 240°\,V}{\sqrt{3}} \times 0.70$		
	$E_S = 92{,}953.7\angle 240°\,V$		
Eq. (39)	$E_R = \dfrac{V_{LL}\angle 0°}{\sqrt{3}}$		
	$E_R = \dfrac{230{,}000\angle 0°\,V}{\sqrt{3}}$		
	$E_R = 132{,}791\angle 0°\,V$		
Positive sequence impedance data (with transfer impedance Z_{TR} set to a large value).			
Given:	$Z_S = 2 + j10\,\Omega$	$Z_L = 4 + j20\,\Omega$	$Z_R = 4 + j20\,\Omega$
Given:	$Z_{TR} = Z_L \times 10^{10}\,\Omega$		
Total impedance between the generators.			
Eq. (40)	$Z_{total} = \dfrac{(Z_L \times Z_{TR})}{(Z_L + Z_{TR})}$		

Table 6: Example Calculation (Lens Point 5)	
	$Z_{total} = \frac{\left((4+j20)\,\Omega \times (4+j20) \times 10^{10}\,\Omega\right)}{\left((4+j20)\,\Omega + (4+j20) \times 10^{10}\,\Omega\right)}$
	$Z_{total} = 4 + j20\,\Omega$
Total system impedance.	
Eq. (41)	$Z_{sys} = Z_S + Z_{total} + Z_R$
	$Z_{sys} = (2 + j10\,\Omega) + (4 + j20\,\Omega) + (4 + j20\,\Omega)$
	$Z_{sys} = 10 + j50\,\Omega$
Total system current from sending-end source.	
Eq. (42)	$I_{sys} = \frac{E_S - E_R}{Z_{sys}}$
	$I_{sys} = \frac{92{,}953.7\angle 240°\,V - 132{,}791\angle 0°\,V}{10 + j50\,\Omega}$
	$I_{sys} = 3{,}854\angle 125.5°\,A$
The current, as measured by the relay on Z_L (Figure 3), is only the current flowing through that line as determined by using the current divider equation.	
Eq. (43)	$I_L = I_{sys} \times \frac{Z_{TR}}{Z_L + Z_{TR}}$
	$I_L = 3{,}854\angle 125.5°\,A \times \frac{(4+j20) \times 10^{10}\,\Omega}{(4+j20)\,\Omega + (4+j20) \times 10^{10}\,\Omega}$
	$I_L = 3{,}854\angle 125.5°\,A$
The voltage, as measured by the relay on Z_L (Figure 3), is the voltage drop from the sending-end source through the sending-end source impedance.	
Eq. (44)	$V_S = E_S - (Z_S \times I_L)$
	$V_S = 92{,}953.7\angle 240°\,V - [(2 + j10\,)\,\Omega \times 3{,}854\angle 125.5°\,A]$
	$V_S = 65{,}270.5\angle -99.4°\,V$
The impedance seen by the relay on Z_L.	
Eq. (45)	$Z_{L-Relay} = \frac{V_S}{I_L}$
	$Z_{L-Relay} = \frac{65{,}270.5\angle -99.4°\,V}{3{,}854\angle 125.5°\,A}$
	$Z_{L-Relay} = -12.005 + j11.946\,\Omega$

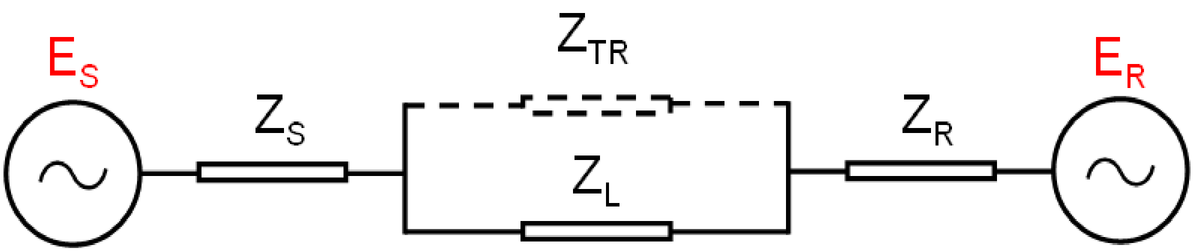
Table 7: Example Calculation (Lens Point 6)			
This example is for calculating the impedance sixth point of the lens characteristic. Unequal source voltages are used for the 230 kV (base) line with the receiving-end voltage (E_R) at 70% of the sending-end voltage (E_S) and the sending-end voltage leading the receiving-end voltage by 240 degrees. See Figures 3 and 4.			
Eq. (46)	$E_S = \frac{V_{LL}\angle 240°}{\sqrt{3}}$		
	$E_S = \frac{230{,}000\angle 240°\ V}{\sqrt{3}}$		
	$E_S = 132{,}791\angle 240°\ V$		
Eq. (47)	$E_R = \frac{V_{LL}\angle 0°}{\sqrt{3}} \times 70\%$		
	$E_R = \frac{230{,}000\angle 0°\ V}{\sqrt{3}} \times 0.70$		
	$E_R = 92{,}953.7\angle 0°\ V$		
Positive sequence impedance data (with transfer impedance Z_{TR} set to a large value).			
Given:	$Z_S = 2 + j10\ \Omega$	$Z_L = 4 + j20\ \Omega$	$Z_R = 4 + j20\ \Omega$
Given:	$Z_{TR} = Z_L \times 10^{10}\ \Omega$		
Total impedance between the generators.			
Eq. (48)	$Z_{total} = \frac{(Z_L \times Z_{TR})}{(Z_L + Z_{TR})}$		
	$Z_{total} = \frac{\left((4 + j20)\ \Omega \times (4 + j20) \times 10^{10}\ \Omega\right)}{\left((4 + j20)\ \Omega + (4 + j20) \times 10^{10}\ \Omega\right)}$		
	$Z_{total} = 4 + j20\ \Omega$		
Total system impedance.			
Eq. (49)	$Z_{sys} = Z_S + Z_{total} + Z_R$		
	$Z_{sys} = (2 + j10)\ \Omega + (4 + j20)\ \Omega + (4 + j20)\ \Omega$		
	$Z_{sys} = 10 + j50\ \Omega$		
Total system current from sending-end source.			
Eq. (50)	$I_{sys} = \frac{E_S - E_R}{Z_{sys}}$		
	$I_{sys} = \frac{132{,}791\angle 240°\ V - 92{,}953.7\angle 0°\ V}{10 + j50\ \Omega}$		
	$I_{sys} = 3{,}854\angle 137.1°\ A$		

Table 7: Example Calculation (Lens Point 6)	
The current, as measured by the relay on Z_L (Figure 3), is only the current flowing through that line as determined by using the current divider equation.	
Eq. (51)	$I_L = I_{sys} \times \frac{Z_{TR}}{Z_L + Z_{TR}}$
	$I_L = 3{,}854\angle 137.1^\circ\ A \times \frac{(4 + j20) \times 10^{10}\ \Omega}{(4 + j20)\ \Omega + (4 + j20) \times 10^{10}\ \Omega}$
	$I_L = 3{,}854\angle 137.1^\circ\ A$
The voltage, as measured by the relay on Z_L (Figure 3), is the voltage drop from the sending-end source through the sending-end source impedance.	
Eq. (52)	$V_S = E_S - (Z_S \times I_L)$
	$V_S = 132{,}791\angle 240^\circ\ V - [(2 + j10\ )\ \Omega \times 3{,}854\angle 137.1^\circ\ A]$
	$V_S = 98{,}265\angle -110.6^\circ\ V$
The impedance seen by the relay on Z_L.	
Eq. (53)	$Z_{L-Relay} = \frac{V_S}{I_L}$
	$Z_{L-Relay} = \frac{98{,}265\angle -110.6^\circ\ V}{3{,}854\angle 137.1^\circ\ A}$
	$Z_{L-Relay} = -9.676 + j23.59\ \Omega$



$$Z_{Total} = Z_S + \frac{Z_L \cdot Z_{TR}}{Z_L + Z_{TR}} + Z_R$$

Figure 6: Reduced two bus system with sending-end source impedance Z_S, receiving-end source impedance Z_R, line impedance Z_L, and parallel transfer impedance Z_{TR}.



$$Z_{sys} = Z_S + Z_L + Z_R$$

Figure 7: Reduced two bus system with sending-end source impedance Z_S, receiving-end source impedance Z_R, and line impedance Z_L with the parallel transfer impedance Z_{TR} removed.

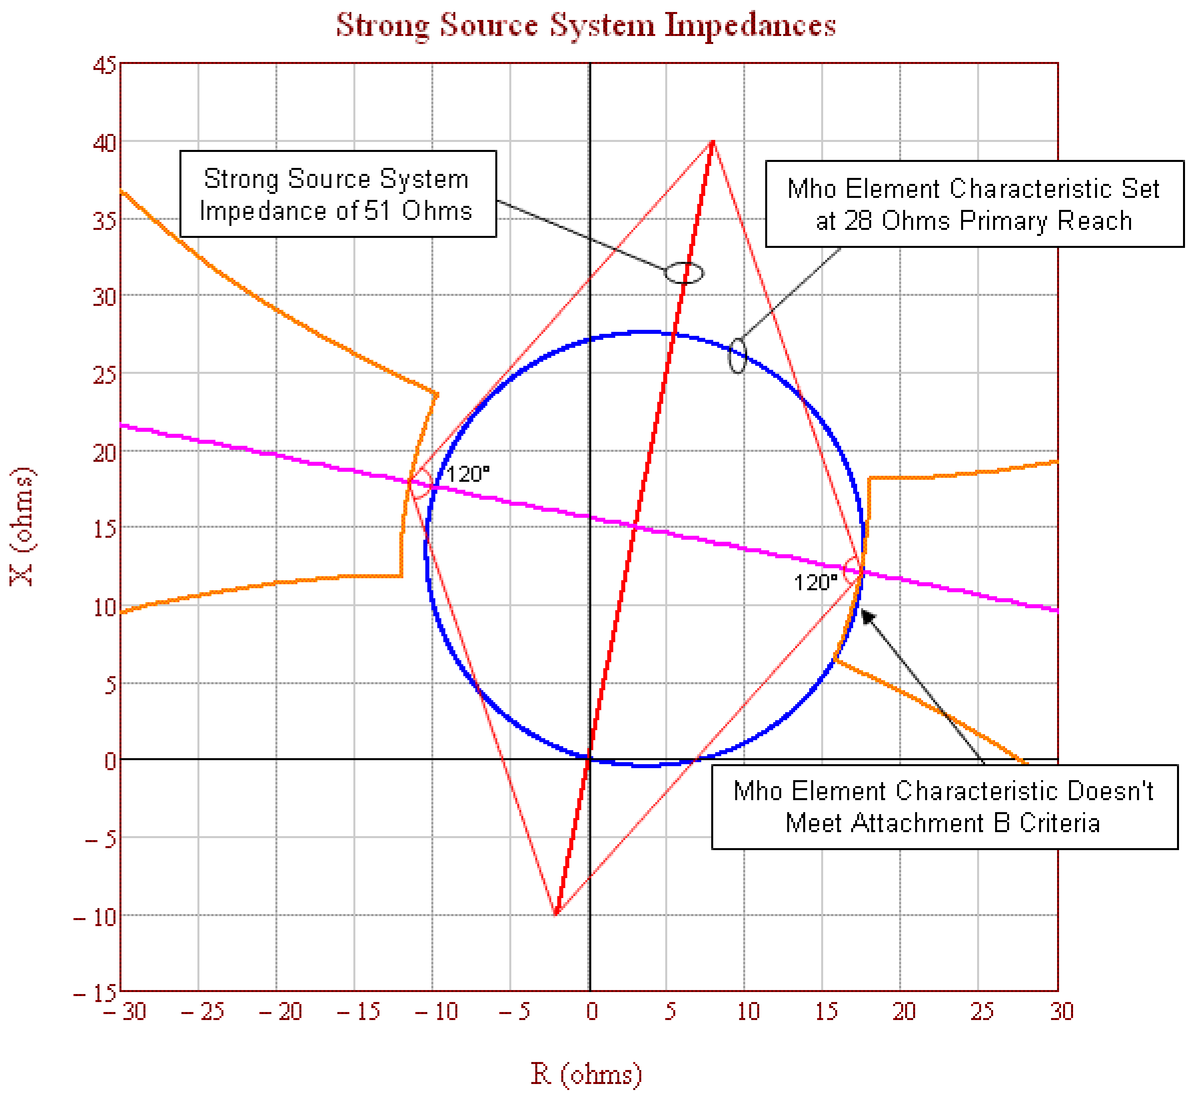


Figure 8: A strong-source system with a line impedance of Z_L = 20.4 ohms (i.e., the thicker red line). This mho element characteristic (i.e., the blue circle) does not meet the PRC-026-2 – Attachment B, Criterion A because it is not completely contained within the unstable power swing region (i.e., the orange characteristic).

Figure 8 above represents a heavily-loaded system with all generation in service and all transmission BES Elements in their normal operating state. The mho element characteristic (set at 137% of Z_L) extends into the unstable power swing region (i.e., the orange characteristic). Using the strongest source system is more conservative because it shrinks the unstable power swing region, bringing it closer to the mho element characteristic. This figure also graphically represents the effect of a system strengthening over time and this is the reason for re-evaluation if the relay has not been evaluated in the last five calendar years. Figure 9 below depicts a relay that meets the PRC-026-2 – Attachment B, Criterion A. Figure 8 depicts the same relay with the same setting five years later, where each source has strengthened by about 10% and now the same mho element characteristic does not meet Criterion A.

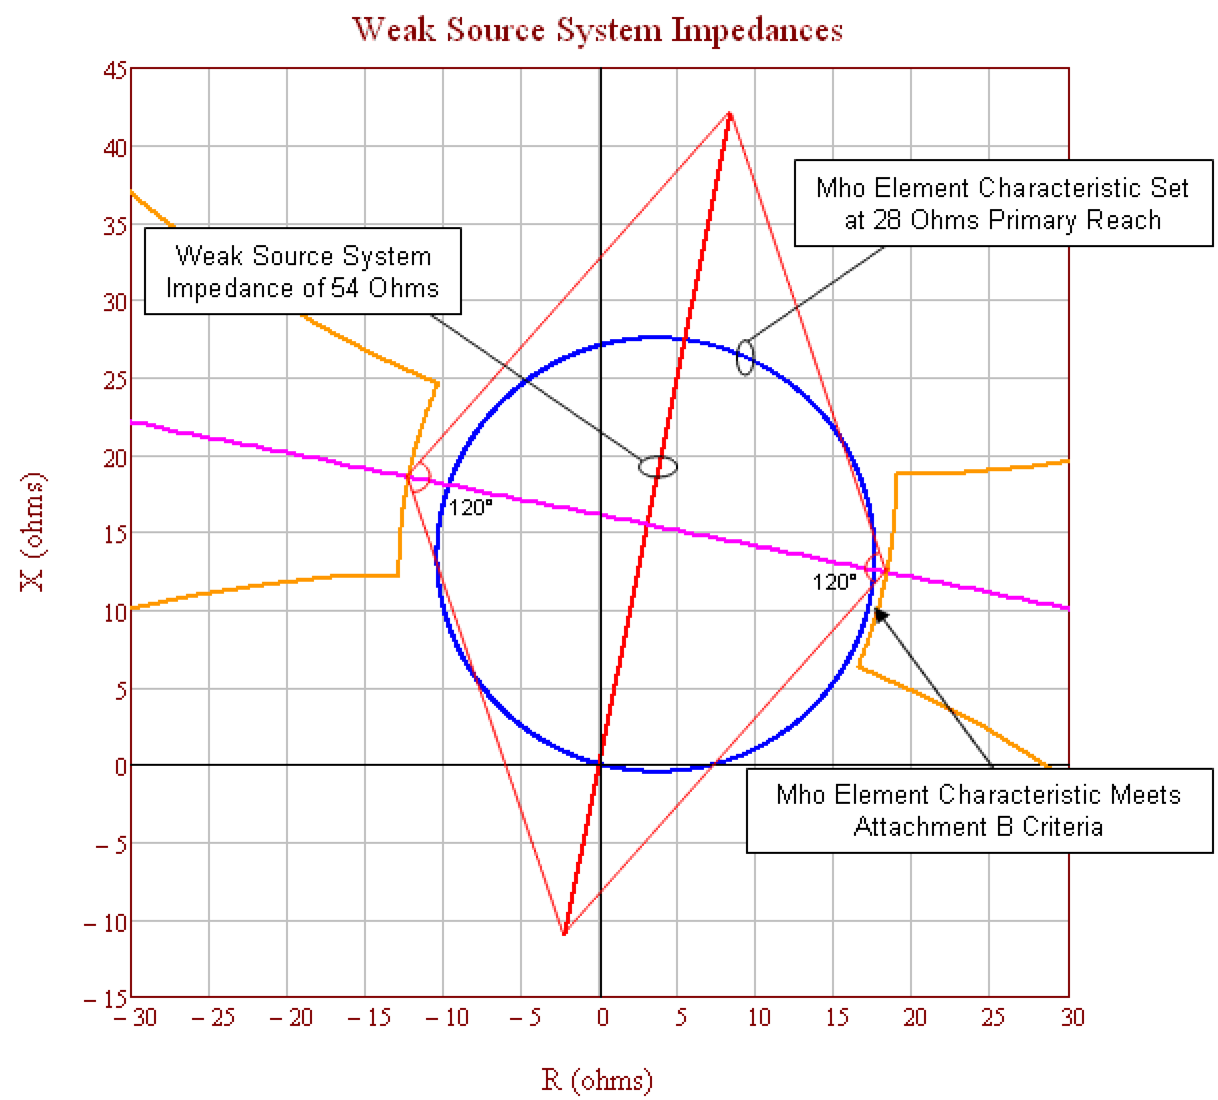

Figure 9: A weak-source system with a line impedance of Z_L = 20.4 ohms (i.e., the thicker red line). This mho element characteristic (i.e., the blue circle) meets the PRC-026-2 – Attachment B, Criterion A because it is completely contained within the unstable power swing region (i.e., the orange characteristic).

Figure 9 above represents a lightly-loaded system, using a minimum generation profile. The mho element characteristic (set at 137% of Z_L) does not extend into the unstable power swing region (i.e., the orange characteristic). Using a weaker source system expands the unstable power swing region away from the mho element characteristic.

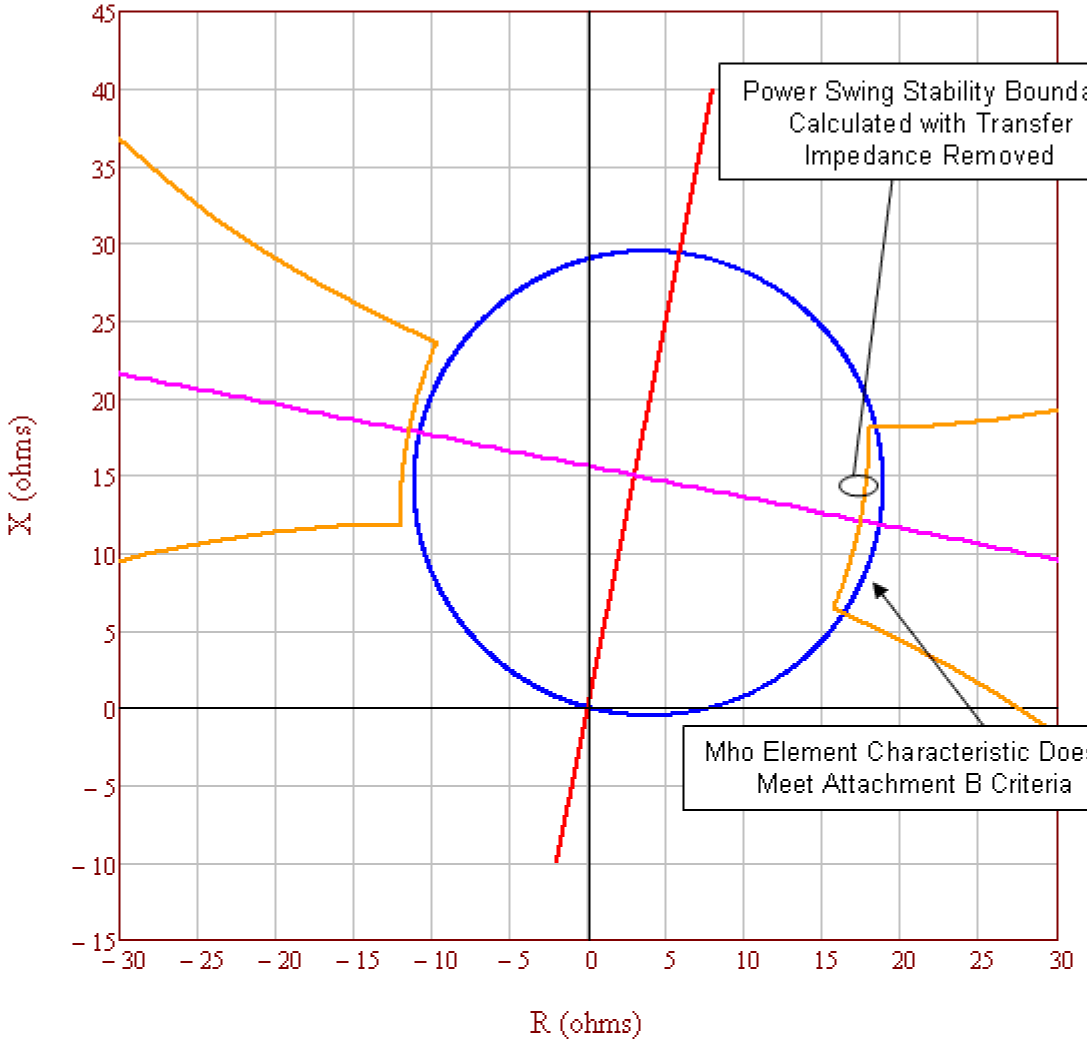

Figure 10: This is an example of an unstable power swing region (i.e., the orange characteristic) with the parallel transfer impedance removed. This relay mho element characteristic (i.e., the blue circle) does not meet PRC-026-2 – Attachment B, Criterion A because it is not completely contained within the unstable power swing region.

Table 8: Example Calculation (Parallel Transfer Impedance Removed)	
Calculations for the point at 120 degrees with equal source impedances. The total system current equals the line current. See Figure 10.	
Eq. (54)	$E_S = \frac{V_{LL}\angle 120°}{\sqrt{3}}$
	$E_S = \frac{230{,}000\angle 120°\ V}{\sqrt{3}}$
	$E_S = 132{,}791\angle 120°\ V$

Table 8: Example Calculation (Parallel Transfer Impedance Removed)			
Eq. (55)	$E_R = \frac{V_{LL}\angle 0°}{\sqrt{3}}$		
	$E_R = \frac{230{,}000\angle 0°\ V}{\sqrt{3}}$		
	$E_R = 132{,}791\angle 0°\ V$		
Given impedance data.			
Given:	$Z_S = 2 + j10\ \Omega$	$Z_L = 4 + j20\ \Omega$	$Z_R = 4 + j20\ \Omega$
Given:	$Z_{TR} = Z_L \times 10^{10}\ \Omega$		
Total impedance between the generators.			
Eq. (56)	$Z_{total} = \frac{(Z_L \times Z_{TR})}{(Z_L + Z_{TR})}$		
	$Z_{total} = \frac{\left((4 + j20)\ \Omega \times (4 + j20) \times 10^{10}\ \Omega\right)}{\left((4 + j20)\ \Omega + (4 + j20) \times 10^{10}\ \Omega\right)}$		
	$Z_{total} = 4 + j20\ \Omega$		
Total system impedance.			
Eq. (57)	$Z_{sys} = Z_S + Z_{total} + Z_R$		
	$Z_{sys} = (2 + j10)\ \Omega + (4 + j20)\ \Omega + (4 + j20)\ \Omega$		
	$Z_{sys} = 10 + j50\ \Omega$		
Total system current from sending-end source.			
Eq. (58)	$I_{sys} = \frac{E_S - E_R}{Z_{sys}}$		
	$I_{sys} = \frac{132{,}791\angle 120°\ V - 132{,}791\angle 0°\ V}{10 + j50\ \Omega}$		
	$I_{sys} = 4{,}511\angle 71.3°\ A$		
The current, as measured by the relay on Z_L (Figure 3), is only the current flowing through that line as determined by using the current divider equation.			
Eq. (59)	$I_L = I_{sys} \times \frac{Z_{TR}}{Z_L + Z_{TR}}$		
	$I_L = 4{,}511\angle 71.3°\ A \times \frac{(4 + j20) \times 10^{10}\ \Omega}{(4 + j20)\ \Omega + (4 + j20) \times 10^{10}\ \Omega}$		
	$I_L = 4{,}511\angle 71.3°\ A$		

Table 8: Example Calculation (Parallel Transfer Impedance Removed)	
The voltage, as measured by the relay on Z_L (Figure 3), is the voltage drop from the sending-end source through the sending-end source impedance.	
Eq. (60)	$V_S = E_S - \left(Z_S \times I_{sys}\right)$
	$V_S = 132{,}791\angle 120°\ V - [(2 + j10\ \Omega) \times 4{,}511\angle 71.3°\ A]$
	$V_S = 95{,}757\angle 106.1°\ V$
The impedance seen by the relay on Z_L.	
Eq. (61)	$Z_{L-Relay} = \frac{V_S}{I_L}$
	$Z_{L-Relay} = \frac{95{,}757\angle 106.1°\ V}{4{,}511\angle 71.3°\ A}$
	$Z_{L-Relay} = 17.434 + j12.113\ \Omega$

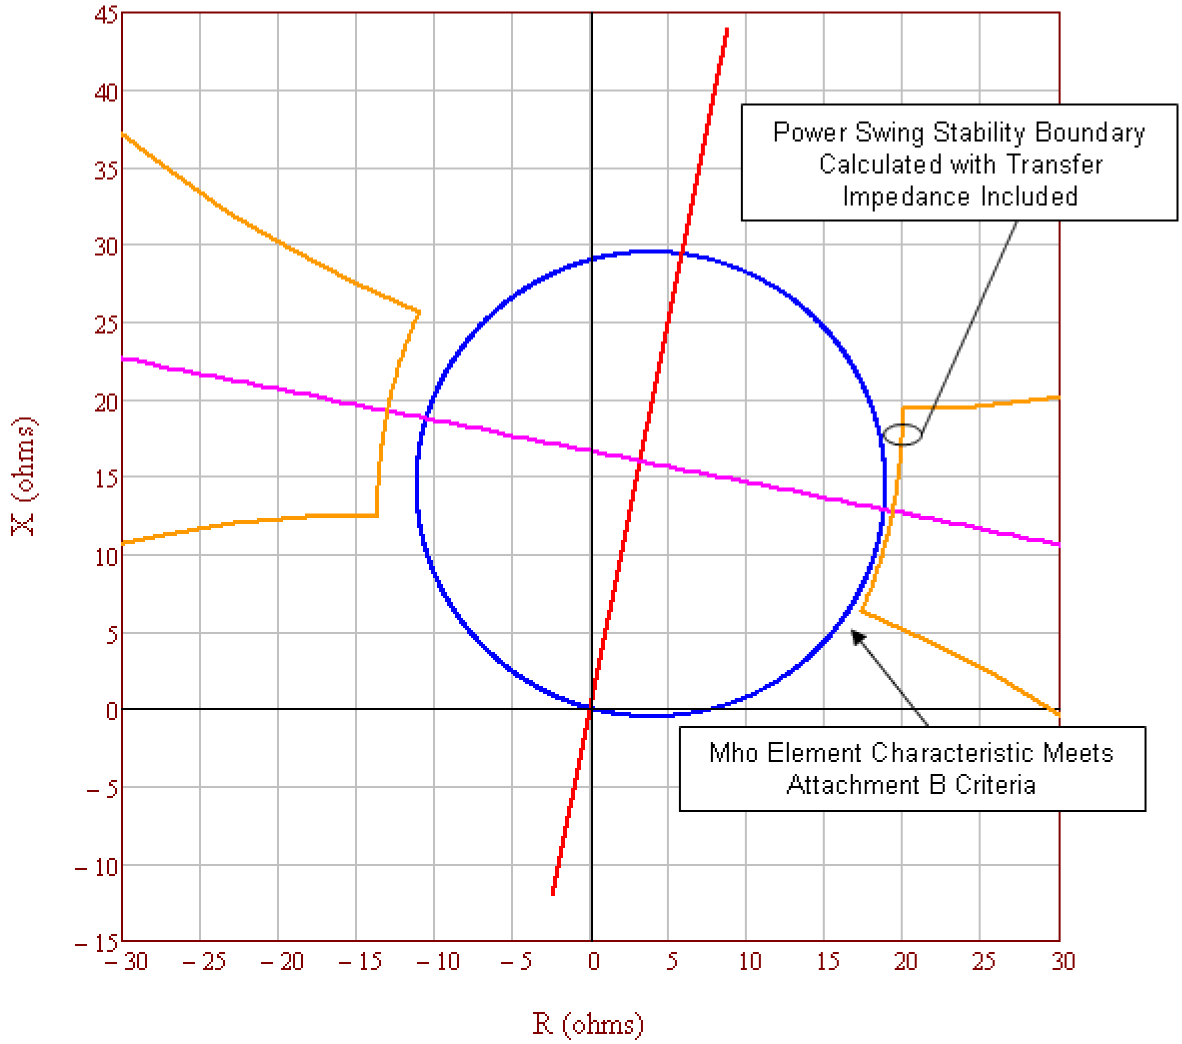

Figure 11: This is an example of an unstable power swing region (i.e., the orange characteristic) with the parallel transfer impedance included causing the mho element characteristic (i.e., the blue circle) to appear to meet the PRC-026-2 – Attachment B, Criterion A because it is completely contained within the unstable power swing region. Including the parallel transfer impedance in the calculation is not allowed by the PRC-026-2 – Attachment B, Criterion A.

In Figure 11 above, the parallel transfer impedance is 5 times the line impedance. The unstable power swing region has expanded out beyond the mho element characteristic due to the infeed effect from the parallel current through the parallel transfer impedance, thus allowing the mho element characteristic to appear to meet the PRC-026-2 – Attachment B, Criterion A. Including the parallel transfer impedance in the calculation is not allowed by the PRC-026-2 – Attachment B, Criterion A.

Table 9: Example Calculation (Parallel Transfer Impedance Included)			
Calculations for the point at 120 degrees with equal source impedances. The total system current does not equal the line current. See Figure 11.			
Eq. (62)	$E_S = \frac{V_{LL}\angle 120°}{\sqrt{3}}$		
	$E_S = \frac{230{,}000\angle 120°\ V}{\sqrt{3}}$		
	$E_S = 132{,}791\angle 120°\ V$		
Eq. (63)	$E_R = \frac{V_{LL}\angle 0°}{\sqrt{3}}$		
	$E_R = \frac{230{,}000\angle 0°\ V}{\sqrt{3}}$		
	$E_R = 132{,}791\angle 0°\ V$		
Given impedance data.			
Given:	$Z_S = 2 + j10\ \Omega$	$Z_L = 4 + j20\ \Omega$	$Z_R = 4 + j20\ \Omega$
Given:	$Z_{TR} = Z_L \times 5$		
	$Z_{TR} = (4 + j20)\ \Omega \times 5$		
	$Z_{TR} = 20 + j100\ \Omega$		
Total impedance between the generators.			
Eq. (64)	$Z_{total} = \frac{(Z_L \times Z_{TR})}{(Z_L + Z_{TR})}$		
	$Z_{total} = \frac{(4 + j20)\ \Omega \times (20 + j100)\ \Omega}{(4 + j20)\ \Omega + (20 + j100)\ \Omega}$		
	$Z_{total} = 3.333 + j16.667\ \Omega$		
Total system impedance.			
Eq. (65)	$Z_{sys} = Z_S + Z_{total} + Z_R$		
	$Z_{sys} = (2 + j10)\ \Omega + (3.333 + j16.667)\ \Omega + (4 + j20)\ \Omega$		
	$Z_{sys} = 9.333 + j46.667\ \Omega$		
Total system current from sending-end source.			
Eq. (66)	$I_{sys} = \frac{E_S - E_R}{Z_{sys}}$		
	$I_{sys} = \frac{132{,}791\angle 120°\ V - 132{,}791\angle 0°\ V}{9.333 + j46.667\ \Omega}$		

Table 9: Example Calculation (Parallel Transfer Impedance Included)	
	$I_{sys} = 4{,}833\angle 71.3°\ A$
The current, as measured by the relay on Z_L (Figure 3), is only the current flowing through that line as determined by using the current divider equation.	
Eq. (67)	$I_L = I_{sys} \times \frac{Z_{TR}}{Z_L + Z_{TR}}$
	$I_L = 4{,}833\angle 71.3°\ A \times \frac{(20 + j100)\ \Omega}{(4 + j20)\ \Omega + (20 + j100)\ \Omega}$
	$I_L = 4{,}027.4\angle 71.3°\ A$
The voltage, as measured by the relay on Z_L (Figure 3), is the voltage drop from the sending-end source through the sending-end source impedance.	
Eq. (68)	$V_S = E_S - \left(Z_S \times I_{sys}\right)$
	$V_S = 132{,}791\angle 120°\ V - [(2 + j10\ \Omega) \times 4{,}833\angle 71.3°\ A]$
	$V_S = 93{,}417\angle 104.7°\ V$
The impedance seen by the relay on Z_L.	
Eq. (69)	$Z_{L-Relay} = \frac{V_S}{I_L}$
	$Z_{L-Relay} = \frac{93{,}417\angle 104.7°\ V}{4{,}027\angle 71.3°\ A}$
	$Z_{L-Relay} = 19.366 + j12.767\ \Omega$

Table 10: Percent Increase of a Lens Due To Parallel Transfer Impedance.	
The following demonstrates the percent size increase of the lens characteristic for Z_{TR} in multiples of Z_L with the parallel transfer impedance included.	
Z_{TR} in multiples of Z_L	Percent increase of lens with equal EMF sources (Infinite source as reference)
Infinite	N/A
1000	0.05%
100	0.46%
10	4.63%
5	9.27%
2	23.26%
1	46.76%
0.5	94.14%
0.25	189.56%

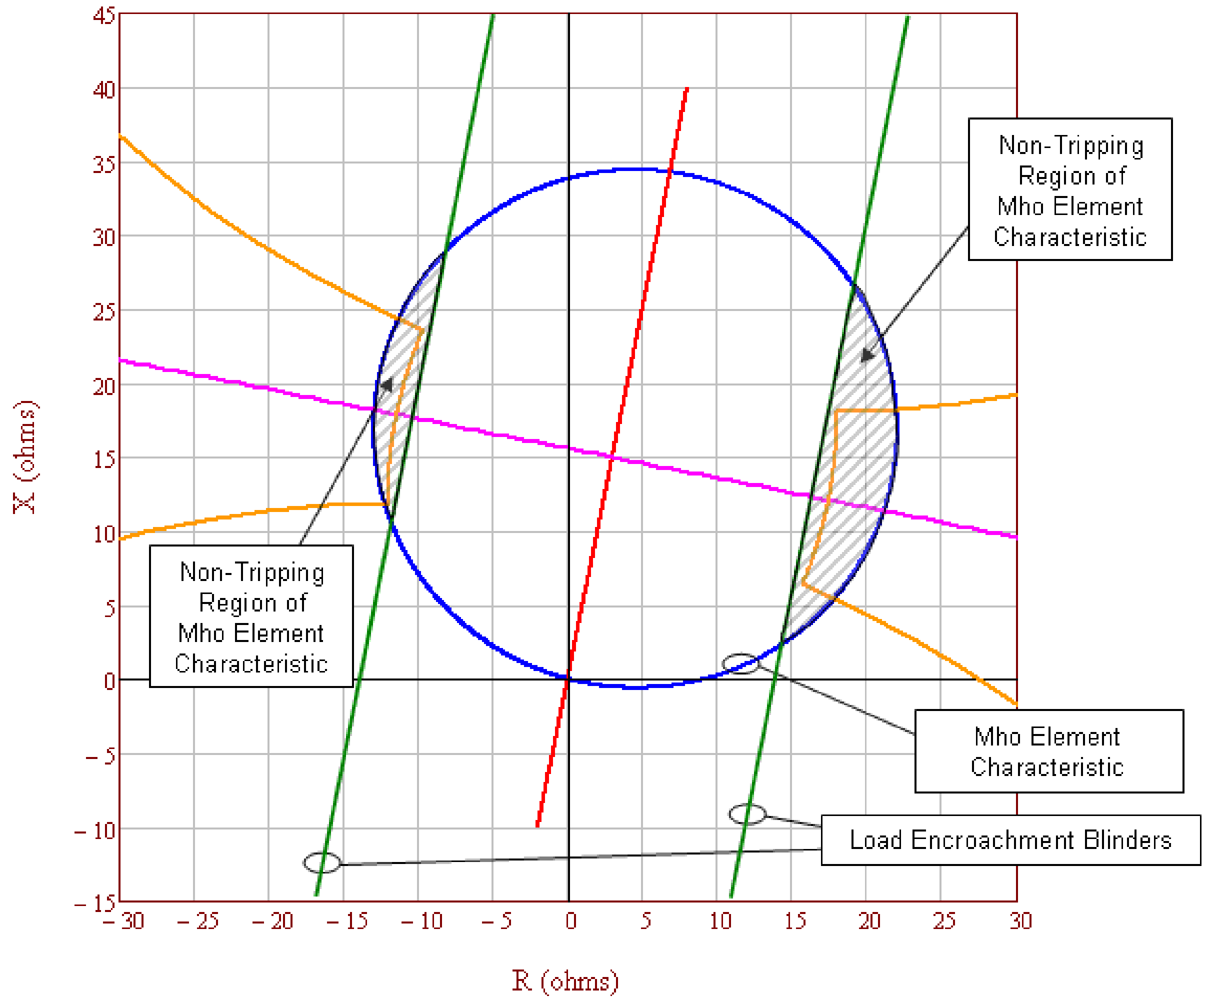

Figure 12: The tripping portion of the mho element characteristic (i.e., the blue circle) not blocked by load encroachment (i.e., the parallel green lines) is completely contained within the unstable power swing region (i.e., the orange characteristic). Therefore, the mho element characteristic meets the PRC-026-2– Attachment B, Criterion A.

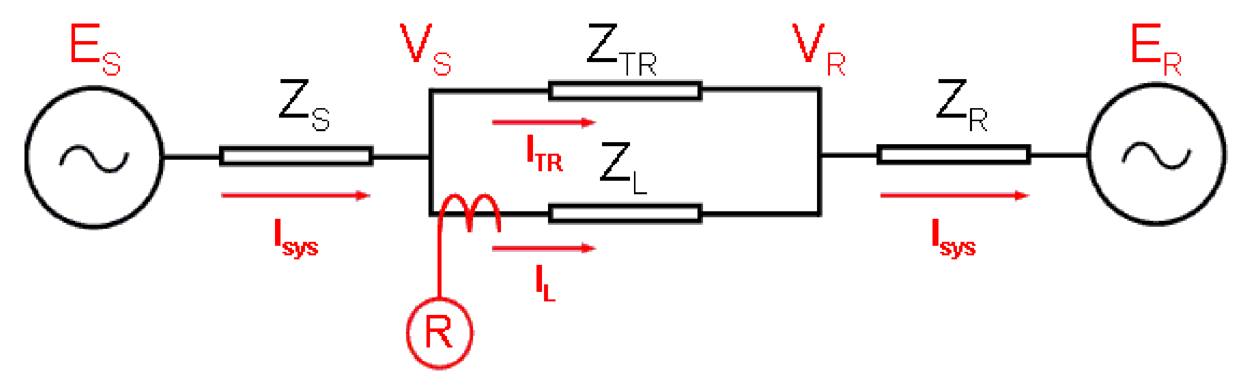

Figure 13: The infeed diagram shows the impedance in front of the relay R with the parallel transfer impedance included. As the parallel transfer impedance approaches infinity, the impedances seen by the relay R in the forward direction becomes $Z_L + Z_R$.

Table 11: Calculations (System Apparent Impedance in the forward direction)

The following equations are provided for calculating the apparent impedance back to the E_R source voltage as seen by relay R. Infeed equations from V_S to source E_R where $E_R = 0$. See Figure 13.

Eq. (70)	$I_L = \dfrac{V_S - V_R}{Z_L}$			
Eq. (71)	$I_{sys} = \dfrac{V_R - E_R}{Z_R}$			
Eq. (72)	$I_{sys} = I_L + I_{TR}$			
Eq. (73)	$I_{sys} = \dfrac{V_R}{Z_R}$	Since $E_R = 0$	Rearranged:	$V_R = I_{sys} \times Z_R$
Eq. (74)	$I_L = \dfrac{V_S - I_{sys} \times Z_R}{Z_L}$			
Eq. (75)	$I_L = \dfrac{V_S - [(I_L + I_{TR}) \times Z_R]}{Z_L}$			
Eq. (76)	$V_S = (I_L \times Z_L) + (I_L \times Z_R) + (I_{TR} \times Z_R)$			
Eq. (77)	$Z_{Relay} = \dfrac{V_S}{I_L} = Z_L + Z_R + \dfrac{I_{TR} \times Z_R}{I_L} = Z_L + Z_R \times \left(1 + \dfrac{I_{TR}}{I_L}\right)$			
Eq. (78)	$I_{TR} = I_{sys} \times \dfrac{Z_L}{Z_L + Z_{TR}}$			
Eq. (79)	$I_L = I_{sys} \times \dfrac{Z_{TR}}{Z_L + Z_{TR}}$			

Table 11: Calculations (System Apparent Impedance in the forward direction)	
Eq. (80)	$\frac{I_{TR}}{I_L} = \frac{Z_L}{Z_{TR}}$
The infeed equations shows the impedance in front of the relay R (Figure 13) with the parallel transfer impedance included. As the parallel transfer impedance approaches infinity, the impedances seen by the relay R in the forward direction becomes $Z_L + Z_R$.	
Eq. (81)	$Z_{Relay} = Z_L + Z_R \times \left(1 + \frac{Z_L}{Z_{TR}}\right)$
