FirstEnergy	1. In R1.4 it should be clear that the unit is achieving the 5% capacity factor for the first time over the last three calendar years.2. R9 states that the Generator Operator shall make documentation demonstrating the excitation system model's response is appropriate available for inspection and technical review 'to' the RC, TOP, and PC. The term "make available" is vague and should be revised to provide more specifics as to how this information is to be made available for inspection and technical review 'by' the RC, TOP, and PC.3. The term "Capacity Factor" is not NERC defined and is shown as capitalized in the standard. We suggest the team develop either a standard-specific or NERC Glossary definition. The following is a suggestion: "Capacity Factor (expressed as a percent) - The net actual energy generation (MW-hours) divided by the product of the period (hours) and the net maximum nameplate rating (MW)."4. Sec. 4 Applicability - We do not agree with the criteria proposed for the Eastern Interconnection and believe it may leave out some important or critical units. Also, it may be better to just have one criteria throughout the interconnections. We recommend the SDT consider using the NERC Registry Criteria for all units based on plant aggregate of 75 MVA or greater and unit size of 20 MVA or greater.5. Per Question 10 above, why wouldn't the Regional Entity procedures or guidelines be allowable for compliance after the first 5 years? [Note: It is assumed that the SDT intended to say "first" 5 years, not "last" five years in the description after Box 3 of that question]
Response: Thank you for your comments. Based on industry comments, the second draft of the standard has been modified to make clear in the Applicability section (including related footnote) that only the capacity factor three year average must be checked once every 10 years . Note that there are other mechanisms in the standard that could result in low capacity factor units being verified (refer to Requirement R6, reference Requirement R2 in the revised standard). Regarding the term "make …available", the SDT has reworded the language, now contained in Requirement R2 that does away with the term "make…available". The SDT agrees that the term "capacity factor" was incorrectly capitalized in the draft standard and has been corrected in the second draft. The SDT did consider using the NERC Registry Criteria, but the SDT recognized that the excitation system models and model data are already collected through the processes identified in standards MOD-012 and MOD-013 and, with few exceptions, already establish a quality dynamics database. Therefore, based in part on recent entity experience with verifying excitation system models, the SDT is proposing to require verification of excitation systems associated with 80% or greater of the connected MVA per Interconnection. The vast majority of industry responders agree with t this approach (reference Question 8). Also note that the second draft of the standard includes a process for selecting additional units for excitation control system model verification. Regarding the implementation plan, the SDT has clarified the language for models already verified by Regional Procedures	

Organization	Question 13 Comments
through year 5.	
Entergy Fossil Operations	In Requirement R5 in the event that a model is determined to be unusable and is returned to the Generator Owner for further action the transmission operator should be required to also provide the steps he has taken to exercise due diligence in the integration of the exciter system model into the over all model. This should take the form of review of data inserted against data provided, model name reviewed against model provided, etc.The transmission operator should also provide the Generator operator witih text copy of the actual exciter and generator portion of the overall model.
Response: Thank you for your comments. The SDT believes that both parties have a vested interest in resolving issues leading to unusable models. As such, the SDT does not believe that specific details regarding the exchange of information during entity collaboration needs to be specified in the Requirements.	
IRC Standards Review Committee	We offer the following comments: a. The proposed standard lacks clarity needed for implementation as a mandatory standard. Specifically, there are different views in the industry as to what exactly is a model data sheet. Is it the block diagram of the excitation system's control system and parameters, or is it the simulation software's model sheet such as, for example, a vendor's data sheet for a specific type of exciters which it is capable of modeling in its simulation software, say, IEEEST, EXST1, or whatever name it may be, etc. We suggest clearer language be used to more specifically describe what a model data sheet means. Also, verification is subject to interpretation: is it a comparison of the expected input/output response of the excitation system versus actual response, or the expected performance of the generators when a computer simulation is conducted? b. A number of points/bullets in several requirements need to be performed to meet the intent of the main requirements, even though some of them ar e mutually exclusive (i.e. either/or). As such, they should be labeled sub-requirements. These include:- R1: Points number 1 and 2- R4: Points number 1 to 5- R11: All bullets- R10: Both bullets- R12: The last 2 bulletsc. R5: The condition that "if the excitation system model is usable" needs further elaboration. Evidence showing either Conditions (1) or (2) may suggest that either the model incorrectly reflects the excitation system or the excitation system itself, despite being modeled correctly, gives rise to the observed condition. The word "usable" thus needs to be expanded to more properly indicate whether the data is not usable or the excitation system is no useable. d. R6: The above comment on R5 also applies to R6.
Response: Thank you for your comments. The SDT has modified the language (reference Requirement R1 in the revised standard) to contain the phrase "software manufacturer's dynamic excitation control system or plant volt/var control function system model library block diagrams and/or data sheets". Verification specified in Requirement R8 (reference Requirement R2 of the revised standard), is achieved when it is shown that the excitation system model's response (i.e., predicted response utilizing the model in a dynamic simulation) matches the recorded response for a voltage excursion at the generator terminals. The structure of Requirements in the first draft was envisioned to make it easier to construct Measures, Violation Severity Levels etc.. Requirement number and bullet lists conform with standard development protocol. Specifically, a number list indicates all requirement list actions must be performed by the entity whereas the bullet list indicates the entity selects which of the requirement list actions is appropriate to perform. Action for determining if the model is useable or not should not be confused with model verification for ensuring the model response matches the actual equipment response. A model is considered "useable" if it does not cause angle drift during a no-disturbance simulation or does not causes poor or undamped oscillations in a dynamic simulation of a mild system fault disturbance. Requirement R5 (reference Requirement R6 in the revised standard) does not reference the ability of the model to accurately predict the expected actual response of the equipment.	

Organization	Question 13 Comments
FEUS	The excitation models as currently required are comprised of testing and data collection to determine the variables for the model parameters. How does additional testing, over and above what was done to construct the model, accomplish anything and how would it be any different than original testing to complete the model?
Response: Thank you for your comments. The SDT assumes your comments refer to the periodicity for verification. The SDT believes that a 10 year timeframe is a reasonable re-verification requirement. This timeframe is supported by an overwhelming majority of industry comments.	
Exelon Corporation	The proposed standard and comment form presuppose the generator owners have the expertise necessary to model and simulate the excitiation systems on the units they own. They do not in most cases. Software requirements need to be considered. Not all transmission planners use the same software for dynamic simulations. A single generation owner may have units in multiple regions involving different transmission planners and would have to provide models for more than one simulation program. The standard needs to allow the Transmission Planner/Operator/Owner to provide expertise to the generator owner. The comment form and the WebEx meetings are more specific regarding software simulations than what is specified in the draft standard. The software simulations should be specified in more detail in the standard.
Response: Thank you for your comments. The SDT agrees that a cooperative effort is required among NERC functional model entities in order to develop a robust excitation system model. As mandated by Reliability Standard process, only one entity is assigned responsibility for excitation system model verification. The SDT believes it has incorporated into the draft standard all necessary interactions with other functional model entities required for ensuring model verification success. The Generator Owner is responsible for model verification. It is anticipated that the Generator Owner could delegate model verification activities to other entities by contractual agreement as appropriate. The draft standard does not require the Generator entity to perform dynamic simulations to determine Bulk Electric System limits. The generator entity is responsible for ensuring that the excitation system model response matches the response from a recorded voltage excursion. This can be accomplished through software that is much simpler than full dynamic simulation software utilized by Transmission Planners for assessing BES limits. The standard cannot list specific commercial software options.	
Constellation Power Generation & Constellation Nuclear	The standard needs to clarify what verification of excitation system model entails; does this involve testing of excitation parameters? Online or offline. On line testing of excitation parameters will present an unacceptable tripping risk to nuclear units.Recommend nuclear units be exempt from excitation system model verification if it involves online testing.
Response: Thank you for your comments. Online testing is not required. The SDT believes it is best to leave the technical details of model verification to the experts. The draft standard simply requires demonstration that a recorded excitation control system response matches the model predicted response. The recorded excitation control system response could be obtained by ambient monitoring or an open circuit step in voltage test, neither of which is an online test. In part because online testing is not required, the SDT does not foresee a reliability need to exempt nuclear units from model verification.	
Southern Company	Paragraph 4.1.1.1 3rd Section: The plant criteria should be assessed on a switchyard basis instead of all inclusive. For example: 5 unit station with 4 units > 100 MVA each connected at 500 kV and one unit <50 MVA connected at 115 kV. Why do I need to do the small unit? Paragraph R1.2: See discussion in question 3 above regarding the criterion of 'sited at the same physical location and MVA ratings.' We see

Organization	Question 13 Comments
	no need for these restrictions. Paragraph R7: A third option is to do more testing/technical assessment with a longer time allowed (>90 days) should be included. Paragraph R8: The last part of this requirement is unclear: 'within 90 calender days. verification.' Change the wording from 90 calendar days of competion to 90 calendar days after completion. The requirement will than read, " The Generator Operator shall provide to the Transmission Planner documentation demonstrating that the excitation's system model's response matches the recorded response for a voltage excursion at the generator from either a staged test or a measured system disturbance (i.e., an ambient event) within 90 calendar days after completion of the excitation system model verification ."Paragraph R12: The second and third bullets should be combined to cover any DCS/AVR inter-actions.
Response: Thank you for your comments. The concern expressed in your first comment has been addressed in the 2nd draft of the standard by modifying the language in the Applicability section to make it clear that the thresholds identified are for units interconnected to the same transmission voltage level bus. For your second comment, please reference Question 3. Regarding your third comment, the second draft of the standard allows for the verified model and documentation to be provided to the Transmission Planner within one year from the date that the recorded voltage excursion used for model verification was collected (reference Requirement R2 in the draft standard, and the Periodicity Attachment). The SDT agrees with recommended modifications to Requirement R8 (reference Requirement R2, Part 2.1 in the revised standard) language and has made the modification. Regarding the last comment, the two DCS activities referenced could be combined however the SDT thought maintaining these as separate activities improved clarity.	
E.ON U.S.	E.ON U.S. believes that the staggered implementation time tables for the various standard requirements could needlessly complicate initial compliance efforts. E ON U.S. requests that the SDT review these deadlines and standardize using the most lenient implementation period set forth in the second draft. E.ON U.S. recommends that the standard explicitly state in the purpose statement that voltage regulators be included in excitation system models. Voltage regulators are explicitly mentioned in R4.3 and R12.E.ON U.S. recommends that study data inputs and results only be made publicly available pursuant to Requirement 2. Depending on arrangements with vendors, actual model configuration may be proprietary and require confidential disclosure arrangements
Response: Thank you for your comments. Not requiring excitation control system model verification for 10 years is not considered acceptable by the SDT. Note that Requirement R2 (reference Requirement R2, Part 2.1 in the revised standard) indicates only models on the list of acceptable excitation control system models can be utilized and it is not expected that any of these acceptable models will be confidential or proprietary given this would unduly disrupt the dynamic data base process which is necessary for Interconnection wide security analysis. After reviewing IEEE 421.1, the SDT believes that the term “excitation control system model” is more appropriate to use in the standard then “excitation system model.” This is because the term “excitation control system model” references the entire closed loop system including the synchronous machine. The SDT has adopted this language in the second draft of the standard; which also includes excitation system limiters that are part of the exciter.	
Consumers Energy Company	It is our opinion that the SDT made a fundamental error in assigning the modeling to an entity that doesn't need the results of the model. To correct this error, this Standard needs very significant revision. As it stands, the Draft Standard imposes irrational requirements upon the Generator Operator.
Response: Thank you for your comments. The SDT understands that no matter who is assigned responsibility in the proposed continent-wide standard, it would potentially change the current business model of the functional entity. The majority of the SDT believes that a generation entity should have both final excitation system model responsibility and authority, Based on the majority of industry comments and guidance from the FMWG, the second draft of the standard assigns responsibility to	

Organization	Question 13 Comments
the Generator Owner. Generator Owners have access to the equipment, along with access to the equipment's Original Equipment Manufacturer for assistance with technical issues. Historically, the Transmission Planner and Generator Owner entities used to work for the same company, but in today's functional model environment, Transmission Planners could easily work for a different company than the generation entity. As such, the stated access advantages for the generation entity do not transfer to the Transmission Planner. Note that existing business practices that utilize Transmission Planners can still exist; the only difference is that the Generator Owner would be ultimately responsible for the excitation system model verification from a compliance perspective. Also, the SDT is proposing an Implementation Plan to allow the Generator Owner time to develop in-house expertise to perform model verification if they do not desire to hire consultants.	
Wisconsin Public Service	At plants with 200MW or higher capacity, it is unreasonable to assume multiple units of 20MW to malfunction simultaneously. Therefore, applying the standard to each unit of >/= 20MW if these are at the same contiguous plant of combined capacity of 200MW is placing unreasonable burden on owners of small generators. One must reason that, in the contest of the whole eastern interconnect, comprising a total capacity of 600,000MVA and higher, individual generators of less than 100MVA would not impact the system to any significant degree except for very localized regions.
Response: Thank you for your comments. Please note that the Applicability section is based on MVA instead of MW. The MVA threshold specified are less stringent than the NERC Compliance Registry and appears to represent an appropriate threshold based on industry responses received.	
American Electric Power	(1) The added expense to fulfill the requirements of this standard where such model verification is not generally being done could be high. Since this is a new imposition on the industry in that required excitation model verification has never before been imposed in many areas, this leads to the question of cost versus reliability benefit of what is being proposed. We request that the SDT please comment more on the cost vs. reliability benefits. (2) With respect to R2, we suggest that it be revised and expanded as follows: "The Transmission Planner shall provide the Generator Operator a set of model data sheets for the acceptable excitation system models (models cannot be confidential or proprietary) for use in dynamic simulation software, with each data sheet including the excitation system model block diagram structure and data requirements and a system dynamics model, within 30 calendar days of a request from the Generator Operator." (3) With respect to R6, revise and expand the last sentence as follows: "If the TP determines the excitation system model is not useable, the TP shall provide the Generator Operator with a description of the problem and any relevant details, including the system dynamics case used in the evaluation." (4) With respect to last sentence in R9, revise and expand as follows, "?. after the receipt of a request that includes the measured data following a system disturbance and a suitable system dynamics case associated with the system disturbance.
Response: Thank you for your comments. Note that excitation control system model verification is part of the original NERC Planning Standards. Also, a major conclusion of the standard MOD-026 field testing performed for Phase III-IV is that verification of excitation models did provide a reliability benefit. Since the software used by a Generator Owner to perform model verification activities does not have to be a full dynamic simulation software package, the SDT does not see a need to add additional requirements for the Transmission Planner to provide system dynamic cases to the Generator Owner. However, if such cases are needed to resolve a model verification issues, then it would be beneficial and in the best interest of the Transmission Planner to provide dynamic cases to the Generator Owner.	

Organization	Question 13 Comments
Arizona Public Service Co.	The standard appears to be too unnecessary complicated. We have the following suggestion for simplification. 1)Requirements R1, R4, R11 and R12 are the only reliability related requirements and should be kept. 2)R8 is part of providing data and should be a part of R4 3)All other requirements are simply indicate process and do not belong in the standard. They should be part of a white paper on the subject or in an appendix.
Response: Thank you for your comments. The SDT combined several requirements in an effort to simplify the standard and improve clarity.	
Wisconsin Electric	Please consider the use of offline measurement of generator excitation response as a possible means to comply.
Response: Thank you for your comment. An open circuit step in voltage test, which is a test that is performed before the generator is synchronized to the transmission system, is acceptable. Also, note that the SDT drafted a Standard that concentrates on “stating what is required” but not “stating how to accomplish what is required”. Any technique that shows the excitation system model’s response matches the recorded response for a voltage excursion at the generator from either a staged test or a measured system disturbance (i.e., an ambient event) is acceptable.	
Manitoba Hydro	The MOD-026 Standard uses different terminiology in two different places. In requirement 4, the fourth bullet uses the term Reactive compensation and in Requirement 12, the fourth bullet uses impedance compensator. Either term is fine to use, but should be consistent throughout the standard.
Response: Thank you for your comments. The SDT believes it has revised the standard such that the use of the term “compensation” is appropriate where utilized. The SDT would appreciate your feedback verifying that this has been accomplished.	
Progress Energy, Inc.	Requirement 1 Item 1) should be clarified to state that "new equipment commissioning date" applies to modifications of existing units. Requirement numbering for R1, R4, R5, R7-12 needs to be revised to conform to proper format.
Response: Thank you for your comments. Formatting for the second draft of the standard has been modified significantly to minimize confusion. The periodicity requirements have been transferred into a separate Attachment to avoid confusion over verification timing requirements.	
Ameren	(1) Requirement 1 states that testing should occur "for new or existing units within 180 days of commerical operation". We believe the testing for the new units should be done before commerical operation. (2) In Requirement R2, the Transmission Planner would not necessarily have any idea which model would best fit the installed equipment. The only workable way to comply with this requirement is for the Transmission Planner to give the Generator Operator the data sheets for the entire library of available exciter models. The Generator Operator would then need to determine which of these models would provide the best fit for the excitation system equipment to be modeled. We believe that this requirement should recognize that deriving "acceptable" model

Organization	Question 13 Comments
	for a specific excitation system is a cooperative effort between manufacturer, GO/GOP, and TP. (3) While wind generators would generally fall below the unit size thresholds as specified in Requirement 4.1.1, it would be very helpful in conducting dynamic simulations involving wind generators if their dynamic representations would be fit into one of the standard library models. (4) There are several 90 day periods mentioned in the Requirements. It might be helpful to be more specific as to which 90 day interval is meant. For example, Requirement R8 should read something like "?within 90 days of completion of the excitation system model verification as specified in Rx." (5) This comment is in reference to MOD-026-1, R.12. We believe that Digital Control Systems do not effect excitation systems models. Therefore we suggest removing requirements associated with Digital Control Systems.

Response: Thank you for your comments. The SDT notes some areas have existing grid code that require excitation control system model verification before commercial operation occurs. The SDT recognizes transmission entities can adopt more stringent requirements. The SDT believes that the process described in Item 2 is desirable and expects involved entities to follow this process.

Regarding Item 3: The MVA thresholds in the Applicability section of the first posting of MOD-026 resulted in wind powered units not being subject to this standard because no single wind unit is rated greater than 20 MVA. However, there is an increasing number of wind farms with significantly larger aggregate MVA. As such, their impact on the reliability of the Bulk Electric System cannot be ignored – otherwise, a reliability gap would be created.

Therefore, based on your comments and other industry comments, the SDT discussed the possibility of requiring verification of dynamic models that represent the aggregate of numerous small units and any necessary auxiliary equipment as required due to the technology of the small units. This could include plant dynamic voltage control and reactive support of all the units and auxiliary equipment (such as individual WTG response, plant-wide volt/var controller response, and response from separate volt/var regulation devices contained in the plant, such as SVC/STATCOM/Synchronous Condenser) contained in any technology generation plant, including a wind farm (plant), that exceeds appropriate aggregate nameplate MVA threshold.

There are dynamic models that adequately replicate wind unit performance for some wind units today. However, there are many existing wind units for which there are no publicly available models supplied by the Original Equipment Manufacturer. Generic wind models (i.e., type I, II, III and IV) are in various stages of development. Also, there are ongoing efforts involving Regional Entities and manufactures to close any large gaps that may exist in current generic models. Given that there will be significant time between now and the time that this standard could be approved by FERC, it is expected that generic wind farm (plant) models will reach an appropriate state of maturity for establishing boundary conditions in Bulk System Studies. In order to mitigate the reliability gap, the Applicability section will be expanded in the second posting of the standard to include significant MVA percentage of all generation for all technologies.

Regarding the comment indicating that the 90 day periods referenced in the previous posting of the standard did not always clearly communicate schedule expectations, the SDT has moved required model verification periodicity information into a stand-alone Attachment attached to the standard for making it clear that model verification periodicity would occur at least every 10 years. The SDT has also ensured that other timing references in the second draft of the standard are clearly understood.

Finally, several SDT team members have observed that DCS changes can affect excitation system performance within the timing cycle of the excitation system model...

Organization	Question 13 Comments
AESO	The AESO agrees with the SRC ISO/RTO comments. We would also like to empahsize the importance of complete unit testing as noted in our response to Question 4.
Response: Thank you for your comments. The SDT was unable to identify the other comment mentioned in Question 4. Please refer to that comment to review the SDT response provided.	
Duke Energy	Section 4.1Should the standard be revised to include small units that are part of an aggregate 200 MW facility? For example : wind farms with many 1.5 MW turbines Recommend changing R5.1) to read The model initializes properly and a no-disturbance simulation contains no transients The second bullet of R7 allows an unusable model to not be corrected. Unless the point is that the unit would be out of compliance, this seems to negate requiring verification. Recommend the team to consider that all units that meet the applicability have usable models. For R12, rather than only listing the high level components, we recommend the team also note that other generator components such as a new excitation system power transformer (not a like-for-like changeout) can have an impact on aspects of the model.
Response: The MVA thresholds in the Applicability section of the first posting of MOD-026 resulted in wind powered units not being subject to this standard because no single wind unit is rated greater than 20 MVA. However, there is an increasing number of wind farms with significantly larger aggregate MVA. As such, their impact on the reliability of the Bulk Electric System cannot be ignored – otherwise, a reliability gap would be created. Therefore, based on your comments and other industry comments, the SDT discussed the possibility of requiring verification of dynamic models that represent the aggregate of numerous small units and any necessary auxiliary equipment as required due to the technology of the small units. This could include plant dynamic voltage control and reactive support of all the units and auxiliary equipment (such as individual WTG response, plant-wide volt/var controller response, and response from separate volt/var regulation devices contained in the plant, such as SVC/STATCOM/Synchronous Condenser) contained in any technology generation plant, including a wind farm (plant), that exceeds appropriate aggregate nameplate MVA threshold. There are dynamic models that adequately replicate wind unit performance for some wind units today. However, there are many existing wind units for which there are no publicly available models supplied by the Original Equipment Manufacturer. Generic wind models (i.e., type I, II, III and IV) are in various stages of development. Also, there are ongoing efforts involving Regional Entities and manufactures to close any large gaps that may exist in current generic models. Given that there will be significant time between now and the time that this standard could be approved by FERC, it is expected that generic wind farm (plant) models will reach an appropriate state of maturity for establishing boundary conditions in Bulk System Studies. In order to mitigate the reliability gap, the Applicability section will be expanded in the second posting of the standard to include significant MVA percentage of all generation for all technologies. The SDT agrees with the comment to add the phrase "model initializes properly" and has included this language in the second draft of the standard. Regarding Requirement R12 (reference Requirement R2 in the revised standard), the bullet point examples are not-inclusive (given the main requirement includes the phrase: "includes but are not limited to"). The SDT aimed to include examples likely to occur and while the example provided is valid, the SDT does not believe it is one of the most likely scenarios to occur.	

Organization	Question 13 Comments
Xcel Energy	Capacity Factor needs to be defined.
Response: Thank you for your comments. In the second draft standard, capacity factor is not capitalized and has been clarified in the Applicability section (also refer to the footnote).	
Independent Electricity System Operator	We offer the following comments: a. A number of points/bullets in several requirements need to be performed to meet the intent of the main requirements, even though some of them are mutually exclusive (i.e. either/or). As such, they should be labeled subrequirements. These include:- R1: Points number 1 and 2- R4: Points number 1 to 5- R11: All bullets- R10: Both bullets- R12: The last 2 bullets b. R5: The condition that "if the excitation system model is useable" needs further elaboration. Evidence showing either Conditions (1) or (2) may suggest that either the model incorrectly reflects the excitation system or the excitation system itself, despite being modeled correctly, gives rise to the observed condition. The word "useable" thus needs to be expanded to more properly indicate whether the data is not useable or the excitation system is not useable. c. R6: The above comment on R5 also applies to R6.
Response: Thank you for your comments. Regarding the organization recommendations provided, Requirement R1 details have been moved to a stand alone periodicity Attachment attached to the standard and the SDT significantly re-formatted the standard to reduce and simplify requirements so that entities will have a clear understanding of how to be compliant. The Violation Severity Levels will define treatment of these requirements for compliance. Additionally, there has been significant effort to streamline the draft standard. The SDT believes the new format is robust, fair, and will result in reasonable VRF and VSL determination. Regarding the use of the term "usability", the second draft of the standard identifies benchmarks which determine if the model is useable or not. As recommended by industry, the requirement that the model must initialize properly has been added to the standard. The SDT believes that the criteria defining model usability has been adequately specified.	
American Transmission Company	ATC disagrees with portions of Requirement 2 which stipulates that the TP shall provide the excitation system model block diagram (block diagram) structure and data requirements. Many manufactures currently make their block diagrams and data requirements available to the GO/GOP. In addition, IEEE Standard Definitions for Excitation System for Synchronous Machines allows a GO/GOP to identify the type of exciter and/or PSS installed on their units along with the corresponding block diagrams and data requirements. Recommend that the words following "dynamic simulation software." be deleted.
Response: Thank you for your comments. The SDT believes that it is critical for the Transmission Planner to provide the Generator Operator block diagram structures and data requirements that can be represented in the Transmission Planner dynamic simulation software package. Otherwise, the Generator Operator could perform verification with a model that would not run in the Transmission Planner dynamic simulation software package.	
US Bureau of Reclamation	We see a blurring of the requirements between Standards MOD-012-0-Dynamics Data for Transmission System Modeling and Simulation; MOD-013-0- RRO Dynamics Data Requirements and Reporting Procedures; and the draft of MOD-026-1 - Verification of Models and Data for Generator Excitation System Functions. If entities are in compliance with MOD-012-0 and MOD-013 we see no additional enhancement to

Organization	Question 13 Comments
	reliability by the addition of this draft standard.
Response: Thank you for your comments. Standards MOD-012 and MOD-013 state requirements for submission of data, including excitation control system model data. Standard MOD-026 state requirements for the verification of that data (i.e., that model and the model data adequately predict the expected actual performance of the equipment).	
Luminant Power	NA
Dynegy	None at this time.
Northeast Power Coordinating Council	No.

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

SAR authorized by Standards Committee for development as a reliability standard July 12, 2007.

Standard Drafting Team appointed by Standards Committee September 11, 2007.

Proposed Action Plan and Description of Current Draft:

This is the first draft of the proposed revision to this standard and includes requirements without violation risk factors, time horizons, measures or Violation Severity Levels. This first posting is for a 30-day comment period from January 6 through February 5, 2010.

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Post response to comments and second version draft revision of standard.	June 2010
2. Post response to comments and request authorization to ballot the revised standard.	September 2010
3. Conduct initial ballot.	October 2010
4. Post response to comments.	November 2010
5. Conduct recirculation ballot.	December 2010
6. BOT adoption.	February 2011
7. File with regulatory authorities.	March 2011

A. Introduction

1. **Title:** **Verification and Data Reporting of Generator Real Power Capability**

2. **Number:** **MOD-024-2**

3. **Purpose:** To ensure that planning entities have accurate generator Real Power capability modeling data used in system planning studies.

4. **Applicability:**

   4.1 Functional Entities:

   4.1.1 Generator Owner

   4.1.2 Planning Coordinator

   4.1.3 Resource Planner

   4.2 Facilities:

   4.2.1 Generating Facilities connected at the point of interconnection at 100 kV or above, containing an individual generating unit greater than 20 MVA (individual gross nameplate rating)

   4.2.2 Generating plants/Facilities connected at the point of interconnection at 100 kV or above, containing greater than 75 MVA (gross aggregate nameplate rating).

   4.2.3 Variable energy units such as wind generators, solar, and run of river hydro are exempt from the requirements of this Standard.

5. **Effective Date:** All requirements of MOD-024-2 become effective the first day of the first calendar quarter six months after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, the standard shall become effective on the first day of the first calendar quarter six months after Board of Trustees adoption.

   Verification requirements in this standard cover the summer and winter peak periods; the compliance monitoring:

   - for units to be verified annually per MOD-024-2 Attachment 1 - Verification of Summer and Winter Generating Unit Capability, section number 4, will begin 30 calendar days following the first summer or winter peak period that begins at least 60 calendar days following the effective date.
   - for units to be verified every five years per MOD-024-2 Attachment 1 - Verification of Summer and Winter Generating Unit Capability, section number 4, will begin five years after the compliance implementation date for annual units.

B. Requirements

R1. Each Generator Owner shall verify the summer and winter Real Power generating capability for each of its units in accordance with MOD-024-2 Attachment 1 - Verification of Summer and Winter Generating Unit Capability and record and submit the information via MOD-024-2 Attachment 2 - One-line Diagram, Table and Summary for Verification Information Reporting.

[Violation Risk Factor: TBD] [Time Horizon: TBD]

R2. Each Resource Planner and Planning Coordinator that seeks verified generating unit Real Power capability data shall provide each Generator Owner:

- the desired temperature to which the data is to be adjusted.
- <u>and</u> the reporting schedule consistent with section number 4 of the MOD-024-2 Attachment 1 - Verification of Summer and Winter Generating Unit Capability.

[Violation Risk Factor: TBD] [Time Horizon: TBD]

R3. Each Generator Owner shall report to its Resource Planner and Planning Coordinator any change in the gross Real Power generating capability of any unit that is:

- greater than 50 MW compared with the last verification submittal
- <u>and</u> expected to last more than six months

within 15 calendar days of the determination that the change in capability is expected to last more than 6 months.

[Violation Risk Factor: TBD] [Time Horizon: TBD]

C. Measures:

M1. Each Generator Owner has evidence that it performed the verification (such as a completed MOD-024-2 Attachment 2) and has evidence that it submitted the information (such as dated electronic mail messages or mail receipts) in accordance with Requirement R1.

M2. Each Resource Planner and each Planning Coordinator has evidence (such as dated electronic mail messages or mail receipts) that it provided each Generator Owner the desired temperature to which the verified Real Power generating capability is to be adjusted and the report schedule as specified in Requirement R2.

M3. Each Generator Owner has evidence (such as dated electronic mail messages or mail receipts) that it reported the amount of a change in a unit's gross Real Power capability as specified in Requirement R3.

MOD-024-2 Attachment 1 — Verification of Summer and Winter Generating Unit Capability

1. **Verify generating unit summer gross Real Power generating capability as follows:**

   1.1. For nuclear and fossil units, record data for one continuous hour of normal operation during the summer period.

   1.2. For hydro (other than run of river hydro) and pumped storage units, record data for one continuous hour of normal operation at any time during the year. Adjust the collected data to reflect forecasted reservoir levels or water flow conditions to reflect expected normal operation during the summer season.

   1.3. For units of less than 20 MVA that are part of a plant greater than 75 MVA in aggregate, record data either on an individual unit basis or as a group.

2. **Verify generating unit winter gross Real Power generating capability as follows:**

   2.1. For nuclear and fossil units, record data for one continuous hour of normal operation during the winter period.

   2.2. For hydro (other than run of river hydro) and pumped storage units, record data for one continuous hour of normal operation at any time during the year. Adjust the collected data to reflect forecasted reservoir levels or water flow conditions to reflect expected normal operation during the winter season.

   2.3. For units of less than 20 MVA that are part of a plant greater than 75 MVA in aggregate, record data either on an individual unit basis or as a group.

   2.4. Alternatively for any unit listed in 2.1, 2.2 or 2.3, by making a temperature correction to the most recent summer gross Real Power generating capability verification. The method used shall be indicated on the form used to record verified data.

3. Data recorded either during or associated with the summer and winter gross Real Power generating capability verification as specified in Number 1 and 2 of this Attachment shall include:

   3.1. The average value of the summer and winter gross Real Power generating capabilities over the verification period.

   3.2. The average ambient air temperature over the verification period.

   3.3. The date of the verification period, including start and end time

   3.4. The average megawatt values of the auxiliary Real Power loads and associated system connections, including nominal connection voltage, and an indication if such loads were metered or calculated.

      3.4.1. Include Real Power consumption by common auxiliary loads at a multiple unit facility (for example, coal-handling) by prorating the consumption among the appropriate units in the plant and assuming expected normal full load equipment operation of all units.

3.4.2. Provide an engineering estimate and associated calculations within 30 days of a request from the Resource Planner or Planning Coordinator for reported loads that were calculated since metering did not exist to measure such auxiliary load(s).

3.4.3. Include Generator Step-Up (GSU) and auxiliary transformers in MOD-024-2 Attachment 2 - One-line Diagram, Table and Summary for Verification Information Reporting.

3.4.4. Show Real Power flows assuming expected normal full load equipment operation of all units in Attachment 2.

3.4.5. Data adjusted according to the respective temperature specified by the Planning Coordinator and Resource Planner in accordance with requirement R2.

4. The periodicity for performing summer and winter Real Power generating capability verification is as follows:

4.1. For each generating unit with a generator maximum nameplate rating of greater than or equal to 75 MVA, annually.

4.2. For each generating unit with a generator maximum nameplate rating less than 75 MVA but greater than 20 MVA and with an average capacity factor over the last three years that is greater than five percent, annually.

4.3. For each individual generating units not included under 4.1 or 4.2 that is either greater than 20 MVA (gross nameplate rating) or is part of a generating plant/facility greater than 75 MVA (gross aggregate nameplate rating), either on an individual unit basis or as a group, verify at least once every five years.

4.4. Alternatively for multiple units installed at the same site where the units have identical designs, identical major components, identical significant control system settings and similar verified capabilities:

4.4.1. Verify approximately 20 percent of all such units annually with all units being verified over a five year period.

4.4.2. Verify at least one unit each year if fewer than five units meet the criteria in 4.4.

4.5. For a generating unit that does not run within the periodicity described in 4.1 through 4.4, verify the unit the next time the unit is run for one continuous hour of normal operation.

MOD-024-2 Attachment 2

One-line Diagram, Table and Summary for Verification Information Reporting

Note: If the configuration of the generation facility does not lend itself to the use of the diagram, tables or summaries for reporting the required information, changes may be made to this form provided that all required information (identified in MOD-024-Attachement 1) is reported.

Company ______________________________ Reported By (name)________________________

MOD-024-2 Attachment 2 (continued)

Summer Verification Data

(Provide data by unit or Facility as appropriate)

	Gross Real Power generating Capability (MW *)	Aux Power (MW *)	Gross Capability (MW *) minus Aux Power (MW *) equals Net Capability (MW *)
Recorded			
Adjusted			

* Note: Enter average values for the verification hour.

Summary of Summer Verification

- Date of Verification ______________________Verification Start Time; _____, Verification End Time ______

- Average ambient air temperature over verification period:

  Air temperature: _________°F

- The recorded MW values were adjusted for the following average temperature conditions:

  Air temperature: _________°F

MOD-024-2 Attachment 2 (continued)

Winter Verification Data

Provide data by unit or Facility as appropriate.

	Gross Real Power generating Capability (MW *)	Aux Power (MW *)	Gross Capability (MW *) minus Aux Power (MW *) equals Net Capability (MW *)
Recorded			
Adjusted			

* Note: Enter average values for the verification hour.

Check One:

☐ The winter data above is based on adjusted summer values

☐ The winter data above is based on tracking during a winter hour.

Comments:

Summary of Winter Verification

- Date of Verification[1] ___________Verification Start Time; ____________,

  Verification End Time ____________

- Average ambient air temperature over verification period:

  Air temperature: _________°F

- The recorded MW values were adjusted for the following average temperature conditions:

  Air temperature: _________°F

[1] If the winter verification is based on Summer data, provide only the date of the verification, not the start and end times.

Implementation Plan for MOD-024-2

Prerequisite Approvals

There are no other Reliability Standards or Standard Authorization Requests (SARs), in progress or approved, that must be implemented before this standard can be implemented.

MOD-024-2 — Verification and Data Reporting of Generator Real Power Capability

Revision to Sections of Approved Standards and Definitions

There are no proposed revisions to requirements in other already approved standards. There are no new definitions in the proposed standard.

Compliance with Standard

The standard applies to Generator Owners, Planning Coordinators and Resource Planners.

Effective Date

All requirements of MOD-024-2 become effective the first day of the first calendar quarter six months after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, the standard shall become effective on the first day of the first calendar quarter six months after Board of Trustees adoption.

Verification requirements in this standard cover the summer and winter peak periods; the compliance monitoring:

- for units to be verified annually per MOD-024-2 Attachment 1 — Verification of Summer and Winter Generating Unit Capability, section number 4, will begin 30 calendar days following the first summer or winter peak period that begins at least 60 calendar days following the effective date.
- for units to be verified every five years per MOD-024-2 Attachment 1 — Verification of Summer and Winter Generating Unit Capability, section number 4, will begin five years after the compliance implementation date for annual units.

Unofficial Comment Form for 1st Draft of MOD-024-2 Verification and Data Reporting of Generator Real Power — Project 2007-09 Generator Verification

Please DO NOT use this form. Please use the electronic form located at the link below to submit comments on the proposed 1st draft of MOD-024-2 Verification and Data Reporting of Generator Real Power developed by the standard drafting team as part of Project 2007-09 – Generator Verification. Comments must be submitted by **February 18, 2010**. If you have questions please contact Harry Tom at Harry.Tom@nerc.net or by telephone at (860) 550-4157.

http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html

Background Information
The purpose of Project 2007-09 Generator Verification is:

- To ensure that generators will not trip off-line during specified voltage and frequency excursions or as a result of improper coordination between generator protective relays and generator voltage regulator controls and limit functions (such coordination will include the generating unit's capabilities).
- To ensure that generator models accurately reflect the generator's capabilities and operating characteristics.

The standard drafting team (SDT) for Project 2007-09 Generator Verification based its work on two existing NERC Board approved standards:

- MOD-024 — Verification of Generator Gross and Net Real Power Capability.
- MOD-025 — Verification of Generator Gross and Net Reactive Power Capability.

And four draft standards developed by the Phase III & IV SDT that were fielded tested by four Regions from mid 2006 through mid 2007.

- PRC-019 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection
- PRC-024 — Generator Performance During Frequency and Voltage Excursions
- MOD-026 —Verification of Models and Data for Generator Excitation System Functions
- MOD-027 — Verification of Generator Unit Frequency Response

Before beginning the detailed work of developing the standards, the SDT was presented the recently completed field test results by the participants from the four field test Regions. The SDT also reviewed how and to what extent the two NERC Board approved standards were used across all the Regions. As a result of its initial review, the SDT decided that it was appropriate to develop each standard separately and not attempt to combine or merge any of the standards. The SDT felt that Generator Owners and Generator Operators could possibly perform some of the requirements of more than one standard at a time but most likely would not.

Since each standard will be standing on its own merit, the SDT has decided to post for comment the standards on an "as ready" basis.

MOD-024-2 Verification and Data Reporting of Generator Real Power was developed with consideration to key issues stated in the SAR:

- Provide more details to the applicability section
- Replace the “fill in the blanks” requirements assigned to the Regional Reliability Organization with a set of “continent-wide” requirements
- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the Regional Reliability Organization

1. Consider and address issues identified in FERC orders, including the modifications to MOD-024-1 as proposed in FERC Order 693
2. Consider and address issues identified during Phase III & IV field testing

The SDT first considered the “applicability” using the guidance set forth in the Functional Model. Initially, the SDT thought that although the Generator Owner may be responsible for the verified values of a unit’s capability, it is the Generator Operator that is the responsible entity to “operate” the unit in such a way as to obtain the required verification and any associated analysis – under the permission of the Generator Owner. The SDT felt that it is up to the Generator Owner and Generator Operator to work out any contractual arrangements associated with this relationship and not add requirements related to the Generator Owner providing approvals for the Generator Operator to perform such operations. After conferring with the Functional Model Working Group, the SDT was directed to change the applicability to Generator Owner based on roles and responsibilities assigned to the Generator Owner.

The SDT considered the extent of the facilities to be verified and how to reflect this in the “applicability”. Approximately 4% of the system capacity is connected at a voltage less than 100kV. The SDT concluded that 4% was not an impact on reliability, and did not require verification of units connected below 100kV. The SDT has proposed that this standard be consistent with the more general Compliance Registry Guidelines.

The SDT determined that attempting to verify the MW output of variable energy units is not material to the reliability of the Bulk Electric System since use of this data in simulations would not be appropriate, only partial operation would be expected for planning studies, and they are therefore exempted from the requirements of this standard.

During its review of current practices related to verification, it was evident that many entities that use generator real power capability data depend more heavily on data submitted in accordance with other and, in some areas, verification associated with regional requirements and required by markets. The SDT found that system planners across the continent have different views on how detailed the verification needs to be and what is the appropriate duration of the verification. This results from the fact that system planning studies reflect different conditions, such as range of temperatures, type of generators, extent of uncertainty included in the study, value of current verification on longer term studies, etc. As a result the SDT decided that a regimented verification was not appropriate and would not provide the “value added”. Instead the SDT has taken the approach that the Transmission Planner needs to communicate the conditions under which the Generator Owner is to provide verified values. The standard allows the Generator Owner to perform verification at any time during specific periods and use its experience and knowledge base of each unit to apply the appropriate adjustments to the verified values. This will help eliminate the need to run the unit through a potentially costly exercise to provide verified data that can be developed in a practical manner based on previous operation. This will also provide verified data consistent with the conditions the Transmission Planner expects to use them for.

In line with minimizing potentially unnecessary work by the Generator Owner and providing maximum benefit to the Transmission Planner, the SDT has developed a "diagram" guideline in the form of Attachment 1 to the standard. The Attachment can be used directly or modified as necessary to reflect the dozens of actual installation configurations. The Attachment sets the basic structure and data needed. The visual diagram provides for easier entry by the Generator Owner and application of information for Transmission Planner simulation models.

The following questions will assist the SDT in finalizing the development of MOD-024-2 Verification and Data Reporting of Generator Real Power. For questions where you agree with the SDT, please state that you agree and if available, please provide supporting documentation. If you disagree with the SDT, please explain why you disagree and provide data to support your position. To improve this first draft of MOD-024-2 Verification and Data Reporting of Generator Real Power, the SDT would appreciate responses to as many of these questions as you can answer.

1. MOD-024-1, Verification of Generator Gross and Net Real Power Capability, was approved by the NERC Board 2/7/2006. It has not been approved for enforcement under Section 215 by FERC because it contains "fill-in-the-blank" characteristics with responsibilities assigned to the Regional Reliability Organization. Megawatt data is currently collected and reported under several other standards as well as many market rules. Do you feel that there is a reliability need for this additional empirical data, or should this standard be retired? Please explain.

   ☐ Yes

   ☐ No

   Comments:

2. The SDT believes that verification should be performed on units that are connected down to 100 kV. The SDT believes this is consistent with the current Compliance Registry. The SDT has also provided how verification should be handled in plants/facilities that are greater than 75 MVA in aggregate gross nameplate rating. The Standard requires a separate verification for every unit greater than 20 MVA gross nameplate rating and connected at the point of interconnection of 100 kV or above. The remaining units in a plant/facility can be verified separately or in aggregate as the Generator Owner chooses. Do you agree with the SDT's decision to have the Standard be applicable to facilities connected to 100 kV and above and verified as proposed? Please explain.

   ☐ Yes

   ☐ No

   Comments:

3. After much discussion the SDT decided to require the verification be performed over a period of at least "one continuous hour" regardless of the type of unit because most units have reached steady state operation within one hour. Do you agree with this approach? If not, please explain.

   ☐ Yes

   ☐ No

   Comments:

4. The SDT felt that units that cannot sustain continuous operation, oftentimes known as intermittent, variable or limited energy units, such as a Wind Generating Station or run-of-river hydro, etc., should be exempt from this standard because such units are typically represented in studies with "on average" or "discounted" values. Do you agree with this approach? If not, please explain.

   ☐ Yes

   ☐ No

   Comments:

5. The SDT has developed a separate periodicity approach for identical units at the same site in Number 4.4 of Attachment 1. The Generator Owner would only be required to verify 20% of these units per year. Do you agree with this approach? If not, please explain.

   ☐ Yes

   ☐ No

   Comments:

6. The SDT believes that every Resource Planner and Planning Coordinator does not necessarily perform studies involving generating unit verified capability at the same time each year nor do they necessarily need current verified information at the same time. The SDT has developed Requirement R2 that requires the Resource Planner and Planning Coordinator to provide a schedule for receiving verified information that best fits the schedule and needs for performing studies. Do you agree with this approach? If not, please explain.

   ☐ Yes

   ☐ No

   Comments:

7. Are you aware of any regional variances that would be required for this standard?

   ☐ Yes

   ☐ No

   Comments:

8. Are you aware of any conflicts between the proposed standard and any regulatory function, rule, order, tariff, rate schedule, legislative requirement, or agreement?

   ☐ Yes

   ☐ No

   Comments:

9. Do you have any other questions or concerns with the proposed standard that have not been addressed? If yes, please provide a reference to the section, requirement or subrequirement that you believe should be changed, added or deleted and the rationale for your proposal.

   ☐ Yes

   ☐ No

Resolution of Issues Associated with MOD-024-1

Source	Reference No.	Standard No.	Project No	Language	Resolution
Fill in the Blank Team		MOD-024-1	2007-09	Review MOD-024 and MOD-025 concurrently to transition to uniform North American standards.	The SDT has decided to issue both MOD-024 and MOD-025 concurrently for Balloting.
Fill in the Blank Team		MOD-024-1	2007-09	Remove the fill-in-the-blank aspects (correct reference to "…Regional Reliability Organization's procedures…").	The SDT is addressing the fill-in-the-blank issue through its drafting of proposed revisions to MOD-024; the proposed revisions include the verification requirements within the body of the standard.
Fill in the Blank Team		MOD-024-1	2007-09	Goal is uniform North American standards for real and reactive power verification. Look at regional requirements and identify the best practice, commonalities and differences, and whether differences are needed for reliability.	The SDT reviewed the results of field testing of these standards – the field tests were conducted over multiple regions without the need for any regional variances. The GV SDT does not make any distinction in its proposed revision of MOD-024 between regional location of generator. This will be a continent-wide Standard.
Phase III/IV Team		MOD-024-1	2007-09	No requirement for the RRO to demonstrate that its procedures result in accurate information of gross and net real power capability of generators for steady state models	The GV SDT does not make any distinction in proposed revision of MOD-024 between regions and has developed language to permit the use of ambient data collection method.
Phase III/IV Team		MOD-024-1	2007-09	It is not clear in R3 to whom the Generator Owner will report the information.	The proposed revision of MOD-024 clarifies this issue by specifying the recipients of the information.
Phase III/IV Team		MOD-024-1	2007-09	Non compliance levels are too strict. A small utility with 15-20 units will be L4 non-compliant if they miss one unit	Compliance elements not yet drafted. SDT considering several potential solutions. The SDT must propose Violation Severity Levels (VSLs) (which have replaced levels of noncompliance) that meet FERC guidelines for setting VSLs - and one of those guidelines stipulates that VSL assignments should be based on a single violation, not on a cumulative number of violations
Team Comments		MOD-024-1	2007-09	Provide clarity where the Planning Authority is mentioned	The SDT has assigned a requirement to the Planning Coordinator in MOD-024 revision and, in accordance with the Functional Model, this is an appropriate assignment. The requirement assigned to the Planning Coordinator assumes that the Planning Coordinator needs data from

Source	Reference No.	Standard No.	Project No	Language	Resolution
					the Generator Owner for planning models.
FERC Order 693		MOD-024-1	2007-09	Require users, owners, and operators of the system to provide this information.	The proposed revision of MOD-024 clarifies this issue by specifying the appropriate functional entities in the Applicability section and by updating the requirements so that there are no fill-in-the-blank elements.
FERC Order 693		MOD-024-1	2007-09	Document test conditions and the relationships between test conditions and generator output so that the amount of power that can be expected to be delivered from a generator at different conditions can be determined.	This issue is addressed by having the Generator Owner provide the data corrected to the temperature value specified by the Resource Planner and Planning Coordinator.
FERC Order 693		MOD-024-1	2007-09	Clarify requirement R2 that specifies that the regional reliability organization shall provide generator gross and net real power capability verification within 30 calendar days of approval. The confusion centers on “approval” and when the 30-day period starts.	The SDT is addressing the fill-in-the-blank issue through its drafting of proposed revisions to MOD-024. The proposed revision achieves the same reliability intent as the original MOD-024 without including any references to approvals or 30-day periods.
FERC Order 693		MOD-024-1	2007-09	Provide a work plan and compliance filing regarding the collection of information specified for standards that are deferred.	See 3 year Work Plan filed each year in the 4th Quarter. This item is for NERC, not the SDT.

Project 2007-09: Generator Verification

The Generator Verification Standard Drafting Team is seeking comments on the following documents **until 8 p.m. EST on February 18, 2010**:

- MOD-024-2 — Verification and Data Reporting of Generator Real Power Capability
- Implementation Plan

The drafting team has also posted a table explaining how it is addressing issues identified for MOD-024-1.

Instructions

Please use this electronic form to submit comments. If you experience any difficulties in using the electronic form, please contact Lauren Koller at Lauren.Koller@nerc.net. An off-line, unofficial copy of the comment form is posted on the project page: http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html

Next Steps

The drafting team will draft and post responses to comments received during this period.

Project Background

This project includes six standards to address generator verification needed to support bulk power system reliability – four proposed standards and revisions to two existing standards. The purpose of the project is:

- To ensure that generators will not trip off-line during specified voltage and frequency excursions or as a result of improper coordination between generator protective relays and generator voltage regulator controls and limit functions (such coordination will include the generating unit's capabilities).
- To ensure that generator models accurately reflect the generator's capabilities and operating characteristics.

Applicability (MOD-024-2)

Generator Owner
Planning Coordinator
Resource Planner
Specific facilities (see standard)

Standards Development Process

The Reliability Standards Development Procedure contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

Ray Phillips
AMEA
No
The two questions the SDT asked on question 1 could have two different answers. I answered no to the additional data and yes to retire this standard. The MOD-024-2 draft removes the regions and entities like the Planning Coordinator from the decision making ability as to which generators are material to the BES but instead provides a blanket approach that will include generators that are and are not material to the BES.
No
The MOD-024-2 draft removes the regions and entities like the Planning Coordinator from the decision making ability as to which generators are material to the BES but instead provides a blanket approach that will include generators that are and are not material to the BES. The many of the regions have identified generators connected below 100 kV that are material to the BES and likewise have identified generators connected at or above 100 kV that are not material to the BES.
No
The MOD-024-2 draft removes the regions and entities like the Planning Coordinator from the decision making ability as to which generators are material to the BES but instead provides a blanket approach that will include generators that are and are not material to the BES.
Yes
The MOD-024-2 draft removes the regions and entities like the Planning Coordinator from the decision making ability as to which generators are material to the BES but instead provides a blanket approach that will include generators that are and are not material to the BES.
No
The MOD-024-2 draft removes the regions and entities like the Planning Coordinator from the decision making ability as to which generators are material to the BES but instead provides a blanket approach that will include generators that are and are not material to the BES.
No
The MOD-024-2 draft removes the regions and entities like the Planning Coordinator from the decision making ability as to which generators are material to the BES but instead provides a blanket approach that will include generators that are and are not material to the BES.
Yes
The current MOD-024-1 allows the regions to determine which generators must provide the requied data. Regions like SERC have developed regional supplemental standards that identifies such generators. The draft MOD-024-2 contradicts SERC's regional supplemental standards and totally removes SERC and other regions from the decision making process.
Yes
Since SERC's supplemental standards have not yet been approved by FERC I consider them proposed standards. The current MOD-024-1 allows the regions to determine which generators must provide the requied data. Regions like SERC have developed regional supplemental standards that identifies such generators. The draft MOD-024-2 contradicts SERC's regional supplemental standards and totally removes SERC and other regions from the decision making process. The draft MOD-024-2 conflicts with the new CIP standards regarding the size of significant generators.
Yes
The draft MOD-024-2 removes the decision making ability of the only entities (PC, regions, etc.) that actually know which generators are material to the BES. Instead the draft uses a blanket approach to basically include all generators 20 MVA and above connected at 100 kV and above. This approach will reduce the reliability of the BES due to distraction caused by the deluge of data from a multitude of generators that are not material to the BES and will exempt material generators that are connected below 100 kV.

Generators Supporting Elimination of MOD-024
Thomas J Bradish
No
The generator owner/operator provides unit real power capability in six standards other than in MOD-024 plus the TOP/RC/BA/ISO see a unitâ€™s real time output via their EMS. MOD-024 is duplicative and, as such, unnecessary. Planners on the RFC MOD-024 draft standard drafting team argued that they needed to know what a unit could consistently produce over a 7-24 hour period when running their reliability models. They were not interested in knowing short-term unit capability. Another reason for not using the unitâ€™s output under a stressed condition is that it is not at a level of reliable output. A unit can generate the real power during a test but many times not under actual system conditions. These tests are conducted at the most favorable time for unit performance and are only indicative of unit performance at that point in time. They are no guarantee of future performance. This results in system operators not getting the real power output that they thought was available to them. This shortage of real power occurs during system emergencies when system operators need the mega-watts the most. Because of this, these mega-watts have been called paper mega-watts. Requiring a test actually fosters a situation counter to ALR. Every unitâ€™s output must be metered and its output is monitored in real time in the TOP, RC and/or ISO Energy Management System (EMS). The EMS would have a history of a units output. This data is the most accurate representation of a unitâ€™s capability under actual system conditions and is a true representation of actual unit capability. This actual unit production data can be made available to the transmission planners. The transmission planners can analyze EMS data and use that period of unit performance that meets their requirements. If they are interested in a unitâ€™s performance during the period of highest demand, they can analyze unit output during the most recent or previous peak demand period. By using actual data, the paper mega-wattâ€™s issue goes away. If the planner has any issues, they can discuss these directly with the generator operator/owner. Requiring the planner to analyze EMS data may have another benefit. It will force the planner to become more engaged and communicate more strongly with the real-time system operators. The planner will become more aware of real-time issues that will enable them to incorporate these anomalies into their system models. Another benefit to using actual unit data is that it will eliminate running the unit to perform the MOD-024 verification. Not having to run a unit that is not needed to meet system demand will result in fewer emissions and fuel consumption yielding a higher level of environmental stewardship. As a nation, we are supposed to be concerned about greenhouse gases and efficient use of carbon-based fuels. Forcing units to run is contrary to these national goals. Unit real power capability is specified in the units interconnection agreement with the TO. The GOP is required to report unit de-rates to the TOP, RC, BA or ISO immediately after they occur. Real power reporting requirements currently appear in six (6) standards as follows: FAC-002-0: R1. The GO, TO, Distribution Provider (DP), and Load-Serving Entity (LSE) seeking to integrate generation facilities, transmission facilities, and electricity end-user facilities shall each coordinate and cooperate on its assessments with its Transmission Planner and Planning Authority. The assessment shall include: R1.1. Evaluation of the reliability impact of the new facilities and their connections on the interconnected transmission systems. R1.4. Evidence that the assessment included steady-state, short-circuit, and dynamics studies as necessary to evaluate system performance in accordance with Reliability Standard TPL-001-0. MOD-010-0 Applicability 4.3. GO specified in the data requirements and reporting procedures of MOD-011-0 R1. MOD-011-0 R1.2. Generating Units (including synchronous condensers, pumped storage, etc.): location, minimum and maximum Ratings (net Real and Reactive Power), regulated bus and voltage set point, and equipment status. TOP-002-2a R13. At the request of the Balancing Authority or Transmission Operator, a Generator Operator shall perform generating real and reactive capability verification that shall include, among other variables, weather, ambient air and water conditions, and fuel quality and quantity, and provide the results to the Balancing Authority or Transmission Operator operating personnel as requested. R14. Generator Operators shall, without any intentional time delay, notify their Balancing Authority and Transmission Operator of changes in capabilities and characteristics including but not limited to: R14.1. Changes in real and reactive output capabilities. (Retired August 1, 2007) R14.1. Changes in real

output capabilities. (Effective August 1, 2007) R15. Generation Operators shall, at the request of the Balancing Authority or Transmission Operator, provide a forecast of expected real power output to assist in operations planning (e.g., a seven-day forecast of real output). TOP-003-1 R1. Generator Operators and Transmission Operators shall provide planned outage information. Each Generator Operator shall provide outage information daily to its Transmission Operator for scheduled generator outages planned for the next day (any foreseen outage of a generator greater than 50 MW). The Transmission Operator shall establish the outage reporting requirements. Such information shall be available by 1200 Central Standard Time for the Eastern Interconnection and 1200 Pacific Standard Time for the Western Interconnection. R2. Each Transmission Operator, Balancing Authority, and Generator Operator shall plan and coordinate scheduled outages of system voltage regulating equipment, such as automatic voltage regulators on generators, supplementary excitation control, synchronous condensers, shunt and series capacitors, reactors, etc., among affected Balancing Authorities and Transmission Operators as required. R3. Each Transmission Operator, Balancing Authority, and Generator Operator shall plan and coordinate scheduled outages of telemetering and control equipment and associated communication channels between the affected areas. TOP-006-2 R1` Each Transmission Operator and Balancing Authority shall know the status of all generation and transmission resources available for use. R1.1 Each Generator Operator shall inform its Host Balancing Authority and the Transmission Operator of all generation resources available for use. Because the generator owner/operator provides unit real power capability in six standards plus the TOP/RC/BA/ISO see a unitâ€™s real time output via their EMS reporting the generator testing and reporting contemplated under MOD-024 is unnecessary. In addition, MOD-026 and 027 have not been considered in this discussion but are anticipated to be approved over the course of the next two years would cause further duplication. Thus, MOD-024 is clearly unnecessary.

The changes in this standard duplicate and conflict the requirement specific under TOP002. Originally this standard was for verification procedures which were used to meet TOP-002. The verification procedures defined in this standard should be incorporated into TOP-002 if this standard is retired.
Yes
No
The intent of the requirement of the previous version was to provide realistic summer and winter generator capability. For hydro units, the process detailed in this version only provides a vague assessment of normal and most likely not be the realistic capability of the generator. The process requires the units to be operated â€œnormallyâ€ which is undefined and to adjust the MW to reflect forecasted (summer or winter) reservoir conditions. Hydro units may be â€œnormallyâ€ operated throughout their operating range. Without specific guidance that the operation should utilize a normal â€œfull loadâ€ condition, the true summer capability may not be known. Specifically, if a generator , at some time other than summer is, operated at 50% gate during the operational snap shot produces xx MW, then the xx MW at 50% gate will be indexed for the summer reservoir level. The true capability of the generator at 100% gate (normal full load) during summer would actually be much higher. The language would need to ensure that the full load would reflect limitations other than those introduced by head.
No
It is not appropriate to consider the variability of wind generating stations comparable to the operation of a run of the river hydro. Run of the river hydro tends to be less variable and pose a lower regulation burden on the BES than wind generation. We justify this position in that the operator can estimate the energy produced during a month and even schedule the capacity at which the generator is operated, whereas wind cannot. As such an operator is able to provide a verification of the capability of our run of the river plants.
Yes

No
This standard is not consistent with the NERC functional model in that it requires the submission of information is not consistent with the role of the Resources Planner. The Resource Plannerâ€™s role is to develop a long term plan for resource adequacy of specific loads within a Resource Planners area. The information furnished under this requirement would be valid for less than one year. Forecast reservoir operations are notoriously inaccurate at more than 9 months. The forecast seasonal variation is relevant for TOP and BA functions. Resource Planners would interested in average seasonal variations and any physical changes to generator capability (e.g. de-rating, up-rating, etc).
Yes
This standard conflicts with TOP-002
Yes
The requirement will result in continuous reporting by the Generator Owner for its hydro units. The capability of hydro units can vary seasonally by more than 50 MW in less than 6 months. It is unclear what reliability purpose is served by this requirement. As stated in the general comment section, Generation capability is forecast, adjusted, and provided to TOPâ€™s and BAâ€™s under TOP-002-2.

Yes the Standard should be retired. This standard appears to duplicate and complicate FAC-008 and FAC-009. If this standard remains, then should generator rating be removed from FAC-008 and FAC-009?
Yes
This approach makes it easy for the owner to know when compliance is necessary. However, 20 MVA redline across the board for any single unit seems too low. Any significant generation will be connected at 100 kV or greater, but not all generation is significant just because it is connected at a certain voltage. A simple redline is easy to manage, but is new small generation development being discouraged with this low bar? I am not dead set against this applicable level, but I think some research into discovering the unintended consequences should be made.
Yes
Yes
Wind generation canâ€™t buttress reliability in a pinch, therefore should not be included. Agree with the run-of-river argument. However, there are other generation plants that are limited by

FERC license to the maximum cubic feet per minute of water permitted to flow through the tail race. Such generation will have name plate ratings well above the allowed possible power generation considering the available prime mover. Therefore the limiting factor is not the ambient temperature, or the thermal aspects of the generation units, but the efficiency of the generation plant to convert the maximum allowed prime mover into electrical power. This efficiency will not change much, if at all, over time. Such units should also be exempt except for a single test at maximum allowed flow.
Yes
Yes
As long as it does not conflict with operational constraints of the generation plant.
No
Yes
Maximum hydraulic flow constraints by operation license can legally prevent maximum name plate capacity verification tests.
Yes
Ambient temperature correction calculation requirements may incur significant compliance costs with little return for the effort. Will the Planner be asking for operation output vs. ambient temperatures way beyond normal levels? If the required ambient temperature is beyond the operational testing ability (i.e. 500 year high), how will the engineering analysis be established and verified?

Yes
There is a need to test the gross and net real power capability because it is a key operating and planning horizon requirement to maintain system reliability. Unit testing is critical to System Operations and their ability to respond to contingencies. Even now, there are concerns with interconnection frequency responses and units not responding to AGC signals as noted in the 2-11-2010 NERC Industry Advisory on interconnection frequency response. In addition, as more and more wind generation is installed, generation capability issues will become more important to System Operators. The standard should not be retired, but the requirements should be incorporated into a new FAC standard or included in FAC-008.
No
SDT should not make reference to a specific voltage level. The SDT should indicate that verification should be performed on units that are connected to the Bulk Electric System as determined by the Region.
No
The SDT should change the verbiage to â€œa minimum of one continuous hour of normal operationâ€ to avoid confusion that the unit can be ramping up to full load during the test.
No
All units meeting the voltage level and output level as specified in Section 4.2 should be tested. From both an operating horizon and planning horizon, it is important to have an accurate model of the system.
No
Please see response to question 4. In addition, terms such as â€œidentical significant control systems settingsâ€ and â€œsimilar verified capabilitiesâ€ are ambiguous. Section 4.4 of Attachment 1 should be removed.
Yes
In addition, different regions of the country may have summer or winter peaking periods and will schedule tests accordingly.
No
No
Yes
MOD-024-2 requires bi-annual testing, while at the same time exempted intermittent units (e.g. wind generators) and stations with multiple units (section 4.4). A reliability standard should support reliability; therefore, all units should be tested at the same frequency. The DT should consider a reliability standard that has an annual test requirement only that tests all generation units, regardless of type (including intermittent units or stations with multiple units). A region

can also develop bi-annual requirements for a summer and winter test if they see a reliability benefit and/or have a market requirement. Concerning R1: The requirement does not specifically state who should receive the generator unit capability data. The PC? The RP?

Yes
Yes
Please revise 4.4 of Attachment 1 4.4. Alternatively for multiple units installed at the same site where the units have identical designs, identical major components, identical significant control system settings and similar â€œtestedâ€ verified capabilities â€œper MOD-024â€: 4.4.1 Verify approximately 20 percent of all such units annually with all units being verified over a five year period. 4.4.2 Verify at least one unit each year if fewer than five units meet the criteria in 4.4.
Yes
R2 should be redacted to include variables and not be so constrained to temperature since there might be other variables besides temperature. These variables would be specified at the Planning Coordinator and Resource Planner discretion.
No
N/A

No
N/A
Yes
Requirement R1 â€“ The requirement should be clarified that in the case of Joint-owned-units, the Operator of the unit is responsible for verifying the capability of the unit. For R1, R2, & R3, we propose a Violation Risk Factor of â€œLowerâ€ and a Time Horizon of â€œOperations Planning, Long-Term Planningâ€. We propose â€œLowerâ€ for the VRF because more accurate real power capability values will be assured by this requirement, but reasonably accurate values are likely without this requirement. We propose â€œOperations Planning, Long-Term Planningâ€ for the TH because RCs and TOPs will use this data in their operations planning studies and PCs and TPs will use this data in their transmission planning studies. For R2, replace â€œdesired temperature to which the dataâ€ with â€œdesired ambient coolant temperature to which the summer and winter dataâ€ for added clarity. In Attachment 1, 3.2; replace â€œambient air temperatureâ€ with â€œambient coolant (air, water, etc.) temperatureâ€ because the capability of different types of generators is affected by the temperature of different cooling medium. In addition, consideration may need to be given to the average pressure level of generating units that use hydrogen for equipment cooling. Introduction, Section 4.2 - As written, small diesel generators at applicable Generating Facilities could be expected to be tested as part of this standard, even if these small generators are intended only for local site power, and are only capable of reaching a 100 KV interconnection by back-feeding through local site distribution circuits and auxiliary transformers. Based on the MVA metrics provided, it would appear their inclusion is not the intent, but the standard is ambiguous as written. On the Implementation Plan for MOD-024-2 for units that are to be verified every five years, they state the verification â €œwill begin five years after the compliance implementation date for annual units.â€ Wouldnâ €™t it make more sense to make them verify in the first year after the MOD-24-02 is adopted or approved and then do it every five years after that? On page 2 of 10, A.5. Effective Date, it seems unclear when they say verification â€œwill begin 30 calendar days following the first summer or winter peak periodâ€ . For example, if the summer peak occurs in June and you expect a higher peak in July or August and it doesnâ€™t occur, then you would be in violation. The same applies for the winter period. They donâ€™t define the summer and winter period. On page 5 of 10, MOD-024-2 Attachment 1. 2. Verify generating unit winter gross Real Power generating capability as follows: 2.1. They donâ€™t define the winter period and what the conditions should be for the verification test period. Please Clarify. On page 5 of 10, MOD-024-2 Attachment 1. 2. Verify generating unit winter gross Real Power generating capability as follows: 2.4. â€œby making a temperature correction to the most recent summer gross Real Power generating capability verification.â€ Under what conditions can temperature corrections be made?

Howard Rulf
No
We feel this requirement could be retired do to the fact that the data is collected and reported under several other standards as well as many market rules. For example, the Midwest ISO has established testing requirements for generators under Module E of the Midwest ISO Open Access Transmission, Energy and Operating Reserve Markets Tariff. We also feel that having multiple different testing and reporting requirements can potentially lead to confusion and errors in reporting. If it is determined to not retire this standard, a provision should be made that if generator testing information is provided to a RTO following prescribed testing standards of the RTO, the submittal of the information to the RTO would meet the requirements of MOD-024-2. There is also a concern regarding the different applicability requirements between MOD-024-2 (Generator Owner, Planning Coordinator, and Resource Planner) and the recently passed MOD-024-RFC-01 (Generator Operator and Planning Coordinator) which further illustrates the problem of consistency of requirements.
Yes
No
To the extent there are multiple reporting requirements for generator capacity data, a standard timeframe for reporting the information should be developed in order to minimize the potential for conflicting data on the same generator from being used for similar modeling purposes. In addition, to the extent that generator capability data will be adjusted based upon ambient conditions, the requirement to verify the summer gross Real Power generating capability only during the summer period is overly restrictive. Current standards for generator testing allows the results from any period of time to be used as long as the results are adjusted based upon

ambient conditions at the time of the test to the ambient conditions that would exist during the summer.
Yes
Under requirement R3, we question the necessity of reporting a 50 MW reduction in a unit within 15 calendar days of the determination that the reduction is expected to last more than 6 months. Given the current wording, this requirement would need to be understood by a very broad base of individuals who may not typically be aware of this reporting requirement (e.g. a maintenance supervisor evaluating the impact of damage to a mill) and the current wording is unclear as to when the 15 day clock would begin. Prior to making this a requirement, an evaluation should be done to determine how big of a problem this is currently causing to any system modeling, what the risks are of waiting until the next test date to report the issue, and whether or not the concerns change if a RTO has an annual testing requirement.

No
No, we do not feel additional empirical data is necessary as we believe this version should include data required in Version 1 as this version gave a better description of what is happening with a generating unit during a test. Yes, we do feel this standard should be retired. We believe this standard is unnecessary since real power verification can and should be handled by generation and transmission agreements. The Generator Owner (GO) & Generator Operator (GOP) provide generation unit real power capability in seven standards other than in MOD-024 plus the Transmission Operator (TOP), Reliability Coordinator (RC), Balancing Authority (BA) and Regional Transmission Organization (RTO) / Independent System Operator (ISO) see a unitâ€™s real time output via their Energy Management System (EMS). Therefore, the generator testing and reporting contemplated under MOD-024 is unnecessary. In addition, MOD-026 and 027 have not been considered in this discussion but are anticipated to be approved over the course of the next two years would cause further duplication. Thus, MOD-024 is clearly unnecessary.
Yes
No
We feel that one hour is too short. We recommend verfication be performed one hour after the unit has reached steady state operation since some units may take different lengths of time to reach steady state.
Yes
Yes
No
We do not agree with this approach. Validation should be performed during a period which is mutually agreed upon by both the GO and TOP to take into account seasonality. For the other periods, validations should not be required.
Yes
Different regions have different peak seasons depending on the climate.

Planning related entities (i.e. Planning Coordinator, Resource Planner and Transmission Planner) need the maximum (normalized)demonstrated capability of generating units for inclusion in their planning models. No other Standard requires this data to be accumulated and reported to these entities. Also, historical EMS data that reflects economic dispatch and regulating requirements is not an alternative source for this data.
Yes
Yes
Yes
Yes
No
The Transmission Planner also needs this generator data. These planning entities should not be required to provide the desired temperature to which the data needs to be adjusted. Generator Owners should simply adjust the actual test data using average temperature data from a location near the plant. This provision has been incorporated in the related RFC Regional Standard MOD-024-RFC-01.
No
No
Yes
1. Applicability 4.1- Transmission Planner needs to be added as a Functional Entity. All Planning related entities (i.e. Planning Coordinator, Resource Planner and Transmission Planner) need the maximum demonstrated capability of generating units for inclusion in their planning models. 2. Requirement R2- Adjustment of generating verification data should not be dependent on a request from a planning entity. This data should be adjusted to an average temperature in all cases and recorded on Attachment 2. 3. Attachment 1, Item 3.4.5- Modify this item to correspond to recommended changes in Requirement R2 (see above comment #2). 4. Attachment 1, Item 4.5- The phrase â€œdoes not run with the periodicity described in 4.1 through 4.4â€ â€ is ambiguous. No â€œperiodsâ€ are included in Items 4.1 through 4.4 in Attachment 1. The intent of this provision needs to be clarified.

We believe there is a reliability need for the Megawatt data collected per this standard and consequently this standard should not be retired.
Yes
Yes
While we agree that one hour of data is adequate to verify the capability, in our experience it takes at least 30 minutes for a steam turbine unit to stabilize if it has been operating at a lower load. We believe the criteria should take into consideration of an applicable "stabilization period" prior to data collection.
Yes
No
We are in agreement with the concept as long as the caveats that the major components and control systems are identical and that the verified capabilities are similar remain in the wording.
Yes
Yes
Some Regional Entities have developed their own requirements as directed under MOD-024-1. These would presumably take precedence over MOD-024-2. Some RTOâ€™s (e.g. MISO) have their own requirements for capability verification.
No
Yes
With regard to Attachment 2, the only ambient condition that is required to be reported is ambient air temperature. This has a significant impact on combustion turbines, but little effect on steam turbines. Condenser cooling water temperature has much more impact on steam turbine capability and we feel this should be recorded for that type of prime mover. Also, we would like to request that a description of the process for performing ambient compensation be included either in Attachment 1 or in a separate Technical Guideline to improve the quality and consistency of the information that is reported.

The standard should be retired. There are several other standards pursuant to which the GO and/or GOP provides real power capability to those parties needing that data. Also, the RTOs, ISOs, in their role as TOP, RC and BA receive actual data continuously via the EMS. Likewise,

those entities performing the same functions in non-ISO areas also receive the data. The actual operating data collected through EMS systems is far superior in quality to that resultant from compliance with MOD-024, both presently and as proposed. Imposing duplicate burdens on generators with no commensurate benefit to reliability should be avoided. Hence, MOD-024 is not necessary.

No
We agree with the approach as stated in Question 3 but have selected NO here because the proposed standard itself does not reflect the approach stated. For Attachment 1, Sections 1.1, 1.2, 2.1, and 2.2, these should be changed to say â€œfor at least one continuous hourâ€¦â€
No
While we have indicated that we disagree with the exemption, it may be more appropriate to address testing of â€œintermittentâ€ resources separately due to their different use in planning

and operational studies. However, we think the basis for exemption by the SDT is incorrect. The SDT has confused the issue of rating with how that rating is used in planning studies. There are two fundamental questions that must be answered for each resource in any planning study: (1) what is the resource capable of producing under some standard set of conditions, and (2) how much will it produce under the conditions assumed in a planning study. Historically, these two questions are merged for resources which are dispatchable and controllable to a sustained output level. In other words, if we test a conventional fossil or nuclear generator and determine it can produce X MW under the test conditions, we assume it can produce X MW under study conditions like peak demand, off-peak or shoulder load conditions. However, we might model the unit as producing zero or something less than its capability due to economic or some other dispatch consideration. We do not try and represent some average value of its production over time. When intermittent resources are considered, we still need to know how much a unit is capable of producing at its maximum output. We would not size the interconnection for â€œaverageâ€ output. We need to know what it might produce under ideal conditions. Taken further, we know that at some point in its operation, the intermittent resource will produce at its tested value, and it will be up to the planner to determine if that condition needs to be studied. For example, 100 MW of nameplate generation may produce 30 MW on the average over a yearâ€™s time, but it might produce the full 100 MW at an off-peak hour, and that may need to be studied. How do we assure ourselves that the 100 MW of nameplate is actually capable of 100 MW? While intermittent resources may not make up a significant portion of supply in most regions at this time, future development may result in significant portions of supply being made up of these resources, and relying on design or nameplate values will be as inappropriate for these units as it is for existing generation. The standard should focus on determining the appropriate generator ratings to be supplied to the planning processes, not how they are ultimately used. As the standard itself states: 3. Purpose: To ensure that planning entities have accurate generator Real Power capability modeling data used in system planning studies
Yes

Yes
COMMENT 1-The first bullet item under R2 should be revised as follows: â€¢ the desired temperature to which the data is to be adjusted for conditions normally experienced for summer and winter periods. COMMENT 2- R3 should be revised as follows: "Each Generator Owner shall report to its Resource Planner and Planning Coordinator any change that is greater than 50 MW in the gross Real Power generating capability of any unit compared with the last verification submittal that is expected to last more than six months. The Generator Owner shall make such report within 15 calendar days of the determination that the change in capability is expected to last more than 6 months." COMMENT 3- For Attachment 1, Section 4.3, in â€œFor each individual generating unitsâ€¦â€ change â€œunitsâ€ to â€œunitâ€. COMMENT 4- Attachment 2, Requirement 3 provides for the RP and PC to provide the GO â€œthe desired temperature to which the data is to be adjustedâ€. Attachment 2 provides a blank to record that value for adjustment in each of the Summer and Winter Verification Data sections stated as: â€œThe recorded MW values were adjusted for the following average temperature conditions:â€ We suggest removing the word "averageâ€ which is inconsistent with R3. COMMENT 5- In Footnote 1, revise as follows for clarification: 1- If the winter verification is based on Summer data, provide only the date of the â€œsummerâ€ verification â€œusedâ€ not the start and end times. COMMENT 6- The standard does not address validation of initial Real Power Capability for new units.

No
IMPA is anwering no to the question "Do you feel that there is a relaiblity need for this additional empirical data", and answering yes to the question "should this standard be retired". The reporting of megawatt data in other reliability standards and in market testing requirements for units is enough.
Yes
IMPA agrees that the standard should be consistent with the current Compliance Registry and supports how units are verified in the standard.
Yes

IMPA agrees with the one hour testing and the reasoning that the SDT used to decide on this time period.
No
If these units cannot sustain continuous operation, then they can report/record the highest hour or an average output for the hour.
Yes
Yes
IMPA agrees with this approach as long as it is for only receiving the verified information and not allowing these entities to specify any type of testing period or requirements outside of this standard.
No
Yes
This standard conflicts with the RFC approved standard, MOD-024-RFC-01. The NERC draft version of MOD-024 has the Generator Owner submitting reports to the proper entities. This conflicts with the RFC standard which has the Generator Operator submitting the reports to the proper entities. IMPA believes that NERC should resolve this issue by having the RFC standard agree with the NERC MOD-024 standard and the Functional Model. The SDT may not be able to resolve this issue, but it needs to be resolved or two different entities could be in non-compliance in the RFC region if a report is not submitted.
Yes
A clarification under number five, the effective date is needed. Under effective date, both sentences need to be clarified. Is the effective date the first day of the first calendar quarter after or part of the six months after applicable regulatory approval. For example, if regulatory approved is received on June 28, 2011 and then six months after is December 28, 2011, is the standard effective on January 1, 2012 (first day of the first calendar quarter after six months) or a date in the six months (before December 28, 2011).
Individual
Armin Klusman
CenterPoint Energy
No
CenterPoint Energy disagrees with having this Standard be applicable to all units connected to facilities 100 kV and above. CenterPoint Energy recommends it should only be applicable to units interconnected to Bulk Electric System facilities - not all facilities 100 kV and above are considered to be part of a Bulk Electric System.
No
CenterPoint Energy disagrees with exempting certain types of generation resources from Requirement 1 and Requirement 3; therefore, CenterPoint Energy recommends deleting 4.2.3 â€œVariable energy units such as wind generators, solar, and run of river hydro are exempt from the requirements of this Standard.â€ CenterPoint Energy agrees that oftentimes such generation resources are represented with â€œon averageâ€ or â€œdiscountedâ€ values. However, all planning models do not use â€œon averageâ€ or â€œdiscountedâ€ values as there are needs to study expected generation patterns. For example, wind generation typically peaks in the early morning hours in west Texas and should be modeled at a lower output in planning models which represent the peak load hour which occurs in the summer, typically around 5 PM. Transmission planners would need to ensure that there is adequate transmission when west Texas wind is operating at its peak output in the early morning hours. For this purpose, there is a need for a planning model with all wind generation operating at peak output. In addition, wind generation typically reaches a peak coincident with the peak load hour in the Gulf Coast area. So, this generation would be modeled at peak output in a planning model representing the peak load hour. In both of these cases, planning models need the net real power capability of wind units verified by actual unit testing.
Group
E.ON U.S.
Brent Ingebrigtson

Yes
obtaining the additional empirical data is helpful. The data required in Version 1 as established by the Regions gives a better description of what is happening with a generating unit during a test; this version only requires capability, auxiliary power usage, and temperaturesâ€"which does not give one a picture of what is occurring during a test and why the capabilities might have been the way they were.
Yes
No
One hour is too short. This period could allow a company to provide more of an "optimum" or "maximum" capability, rather than an average capability (e.g., during one hour soot blowers might not have to be run, etc.). The current 4-hour average test is more reasonable/reliable. Attachment 1 should be revised to specify a verification period of "at least 1 hour." The use of the term "normal operation" in Attachment 1 is not specific enough and is open to interpretation. Since generating capacity has market value, Gen Owners may desire to maximize the verified/reported capability of their units - even if such performance can only be attained for a single hour. This would not be consistent with the notion of dependable or continuous capacity which should be the basis used for reliability planning purposes.
Yes
E.ON U.S. believes that this is reasonable at the present time but with the proposed massive build-out of wind generation this may need to be re-visited in the future.
Yes
The language of 4.4 isnâ€™t clear â€"E.ON U.S. suggests revising to â€œIf 5 or more units are at a single site, verifyâ€¦.â€. Does â€œapproximately 20 percentâ€ imply rounding to the closest whole number? If 2 identical units are at the same site â€" no annual test is required but both units need to be verified within a 5 year interval?
No
The fundamental concept is correct; but, rather than ambient temperature, seasonal back pressure is much more appropriate to use for corrective factors. (e.g. with temperatures â€" is it wet bulb/dry bulb; humidity or not; how clean are the condenser/cooling tower?) All of these factors are satisfied by correcting to back-pressure conditions).
No
Summer peaking regional requirements are different than winter peaking regional requirements
No
This information requires some duplicate reporting. For example, the Kentucky Public Service Commission requires resource adequacy planning and reporting of the same data.
Yes
The first bullet under R2 should be modified as follows: â€œthe desired temperature and/or backpressure to which the data is to be adjusted.â€ Other criteria may also be required during the test. (e.g. MVARs, etc.) Clarify R3 language that 50MW is the change in unit rating â€" not any unit greater than 50MW. E.ON U.S. questions whether a 50MW threshold for capability change is less meaningful than using a percent of unit capacity threshold. Is the need to report such changes to NERC consistent with any Regional requirement? On Attachment 2, are data measuring points A,B,C and D to be reported as peak or average (over the verification period) values? MOD-024 and MOD-025 are linked and the STD has decided to revise each standard independently. This makes compliance difficult to maintain and test while the two linked standards are undergoing revision.
Group
Luminant
Rick Terrill
Yes
Luminant believes the verification of capability is needed to ensure unit capabilities utilized for resource planning, operating reserves and real time operations are accurate. â€œPaper Megawattsâ€ can have a detrimental effect on grid reliability.
Yes
No
Luminant would prefer 30 minutes at full load, as this approach has been utilized effectively in ERCOT for several years.
Yes
Yes

No
Luminant believes the test results should be submitted within 30 days of completion of the annual verification. Luminant submits the following modification to Requirements R1 and R2 to address this issue. R1. Each Generator Owner shall verify the summer and winter Real Power generation capability for each of its units in accordance with MOD-024-02 Attachment 1, Verification of Sumer and Winter Generating Unit Capability,and record and submit the verification information via MOD-024-02 Attachment 2, One-line Diagram, Table and Summary for Verification Information Reporting (or similar diagram and form), to the Resoruce Planner and Planning Coordinator within 30 calendar days of the completion of the Real Power capability verification. R2. Each Resourc Planner and Planning Coordinator that seeks verified generating unit Real Power capability data shall provide each Generator Owner: - the desired temperature to which the data is to be adjusted - the calendar dates that encompass the summer period and winter period.
No
No
Yes
Upon approval of MOD-024, Verification of Real Power and the companion standard MOD-025, Verification of Reactive Power, the applicability to Generator Owners and/or Generator Operators needs to be removed from FAC-008 and FAC-009. With actual verification of Real and Reactive Power, the FAC-008 and FAC-009 requirements become redundant for generators. Attachment 1 verbage needs to be consistent between the words "period" and "season". They are currently used interchangeably. Attachment 1, section 4.5, needs to be expanded so that when a lessor utilized unit is started up, it does not necessarily have to immediately run a maximum capacity test. The unit could have been brought online for capacity and the BA may not allow it to run at maximum output. Emergency situations may preclude running the test. This type of unit should be tested based on a schedule coordinated with the BA. All references to Attachment 2 should also include the "or similar diagram and form" language.

FirstEnergy
Sam Ciccone
Yes
We believe that there is a need for this standard. The argument that "megawatt data is currently collected and reported under several other standards as well as many market rules" is not well founded. All Standard Drafting Teams assigned to revise existing standards that include some form of generator verification are proposing to retire their respective requirements because they intended that MOD-024-2 include these requirements. A specific example is the RTO SDT (Project 2007-03) which has proposed to remove requirements dealing with Real Power generator verification in TOP-002 (R13, R14, and R15) because they believe these requirements should be addressed by this GV SDT. The second part of the argument that these verifications are required by "many market rules" is also problematic because not every entity across the continent participates in a market and market rules are not enforceable Reliability Standard requirements.
Yes
We agree with the proposed thresholds because they are consistent with the NERC compliance registry.
No
We do not agree that one hour is sufficient for Fossil and Nuclear units (per Attachment 1 Sec. 1.1 and 2.1). The SDT should consider at least 4 hours or, at a minimum, require that the unit demonstrates it has reached equilibrium.
No
We believe that capabilities of intermittent units such as wind and solar can be adequately verified by testing, tracking of operational data, or calculations if testing or operational data is not possible or incomplete. Furthermore, it has been forecasted that utilization of these types of units will expand and most states will have Renewable Energy requirements of 20-25% of generation in the future. This would represent a large percentage of generating unit Real Power Capability not being verified. Excluding these units from verifying their capability will not improve reliability but will reduce it. The goal of this standard is to determine the capabilities of all generating units. The Generator Owner of intermittent units should provide their maximum capability through verification, test or calculation along with capacity factor data. This information could then be used by the Transmission Planner to plan for a reliable system based on the Transmission Planner's engineering judgment and considering other factors as the units Interconnection Agreement contractual arrangements (i.e. energy only unity, participates in a capacity market, etc.) Therefore, we suggest that this SDT incorporate requirements to verify

intermittent, variable, and limited energy units. We also suggest the SDT should consider language similar to RFC standard MOD-024-RFC-01 Requirement R2.2.3 to accomplish verification of intermittent, variable, and limited energy unit capabilities.
No
Item 4.4 of Attachment 1 should begin with the statement "For units that require annual verification ..." This would better clarify that the identical unit exemption is aimed at units that qualify under item 4.1 and 4.2. We agree that not all identical units should be required to be verified annually . However, the proposal should include a statement by the Generator Owner annually confirming which units that are deemed identical when providing annual verification updates for one of the identical units. Also, the wording proposed in 4.4, "approximately 20%", is ambiguous and up for interpretation in an audit. We suggest 4.4.1 be removed. We suggest replacing items 4.4.1 and 4.4.2 with the following: "The Generator Owner of identical generator units shall verify unit capability of at least one unit annually, such that all units are verified over a five year period."
No
It is unclear if R2 is intended to be a one-time submission of temperature adjustment information and schedule by the RP and PC or if this is something that is required each and every time the RP and PC would "seek" the data. Requirement R2 brings into question if the GO is simply holding verification data until requested to provide by an entity who "seeks" the data. Also, as written the RP and PC could provide conflicting temperature data and schedule expectations that would needlessly overburden the GO. As described in our item 4 in our Q9 response, FE suggests that R1 is ambiguous in regards to who the GO is to provide data to on an annual or every 5 year basis. FE suggests the team modify requirement R1 or Attachment 2 to clarify the intended recipients for either annual or 5-year generation verification data. In our opinion the GO should automatically provide the data to the intended recipients. Additionally, we propose the team to set a firm expectation that summer and winter verifications would be provide to the appropriate entities within 90 days of the conclusion of the applicable summer or winter peak period. In regards to temperature adjustment, the GO should simply provide any applicable temperature adjustment data used for the data provided and respond to inquiries from data recipients as needed and upon request. If the team elects to accept FE's proposed changes it is our opinion that R2 can be removed from the standard.
Yes
Our preference is that RFC retire their regional standard for Real Power verification (MOD-024-RFC-01) upon completion of this continent-wide standard. However, if RFC believes their standard is still needed after this NERC standard is completed, then there may be potential regional variances required as follows: 1. The threshold for periodicity of verification for RFC is 85 MVA; NERC is proposing 75 MVA. The gap between 75 and 85 MVA would need to be addressed. 2. RFC explicitly allows for testing, including commissioning tests for new units, in lieu of operational tracking. 3. The applicability for RFC is the Generator Operator while NERC proposes applicability to the Generator Owner. 4. RFC explicitly allows for exemptions and delays in verifications when system conditions or generator issues prevent verification.
No
Yes
FirstEnergy offers the following additional suggestions and comments: 1. We question the applicability to the Generator Owner (GO) instead of the Generator Operator (GOP). We believe the standard should apply to the GOP because the operation of the unit (operational verification and testing) impacts reliability more directly than ownership. In addition multiple ownership confuses responsibility and compliance. Only one GOP will operate a unit and perform the required verification, testing and data reporting. 2. The proposed requirements in this standard do not specifically allow for testing in lieu of operational tracking. We suggest the team add testing as an explicit alternative. 3. Several terms used in this standard should be defined to alleviate any varying interpretations; we suggest the following definitions: a. Summer/Winter Peak Period â€“ For the summer season, the Peak Period extends from the first day of June to the last day of August. For the winter peak season, the Peak Period extends from the first day of December to the last day of February. b. Peak Period Hours â€“ The four summer hours ending at 3 PM, 4 PM, 5 PM and 6 PM. The four winter hours ending 8 AM, 9 AM, 7 PM and 8 PM. c. Capacity Factor (expressed as a percent) - Is the net actual energy generation (MW-hours) divided by the product of the period (hours) and the net max capacity rating (MW) 4. R1 - It is not clear to whom the GO must submit this information. We suggest that the SDT add language in R1 that states the GO be required to submit verification information "as requested, in accordance with a predetermined schedule and format specified by a requesting Resource Planner, Planning Coordinator, or Transmission Planner". 5. R2 - First Bullet â€“ The phrase "The desired temperature" is too broad; we suggest a change to "The desired ambient temperature". 6. R2 â€“ If R2 is retained (see proposal to remove in our response to Q6), FE suggests the phrase "that seeks" be replaced with "having a reliability need for" since as written could have the unintended meaning that any RP or PC could request information of a particular generator

unit owner. 7. R3 - Regarding the 50MW level, it should be clear that this would be for situations where the MW level decreased by more than 50 MW. Significant increases in MW levels could violate interconnection agreements and be used by an entity to sidestep the required studies for facility uprates 8. Att. 2 - Diagram - The transformer downstream from the GSU should be the Start-Up Transformer, not Aux Transformer as currently shown. 9. In the background information provided by the SDT on pg.2 it states "... the SDT has taken the approach that the Transmission Planner needs to communicate the conditions under which the Generator Owner is to provide verified values..". It is not clear how this standard requires the TP to communicate the conditions. Was it the SDTâ€™s intent to say the PC or RP needs to communicate the conditions as stated in R2?

Yes
While data is reported under MOD-010, MOD-024 provides for validation of the data.
Yes
No
Need to reword Attachment 1, section 2.1 to add clarity. Suggested rewording: For nuclear and fossil units, record data for at least one continuous hour of normal operation during the winter period. More time may be required or used to achieve stable conditions.
Yes
Yes
Yes
No
No
Yes
Industry guidance is needed on how to adjust recorded test data in Requirement R2 and Section 3.4.5 on Attachment 1. Itâ€™s unclear what is being sought by â€œadjustingâ€ data to a desired temperature. Ambient air temperature may not impact output nearly as much as coolant temperature, when the machine is not air cooled. Also, Section 3.4.5 should be expanded to allow for adjusting of data for factors other than ambient air temperature (e.g. steam leaks, condenser cooling water temperature, out of service reheaters, condenser fouling, turbine blade wearâ€¦.). Planners need to model to the unitâ€™s expected sustained capability. If tests are conducted under degraded plant or equipment conditions the test results need to be adjusted. Otherwise planners could plan the system for less than the full capability of the unit, which would yield a non-conservative result. Guidance is needed on how to report (i.e. actual data, adjusted data and a prognosis for sustained capability that may be achieved). The test should represent the actual condition of the equipment. If it is degraded then the unit would have less capability. However capability could be restored during a repair or outage, and demonstrated with another test.
Group
Electric Power Supply Association (EPSA)
Jack Cashin
Yes
See answer to question 9.
Yes
EPSA agrees with many of the SDTâ€™s findings in its review of current verification and data reporting practices. Entities that use generator real power capability data already receive and depend on the necessary data. The SDTâ€™s review confirms that capability data is often

already being provided due to existing requirements that should reduce the frequency for real power capability testing set forth in MOD-024. While planners have asserted the need for the data to improve modeling accuracy â€“ the SDT review of different planning models finds that they have inconsistent needs and donâ€™t facilitate a standard that supports reliability. EPSA respectfully requests that the SDT recognize the following objectives in crafting a standard that is responsive to FERCâ€™s directives in Order No. 693 (see 1310): 1. MOD-24 should not preempt or duplicate the real power verification procedures that already exist in the organized markets. 2. the frequency of real power verification in the organized market regions is driven by the annual capacity markets. System planning is a longer-term endeavor and as such real power verification for system planning purposes does not require the same annual frequency or level of precision. Thus, annual verification should not be required for any units, but rather all units should verify their real power capability on a longer cycle â€“ i.e., the five (5) year cycle currently proposed for certain smaller and low capacity factor units. A longer verification cycle reduces the need for unnecessary fuel burn and the uniformity results in better clarity as well as ease of implementation for Generator Operators.(note below) The SDT in its review also found that enhanced communication between entities will best facilitate the exchange of generator capability data. Further, it is worth noting that the Transmission Operator (TOP), Reliability Coordinator (RC), Balancing Authority (BA) and Regional Transmission Organization (RTO) / Independent System Operator (ISO) have access to a unitâ€™s real time output through their Energy Management System (EMS). The EMS provides updated information on a real-time basis, making further testing and reporting under MOD-24 duplicative and unnecessary. In addition, the GOP is required by other reliability standards to report unit de-rates to the TOP, RC, BA or ISO immediately after they occur, again making more frequent testing and data reporting under MOD-24 unnecessary. In addition, several existing Standards require the GOP to provide data related to generating unit capability status. Note: The capacity factor limitation simply may not be implementable if a unit has a capacity factor that fluctuates from year (i.e., if a 25 MVA unit has a CF less than 5% in years 1&2, but then exceeds 5% in year 3, then it needed to be tested annually and is non-compliant).

American Transmission Company
Yes
The requirements of this standard will provide empirical data that will improve system reliability.
Yes
The generating unit qualifications are consistent with the presently Compliance Registry criteria.
Yes
Yes
Yes
Yes
No
No
Yes
For R1, R2, & R3, we propose a Violation Risk Factor of â€œLowerâ€ and a Time Horizon of â€œOperations Planning, Long-Term Planningâ€. We propose â€œLowerâ€ for the VRF because more accurate real power capability values will be assured by this requirement, but reasonably accurate values are likely without this requirement. We propose â€œOperations Planning, Long-Term Planningâ€ for the TH because RCs and TOPs will use this data in their operations planning studies and PCs and TPs will use this data in their transmission planning studies. For R2, replace â€œdesired temperature to which the dataâ€ with â€œdesired ambient coolant temperature to which the summer and winter dataâ€ for added clarity. In Attachment 1, 3.2; replace â€œambient air temperatureâ€ with â€œambient coolant (air, water, etc.) temperatureâ€ because the capability of different types of generators is affected by the temperature of different cooling medium. In addition, consideration may need to be given to the average pressure level of generating units that use hydrogen for equipment cooling. Requirement 1: ATC believes that some additional clarity is needed as to those entities that will receive the information. Suggestion: â€œâ€¦submit to the Resource Planner and/or Planning Coordinator the information view MOD-024-2 Attachment 2â€¦â€ General Comment: It should be made clear that a GO validating and reporting a change in a unitâ€™s gross Real Power capability, in particular an increase in output, to comply with this standard, does not enable or give a GO the right to inject

said incremental output onto the transmission system. Any MW increase (regardless of duration or ambient conditions) must be formally considered via separate mechanisms for study and verification of the BESâ€™s ability to reliably support any such increase beyond that previously approved and included in a generation-transmission interconnection agreement.

Group

SERC Generation Subcommittee (GS)

Joe Spencer (SERC staff) / Jose Medina (NextEra-GS Chair)

The SERC Generation Subcommittee (GS) could not answer this definitively yes or no. The GS believes that reporting on MOD-024 is duplicative with other standards and may be retired. While this data is important, it is covered under: FAC-008/009, TOP-002, MOD-010/011, etc.

Yes

Stated or assigned values should be sufficient for modeling purposes for units having nameplate ratings < 75 MVA. This should apply to many regions. If the BA or TOP needs validated data on a smaller unit or group of units then these requirements can be made known to the GOP per TOP-002-2 R13.

No

We agree with the approach as stated in the questions but have selected NO here because the standard does not reflect the approach stated. For Attachment 1, Sections 1.1, 1.2, 2.1, and 2.2, these should be changed to say â€œfor at least one continuous hourâ€¦â€ to assure stable conditions.

No

While intermittent resources may not make up a significant portion of supply in most regions at this time, future development may result in significant portions of supply being made up of these resources, and relying only on design or nameplate values, for the purposes of transmission planning, will be as inappropriate for these units as it is for existing generation. The standard should focus on determining the appropriate generator ratings to be supplied to the planning processes, not how they are ultimately used.

Yes

Yes

Yes

The SERC Region is a summer peaking load region. Since unit capability (excluding hydro) is either independent of seasonal differences or will exhibit increased capacity for non summer periods, winter validation is not necessary. This would apply to summer peaking entities or regions.

No

Yes

Assuming this standard is not retired, the first bullet item under R2 should be deleted. If it is not, it should be revised as follows: â€¢ The data is to be adjusted for conditions normally experienced for summer and winter peak periods, as applicable. Industry guidance is needed on how to adjust recorded test data in Requirement R2 and Section 3.4.5 on Attachment 1. Section 3.4.5 should be expanded to allow for adjusting of data for factors other than ambient air temperature. Itâ€™s unclear what is being sought by â€œadjustingâ€ data to a desired temperature. For steam turbines, ambient air temperature may not impact output nearly as much as coolant temperature, when the machine is not air cooled.

Individual

Kasia Mihalchuk

Manitoba Hydro

Yes

If FAC-008 and FAC-009 are based upon design data and Engineering Analysis, a standard is required to complete field verification of the unit real power capability. There should be clear distinctions between these standards.

Yes

Agree to include units connected to 100 KV and above.

Yes

One hour testing is sufficient, and does not expose the unit to unnecessary stress or take excessive time to complete.

Yes

Wind generation and run of the river hydro units should be exempted.

Yes

Can the verification frequency of units be lowered to less than 20% for indentical units. Can it be 10% of identical uinits, as deterioration of unit real capacity is a very slow process unless a failure occurs (and failures are picked up by other standards)
Yes
State clearly who provides a schedule to whom. Is it Planning coordinator will provide a schedule to Resource planner for verified capability information of units? We would prefer that the requirement be to complete the testing at the required frequency, and to delete the requirement for creation and submission of a plan.
Yes
Regions with considerable hydraulic generation require verification of unit output that will be modified by calculation for rated head output for comparison. Exempting run of river plants removes this need for exemption.
No
MAPP was requiring unit capability tests in MRO region prior to MOD-024 NERC standard. The overlap with FAC-008 and FAC-009 should be carefully examined to avoid confusion.
Yes
The requirement R1 should be rewritten to include derivation of Summer and Winter ratings for Thermal units, and measured capacity corrected to design net head for Hydraulic units. R3 should be clarified to ensure it is only changes greater than 50MW that must be reported, not "any change for units that are greater than 50MW".
Individual
James Sharpe
South Carolina Electric and Gas
No
This standard appears to be redundant with TOP-002 R13. Also, Generator ratings are established in FAC-008. If a verification run by MOD-024-2 contradicts a rating established in FAC-008, which rating should an entity use? If the rating established by verification were used, would this not alter an entity's facility rating methodology?
Yes
Yes
Yes
No
Even though units may be identical in nature, variables such as actual in service time could lead to deratings and make two identical units unique. If the intent of the standard is to ensure unit generating capabilities are correct for studies, then shouldn't verification be made for all units?

We feel this standard is unnecessary since real power verification can and should be handled by generation and transmission agreements. Most traditional utilities already have a process in place to validate and/or certify unit capabilities. In the case of an IPP, this requirement can be addressed in the Transmission Interface documents. If this standard moves forward, then TOP-002-2 R13 must be deleted or at a minimum, revised to indicate that it addresses short term equipment issues in the operations horizon.
No
We recommend limiting the unit size requiring real power capability validation in paragraph 4.2 to the following: â€œGenerating Facilities connected at the point of interconnection at 100kV or above, containing an individual generating unit greater than or equal to 75MVA (individual gross nameplate rating)â€, for the following reasons: â€¢ Including only units > 75MVA will represent the vast majority of the total (cumulative) connected MW sources in the country â€¢ This cumulative MW class represents the units that are capable of having the largest impact to the stability and reliability of the BES â€¢ Excluding the smaller units will avoid unnecessary waste in time and money on the smaller units which individually do not appreciably affect the stability and reliability of the BES. â€¢ Stated or assigned values should be sufficient for modeling purposes for units having nameplate ratings < 75 MVA. If the BA or TOP needs validated data on a smaller unit or group of units then these requirements can be made known to the GOP per TOP-002-2 R13.
Yes
No
We recommend all hydro units be excluded since capability is dependent on available water levels. GOP's with appreciable hydro capacity have established procedures or processes to predict the capability of these units.
Yes
Yes
We agree with this requirement.
Yes
The SERC Region is a summer peaking load region. Since unit capability (excluding hydro) is either independent of seasonal differences or will exhibit increased capacity for non summer periods, winter validation is not necessary.
No
Yes
1. The subject standard should not require annual staged full load capability demonstration for verifying MW capability. There are many factors such as system load, economic dispatch, etc that determine if a unit is expected to be called to full load. This is especially true for the smaller (<75 MVA) units. 2. The requirement for ambient temperature monitoring during the verification period is unreasonable. The ambient temperature is not needed for unit operation, and may not be tracked, and in some cases may not be reliable. In these cases, either inaccurate data would be collected or added investment would be required. (The official ratings mentioned above are

based on performance data taken at or adjusted to specified ambient conditions.) 3. Allowances for different reporting format from that in attachment 2 should be permitted. We prefer a tabular reporting method due to the number of units in our fleet. An allowance for tabular reporting of the same information as indicated in attachment 2 should be permitted. 4. In Paragraph 3 of Page 5, we recommend replacing â€œNumberâ€ with â€œParagraphâ€. 5. The following comments relate to Attachment 2: a. On Page 7 we recommend the following: â€¢ moving the â€œDate of Reportâ€ and the associated blank line to the same line as â€œUnit Noâ€. â€¢ changing â€œAuxiliary Transformer(s)â€ below point A to â€œUnit Auxiliary Transformer(s)â€ â€¢ changing â€œAuxiliary Transformer(s)â€ below point C to â€œStation Auxiliary Transformer(s)â€ â€¢ splitting the bus just below the â€œPoint of Interconnectionâ€ and eliminating the single line diagram associated with point D. â€¢ adjusting single line diagram to fit on the page (displayed on a PC monitor) â€¢ change â€œMW (tertiary load, if any)â€, to â€œMW (GSU tertiary load, if any)â€ at the bottom of the page b. On Page 8, we recommend the following: â€¢ delete the point D measurement line from page 8 c. On Page 9 (Summer Verification Data), we recommend the following: â€¢ Insert a blank line between the â€œDate of Verificationâ€¦â€ line and the â€œVerification End Timeâ€¦â€ line.- in other words, make the summer and winter verification forms identical with respect to the Date of Verification, Verification Start Time, Verification End Time d. On Page 9 & 10 (Summer and Winter Verification Data), we recommend the following: â€¢ specify if the Aux Power (MW*) column in the table is â€œthe sum of the auxiliary loads shown on page 7â€ 6. R2 is not a requirement as currently written. It is a choice that the RP or PC makes. If he seeks verfied data, then he must provide certain things to the GO. If he chooses to not seek verified data, then he is not required to do anything. This means that M2 is wrong. The RP and PC should not be required to have evidence if they chose not to seek the data. 7. R1 requires the GO to submit information but it does not indicate to whom the data should be submitted. 8. R3: The threshhold for reporting a change in MW output is too high. A change of 10 to 50 MW in a generator's output could have an impact to system stability. The threshhold should be 10 MW. 9. Paragraph 2.4 in Att 1: The first word grouping is not a sentence and reads awkwardly. It is suggested that the words "an acceptable value can be obtained" be place in front of the words "by making a temperature". 10. Paragraph 3.4.2 in Att 1: Replace the word "since" with "if" for better clarity. 11. Paragraph 3.4.4 in Att 1: Move the words "in Attachment 2" to the position just after the word "flows". This will make it clear that the sentence refers to flows in Attachments 2 rather than units in Attachment 2.

Laura Zotter
ERCOT ISO
Yes
ERCOT ISO believes there is a need for this data. The verification methodologies, including the scheduling and timing of verification testing, should be left to the discretion of the relevant NERC functional entities â€“ e.g. the Planning Coordinator / Transmission Planner.
No
ERCOT ISO disagrees with this aspect of the proposal. Although, as a general matter, the relevant set of supply resources for reliability will be interconnected at 100 kV or greater, that is not an absolute rule. In fact, in the ERCOT Region there is a good amount of generation connected at 69 kV. The SDT should not preclude application of the proposed Standard to supply resources connected to facilities below 100 kV. 100 kV can be the default, but the requirement should provide for adequate flexibility to encompass other supply resources the methodology established by the relevant NERC functional entity includes such resources. Furthermore, this is consistent with the NERC Registry methodology, which accommodates facilities below 100 kV where they are necessary for/affect reliability of the Bulk Electric System.
No
ERCOT ISO disagrees with this aspect of the proposal. The methodology for verification should be left to the relevant NERC functional entities. As noted by the SDT, the Transmission Planner needs to communicate the conditions under which the resource is required to verify its real-power capability. This discretion afforded the TP should apply to all aspects of the verification, including the time period the unit must run. At a minimum, the proposed one-hour time period should be a default and the requirement should provide for alternative time periods to accommodate regional differences and different testing purposes â€“ e.g. for ancillary services.
No
ERCOT ISO disagrees with this aspect of the proposal because the performance/capability of all resources, including variable output resources, effects system planning and operations. Accordingly, contrary to the position of the SDT, the data from variable energy resources (e.g. intermittent renewable) is also needed for reliability. Although these resources are subject to the variability in terms of their fuel source (e.g. wind), there are methods of estimating the capacity and energy from these resources. These estimates provide value for the purposes of this standard. Variable energy resources should not be exempt from this requirement. The Standard should include these resources, provided that they are subject to rules that reflect the variability of their production. The verification methodologies established by the respective NERC functional

entities can accommodate variable resources in a manner that is consistent with the practices within their respective regions.
No
ERCOT disagrees with this aspect of the proposal. The assumption that all units of similar type at a plant are going to perform identically is not valid in all situations. Accordingly, to ensure any potential variances between similar units at the same site are accurately captured all such units should be required to provide verification annually.
Yes
ERCOT ISO supports this aspect of the proposal. The verification methodology and timing should be left to the discretion of the relevant NERC functional entities. As noted by the SDT, the needs for different Resource Planners and Planning Coordinators may vary. The Standard should enable the relevant entities to respect those needs, including the timing of the verification tests. By simply stating these entities should provide a schedule, the proposal provides adequate flexibility to respect regional differences. To accommodate the potential need for ad hoc testing, the requirement should provide for testing pursuant to the contemplated schedules â€œor as requested by the RP or PCâ€.
No
As discussed above, ERCOT ISO believes that there may be regional differences in the planning and operational studies where this information provides value. However, if the Standard is drafted to prescribe the reliability â€œendâ€ result or obligation, and it provides for adequate flexibility with respect to how the means implemented by the relevant entities to comply with the obligation, there should not be a need for regional differences. Revising the Standard in accordance with this general principle and the specific comments provided herein should affect this result and obviate, or at least mitigate to a great extent, the need for regional variances.
See response to Question 7 â€“ if the Standard provides adequate flexibility with respect to the means for complying with the reliability end prescribed by the requirements, this should mitigate any potential conflict.
Yes
ERCOT ISO believes R1 should clearly state to whom the Generator Owner of the Attachment 1 and Attachment 2 data should be submitted.

No
: Information required under the proposed standard is currently submitted with FERC Form 1 and for FAC-008 compliance. This standard is redundant and should be retired.
Yes
No
: Sufficient detail on the data requirements during the one hour sampling period required under the proposed standard has not been provided. Please provide some direction on the required sampling rate and acceptable methods for data collection. It is unreasonable to require that a maximum boiler capacity test be performed twice a year to validate the unit real power capability. Biannual capture of historical data would be the preferred method of unit capability validation. Water resource impacts on hydroelectric facility capability have not been addressed sufficiently by the proposed standard. Please provide clarification on expectations for data collection at hydro facilities when water resources do not support operation at unit capability.
Yes
No
Current policies within the WECC require a testing interval of five years. This interval has been sufficient for stability studies to date. We suggest incorporation of a five year interval for generator real power capability validation in the proposed standard.
No
: Scheduling of generator capability verification should be set by the generator owner and generator operator within the five year cycle suggested in the Item 5 comments.
No
Yes
: Again, water resource impacts on hydroelectric facility capability have not been addressed sufficiently by the proposed standard and may result in conflict with other regulatory standards. Please provide clarification on expectations for data collection at hydro facilities when water resources do not support operation at unit capability.

Yes
: Suggest language in Section 2.2 to read â€œthe resource planner will assess the stated winter generating capability based on a test hour of generation corrected for actual vs forecasted water elevations and flows.â€

Frank Gaffney
Yes
There are two potential reasons for the need to test generator capability related to the standards: 1) MOD-010-0 for accuracy of modeling purposes; and 2) for a potential standard on resource adequacy in the planning horizon (Project 2009-05?).
Yes
There is no need to expand the scope of the standard beyond the registration criteria. As the SDT has pointed out, only about 4% of the power system capacity is connected below 100 kV. Most of these generators are modeled, and many are already tested beyond the scope of the standard. So, causing regulation of generator verification to these generators may only improve accuracy for a small portion of the 4%. Such gain in accuracy at < 100 kV is easily overwhelmed by the inaccuracy of load forecasts, and by the variation of generator output with ambient conditions (e.g., temperature, humidity, barometric pressure, etc.) outside of forecasted ambient conditions. So, such effort is wasted because any supposed gain in accuracy by going below 100 kV is illusory and lost as compared to other forecast inaccuracies outside the control of anyone (e.g., the weather). If anything, the level of verification required in the standards could be reduced for smaller units (e.g., less frequent), even more so than as described in the standard. However, this would create a complex â€œtieredâ€ standard difficult to understand and monitor. Hence, we congratulate the SDT on developing a balanced perspective that truly focuses on what is important to maintain the reliability of the BES.

SERC Planning Standards Subcommittee
Philip R. Kleckley
Yes
There is a reliability need to verify real power capability for larger units on the system as discussed in our response to Question 2 below.
No
In general there is no reliability need to verify MW values for small units because they don't significantly affect the reliability of the system. The criteria should be to verify individual units which are 75 MVA or larger or aggregates of units which are 75 MVA or larger. Also provision could be made for the TP or PC to request verification of units which are smaller than 75 MVA for the rare case in which they do impact the reliability of the system.
Yes
Yes
Yes
Yes
No

No
Yes
R2 is not a requirement as currently written. It is a choice that the RP or PC makes. If he seeks verfied data, then he must provide certain things to the GO. If he chooses to not seek verified data, then he is not required to do anything. This means that M2 is wrong. The RP and PC should not be required to have evidence if they chose not to seek the data. This situation can be fixed by revising R2 to read: "Each Resource Planner and Planning Coordinator shall request verified generating unit Real Power capability data and shall provide each Generator Ownerâ€¦" R1 requires the GO to submit information but it does not indicate to whom the data should be submitted. We recommend that R1 be changed to read: "Each Generator Owner shall verify the summer and winter Real Power generating capability for each of its units in accordance with MOD-024-2 Attachment 1 - Verification of Summer and Winter Generating Unit Capability and record and submit the information to its Resource Planner and Planning Coordinator via MOD-024-2 Attachment 2 - One-line Diagram, Table and Summary for Verification Information Reporting." R3: The threshhold for reporting a change in MW output is too high. A change of 10 to 50 MW in a generator's output could have an impact to system stability. The threshhold should be a 10 MW change or greater. Paragraph 2.4 in Att 1: The first word grouping is not a sentence and reads awkwardly. It is suggested that the words "an acceptable value can be obtained" be place in front of the words "by making a temperature". Paragraph 3.4.2 in Att 1: Replace the word "since" with "if" for better clarity. Paragraph 3.4.4 in Att 1: Move the words "in Attachment 2" to the position just after the word "flows". This will make it clear that the sentence refers to flows in Attachments 2 rather than units in Attachment 2. The comments expressed herein represent a consensus of the views of the above named members of the SERC Planning Standards Subcommittee only and should not be construed as the position of SERC Reliability Corporation, its board or its officers.

Catherine Koch
Puget Sound Energy
Yes
Note: The way the question is worded with two opposite ideas makes it difficult to determine which box to check. Puget Sound Energy feels that this standard should be retired. This standard duplicates information required by other standards, including MOD-010, MOD-012, TOP-002 (R13), as well as FAC-009. Our Transmission Planners already request temperature related Real Power information for generating units through these other standards. Unit derates (proposed R3) are covered under TOP-002 R14, TOP-003, and TOP-006 R1.1. These other standards allow the Transmission Planners to customize their verification needs from the GO/GOP and not have a one-size fits all solution imposed on them as prescribed in this proposed standard.
Yes
Puget Sound Energy agrees with being consistent with the Compliance Registry. It seems that the compliance registry criteria would determine whether an entity has to comply with any of the NERC standards including this one and then the current BES definition would establish what facilities are applicable. The need to describe the Faclities under section 4.2 is not clear. We assume that any approved regional definition of the BES would dictate applicability ultimately. Regarding the verification requiremetns as proposed, it is unclear why annual verification (for most units) is necessary as much of the data will not change over an annual timeframe and most change that may occur would likely not cause a reliablity impact as it relates to the study work the Planning Coordinator or Resource Planner uses this information for. We would request that the testing be done on a 5 year cycle which follows other practices for providing data (i.e., WECC has been using a 5 year cycle for testing since 1997, and the results have proven to be entirely adequate).
Yes
Yes
Yes
However, we encourage this approach to test over a 5 year period for more that just identical units as discussed in our response to question 1. A 5 year cycle for testing is adequate.
No
While R2 allows flexibility in determining when the data is submitted, the Resource Planner/Planning Coordinator may not need this information each year. If that is the case, this annual requirement imposes an unnecessary burden on Planners and Generators to provide this information more frequently than necessary.
Yes

The WECC may want to continue using a 5 year cycle for testing. From the WECC experience testing annually for most units would be unnecessarily frequent.

North Carolina Electric Membership Corporation
Yes
While we agree that there is a reliability need to verify real power capability for larger units on the system, we are of the opinion that the SDT should direct the verification at units that significantly affect the reliability of the BES.
No
In general there is no reliability need to verify MW values for small units because they don't significantly affect the reliability of the system. The criteria should be to verify individual units which are at least 100 MVA or larger or aggregates of units which are 100 MVA or larger and units that are connected to the transmission at 200 kV and above unless the generating units have been deemed by the Planning Coordinator as critical to the reliability of the BES. This is similar to what has been proposed in the PRC-023 standard under development. All other generators that do not meet this critieria should be exempt.
Yes
No
Peaking units that have a limited cumulative energy per year (i.e. low capacity factor below 5%) should be provided the same treatment. The SDT should consider providing the PC with the flexibility for designing tests â€œneededâ€ for verification such that all units are either handled in the same way.
No
The SDT should not be concerned with administrative details.
No
The concept that regular period-specific verification is not necessary. If the SDT is insistent on such a schedule established by the RP/PC, we would ask the SDT to consider circumstances where the same GO owns generators in multiple operating areas thus having to comply with varying requirements by multiple PCs. This would potentially result in the GO having to comply with different schedules of these multiple PCs which could be very difficult for the GO to comply with.
No
No
Yes
R2 is not a requirement as currently written. It is a choice that the RP or PC makes. If he seeks verfied data, then he must provide certain things to the GO. If he chooses to not seek verified data, then he is not required to do anything. This means that M2 is wrong. The RP and PC should not be required to have evidence if they chose not to seek the data. This situation can be fixed by revising R2 to read: "Each Resource Planner and Planning Coordinator shall request verified generating unit Real Power capability data and shall provide each Generator Ownerâ€¦" R1 requires the GO to submit information but it does not indicate to whom the data should be submitted. We recommend that R1 be changed to read: "Each Generator Owner shall verify the summer and winter Real Power generating capability for each of its units in accordance with MOD-024-2 Attachment 1 - Verification of Summer and Winter Generating Unit Capability and record and submit the information to its Resource Planner and Planning Coordinator via MOD-024-2 Attachment 2 - One-line Diagram, Table and Summary for Verification Information Reporting." Paragraph 2.4 in Att 1: The first word grouping is not a sentence and reads awkwardly. It is suggested that the words "an acceptable value can be obtained" be place in front of the words "by making a temperature". Paragraph 3.4.2 in Att 1: Replace the word "since" with "if" for better clarity. Paragraph 3.4.4 in Att 1: Move the words "in Attachment 2" to the position just after the word "flows". This will make it clear that the sentence refers to flows in Attachments 2 rather than units in Attachment 2.

Dan Rochester
Independent Electricity System Operator

Yes
Accurate data for real power output of a generating unit/plant is critical to system modeling for resource adequacy and transmission reliability analyses. Unless other standards already cover the requirement for this data, this standard needs to be retained but some of the details for the additional empirical data are not necessary. Please see our comments under Q9.
Yes
This is a simple approach that should be supported. Notwithstanding our response and consistent with our reply to Q1, where the provision of this information is already required in other standards, those requirements should not be duplicated here.
Yes
Yes
We do not have any concern with the proposed approach. Individual Regions or markets that identify a need to verify such units to meet local requirements can establish regional specific criteria and market rules as they see appropriate.
Yes
No
We agree with the RPs and PCs to specify the schedule for receiving verified information to suit their needs. However, we have concerns with the applicability which relates to the purpose of the standard. a. The purpose of the existing MOD-024-1 is: â€œTo ensure accurate information on generator gross and net Real Power capability is available for steady-state models used to assess Bulk Electric System reliability.â€ This implies that the data is also used for accurate modeling of the BES which the TPs, TOPs and RCs use to assess transmission system performance. The purpose of the proposed MOD-024-2 appears to have been changed somewhat: â€œTo ensure that planning entities have accurate generator Real Power capability modeling data used in system planning studies.â€ This change was not mentioned in the SAR for the project (posted for comment in April 2007). We have two concerns with this change and the corresponding requirements: (i) The data is not only used for planning, it is also used for operational planning and near-term adequacy assessments (ii) If the intent of the existing standard is to continue, then the data is used for transmission reliability assessment as well. Other applicable entities need to be added. We suggest the SDT to assess the intended users of the generatorâ€™s real power capability data. Is the data used for resource adequacy assessment only, or is it also used for system model for transmission reliability/adequacy assessment? If it is the former, then RPs and PCs would be the only users. If itâ€™s the latter, then TPs, TOPs, and RCs can be the other users. b. In the Background Information section of the comment form, the SDT indicates that it â€œhas taken the approach that the Transmission Planner needs to communicate the conditions under which the Generator Owner is to provide verified values.â€ The proposed requirement does not include TPs. We wonder if the Background Information quoted the incorrect entities, or the standard is missing the TP as an applicable entity.
No
No
Yes
The detailed requirements in Attachment 1 are overly prescriptive. Specifically, the requirements listed in Item 3 are too detailed, and most of them are not needed for reliability. We believe Attachment 1 needs only to specify the sustainability (Items 1 and 2), periodicity (Item 4) and the ambient conditions of the verification (some of Item 3). Using the form and the one-line diagram do not contribute to reliability. A requirement to ask for both gross and net capability would suffice.

BPA suggests reducing the frequency of data collection ... not sure it needs to be every 5 years, it is just more onerous documentation for something that does not change a lot.
Yes
Yes
Yes
It seems like Wind and Solar should do a report for their peak generation for Summer and Winter

on a periodic basis.
Yes
Yes
No
No
Yes
Attachment 2 needs modification: Attachment 2 should have a measurement point on their diagram for the gross generator output, and the table should specify what values to use in the calculation of each column (Gross capability power = new point F, Aux power = A+B+C+D, Net Power = F-A-B-C-D) Because this standard is paired with MOD-025(reactive), BPA believes they should be commented together.
Group
IRC Standards Review Committee
Ben Li
Yes
The SRC agrees that there is a need for a verification requirement. Given that the GOs are responsible for submitting real power data, there should be a corresponding requirement to verify that data on an as-requested basis. This approach provides the Planners with data that is valid for producing viable forecasts and assessments.
No
There is no need for the SDT to impose a requirement / limitation on what is or is not subject to a NERC standard. The FERC has established those boundaries. To the extent that a PC needs or does not need verification of generators that fall outside those FERC-identified conditions, must be justified on a reliability need or settled outside the NERC-standard process.
No
A Planning Coordinator should be afforded the right to request periods other than one continuous hour as needed for ad hoc evaluations e.g. for Ancillary Service evaluations over a 15 minute period or for special case studies e.g. fuel disruption analysis. The default period may be agreed to as one continuous hour but that should not be the mandated period.
No
The SDT should not be concerned with administrative details. The PC should be responsible for requesting verification when verification is needed as opposed to mandating artificial (i.e. one test for all conditions) verification for the sake of artificial verification.
No
The SRC believes with the concept that regular period-specific verification is not necessary, but does not agree with the SDTâ€™s requirement. Rather the SRC would propose that R1 and R2 be replaced by the following 3 requirements: R.1. Each Planning Coordinator that requires validation of a Generator Ownerâ€™s reported generator capability for use in a NERC-mandated assessment shall submit a request to the Generator Owner specifying the applicable conditions. These conditions may include such parameters as: â€¢ Gross or Net data â€¢ Time (season) required â€¢ Boundary conditions (temperature, wind if appropriate) R.2. Each Generator Owner shall verify the Real Power generating capability for each of its units in accordance with requests from their Planning Coordinator. R.3. The Planning Coordinator shall distribute the verified data to the Resource Planners that request the data, or are known by the PC to use that data. Note: CAISO does not support the proposed R3.
No
Yes
Certain Regional Entities are currently developing or have developed standards to comply with MOD-024-1 and close coordination will be necessary to ensure that no compliance conflicts are created with the approval of this updated standard.

The reliability need has not been adequately demonstrated and the standard should be retired. It's not clear that it's necessary to require a high degree of accuracy on one segment of generation, when another segment (variable generation) is not addressed and loads levels used in studies are estimates.
Yes
We agree with the demarcation but recommend it be reworded to exclude generation units interconnected at voltages below 100 kV and units below 20 MVA to avoid unnecessary discussion of registration criteria.
Yes
No
If there's truly a reliability need for verification of capability, this segment of generation needs to be addressed.
Yes
Yes
No
No
Yes
Combined cycle power plants are often built with peaking capability such as steam injection for power augmentation. The term "normal operation" should be defined and include a statement that peaking capability is included only if the unit routinely operates in this mode. Combined cycle plants are sensitive to a variety of ambient conditions in addition to temperature, such as relative humidity. The standard should be revised to include other ambient data required by the generator to adjust output.

Consideration of Comments on the 1st Draft of MOD-024-2 Verification and Data Reporting of Generator Real Power — Project 2007-09 Generator Verification

The Generator Verification Standard Drafting Team thanks all commenters who submitted comments on the 1st Draft of MOD-024-2 Verification and Data Reporting of Generator Real Power — Project 2007-09 Generator Verification. This standard was posted for a 30-day public comments period from January 18, 2010 through February 18, 2010. The stakeholders were asked to provide feedback on the standards through a special Electronic Comments Form. There were 47 sets of comments, including comments from more than 130 different people from over 60 companies representing 8 of the 10 Industry Segments as shown in the table on the following pages.

http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html

Summary Consideration:

Redundancy: Several commenters indicated that the data addressed in MOD-024-2 is already required to be provided through other standards.

- Considerable time has passed since MOD-024-2 was originally posted, and some of the other standards that previously included data provision requirements have now been proposed for retirement. Some of the duplicate requirements were identified in the TOP series of standards and the TOP requirements have been identified for retirement to avoid duplication with the MOD-024 standard. The requirements slated for retirement include TOP-002 Requirement R 12 which was the closest matching data collection requirement to MOD-024 for real power verification.

The drafting team has reviewed each of the standards identified as possibly containing a requirement redundant with MOD-024 and has confirmed that the proposed requirements in the revised MOD-024 do not duplicate other requirements. To clarify this point the SDT acknowledges that if the correct system operations circumstance exists then the data obtained by performing the Real Power capability verification required by the MOD-024 standard (now incorporated into the MOD-025 standard) for system planning purposes may yield the same results as could be obtained by using equipment nameplate ratings, unit operational data, EMS data, forecast information, etc. required to be provided to the ERO by other standards. Recognize this alternate set of data is collected for other reliability purposes and is not guaranteed to represent actual capability. As such, there is a reliability need to specifically require Real Power capability verification. The SDT also acknowledges it is acceptable to utilize reasonable assumptions when performing long term planning analysis however the SDT also believes it is prudent from a reliability concern to incorporate established unit operational constraints into the planning model when relevant. Units may be derated or constrained for a variety of legitimate long term reasons. Likewise, units derated or constrained today may have restrictions released in the future. Only by performing a Real Power capability verification to determine what the unit is capable of supplying can accuracy of needed reliability data be assured.

Applicability: The requirement for the Resource Planner and Planning Coordinator to provide the Generator Owner with schedules and temperature adjustments was deleted, and the applicability section of the standard was revised to omit the Planning Coordinator and Resource Planner.

Several commenters had specific suggestions for modifications to the proposed applicability, and the drafting team defaulted to using the same facility criteria for generating units as listed in the compliance registration criteria.

Several commenters provided support for including variable units, such as solar wind and run of river hydro, in the real power verification because these units are important to the model of the system, even though they might not reach their maximum real power capability on any given day due to the resource they depend on as a ‘prime mover’. The revised standard does not exempt these units from the verification requirements.

Requirement R1: Several commenters indicated that Requirement R1 didn’t specify where to send the verified data. The requirement was modified to clarify that the data must be sent to the Planning Coordinator. The Functional Model indicates that all planning entities are required to collect data for models, and also indicates that these entities are required to coordinate the update of models with other planning entities. As envisioned, the Planning Coordinator will share the data from the Generator Owner with its Resource Planners and Transmission Planners.

Some commenters suggested that the verified data should be shared with all operating and planning entities and this suggestion was not adopted. The revised standard does not provide the data to any operating entities as the data is verified for its applicability in long-range planning studies, and the data needed for operating monitoring and operational analysis needs to be more current than needed for planning studies.

Several commenters suggested that verifications are not needed every year – and proposed a five year cycle and this was adopted. Seasonal verifications are not included in the revised standard.

The SDT has combined the requirements of MOD-024 and MOD-025 into MOD-025. Under the combined standard, all applicable units will be verified for both real and reactive power capability just once every five years. To avoid having many units requiring verification in any one year, the initial implementation period proposed requires verification of 20% of an entity’s units each year.

Requirement R2: The first draft of MOD-024-2 required the Generator Owner to provide its verified data to both the Planning Coordinator and the Resource Planner according to a schedule defined by the planning entity. The majority of respondents supported having the Resource Planner and Planning Coordinator provide a schedule for performing the verifications which was the SDT’s initial proposal; however, the stakeholder comments indicated that this approach may result in a large number of different schedules, potentially causing confusion among the entities that must provide the data. The SDT has dropped the requirement to have the planning entities provide the Generator Owner with a schedule for conducting verifications since the periodicity for conducting verifications was revised to 5 years.

Requirement R3: The first draft of MOD-024-2 required the Generator Owner to provide the Resource Planner and Planning Coordinator with updates to its verified capabilities when the change to gross Real Power generating capability was expected to last at least six months and involve at least 50 MW. Several comments suggested that the 50 MW threshold should be modified and the SDT has proposed a 10% change to the last verified capability as the threshold in the revised standard. Note that in the revised standard this update is addressed in Attachment 1 and is considered part of Requirement R1.

All persons and entities that have provided comments on MOD-024-2 are encouraged by the SDT to review the first posting of MOD-025-2.

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comments serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herb Schrayshuen, at 609-452-8060 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

Index to Questions, Comments, and Responses

1. MOD-024-1, Verification of Generator Gross and Net Real Power Capability, was approved by the NERC Board 2/7/2006. It has not been approved for enforcement under Section 215 by FERC because it contains "fill-in-the-blank" characteristics with responsibilities assigned to the Regional Reliability Organization. Megawatt data is currently collected and reported under several other standards as well as many market rules. Do you feel that there is a reliability need for this additional empirical data, or should this standard be retired? Please explain. 13

2. The SDT believes that verification should be performed on units that are connected down to 100 kV. The SDT believes this is consistent with the current Compliance Registry. The SDT has also provided how verification should be handled in plants/facilities that are greater than 75 MVA in aggregate gross nameplate rating. The Standard requires a separate verification for every unit greater than 20 MVA gross nameplate rating and connected at the point of interconnection of 100 kV or above. The remaining units in a plant/facility can be verified separately or in aggregate as the Generator Owner chooses. Do you agree with the SDT's decision to have the Standard be applicable to facilities connected to 100 kV and above and verified as proposed? Please explain. 29

3. After much discussion the SDT decided to require the verification be performed over a period of at least "one continuous hour" regardless of the type of unit because most units have reached steady state operation within one hour. Do you agree with this approach? If not, please explain. 37

4. The SDT felt that units that cannot sustain continuous operation, oftentimes known as intermittent, variable or limited energy units, such as a Wind Generating Station or run-of-river hydro, etc., should be exempt from this standard because such units are typically represented in studies with "on average" or "discounted" values. Do you agree with this approach? If not, please explain. 45

5. The SDT has developed a separate periodicity approach for identical units at the same site in Number 4.4 of Attachment 1. The Generator Owner would only be required to verify 20% of these units per year. Do you agree with this approach? If not, please explain. 53

6. The SDT believes that every Resource Planner and Planning Coordinator does not necessarily perform studies involving generating unit verified capability at the same time each year nor do they necessarily need current verified information at the same time. The SDT has developed Requirement R2 that requires the Resource Planner and Planning Coordinator to provide a schedule for receiving verified information that best fits the schedule and needs for performing studies. Do you agree with this approach? If not, please explain. 59

7. Are you aware of any regional variances that would be required for this standard? 69

8. Are you aware of any conflicts between the proposed standard and any regulatory function, rule, order, tariff, rate schedule, legislative requirement, or agreement? 75

9. Do you have any other questions or concerns with the proposed standard that have not been addressed? If yes, please provide a reference to the section, requirement or

subrequirement that you believe should be changed, added or deleted and the rationale for your proposal. 80

The Industry Segments are:

1 — Transmission Owners
2 — RTOs, ISOs
3 — Load-serving Entities
4 — Transmission-dependent Utilities
5 — Electric Generators
6 — Electricity Brokers, Aggregators, and Marketers
7 — Large Electricity End Users
8 — Small Electricity End Users
9 — Federal, State, Provincial Regulatory or other Government Entities
10 — Regional Reliability Organizations, Regional Entities

1. **MOD-024-1, Verification of Generator Gross and Net Real Power Capability, was approved by the NERC Board 2/7/2006. It has not been approved for enforcement under Section 215 by FERC because it contains "fill-in-the-blank" characteristics with responsibilities assigned to the Regional Reliability Organization. Megawatt data is currently collected and reported under several other standards as well as many market rules. Do you feel that there is a reliability need for this additional empirical data, or should this standard be retired? Please explain.**

Summary Consideration:

The intent of question 1 was to obtain input from industry as to whether MOD-024 was required to ensure reliability, or should it be retired because real power data is collected and reported under other NERC standards and market rules. The originally proposed MOD-024-2 had three requirements:

- R1 required the Generator Owner to verify summer and winter real power generating capability of each of its units
- R2 required the Resource Planner and Planning Coordinator that wanted verified generating unit real power capability data to provide the Generator Owner with temperature adjustments and a schedule for verification
- R3 required the Generator Owner to report significant changes in gross Real Power generating capability to its Resource Planner and Planning Coordinator

There was a mixture of responses indicating to the Standard Drafting Team (SDT) that the question had been interpreted differently by different commenting entities. In hindsight, the question was worded poorly.

Stakeholders indicated that the following standards include requirements that duplicate the requirements the SDT had originally proposed with MOD-024:

FAC-002-0, Requirements R1 and R1.1 and R1.4

- The requirements identified require evidence of coordination in conducting studies before integrating facilities. The requirements do not require identification or sharing of specific capability data.

FAC-008/009

- FAC-008-1 requires the facility owner to document and share its facility rating methodology – it does not require sharing any facility ratings
- FAC-009-1 requires the facility owner to develop and communicate its facility ratings. The facility rating is not the same as the capability.

TOP-002, Requirement R12/R13, R14 and R15

- Requirement R13 requires the Generator Operator to perform real and reactive power capability verifications, but this requirement has been proposed for retirement under Project 2007-03 to avoid duplication with MOD-024.
- Requirement R14 requires the Generator Operator to notify the Balancing Authority of changes in capabilities and characteristics. This requirement involves different functional entities for both reporting and receiving data – it has a different reliability objective from MOD-024-2 (now MOD-025).
- Requirement R15 has been proposed for retirement under Project 2007-03.

TOP-003, Requirements R1, R2, and R3

- Requirements R1, R2, and R3 are all related to sharing of outage information. Requirement R3 from the originally proposed MOD-024-2 has been modified and absorbed in the attachment associated with Requirement R1 of MOD-025. Now outage information that leads to different real or reactive power capability only needs to be reported if the outage changes the capability by at least 10% for at least 6 months. The drafting team working on TOP-003 has proposed modifications that eliminate requirements to provide specific data – the revised standard, as proposed, allows each TOP to identify what data it needs and to request that data from the entities that have that data. Neither the original TOP-003 nor the proposed revisions to TOP-003 address provision of the same data to the same entities as the data proposed to be provided by the Generator Owner to the Resources Planner and Transmission Planner in MOD-024 (now MOD-025.)

TOP-006, Requirements R1 and R1.1

- Requirements R1 and R1.1 in TOP-006 do not duplicate the proposed requirements in MOD-024 (now MOD-025). The requirements in TOP-006 require the TOP to 'know' the status of generation resources available for use – and require the Generator Operator to provide the Transmission Operator with that information. The requirements in TOP-006 are intended for exchange of information for near real-time use, and don't involve the same data or the same entities as proposed to be provided in MOD-024 (now MOD0-025).

MOD-010/011

- MOD-011 Requirement R1.2 does require the RRO to develop a specification for entities to provide net generator minimum and maximum Ratings for both real and reactive power and MOD-010 does require the Generator Owner to provide the requested data. The minimum and maximum ratings are not the same as the capabilities.

MOD-012, R1

- MOD-012, Requirement R1 requires Generator Owners to provide equipment characteristics to the Regional Reliability Organization, which is not the same as providing unit capabilities collected under specific conditions.

MOD-026/027

- MOD-026-1 requires Generator Owners to provide generator excitation control system and plant volt/var control function models to accurately represent control response behavior during dynamic simulation, which is reactive power response behavior.
- MOD-027-1 requires Generator Owners to provide turbine/governor and load control or active power/frequency function models to accurately represent control response behavior during dynamic simulation, which is not the same as Real Power capabilities.

Please see the proposed revisions to MOD-024 that have been absorbed into MOD-025. The changes allow use of historical data; merge the requirements for the two standards into a single standard for efficiency when conducting the verifications.

Organization	Yes or No	Question 1 Comment
SERC Generation Subcommittee (GS)		The SERC Generation Subcommittee (GS) could not answer this definitively yes or no. The GS believes that reporting on MOD-024 is duplicative with other standards and may be retired. While this data is important, it is covered under:FAC-008/009, TOP-002, MOD-010/011, etc.
Response: Thank you for your comments. Please see the summary consideration. The drafting team reviewed FAC-008/009, TOP-002 and MOD-010/MOD011 as well as other standards for potential duplication and did not find duplication with the proposed requirements. After thorough consideration of all responses and additional deliberation, the SDT is proposing that the revised standard require the Generator Owner to collect real power verification data at the same time as reactive power verification data, and merged MOD-024 requirements in MOD-025. To perform the reactive power verification it is necessary to go to the rated real power operating point. Therefore, recording and reporting both the real and reactive power data as part of the MOD-025 verification only makes sense for efficiency.		
American Electric Power	No	
ITC Holdings	No	
PacifiCorp	No	: Information required under the proposed standard is currently submitted with FERC Form 1 and for FAC-008 compliance. This standard is redundant and should be retired.
Response: Thank you for your comments. Data provided under FERC Form 1 is not required to be shared with entities that need the data for modeling. FAC-008-1 does not require sharing of capabilities, it requires developing a facility rating methodology. FAC-009 requires sharing of facility ratings developed according to the rating methodology, however facility ratings are not the same as capabilities.		
Indiana Municipal Power Agency	No	IMPA is anwering no to the question "Do you feel that there is a relaiblity need for this additional empirical data", and answering yes to the question "should this standard be retired". The reporting of megawatt data in

Organization	Yes or No	Question 1 Comment
		other reliability standards and in market testing requirements for units is enough.
Response: Thank you for your comments. Please see the summary consideration. The drafting team reviewed several standards for potential duplication and did not find duplication with the proposed requirements. Data provided under FERC Form 1 is not required to be shared with entities that need the data for modeling. **After thorough consideration of all responses and additional deliberation, the SDT is proposing that the revised standard require the Generator Owner to collect real power verification data at the same time as reactive power verification data, and merged MOD-024 requirements in MOD-025. To perform the reactive power verification it is necessary to go to the rated real power operating point. Therefore, recording and reporting both the real and reactive power data as part of the MOD-025 verification only makes sense for efficiency.**		
GO/GOP	No	No, we do not feel additional empirical data is necessary as we believe this version should include data required in Version 1 as this version gave a better description of what is happening with a generating unit during a test. Yes, we do feel this standard should be retired. We believe this standard is unnecessary since real power verification can and should be handled by generation and transmission agreements. The Generator Owner (GO) & Generator Operator (GOP) provide generation unit real power capability in seven standards other than in MOD-024 plus the Transmission Operator (TOP), Reliability Coordinator (RC), Balancing Authority (BA) and Regional Transmission Organization (RTO) / Independent System Operator (ISO) see a unit's real time output via their Energy Management System (EMS). Therefore, the generator testing and reporting contemplated under MOD-024 is unnecessary. In addition, MOD-026 and 027 have not been considered in this discussion but are anticipated to be approved over the course of the next two years would cause further duplication. Thus, MOD-024 is clearly unnecessary.
Response: Thank you for your comments. Please see the summary consideration. The drafting team reviewed several standards for potential duplication and did not find duplication with the proposed requirements. Note that the standard was modified and the second draft does allow use of historical data from actual output.		
Bauer	No	The changes in this standard duplicate and conflict the requirement specific under TOP002. Originally this standard was for verification procedures which were used to meet TOP-002. The verification procedures defined in this standard should be incorporated into TOP-002 if this standard is retired.
Response: Thank you for your comments. TOP-002-2a Requirement R13 requires the Generator Operator to perform real and reactive power capability verifications, but this requirement has been proposed for retirement under Project 2007-03 to avoid duplication with MOD-024. Please see the summary consideration.		
Generators Supporting	No	The generator owner/operator provides unit real power capability in six standards other than in MOD-024 plus the TOP/RC/BA/ISO see a unit's real time output via their EMS. MOD-024 is duplicative and, as such,

Organization	Yes or No	Question 1 Comment
Elimination of MOD-024		unnecessary. Planners on the RFC MOD-024 draft standard drafting team argued that they needed to know what a unit could consistently produce over a 7-24 hour period when running their reliability models. They were not interested in knowing short-term unit capability. Another reason for not using the unit's output under a stressed condition is that it is not at a level of reliable output. A unit can generate the real power during a test but many times not under actual system conditions. These tests are conducted at the most favorable time for unit performance and are only indicative of unit performance at that point in time. They are no guarantee of future performance. This results in system operators not getting the real power output that they thought was available to them. This shortage of real power occurs during system emergencies when system operators need the mega-watts the most. Because of this, these mega-watts have been called paper mega-watts. Requiring a test actually fosters a situation counter to ALR.Every unit's output must be metered and its output is monitored in real time in the TOP, RC and/or ISO Energy Management System (EMS). The EMS would have a history of a units output. This data is the most accurate representation of a unit's capability under actual system conditions and is a true representation of actual unit capability. This actual unit production data can be made available to the transmission planners. The transmission planners can analyze EMS data and use that period of unit performance that meets their requirements. If they are interested in a unit's performance during the period of highest demand, they can analyze unit output during the most recent or previous peak demand period. By using actual data, the paper mega-watt's issue goes away. If the planner has any issues, they can discuss these directly with the generator operator/owner.Requiring the planner to analyze EMS data may have another benefit. It will force the planner to become more engaged and communicate more strongly with the real-time system operators. The planner will become more aware of real-time issues that will enable them to incorporate these anomalies into their system models.Another benefit to using actual unit data is that it will eliminate running the unit to perform the MOD-024 verification. Not having to run a unit that is not needed to meet system demand will result in fewer emissions and fuel consumption yielding a higher level of environmental stewardship. As a nation, we are supposed to be concerned about greenhouse gases and efficient use of carbon-based fuels. Forcing units to run is contrary to these national goals.Unit real power capability is specified in the units interconnection agreement with the TO. The GOP is required to report unit de-rates to the TOP, RC, BA or ISO immediately after they occur. Real power reporting requirements currently appear in six (6) standards as follows: FAC-002-0: R1. The GO, TO, Distribution Provider (DP), and Load-Serving Entity (LSE) seeking to integrate generation facilities, transmission facilities, and electricity end-user facilities shall each coordinate and cooperate on its assessments with its Transmission Planner and Planning Authority. The assessment shall include: R1.1. Evaluation of the reliability impact of the new facilities and their connections on the interconnected transmission systems.

Organization	Yes or No	Question 1 Comment
		R1.4. Evidence that the assessment included steady-state, short-circuit, and dynamics studies as necessary to evaluate system performance in accordance with Reliability Standard TPL-001-0. MOD-010-0 Applicability 4.3. GO specified in the data requirements and reporting procedures of MOD-011-0 R1. MOD-011-0 R1.2. Generating Units (including synchronous condensers, pumped storage, etc.): location, minimum and maximum Ratings (net Real and Reactive Power), regulated bus and voltage set point, and equipment status. TOP-002-2a R13. At the request of the Balancing Authority or Transmission Operator, a Generator Operator shall perform generating real and reactive capability verification that shall include, among other variables, weather, ambient air and water conditions, and fuel quality and quantity, and provide the results to the Balancing Authority or Transmission Operator operating personnel as requested. R14. Generator Operators shall, without any intentional time delay, notify their Balancing Authority and Transmission Operator of changes in capabilities and characteristics including but not limited to: R14.1. Changes in real and reactive output capabilities. (Retired August 1, 2007) R14.1. Changes in real output capabilities. (Effective August 1, 2007) R15. Generation Operators shall, at the request of the Balancing Authority or Transmission Operator, provide a forecast of expected real power output to assist in operations planning (e.g., a seven-day forecast of real output). TOP-003-1 R1. Generator Operators and Transmission Operators shall provide planned outage information. Each Generator Operator shall provide outage information daily to its Transmission Operator for scheduled generator outages planned for the next day (any foreseen outage of a generator greater than 50 MW). The Transmission Operator shall establish the outage reporting requirements. Such information shall be available by 1200 Central Standard Time for the Eastern Interconnection and 1200 Pacific Standard Time for the Western Interconnection. R2. Each Transmission Operator, Balancing Authority, and Generator Operator shall plan and coordinate scheduled outages of system voltage regulating equipment, such as automatic voltage regulators on generators, supplementary excitation control, synchronous condensers, shunt and series

Organization	Yes or No	Question 1 Comment
		capacitors, reactors, etc., among affected Balancing Authorities and Transmission Operators as required. R3. Each Transmission Operator, Balancing Authority, and Generator Operator shall plan and coordinate scheduled outages of telemetering and control equipment and associated communication channels between the affected areas. TOP-006-2 R1` Each Transmission Operator and Balancing Authority shall know the status of all generation and transmission resources available for use. R1.1 Each Generator Operator shall inform its Host Balancing Authority and the Transmission Operator of all generation resources available for use. Because the generator owner/operator provides unit real power capability in six standards plus the TOP/RC/BA/ISO see a unit's real time output via their EMS reporting the generator testing and reporting contemplated under MOD-024 is unnecessary. In addition, MOD-026 and 027 have not been considered in this discussion but are anticipated to be approved over the course of the next two years would cause further duplication. Thus, MOD-024 is clearly unnecessary.

Response: Thank you for your comments. The revised MOD-025 (which includes Requirement R1 from the originally proposed MOD-024-2) does allow the use of operational data.

The SDT acknowledges that if the correct system operations circumstance exists then the data obtained by performing the Real Power capability verification required by the MOD-024 standard (now incorporated into the MOD-025 standard) for system planning purposes may yield the same results as could be obtained by using equipment nameplate ratings, unit operational data, EMS data, forecast information, etc. required to be provided to the ERO by other standards. Recognize this alternate set of data is collected for other reliability purposes and is not guaranteed to represent actual capability. As such, there is a reliability need to specifically require Real Power capability verification. The SDT also acknowledges it is acceptable to utilize reasonable assumptions when performing long term planning analysis however the SDT also believes it is prudent from a reliability concern to incorporate established unit operational constraints into the planning model when relevant. Units may be derated or constrained for a variety of legitimate long term reasons. Likewise, units derated or constrained today may have restrictions released in the future. Only by performing a Real Power capability verification to determine what the unit is capable of supplying can accuracy of needed reliability data be assured.

Requiring a one hour capability test period is based on engineering judgment. The SDT envisions Generator Owners will first realize steady state conditions at maximum capability before commencing the one hour verification test. The SDT believes demonstrating a unit can operate at maximum capability during steady state conditions for one hour also proves the unit can operate indefinitely in this manner. Also, the proposed PRC-024-1 standard requires generator performance by remaining connected during voltage and frequency excursions.

The SDT agrees in general with comments raised regarding environmental stewardship concerns and believes this consideration is rendered moot by requiring verification once every five years. It is reasonable to assume that the unit will run for at least one hour at maximum capability during the five

Organization	Yes or No	Question 1 Comment
year period. **Please see the summary consideration. The drafting team reviewed each of the standards and requirements you've identified for potential duplication and did not find duplication with the proposed requirements. Note that the standard was modified and the second draft does allow use of historical data from actual output.**		
Calpine Corporation	No	The reliability need has not been adequately demonstrated and the standard should be retired. It's not clear that it's necessary to require a high degree of accuracy on one segment of generation, when another segment (variable generation) is not addressed and loads levels used in studies are estimates.
Response: Thank you for your comment. The reliability-related need for this project was established at the SAR development stage of this project.		
Hydro-Quebec TransEnergie (HQT)	No	The SDT is asking two question at the same time, with possible contradicting answer.There is reliability need to collect this data. NERC staff should coordinate and ensure that the collection of this data is incorporated in existing standards. If it is, the Standard (MOD-024) should be retired. If it is not done in other Standards this project should be pursued. Even if the collection of this data is already addressed through tariffs, Market Rules, and Interconnection Agreements, in what way would the compliance and sanction be addressed? If there is a Standard that make it obligatory to respect tariffs, Market Rules, and Interconnection Agreements, this project could be retired.
Response: Thank you for your comments. Please see the summary consideration. The drafting team reviewed several standards for potential duplication and did not find duplication with the proposed requirements. After thorough consideration of all responses and additional deliberation, the SDT is proposing that the revised standard require the Generator Owner to collect real power verification data at the same time as reactive power verification data, and merged MOD-024 requirements in MOD-025. To perform the reactive power verification it is necessary to go to the rated real power operating point. Therefore, recording and reporting both the real and reactive power data as part of the MOD-025 verification only makes sense for efficiency.		
Exelon Generation Co LLC	No	The standard should be retired there is presently an number of different standards the require Generators to provide the same information.
Response: Thank you for your comment. Please see the summary consideration. The drafting team reviewed several standards for potential duplication and did not find duplication with the proposed requirements.		
Public Service Electric and Gas Company	No	The standard should be retired. There are several other standards pursuant to which the GO and/or GOP provides real power capability to those parties needing that data. Also, the RTOs, ISOs, in their role as TOP,

Organization	Yes or No	Question 1 Comment
		RC and BA receive actual data continuously via the EMS. Likewise, those entities performing the same functions in non-ISO areas also receive the data. The actual operating data collected through EMS systems is far superior in quality to that resultant from compliance with MOD-024, both presently and as proposed. Imposing duplicate burdens on generators with no commensurate benefit to reliability should be avoided. Hence, MOD-024 is not necessary.
Response: Thank you for your comments. Keep in mind ambient monitoring is allowed and EMS system data does not necessarily represent unit maximum capability. The SDT acknowledges that if the correct system operations circumstance exists then the data obtained by performing the Real Power capability verification required by the MOD-024 standard (now incorporated into the MOD-025 standard) for system planning purposes may yield the same results as could be obtained by using equipment nameplate ratings, unit operational data, EMS data, forecast information, etc. required to be provided to the ERO by other standards. Recognize this alternate set of data is collected for other reliability purposes and is not guaranteed to represent actual capability. As such, there is a reliability need to specifically require Real Power capability verification. The SDT also acknowledges it is acceptable to utilize reasonable assumptions when performing long term planning analysis however the SDT also believes it is prudent from a reliability concern to incorporate established unit operational constraints into the planning model when relevant. Units may be derated or constrained for a variety of legitimate long term reasons. Likewise, units derated or constrained today may have restrictions released in the future. Only by performing a Real Power capability verification to determine what the unit is capable of supplying can accuracy of needed reliability data be assured. **Please see the summary consideration. The drafting team reviewed several standards for potential duplication and did not find duplication with the proposed requirements. Note that the standard was modified and the second draft does allow use of historical data from actual output.**		
AMEA	No	The two questions the SDT asked on question 1 could have two different answers. I answered no to the additional data and yes to retire this standard.The MOD-024-2 draft removes the regions and entities like the Planning Coordinator from the decision making ability as to which generators are material to the BES but instead provides a blanket approach that will include generators that are and are not material to the BES.
Response: Thank you for your comment. The generators covered by this standard are those that are owned by Generator Owners required to register for compliance.		
Arizona Public Service Co.	No	There is no reliability need for this standard and it should be retired. It does not serve any purpose and no body uses this data.
Response: Thank you for your comment. The reliability-related need for this standard was established with the SAR for this project. The data is used in models that are then used to conduct assessments of the bulk power system.		
South Carolina Electric and Gas	No	This standard appears to be redundant with TOP-002 R13. Also, Generator ratings are established in FAC-008. If a verification run by MOD-024-2 contradicts a rating established in FAC-008, which rating should an entity use? If the rating established by verification were used, would this not alter an entity's facility rating

Organization	Yes or No	Question 1 Comment
		methodology?
Response: Thank you for your comments. Please see the summary consideration. Generator ratings are not the same as capability. Actual capability can differ from generator rating provided because of derate or constraint conditions. Furthermore, a unit limited today may be released for unrestricted operation in the future. Capability verification identifies actual unit performance that can be achieved with respect to the operational and regulatory constraints existing. The drafting team reviewed several standards for potential duplication, including TOP-002 and FAC-008 and did not find duplication with the proposed requirements.		
The Empire District Electric Company	No	This standard should be retired
Response: Thank you for your comment. A Please see the summary consideration. The drafting team reviewed several standards for potential duplication and did not find duplication with the proposed requirements. Therefore, this standard will not be retired – instead the requirements have been clarified and merged into MOD-025.		
Electric Market Policy	No	We agree that a standard for Verification of Generator Gross and Net Real Power Capability is needed. We support the data being requested in standard MOD-024-2, Attachment 1 and 2.
Response: Thank you for your supportive comment.		
We Energies	No	We feel this requirement could be retired do to the fact that the data is collected and reported under several other standards as well as many market rules. For example, the Midwest ISO has established testing requirements for generators under Module E of the Midwest ISO Open Access Transmission, Energy and Operating Reserve Markets Tariff. We also feel that having multiple different testing and reporting requirements can potentially lead to confusion and errors in reporting. If it is determined to not retire this standard, a provision should be made that if generator testing information is provided to a RTO following prescribed testing standards of the RTO, the submittal of the information to the RTO would meet the requirements of MOD-024-2. There is also a concern regarding the different applicability requirements between MOD-024-2 (Generator Owner, Planning Coordinator, and Resource Planner) and the recently passed MOD-024-RFC-01 (Generator Operator and Planning Coordinator) which further illustrates the problem of consistency of requirements.
Response: Thank you for your comments. Data provided under market rules is not necessarily required to be provided to the planning entities that need this data for modeling. Please see the summary consideration. The drafting team reviewed several standards for potential duplication and did not find duplication with the proposed requirements. **The drafting team consulted with the Functional Model for verification that the Generator Owner is the correct functional entity to provide data about**		

Organization	Yes or No	Question 1 Comment
its facilities. The Functional Model does not provide as much clarity on responsibility for updating models. The Functional Model assigns all three of the planning entities - the Planning Coordinator, Resource Planner and Transmission Planner with responsibility for collecting data to update models, and assigns all three of the planning entities with responsibility for coordinating data collection with other planning entities. To minimize the efforts associated with providing data, the SDT revised the standard so that the Generator Owner is only required to provide data to the Planning Coordinator.		
Southern Company Transmission/Generation	No	We feel this standard is unnecessary since real power verification can and should be handled by generation and transmission agreements. Most traditional utilities already have a process in place to validate and/or certify unit capabilities. In the case of an IPP, this requirement can be addressed in the Transmission Interface documents. If this standard moves forward, then TOP-002-2 R13 must be deleted or at a minimum, revised to indicate that it addresses short term equipment issues in the operations horizon.
Response: Thank you for your comments. Please see the summary consideration. The drafting team reviewed several standards, including TOP-002, for potential duplication and did not find duplication with the proposed requirements.		
Consumers Energy	Yes	
Long island power Authority	Yes	
Independent Electricity System Operator	Yes	Accurate data for real power output of a generating unit/plant is critical to system modeling for resource adequacy and transmission reliability analyses. Unless other standards already cover the requirement for this data, this standard needs to be retained but some of the details for the additional empirical data are not necessary. Please see our comments under Q9.
Response: Thank you for your supportive comment. Please see the summary consideration. After thorough consideration of all responses and additional deliberation, the SDT is proposing that the revised standard require the Generator Owner to collect real power verification data at the same time as reactive power verification data, and merged MOD-024 requirements in MOD-025. To perform the reactive power verification it is necessary to go to the rated real power operating point. Therefore, recording and reporting both the real and reactive power data as part of the MOD-025 verification only makes sense for efficiency.		
Bonneville Power Administration	Yes	BPA suggests reducing the frequency of data collection ... not sure it needs to be every 5 years, it is just more onerous documentation for something that does not change a lot.
Response: Thank you for your comment. All standards must be reviewed and either reaffirmed or revised once every five years. If, once the requirements are implemented, entities find that the data doesn't change much during a five-year period; the standard can be revised to extend the periodicity beyond five years.		

Organization	Yes or No	Question 1 Comment
ERCOT ISO	Yes	ERCOT ISO believes there is a need for this data. The verification methodologies, including the scheduling and timing of verification testing, should be left to the discretion of the relevant NERC functional entities - e.g. the Planning Coordinator / Transmission Planner.
Response: Thank you for your supportive comment. Please see the summary consideration. After thorough consideration of all responses and additional deliberation, the SDT is proposing that the revised standard require the Generator Owner to collect real power verification data at the same time as reactive power verification data, and merged MOD-024 requirements in MOD-025. Some degree of specificity is necessary to ensure that the data can be used as intended.		
Manitoba Hydro	Yes	If FAC-008 and FAC-009 are based upon design data and Engineering Analysis, a standard is required to complete field verification of the unit real power capability. There should be clear distinctions between these standards.
Response: Thank you for your comment. Agree.		
Luminant	Yes	Luminant believes the verification of capability is needed to ensure unit capabilities utilized for resource planning, operating reserves and real time operations are accurate. “Paper Megawatts” can have a detrimental effect on grid reliability.
Response: Thank you for your comment. Agree.		
Puget Sound Energy	Yes	Note: The way the question is worded with two opposite ideas makes it difficult to determine which box to check. Puget Sound Energy feels that this standard should be retired. This standard duplicates information required by other standards, including MOD-010, MOD-012, TOP-002 (R13), as well as FAC-009. Our Transmission Planners already request temperature related Real Power information for generating units through these other standards. Unit derates (proposed R3) are covered under TOP-002 R14, TOP-003, and TOP-006 R1.1. These other standards allow the Transmission Planners to customize their verification needs from the GO/GOP and not have a one-size fits all solution imposed on them as prescribed in this proposed standard.
Response: Thank you for your comments. Please see the summary consideration. The drafting team reviewed several standards (including MOD-010, MOD-012, TOP-002, TOP-006, and FAC-009) for potential duplication and did not find duplication with the proposed requirements. Note that the standard was modified and the second draft does allow use of historical data from actual output. The intent in MOD-024 (now integrated into MOD-025) is to ensure that planning entities have the data they need for accurate models.		

Organization	Yes or No	Question 1 Comment
E.ON U.S.	Yes	obtaining the additional empirical data is helpful. The data required in Version 1 as established by the Regions gives a better description of what is happening with a generating unit during a test; this version only requires capability, auxiliary power usage, and temperatures-which does not give one a picture of what is occurring during a test and why the capabilities might have been the way they were.
Response: Thank you for your comments. Agree that obtaining the data is helpful to reliability. The original standard was not approved by FERC because the details associated with the verifications were developed by each Region. Please see the revised standard and see if you believe additional information should be collected with the verifications.		
Pepco Holdings, Inc	Yes	Planning Coordinators and Planning Authorities need the data
Response: Thank you for your comment. Agree.		
Dynegy Inc	Yes	Planning related entities (i.e. Planning Coordinator, Resource Planner and Transmission Planner) need the maximum (normalized)demonstrated capability of generating units for inclusion in their planning models. No other Standard requires this data to be accumulated and reported to these entities. Also, historical EMS data that reflects economic dispatch and regulating requirements is not an alternative source for this data.
Response: Thank you for your comments. Agree that planning entities need the data identified in the MOD-024 standard (now integrated into MOD-025). Please see the revised standard – the drafting team is proposing to accept the use of some historical data provided it meets specific criteria.		
NERC Standards Review Subcommittee	Yes	Please review the possibility of redundancy within the following NERC standards: FAC-001-0; R1.1, Connection requirements for Generation facilitiesR2.1.3, Voltage level and MW and MVAR capacity or demand at point of connection. FAC-008-1;R1, GO shall each document its current methodology used for determining Facility Ratings...FAC-009-1;R1, GO shall each establish Facility ratings...MOD-010-0;R1, GOPs shall provide this steady-state modeling and simulation data...MOD-012-0;R1, GOPs shall provide appropriate equipment characteristics and system data...TOP-002-2a;R14, GOP shall notify the BA and TOP of changes in capabilities and characteristics...R14.1, Changes in real output capabilities
Response: Thank you for your comments. Please see the summary consideration. The drafting team reviewed several standards (including FAC-001, FAC-008, FAC-009, MOD-010, MOD-012 and TOP-002) for potential duplication and did not find duplication with the proposed requirements.		
Northeast Utilities	Yes	Standard should be retired.The collection of this data is already addressed through tariffs, Market Rules, and Interconnection Agreements. The Standard should be retired. Although data can be reliability related sufficient data is collected as dictated by other standards. NERC staff should coordinate and ensure that the

Organization	Yes or No	Question 1 Comment
		collection of this data is incorporated in existing standards projects.
Response: Thank you for your comments. Data provided under FERC Form 1 is not required to be shared with entities that need the data for modeling. **Please see the summary consideration. The drafting team reviewed several standards for potential duplication and did not find duplication with the proposed requirements.**		
Northeast Power Coordinating Council	Yes	The collection of this data is already addressed through tariffs, Market Rules, and Interconnection Agreements. The Standard should be retired. Although data can be reliability related sufficient data is collected as dictated by other standards. NERC staff should coordinate and ensure that the collection of this data is incorporated in existing standards projects.
Response: Thank you for your comments. Data provided under FERC Form 1 is not required to be shared with entities that need the data for modeling. Please see the summary consideration. The drafting team reviewed several standards for potential duplication and did not find duplication with the proposed requirements.		
American Transmission Company	Yes	The requirements of this standard will provide empirical data that will improve system reliability.
Response: Thank you for your comment. Agree. This is the intent of the standard.		
IRC Standards Review Committee	Yes	The SRC agrees that there is a need for a verification requirement. Given that the GOs are responsible for submitting real power data, there should be a corresponding requirement to verify that data on an as-requested basis. This approach provides the Planners with data that is valid for producing viable forecasts and assessments.
Response: Thank you for your supportive comments. The revised MOD standard (now incorporated into MOD-025) provides a schedule for verifying the data that seems reasonable to both the Generator Owner and the recipients of the data. In most cases, the periodicity for verifications is once every five years.		
Florida Municipal Power Agency and Some Members	Yes	There are two potential reasons for the need to test generator capability related to the standards: 1) MOD-010-0 for accuracy of modeling purposes; and 2) for a potential standard on resource adequacy in the planning horizon (Project 2009-05?).
Response: Thank you for your comments. The reliability-related intent of the MOD-024 requirements is to ensure that planning entities have data for accurate models used to assess the bulk power system. MOD-010 and MOD-011 are focused on the maximum and minimum ratings, which do not		

Organization	Yes or No	Question 1 Comment
necessarily match capabilities. The data verified in the MOD-024 standard (now incorporated in the MOD-025 standard) may be used for resource adequacy studies.		
Consolidated Edison Co. of New York	Yes	There is a need to test the gross and net real power capability because it is a key operating and planning horizon requirement to maintain system reliability. Unit testing is critical to System Operations and their ability to respond to contingencies. Even now, there are concerns with interconnection frequency responses and units not responding to AGC signals as noted in the 2-11-2010 NERC Industry Advisory on interconnection frequency response. In addition, as more and more wind generation is installed, generation capability issues will become more important to System Operators. The standard should not be retired, but the requirements should be incorporated into a new FAC standard or included in FAC-008.
Response: The SDT appreciates your comments and concerns. Frequency response is outside the scope of this standard. The standard requires recording data so that the planner will have both net and gross Real Power generation values. The FAC-008 standard is focused on developing a Facility Rating methodology – which is different from identifying a unit's actual capability.		
SERC Planning Standards Subcommittee	Yes	There is a reliability need to verify real power capability for larger units on the system as discussed in our response to Question 2 below.
Response: Thank you for your comment. The drafting team attempted to limit applicability to those units that do affect reliability of the BES.		
FirstEnergy	Yes	We believe that there is a need for this standard. The argument that "megawatt data is currently collected and reported under several other standards as well as many market rules" is not well founded. All Standard Drafting Teams assigned to revise existing standards that include some form of generator verification are proposing to retire their respective requirements because they intended that MOD-024-2 include these requirements. A specific example is the RTO SDT (Project 2007-03) which has proposed to remove requirements dealing with Real Power generator verification in TOP-002 (R13, R14, and R15) because they believe these requirements should be addressed by this GV SDT. The second part of the argument that these verifications are required by "many market rules" is also problematic because not every entity across the continent participates in a market and market rules are not enforceable Reliability Standard requirements.
Response: Thank you for your comments. Agree. Please see the summary consideration. The drafting team reviewed several standards for potential duplication and did not find duplication with the proposed requirements, in support of your comments.		
Xcel Energy	Yes	We believe there is a reliability need for the Megawatt data collected per this standard and consequently this standard should not be retired.

Organization	Yes or No	Question 1 Comment
Response: Thank you for your comment. Agree.		
Duke Energy	Yes	While data is reported under MOD-010, MOD-024 provides for validation of the data.
Response: Thank you for your comment. Agree.		
North Carolina Electric Membership Corporation	Yes	While we agree that there is a reliability need to verify real power capability for larger units on the system, we are of the opinion that the SDT should direct the verification at units that significantly affect the reliability of the BES.
Response: Thank you for your comment. The drafting team attempted to limit applicability to those units that do affect reliability of the BES.		
Progress Energy	Yes	Yes - there is a reliability need. No, the standard should not be retired.
Response: Thank you for your supportive comment.		
Cowlitz County PUD	Yes	Yes the Standard should be retired. This standard appears to duplicate and complicate FAC-008 and FAC-009. If this standard remains, then should generator rating be removed from FAC-008 and FAC-009?
Response: Thank you for your comment. Please see the summary consideration. The drafting team reviewed several standards (including FAC-008 and FAC-009 for potential duplication and did not find duplication with the proposed requirements.		

2. The SDT believes that verification should be performed on units that are connected down to 100 kV. The SDT believes this is consistent with the current Compliance Registry. The SDT has also provided how verification should be handled in plants/facilities that are greater than 75 MVA in aggregate gross nameplate rating. The Standard requires a separate verification for every unit greater than 20 MVA gross nameplate rating and connected at the point of interconnection of 100 kV or above. The remaining units in a plant/facility can be verified separately or in aggregate as the Generator Owner chooses. Do you agree with the SDT's decision to have the Standard be applicable to facilities connected to 100 kV and above and verified as proposed? Please explain.

Summary Consideration: While most stakeholders who responded to this question indicated support with the proposed applicability, some commenters suggested modifications that would match the compliance registration criteria more accurately, and this suggestion was adopted. The phrase, "connected at point of interconnection" was replaced with "directly connected to the bulk power system".

Generators Supporting Elimination of MOD-024		NA. This standard is not needed for reliability.
Response: Thank you for your comment. Please see the summary response to the first question. The need for entities to provide verified unit capabilities was identified and confirmed with the SAR for this project. There was some question that the requirements in MOD-024 may be duplicated by requirements in other standards, and the drafting team researched the other standards and has determined that there is no duplication. Therefore, the team is moving MOD-024 forward, and is integrating the proposed requirements from MOD-024 into MOD-025.		
CenterPoint Energy	No	CenterPoint Energy disagrees with having this Standard be applicable to all units connected to facilities 100 kV and above. CenterPoint Energy recommends it should only be applicable to units interconnected to Bulk Electric System facilities - not all facilities 100 kV and above are considered to be part of a Bulk Electric System.
Response: Thank you for your comment. Please see the summary consideration. The drafting team now proposes the language, "at the point of interconnection at 100 kV or above", in the latest version of the MOD-025-1 draft standard.		
ERCOT ISO	No	ERCOT ISO disagrees with this aspect of the proposal. Although, as a general matter, the relevant set of supply resources for reliability will be interconnected at 100 kV or greater, that is not an absolute rule. In fact, in the ERCOT Region there is a good amount of generation connected at 69 kV. The SDT should not preclude application of the proposed Standard to supply resources connected to facilities below 100 kV. 100 kV can be the default, but the requirement should provide for adequate flexibility to encompass other supply resources the methodology established by the relevant NERC functional entity includes such resources. Furthermore, this is consistent with the NERC Registry methodology, which accommodates facilities below 100 kV where they are necessary for/affect reliability of the Bulk Electric System.

Response: Thank you for your comments. Regions are free to include other facilities through submission of a request for a variance		
The Empire District Electric Company	No	I believe it is redundant to require both summer and winter ratings. Your summer raitings will be your "worst case" for understanding the maximum equipment output. Requireing winter ratings will only waste money and equipment wear.
Response: Thank you for your comment. The SDT has incorporated the real power verification requirements into the revised MOD-025. In the revised standard, the SDT has eliminated the need for seasonal verification. It is expected that only one periodic verification would be required and other data would be calculated based on that one.		
North Carolina Electric Membership Corporation	No	In general there is no reliability need to verify MW values for small units because they don't significantly affect the reliability of the system. The criteria should be to verify individual units which are at least 100 MVA or larger or aggregates of units which are 100 MVA or larger and units that are connected to the transmission at 200 kV and above unless the generating units have been deemed by the Planning Coordinator as critical to the reliability of the BES. This is similar to what has been proposed in the PRC-023 standard under development. All other generators that do not meet this critieria should be exempt.
Response: Thank you for your comment. The intent was to use the same thresholds as included in the compliance registration criteria.		
SERC Planning Standards Subcommittee	No	In general there is no reliability need to verify MW values for small units because they don't significantly affect the reliability of the system. The criteria should be to verify individual units which are 75 MVA or larger or aggregates of units which are 75 MVA or larger. Also provision could be made for the TP or PC to request verification of units which are smaller than 75 MVA for the rare case in which they do impact the reliability of the system.
Response: Thank you for your comment. The intent was to use the same thresholds as included in the compliance registration criteria.		
Public Service Electric and Gas Company	No	N/A as MOD-024 should be retired as demonstrated by PSE&G response to Question 1.
Response: Thank you for your comment. Please see the response to the comments provided under Question 1		
Consolidated Edison Co. of New York	No	SDT should not make reference to a specific voltage level. The SDT should indicate that verification should be performed on units that are connected to the Bulk Electric System as determined by the Region.
Response: Thank you for your comment. The intent was to use the same thresholds as included in the compliance registration criteria.		

Hydro-Québec TransEnergie (HQT)	No	See answer to Q1.HQT believes that there are some plants/facilities that are not connected to 100 kV but are material to reliability. These facilities should be subject to data collection, be it in this project Standard or in other existing Standards. The importance of generation to reliability is more related to its power than to its connecting voltage.
Response: Thank you for your comments. The regions are free to include other facilities if they see fit by submitting a request for a variance		
AMEA	No	The MOD-024-2 draft removes the regions and entities like the Planning Coordinator from the decision making ability as to which generators are material to the BES but instead provides a blanket approach that will include generators that are and are not material to the BES.The many of the regions have identified generators connected below 100 kV that are material to the BES and likewise have identified generators connected at or above 100 kV that are not material to the BES.
Response: Thank you for your comment. The regions are free to include other facilities if they see fit by submitting a request for a variance.		
Consumers Energy	No	The MVA ratings should be based on Net Demonstrated Capabilities (NDC) rather than nameplate. There is no correlation between reliability and nameplate ratings.
Response: Thank you for your comment. The intent was to use the same thresholds as included in the compliance registration criteria. The default language for generating units includes the phrase, “nameplate rating.”		
IRC Standards Review Committee	No	There is no need for the SDT to impose a requirement / limitation on what is or is not subject to a NERC standard. The FERC has established those boundaries. To the extent that a PC needs or does not need verification of generators that fall outside those FERC-identified conditions, must be justified on a reliability need or settled outside the NERC-standard process.
Response: Thank you for your comments. The intent was to use the same thresholds as included in the compliance registration criteria for generating units and add the criteria for synchronous condensers, which is not identified in the default registration criteria. If the “facilities” section of the applicability section were limited to only listing the criteria for synchronous condensers, this could have been confusing, thus the criteria for generators was also included.		
Pepco Holdings, Inc	No	There is no need to define what already exists in BES definitions and in the compliance registry rules.
Response: Thank you for your comment. The intent was to use the same thresholds as included in the compliance registration criteria for generating units and add the criteria for synchronous condensers, which is not identified in the default registration criteria. If the “facilities” section of the applicability section were limited to only listing the criteria for synchronous condensers, this could have been confusing, thus the criteria for generators was also included.		

Arizona Public Service Co.	No	There is no need to go down to registry level of 20 MVA. The variation in capacity of these small generators has no measurable impact on the grid planning study results. The studies have onsiderable more uncertainties due to other more significant variables. The minimum size should be 100 MVA for each unit or 250 MVA for a plant.
Response: Thank you for your comments. The intent was to use the same thresholds as included in the compliance registration criteria. 20 MVA is the registry criteria.		
Long island power Authority	No	Units below 100 kV may in the future be registered with NERC under the materiality clause. LIPA suggests relying on the MVA rating only. Additionally, LIPA requests that in the Applicability section a statement clarifying that the point of interconnection may not be a BES element.
Response: Thank you for your comments. The intent was to use the same thresholds as included in the compliance registration criteria. The SDT cannot think of an instance where the interconnection point would not be a BES element. Please see the revised standard.		
Southern Company Transmission/Generation	No	We recommend limiting the unit size requiring real power capability validation in paragraph 4.2 to the following: "Generating Facilities connected at the point of interconnection at 100kV or above, containing an individual generating unit greater than or equal to 75MVA (individual gross nameplate rating)", for the following reasons: o Including only units > 75MVA will represent the vast majority of the total (cumulative) connected MW sources in the country o This cumulative MW class represents the units that are capable of having the largest impact to the stability and reliability of the BES o Excluding the smaller units will avoid unnecessary waste in time and money on the smaller units which individually do not appreciably affect the stability and reliability of the BES. o Stated or assigned values should be sufficient for modeling purposes for units having nameplate ratings < 75 MVA. If the BA or TOP needs validated data on a smaller unit or group of units then these requirements can be made known to the GOP per TOP-002-2 R13.
Response: Thank you for your comments. The intent was to use the same thresholds as included in the compliance registration criteria. 20 MVA is the registry criteria.		
American Electric Power	Yes	
Bauer	Yes	
Bonneville Power Administration	Yes	
Duke Energy	Yes	

Dynegy Inc	Yes	
E.ON U.S.	Yes	
Electric Market Policy	Yes	
GO/GOP	Yes	
Luminant	Yes	
NERC Standards Review Subcommittee	Yes	
PacifiCorp	Yes	
Progress Energy	Yes	
South Carolina Electric and Gas	Yes	
Xcel Energy	Yes	
Manitoba Hydro	Yes	Agree to include units connected to 100 KV and above.
Response: Thank you for your comment. The SDT agrees.		
ITC Holdings	Yes	Comments: The 100 kV reporting for this requirement is consistent with other NERC reporting requirements.
Response: Thank you for your comment. The SDT agrees.		
Indiana Municipal Power Agency	Yes	IMPA agrees that the standard should be consistent with the current Compliance Registry and supports how units are verified in the standard.
Response: Thank you for your comment. The SDT agrees.		
Puget Sound Energy	Yes	Puget Sound Energy agrees with being consistent with the Compliance Registry. It seems that the compliance registry criteria would determine whether an entity has to comply with any of the NERC standards including this one and then the current BES definition would establish what facilities are applicable. The need

		to describe the Faclities under section 4.2 is not clear. We assume that any approved regional definition of the BES would dictate applicability ultimately. Regarding the verification requiremetns as proposed, it is unclear why annual verification (for most units) is necessary as much of the data will not change over an annual timeframe and most change that may occur would likely not cause a reliablity impact as it relates to the study work the Planning Coordinator or Resource Planner uses this information for. We would request that the testing be done on a 5 year cycle which follows other practices for providing data (i.e., WECC has been using a 5 year cycle for testing since 1997, and the results have proven to be entirely adequate).
Response: Thank you for your comments. The SDT agrees. The SDT also agrees with the suggested periodicity included this in the revised standard.		
SERC Generation Subcommittee (GS)	Yes	Stated or assigned values should be sufficient for modeling purposes for units having nameplate ratings < 75 MVA. This should apply to many regions. If the BA or TOP needs validated data on a smaller unit or group of units then these requirements can be made known to the GOP per TOP-002-2 R13.
Response: Thank you for your comments. TOP-002, R13 is proposed for retirement.		
Northeast Power Coordinating Council	Yes	The collection of this data is already addressed through tariffs, Market Rules, and Interconnection Agreements. The Standard should be retired. Although data can be reliability related sufficient data is collected as dictated by other standards. NERC staff should coordinate and ensure that the collection of this data is incorporated in existing standards projects.
Response: Thank you for your comments. Tariffs, Market Rules, and Interconnection agreements are independent of the reliability obligations being addressed by this standard. Regarding reliability, the SDT acknowledges that if the correct system operations circumstance exists then the data obtained by performing the Real Power capability verification required by the MOD-024 standard (now incorporated into the MOD-025 standard) for system planning purposes may yield the same results as could be obtained by using equipment nameplate ratings, unit operational data, EMS data, forecast information, etc. required to be provided to the ERO by other standards. Recognize this alternate set of data is collected for other reliability purposes and is not guaranteed to represent actual capability. As such, there is a reliability need to specifically require Real Power capability verification. The SDT also acknowledges it is acceptable to utilize reasonable assumptions when performing long term planning analysis however the SDT also believes it is prudent from a reliability concern to incorporate established unit operational constraints into the planning model when relevant. Units may be derated or constrained for a variety of legitimate long term reasons. Likewise, units derated or constrained today may have restrictions released in the future. Only by performing a Real Power capability verification to determine what the unit is capable of supplying can accuracy of needed reliability data be assured. **Also, please see the summary response to Question 1.**		
American Transmission Company	Yes	The generating unit qualifications are consistent with the presently Compliance Registry criteria.

Response: Thank you for your comment. The SDT agrees.		
Florida Municipal Power Agency and Some Members	Yes	There is no need to expand the scope of the standard beyond the registration criteria. As the SDT has pointed out, only about 4% of the power system capacity is connected below 100 kV. Most of these generators are modeled, and many are already tested beyond the scope of the standard. So, causing regulation of generator verification to these generators may only improve accuracy for a small portion of the 4%. Such gain in accuracy at < 100 kV is easily overwhelmed by the inaccuracy of load forecasts, and by the variation of generator output with ambient conditions (e.g., temperature, humidity, barometric pressure, etc.) outside of forecasted ambient conditions. So, such effort is wasted because any supposed gain in accuracy by going below 100 kV is illusory and lost as compared to other forecast inaccuracies outside the control of anyone (e.g., the weather).If anything, the level of verification required in the standards could be reduced for smaller units (e.g., less frequent), even more so than as described in the standard. However, this would create a complex “tiered” standard difficult to understand and monitor. Hence, we congratulate the SDT on developing a balanced perspective that truly focuses on what is important to maintain the reliability of the BES.
Response: Thank you for your comments. The SDT agrees.		
Cowlitz County PUD	Yes	This approach makes it easy for the owner to know when compliance is necessary. However, 20 MVA redline across the board for any single unit seems too low. Any significant generation will be connected at 100 kV or greater, but not all generation is significant just because it is connected at a certain voltage. A simple redline is easy to manage, but is new small generation development being discouraged with this low bar? I am not dead set against this applicable level, but I think some research into discovering the unintended consequences should be made.
Response: Thank you for your comments. The SDT defaulted to using the same thresholds as used for compliance registration.		
Independent Electricity System Operator	Yes	This is a simple approach that should be supported. Notwithstanding our response and consistent with our reply to Q1, where the provision of this information is already required in other standards, those requirements should not be duplicated here.
Response: Thank you for your comment. Agree. Please see the summary response to Question 1.		
Calpine Corporation	Yes	We agree with the demarcation but recommend it be reworded to exclude generation units interconnected at voltages below 100 kV and units below 20 MVA to avoid unnecessary discussion of registration criteria.
Response: Thank you for your comment. The SDT defaulted to using the same thresholds and wording as used for compliance registration. Identifying a list of units that would be excluded does not seem necessary.		

FirstEnergy	Yes	We agree with the proposed thresholds because they are consistent with the NERC compliance registry.
Response: Thank you for your comment. The SDT agrees.		

3. After much discussion the SDT decided to require the verification be performed over a period of at least "one continuous hour" regardless of the type of unit because most units have reached steady state operation within one hour. Do you agree with this approach? If not, please explain.

Summary Consideration: The majority of respondents felt that one hour would meet reliability requirements. A few respondents felt that it was too long while others felt that the Planner should be allowed to request a longer period. There was concern expressed over hydro unit capability varying with reservoir levels. The SDT felt that these variations fall outside the intent of the verifications envisioned for this standard.

Organization	Yes or No	Question 3 Comment
Generators Supporting Elimination of MOD-024		NA. This standard is not needed for reliability.
Response: Thank you for your comment. Please see the summary response to Question1.		
PacifiCorp	No	: Sufficient detail on the data requirements during the one hour sampling period required under the proposed standard has not been provided. Please provide some direction on the required sampling rate and acceptable methods for data collection. It is unreasonable to require that a maximum boiler capacity test be performed twice a year to validate the unit real power capability. Biannual capture of historical data would be the preferred method of unit capability validation. Water resource impacts on hydroelectric facility capability have not been addressed sufficiently by the proposed standard. Please provide clarification on expectations for data collection at hydro facilities when water resources do not support operation at unit capability.
Response: Thank you for your comments. Sampling rate; unit output is integrated over an hour. **On the unreasonableness concern; The standard allows for the temperature adjustment of the summer verification to satisfy the winter requirement. The SDT agrees that unit performance during verification is not a guarantee of future performance. The standard allows the GO to use operating data. The planning coordinator has the ability to review past unit performance to insure that the verification value submitted is reasonable, indicative of past unit performance. There is nothing in the standard to prevent the planning coordinator from questioning the submitted data. Variable energy units shall report the Real Power obtained that was achieved during the time of the Reactive Power verification. Note that the revised standard requires most verifications only once every five years.**		
IRC Standards Review	No	A Planning Coordinator should be afforded the right to request periods other than one continuous hour as needed for ad hoc evaluations e.g. for Ancillary Service evaluations over a 15 minute period or for special

Organization	Yes or No	Question 3 Comment
Committee		case studies e.g. fuel disruption analysis. The default period may be agreed to as one continuous hour but that should not be the mandated period.
Pepco Holdings, Inc	No	A Planning Coordinator should be afforded the right to request periods other than one continuous hour as needed for ad hoc evaluations e.g. for Ancillary Service evaluations over a 15 minute period or for special case studies e.g. fuel disruption analysis. The default period may be agreed to as one continuous hour but that should not be the mandated period.
Response: Thank you for your comments. If a planning coordinator is performing the ad hoc evaluation for an ISO or RTO then the rules of the ISO or RTO can be structured to meet the intended needs. The SDT agreed that one hour met the needs of modeling data. The standard was drafted to meet reliability needs and not market requirements. Market rules and reliability requirements may be different.		
ERCOT ISO	No	ERCOT ISO disagrees with this aspect of the proposal. The methodology for verification should be left to the relevant NERC functional entities. As noted by the SDT, the Transmission Planner needs to communicate the conditions under which the resource is required to verify its real-power capability. This discretion afforded the TP should apply to all aspects of the verification, including the time period the unit must run. At a minimum, the proposed one-hour time period should be a default and the requirement should provide for alternative time periods to accommodate regional differences and different testing purposes - e.g. for ancillary services.
Response: Thank you for your comments. If ERCOT feels that there is a significant regional difference that requires an enhanced standard for the ERCOT Region then ERCOT ISO should submit a SAR to TRE to develop such a Regional standard. But again the ERCOT ISO is the market that may need different data points and as the market has the right to craft the rules needed to get those data points. The planners on the SDT felt that one hour was a sufficient period for the verification to gather the real power data needed for modeling.		
Luminant	No	Luminant would prefer 30 minutes at full load, as this approach has been utilized effectively in ERCOT for several years.
Response: Thank you for your comment. The planners on the SDT felt that one hour was needed to establish a units' real power capability for modeling, and most stakeholders who responded to this question supported the one hour period.		
Public Service Electric and Gas Company	No	N/A as MOD-024 should be retired as demonstrated by PSE&G response to Question 1.
Response: Thank you for your comment. Please see the summary response to Question 1.		

Organization	Yes or No	Question 3 Comment
Duke Energy	No	Need to reword Attachment 1, section 2.1 to add clarity. Suggested rewording: For nuclear and fossil units, record data for at least one continuous hour of normal operation during the winter period. More time may be required or used to achieve stable conditions.
Response: Thank you for your comment. The standard only requires one continuous hour of data. The standard allows for the GO to conduct the verification over any hour they select.		
E.ON U.S.	No	One hour is too short. This period could allow a company to provide more of an "optimum" or "maximum" capability, rather than an average capability (e.g., during one hour soot blowers might not have to be run, etc.). The current 4-hour average test is more reasonable/reliable. Attachment 1 should be revised to specify a verification period of "at least 1 hour." The use of the term "normal operation" in Attachment 1 is not specific enough and is open to interpretation. Since generating capacity has market value, Gen Owners may desire to maximize the verified/reported capability of their units - even if such performance can only be attained for a single hour. This would not be consistent with the notion of dependable or continuous capacity which should be the basis used for reliability planning purposes.
Response: Thank you for your comments. The idea behind the standard is for the planners to get a real power value of what the unit is capable of producing 24/7. The SDT discussed the verification time period at length and concluded, based on its collective knowledge and experience, proposed that one hour was sufficient for modeling purposes, and most stakeholders who responded to this question agreed with this duration. The planner always has the ability to check the number submitted under the standard against actual unit performance to gauge validity. Normal operation is what a unit is called on to produce during normal conditions. The SDT believes that the GO understands what normal means. It does not mean taking actions such as taking heaters out of service to get maximum output that is allowed in some ISOs that have capacity markets. In fact it is in the best interest of the GO to submit a value that it is sure the unit is capable of producing 24/7. The SDT does not believe that four hour verification is any more accurate or reflective of unit capability than one hour verification. Again this verification does not establish market value it establishes the unit's capability for system modeling for reliability studies.		
Arizona Public Service Co.	No	Our experience is that 30 minutes are adequate to reach steady state conditions. There are no benefits to be derived by going beyond 30 minutes.
Response: Thank you for your comment. The planners on the SDT, based on their collective knowledge and experience, proposed that one hour was needed to establish a unit's real power capability for modeling. Most stakeholders who responded to this question supported the one hour period.		
Exelon Generation Co LLC	No	Short duration testing conducted when conditions are the most favorable do not provide an accurate indication of unit preformance under all conditions.
Response: Thank you for your comment. The standard's goal is to capture the unit's performance under normal operating conditions. The intent of		

Organization	Yes or No	Question 3 Comment
the standard is to capture what the unit can do 24/7 without taking measures that would temporarily increase the unit's output. The planner can always review the TOP's EMS data to check the real power number.		
Bauer	No	The intent of the requirement of the previous version was to provide realistic summer and winter generator capability. For hydro units, the process detailed in this version only provides a vague assessment of normal and most likely not be the realistic capability of the generator. The process requires the units to be operated "normally" which is undefined and to adjust the MW to reflect forecasted (summer or winter) reservoir conditions. Hydro units may be "normally" operated throughout their operating range. Without specific guidance that the operation should utilize a normal "full load" condition, the true summer capability may not be known. Specifically, if a generator , at some time other than summer is, operated at 50% gate during the operational snap shot produces xx MW, then the xx MW at 50% gate will be indexed for the summer reservoir level. The true capability of the generator at 100% gate (normal full load) during summer would actually be much higher. The language would need to ensure that the full load would reflect limitations other than those introduced by head.
Response: Thank you for your comments. The standard references maximum nameplate rating as a reference point for performing the verification. Variable energy units do present a challenge. The SDT understands operational and regulatory constraints may exist; run variable units at what capability can be provided. Constraints are implicitly recognized within the standard process. Refer to Attachment 1, section 2.1 language. The combined MOD-024 and 025 require the GO to report the real power capability at the time of the Reactive Power verification. **The planning coordinator has the ability to review past unit performance to insure that the verification value submitted is reasonable, and indicative of past unit performance. There is nothing in the standard to prevent the planning coordinator from questioning the submitted data. The scope of this standard is focused on verifying the data used in planning models –not in providing updates to capabilities for use in near real-time operations.**		
AMEA	No	The MOD-024-2 draft removes the regions and entities like the Planning Coordinator from the decision making ability as to which generators are material to the BES but instead provides a blanket approach that will include generators that are and are not material to the BES.
Response: Thank you for your comment. The GV SDT has utilized the NERC Registration Criteria and believes that it is appropriate for this continent wide standard. Individual Regions are free to make adjustments if they are deemed necessary, by submitting a request for a variance		
The Empire District Electric Company	No	The nameplate reating should be sufficient for determining output. In this day of being environmentally friendly, why would we as a country want to subject each generator to these types of tests using precious fuel and expelling pollutants when nameplate ratings have been sufficient for years?
Response: Thank you for your comment. The SDT does not agree that nameplate ratings are sufficient to ensure reliability. The SDT acknowledges that if the correct system operations circumstance exists then the data obtained by performing the Real Power capability verification required by the		

Organization	Yes or No	Question 3 Comment
MOD-024 standard (now incorporated into the MOD-025 standard) for system planning purposes may yield the same results as could be obtained by using equipment nameplate ratings, unit operational data, EMS data, forecast information, etc. required to be provided to the ERO by other standards. Recognize this alternate set of data is collected for other reliability purposes and is not guaranteed to represent actual capability. As such, there is a reliability need to specifically require Real Power capability verification. The SDT also acknowledges it is acceptable to utilize reasonable assumptions when performing long term planning analysis however the SDT also believes it is prudent from a reliability concern to incorporate established unit operational constraints into the planning model when relevant. Units may be derated or constrained for a variety of legitimate long term reasons. Likewise, units derated or constrained today may have restrictions released in the future. Only by performing a Real Power capability verification to determine what the unit is capable of supplying can accuracy of needed reliability data be assured. Verification should be performed. The standard does not require units to run for verification only. The SDT agrees in general with comments raised regarding environmental stewardship concerns and believes this consideration is rendered moot by requiring verification once every five years. It is reasonable to assume that the unit will run for at least one hour at maximum capability during the five year period. Please see the revised standard.		
Consolidated Edison Co. of New York	No	The SDT should change the verbiage to “a minimum of one continuous hour of normal operation” to avoid confusion that the unit can be ramping up to full load during the test.
Response: Thank you for your comment. Ramping is not performed during verification. The SDT envisions Generator Owners will first realize steady state conditions at maximum capability before commencing the one hour capability test.		
Progress Energy	No	We agree with the approach as stated in Question 3 but have selected NO here because the proposed standard itself does not reflect the approach stated. For Attachment 1, Sections 1.1, 1.2, 2.1, and 2.2, these should be changed to say “for at least one continuous hour...”
Response: Thank you for your comment. So noted the SDT has made the suggested change.		
SERC Generation Subcommittee (GS)	No	We agree with the approach as stated in the questions but have selected NO here because the standard does not reflect the approach stated. For Attachment 1, Sections 1.1, 1.2, 2.1, and 2.2, these should be changed to say “for at least one continuous hour...” to assure stable conditions.
Response: Thank you for your comment. So noted the SDT has made the suggested change.		
FirstEnergy	No	We do not agree that one hour is sufficient for Fossil and Nuclear units (per Attachment 1 Sec. 1.1 and 2.1). The SDT should consider at least 4 hours or, at a minimum, require that the unit demonstrates it has reached equilibrium.
Response: Thank you for your comment. The idea behind the standard is for the planners to get a real power value of what the unit is capable of producing 24/7. The SDT, using its collective knowledge and experience, discussed the verification time period at length and proposed that one hour		

Organization	Yes or No	Question 3 Comment
was sufficient for modeling purposes. Most stakeholders who responded to this comments agreed with the one hour. The planner always has the ability to check the number submitted under the standard against actual unit performance to gauge validity. The SDT does not believe that four hour verification is any more accurate or reflective of unit capability than one hour verification.		
GO/GOP	No	We feel that one hour is too short. We recommend verification be performed one hour after the unit has reached steady state operation since some units may take different lengths of time to reach steady state.
Response: Thank you for your comment. The idea behind the standard is for the planners to get a real power value of what the unit is capable of producing 24/7. The SDT, using its collective knowledge and experience, discussed the verification time period at length and proposed that one hour was sufficient for modeling purposes. Most stakeholders who responded to this comments agreed with the one hour. The planner always has the ability to check the number submitted under this standard against actual unit performance to gauge validity. The SDT does not believe that four hour verification is any more accurate or reflective of unit capability than one hour verification. Ramping is not performed during verification. The SDT envisions Generator Owners will first realize steady state conditions at maximum capability before commencing the one hour capability test.

Puget Sound Energy	Yes	
SERC Planning Standards Subcommittee	Yes	
South Carolina Electric and Gas	Yes	
Southern Company Transmission/Generation	Yes	
Indiana Municipal Power Agency	Yes	IMPA agrees with the one hour testing and the reasoning that the SDT used to decide on this time period.
Response: The SDT agrees, and thank you for your comment.		
ITC Holdings	Yes	None
Manitoba Hydro	Yes	One hour testing is sufficient, and does not expose the unit to unnecessary stress or take excessive time to complete.
Response: The SDT agrees and thank you for your comment.		
Hydro-Québec TransEnergie (HQT)	Yes	See answer to Q1.

Organization	Yes or No	Question 3 Comment
Response: The SDT agrees, and thank you for your comment.		
Northeast Power Coordinating Council	Yes	The collection of this data is already addressed through tariffs, Market Rules, and Interconnection Agreements. The Standard should be retired. Although data can be reliability related sufficient data is collected as dictated by other standards. NERC staff should coordinate and ensure that the collection of this data is incorporated in existing standards projects.
Response: Thank you for your comments. Please see the summary consideration of comments on Question 1.		
Xcel Energy	Yes	While we agree that one hour of data is adequate to verify the capability, in our experience it takes at least 30 minutes for a steam turbine unit to stabilize if it has been operating at a lower load. We believe the criteria should take into consideration of an applicable "stabilization period" prior to data collection.
Response: Thank you for your comment. Ramping is not performed during verification. The SDT envisions Generator Owners will first realize steady state conditions at maximum capability before commencing the one hour capability test.		

4. **The SDT felt that units that cannot sustain continuous operation, oftentimes known as intermittent, variable or limited energy units, such as a Wind Generating Station or run-of-river hydro, etc., should be exempt from this standard because such units are typically represented in studies with "on average" or "discounted" values. Do you agree with this approach? If not, please explain.**

Summary Consideration: While most stakeholders who responded to this question supported the original proposal, several commenters disagreed with the exemptions for intermittent, variable and limited energy units, and indicated that these units do impact reliability and should be included in the standard if they meet the default thresholds identified in the compliance registration criteria. The SDT revised the standard to require testing of all generating units greater than 20 MVA and all generating plants/facilities containing greater than 75 MVA (gross aggregate name plate rating), directly connected to the bulk power system at 100 kV or above. The standard applies to all generation technologies.

Organization	Yes or No	Question 4 Comment
Generators Supporting Elimination of MOD-024		NA. This standard is not needed for reliability.
Response: Thank you for your comment. Please see the summary consideration of comments on Question 1.		
American Electric Power	No	AEP believes that it is important to have intermittent, variable, and limited energy units to be in compliance with this standard. Technical assumptions made for studies are important, but it is important to ensure that the stated capabilities for such units are verified.
Response: Thank you for your comment. The SDT agrees and has modified the standard to require verification of the real power capability for all generator technologies.		
Consolidated Edison Co. of New York	No	All units meeting the voltage level and output level as specified in Section 4.2 should be tested. From both an operating horizon and planning horizon, it is important to have an accurate model of the system.
Response: Thank you for your comment. The SDT agrees and has modified the standard to require verification of the real power capability for all generator technologies.		
CenterPoint Energy	No	CenterPoint Energy disagrees with exempting certain types of generation resources from Requirement 1 and Requirement 3; therefore, CenterPoint Energy recommends deleting 4.2.3 "Variable energy units such as

Organization	Yes or No	Question 4 Comment
		wind generators, solar, and run of river hydro are exempt from the requirements of this Standard." CenterPoint Energy agrees that oftentimes such generation resources are represented with "on average" or "discounted" values. However, all planning models do not use "on average" or "discounted" values as there are needs to study expected generation patterns. For example, wind generation typically peaks in the early morning hours in west Texas and should be modeled at a lower output in planning models which represent the peak load hour which occurs in the summer, typically around 5 PM. Transmission planners would need to ensure that there is adequate transmission when west Texas wind is operating at its peak output in the early morning hours. For this purpose, there is a need for a planning model with all wind generation operating at peak output. In addition, wind generation typically reaches a peak coincident with the peak load hour in the Gulf Coast area. So, this generation would be modeled at peak output in a planning model representing the peak load hour. In both of these cases, planning models need the net real power capability of wind units verified by actual unit testing.
Response: Thank you for your comments. The SDT agrees and has modified the standard to require verification of the real power capability for all generator technologies.		
ITC Holdings	No	Comments: A one hour typical rating/capability should be provided by the generators for run of river hydros.
Response: Thank you for your comment. The SDT agrees and has modified the standard to require verification of the real power capability for all generator technologies		
ERCOT ISO	No	ERCOT ISO disagrees with this aspect of the proposal because the performance/capability of all resources, including variable output resources, effects system planning and operations. Accordingly, contrary to the position of the SDT, the data from variable energy resources (e.g. intermittent renewable) is also needed for reliability. Although these resources are subject to the variability in terms of their fuel source (e.g. wind), there are methods of estimating the capacity and energy from these resources. These estimates provide value for the purposes of this standard. Variable energy resources should not be exempt from this requirement. The Standard should include these resources, provided that they are subject to rules that reflect the variability of their production. The verification methodologies established by the respective NERC functional entities can accommodate variable resources in a manner that is consistent with the practices within their respective regions.
Response: Thank you for your comments. The SDT agrees and has modified the standard to require verification of the real power capability for all generator technologies.		
Calpine Corporation	No	If there's truly a reliability need for verification of capability, this segment of generation needs to be addressed.

Organization	Yes or No	Question 4 Comment
Response: Thank you for your comment. The SDT agrees and has modified the standard to require verification of the real power capability for all generator technologies.		
Indiana Municipal Power Agency	No	If these units cannot sustain continuous operation, then they can report/record the highest hour or an average output for the hour.
Response: Thank you for your comment. The SDT understands operational and regulatory constraints may exist; run variable units at what capability can be provided. Constraints are implicitly recognized within the standard process. Refer to Attachment 1, section 2.1 language.		
Bauer	No	It is not appropriate to consider the variability of wind generating stations comparable to the operation of a run of the river hydro. Run of the river hydro tends to be less variable and pose a lower regulation burden on the BES than wind generation. We justify this position in that the operator can estimate the energy produced during a month and even schedule the capacity at which the generator is operated, whereas wind cannot. As such an operator is able to provide a verification of the capability of our run of the river plants.
Response: Thank you for your comments. The SDT agrees and has modified the standard to require verification of the real power capability for all generator technologies.		
Public Service Electric and Gas Company	No	N/A as MOD-024 should be retired as demonstrated by PSE&G response to Question 1.
Response: Thank you for your comment. Based on the views of the SDT and the preponderance of industry comments the SDT is recommending retaining the requirement to verify generator real power capability.		
North Carolina Electric Membership Corporation	No	Peaking units that have a limited cumulative energy per year (i.e. low capacity factor below 5%) should be provided the same treatment. The SDT should consider providing the PC with the flexibility for designing tests “needed” for verification such that all units are either handled in the same way.
Response: Thank you for your comment. The SDT has modified the standard to require verification of the real power capability for all generator technologies.		
Pepco Holdings, Inc	No	Providing the Planning Coordinator with the flexibility for designing tests “needed” for verification provides the opportunity to handle all units the same way (i.e. how the PC asked).
Response: Thank you for your comment. The SDT decided to revise the standard and require the Generator Owner to provide the data to the Planning Coordinator – it is then the Planning Coordinator’s responsibility to share the data with other planning entities. The Planning Coordinator has the		

Organization	Yes or No	Question 4 Comment
ability to review past unit performance to insure that the verification value submitted is reasonable, indicative of past unit performance. There is nothing in the standard to prevent the Planning Coordinator from questioning the submitted data.		
FirstEnergy	No	We believe that capabilities of intermittent units such as wind and solar can be adequately verified by testing, tracking of operational data, or calculations if testing or operational data is not possible or incomplete. Furthermore, it has been forecasted that utilization of these types of units will expand and most states will have Renewable Energy requirements of 20-25% of generation in the future. This would represent a large percentage of generating unit Real Power Capability not being verified. Excluding these units from verifying their capability will not improve reliability but will reduce it. The goal of this standard is to determine the capabilities of all generating units. The Generator Owner of intermittent units should provide their maximum capability through verification, test or calculation along with capacity factor data. This information could then be used by the Transmission Planner to plan for a reliable system based on the Transmission Planner's engineering judgment and considering other factors as the units Interconnection Agreement contractual arrangements (i.e. energy only unity, participates in a capacity market, etc.) Therefore, we suggest that this SDT incorporate requirements to verify intermittent, variable, and limited energy units. We also suggest the SDT should consider language similar to RFC standard MOD-024-RFC-01 Requirement R2.2.3 to accomplish verification of intermittent, variable, and limited energy unit capabilities.
Response: Thank you for your comments. The SDT agrees and has modified the standard to require verification of the real power capability for all generator technologies.		
Southern Company Transmission/Generation	No	We recommend all hydro units be excluded since capability is dependent on available water levels. GOP's with appreciable hydro capacity have established procedures or processes to predict the capability of these units.
Response: Thank you for your comment. Based on the views of the SDT and the preponderance of industry comments the SDT is recommending retaining the requirement to verify generator real power capability		
SERC Generation Subcommittee (GS)	No	While intermittent resources may not make up a significant portion of supply in most regions at this time, future development may result in significant portions of supply being made up of these resources, and relying only on design or nameplate values, for the purposes of transmission planning, will be as inappropriate for these units as it is for existing generation.The standard should focus on determining the appropriate generator ratings to be supplied to the planning processes, not how they are ultimately used.
Response: Thank you for your comment. The SDT agrees and has modified the standard to require verification of the real power capability for all		

Organization	Yes or No	Question 4 Comment
generator technologies.		
Progress Energy	No	While we have indicated that we disagree with the exemption, it may be more appropriate to address testing of "intermittent" resources separately due to their different use in planning and operational studies. However, we think the basis for exemption by the SDT is incorrect. The SDT has confused the issue of rating with how that rating is used in planning studies. There are two fundamental questions that must be answered for each resource in any planning study: (1) what is the resource capable of producing under some standard set of conditions, and (2) how much will it produce under the conditions assumed in a planning study. Historically, these two questions are merged for resources which are dispatchable and controllable to a sustained output level. In other words, if we test a conventional fossil or nuclear generator and determine it can produce X MW under the test conditions, we assume it can produce X MW under study conditions like peak demand, off-peak or shoulder load conditions. However, we might model the unit as producing zero or something less than its capability due to economic or some other dispatch consideration. We do not try and represent some average value of its production over time.When intermittent resources are considered, we still need to know how much a unit is capable of producing at its maximum output. We would not size the interconnection for "average" output. We need to know what it might produce under ideal conditions. Taken further, we know that at some point in its operation, the intermittent resource will produce at its tested value, and it will be up to the planner to determine if that condition needs to be studied. For example, 100 MW of nameplate generation may produce 30 MW on the average over a year's time, but it might produce the full 100 MW at an off-peak hour, and that may need to be studied. How do we assure ourselves that the 100 MW of nameplate is actually capable of 100 MW?While intermittent resources may not make up a significant portion of supply in most regions at this time, future development may result in significant portions of supply being made up of these resources, and relying on design or nameplate values will be as inappropriate for these units as it is for existing generation.The standard should focus on determining the appropriate generator ratings to be supplied to the planning processes, not how they are ultimately used. As the standard itself states:3. Purpose: To ensure that planning entities have accurate generator Real Power capability modeling data used in system planning studies
Response: Thank you for your comments. The SDT fundamentally agrees with comments on how planners utilize data. The requirements being incorporated into MOD-025-1 aim to determine unit capability which will be different than nameplate rating in most cases. It is acceptable to utilize reasonable assumptions when performing long term planning analysis however the SDT also believes it is prudent from a reliability concern to incorporate established unit operational constraints into the planning model when relevant. Units may be derated or constrained for a variety of legitimate long term reasons. Likewise, units derated or constrained today may have restrictions released in the future. Only by performing a Real Power capability verification to determine what the unit is capable of supplying can accuracy of needed reliability data be assured. **The majority of industry agrees variable resources require verification. The SDT understands operational and regulatory constraints may exist; run variable units at what capability can be provided. Constraints are implicitly recognized within the standard process. Refer to Attachment 1, section 2.1 language. Capability as determined for variable resources is better representative of expectation for normal planning than rating information or**		

Organization	Yes or No	Question 4 Comment
momentary peak values recorded. The SDT has modified the standard to require verification of the real power capability for all generator technologies.

South Carolina Electric and Gas	Yes	
The Empire District Electric Company	Yes	
We Energies	Yes	
Xcel Energy	Yes	
E.ON U.S.	Yes	E.ON U.S. believes that this is reasonable at the present time but with the proposed massive build-out of wind generation this may need to be re-visited in the future.
Response: Thank you for your comment. Based on the views of the SDT and the preponderance of industry comments the SDT is recommending extending the requirement to verify generator real power capability to all technologies including variable, intermittent, and energy limited generators.		
Bonneville Power Administration	Yes	It seems like Wind and Solar should do a report for their peak generation for Summer and Winter on a periodic basis.
Response: Thank you for your comment. The SDT agrees and has modified the standard to require verification of the real power capability for all generator technologies. The revised standard does not require seasonal (summer and winter) verifications – rather the revised standard requires verifications once every five years.		
AMEA	Yes	The MOD-024-2 draft removes the regions and entities like the Planning Coordinator from the decision making ability as to which generators are material to the BES but instead provides a blanket approach that will include generators that are and are not material to the BES.

Organization	Yes or No	Question 4 Comment
Response: Thank you for your comment. The SDT decided to revise the standard and require the Generator Owner to provide the data to the Planning Coordinator – it is then the Planning Coordinator's responsibility to share the data with other planning entities. The Planning Coordinator has the ability to review past unit performance to insure that the verification value submitted is reasonable, indicative of past unit performance. There is nothing in the standard to prevent the Planning Coordinator from questioning the submitted data.		
Independent Electricity System Operator	Yes	We do not have any concern with the proposed approach. Individual Regions or markets that identify a need to verify such units to meet local requirements can establish regional specific criteria and market rules as they see appropriate.
Response: Thank you for your comment. Based on the views of the SDT and the preponderance of industry comments the SDT is recommending extending the requirement to verify generator real power capability to all technologies including variable, intermittent, and energy limited generators.		
Manitoba Hydro	Yes	Wind generation and run of the river hydro units should be exempted.
Response: Thank you for your comment. Based on the views of the SDT and the preponderance of industry comments the SDT is recommending extending the requirement to verify generator real power capability to all technologies including variable, intermittent, and energy limited generators.		
Cowlitz County PUD	Yes	Wind generation can't buttress reliability in a pinch, therefore should not be included. Agree with the run-of-river argument. However, there are other generation plants that are limited by FERC license to the maximum cubic feet per minute of water permitted to flow through the tail race. Such generation will have name plate ratings well above the allowed possible power generation considering the available prime mover. Therefore the limiting factor is not the ambient temperature, or the thermal aspects of the generation units, but the efficiency of the generation plant to convert the maximum allowed prime mover into electrical power. This efficiency will not change much, if at all, over time. Such units should also be exempt except for a single test at maximum allowed flow.
Response: Thank you for your comments. The SDT understands operational and regulatory constraints may exist; run variable units at what capability can be provided. Constraints are implicitly recognized within the standard process. Refer to Attachment 1, section 2.1 language. Capability as determined for variable resources is better representative of expectation for normal planning than rating information or momentary peak values recorded. The SDT has modified the standard to require verification of the real power capability for all generator technologies.		

5. The SDT has developed a separate periodicity approach for identical units at the same site in Number 4.4 of Attachment 1. The Generator Owner would only be required to verify 20% of these units per year. Do you agree with this approach? If not, please explain.

Summary Consideration: Most stakeholders who responded to this question indicated support for the proposal. In response to other questions, stakeholders indicated that the frequency for testing all units should be once every five years. The SDT is planning to combine the requirements of MOD-024 and MOD-025 into MOD-025. Under the combined standard, all applicable units will be verified once every five years. To avoid having many units requiring verification in any one year, the initial implementation period proposed requires 20% of an entity's units to be done each year.

Organization	Yes or No	Question 5 Comment
Generators Supporting Elimination of MOD-024		NA. This standard is not needed for reliability.
Response: Thank you for your comment. Please see the summary response to comments submitted for Question 1.		
Exelon Generation Co LLC	No	By using information already gathered through the EMS during unit operations for market reasons would elimiate the need for "testing only" runs redusing unnecessary fuel, emmissions and start up stresses on units.
Response: Thank you for your comment. Combining the MOD-024 and MOD-025 verifications will also accomplish minimizing the need for testing runs. Please see the revised standard as it allows use of operational data provided that data meets certain criteria.		
PacifiCorp	No	Current policies within the WECC require a testing interval of five years. This interval has been sufficient for stability studies to date. We suggest incorporation of a five year interval for generator real power capability validation in the proposed standard.
Response: Thank you for your comment. The GV SDT agrees, and has proposed 5 years in the combined (MOD-024 and MOD-025) standard.		
Florida Municipal Power Agency and Some Members	No	Degradation of capacity depends on more factors than design parameters, such as hours of run-time, time from last major maintenance, etc.
Response: Thank you for your comment. The SDT agrees and the new standard will require verification for all applicable units once every five years		

Organization	Yes or No	Question 5 Comment
ERCOT ISO	No	ERCOT disagrees with this aspect of the proposal. The assumption that all units of similar type at a plant are going to perform identically is not valid in all situations. Accordingly, to ensure any potential variances between similar units at the same site are accurately captured all such units should be required to provide verification annually.
Response: Thank you for your comment. Several commenters made the same observation. The GV SDT believes that since under the combined standard all applicable units are tested at some point during the 5 year cycle, this will be accounted for under the requirements.		
South Carolina Electric and Gas	No	Even though units may be identical in nature, variables such as actual in service time could lead to deratings and make two identical units unique. If the intent of the standard is to ensure unit generating capabilities are correct for studies, then shouldn't verification be made for all units?
Response: Thank you for your comment. Several commenters made the same observation. The GV SDT believes that since under the combined standard all applicable units are tested at some point during the 5 year cycle, this will be accounted for under the requirements.		
Pepco Holdings, Inc	No	Identically designed units will not necessarily perform the same.
Response: Thank you for your comment. Several commenters made the same observation. The GV SDT believes that since under the combined standard all applicable units are tested at some point during the 5 year cycle, this will be accounted for under the requirements.		
FirstEnergy	No	Item 4.4 of Attachment 1 should begin with the statement "For units that require annual verification ..." This would better clarify that the identical unit exemption is aimed at units that qualify under item 4.1 and 4.2. We agree that not all identical units should be required to be verified annually . However, the proposal should include a statement by the Generator Owner annually confirming which units that are deemed identical when providing annual verification updates for one of the identical units. Also, the wording proposed in 4.4, "approximately 20%", is ambiguous and up for interpretation in an audit. We suggest 4.4.1 be removed. We suggest replacing items 4.4.1 and 4.4.2 with the following: "The Generator Owner of identical generator units shall verify unit capability of at least one unit annually, such that all units are verified over a five year period."
Response: Thank you for your comments. Under the revised standard (which combines MOD-024 and MOD-025), all applicable units would be verified in the 5 year cycle.		
Public Service Electric and Gas Company	No	N/A as MOD-024 should be retired as demonstrated by PSE&G response to Question 1.

Organization	Yes or No	Question 5 Comment
Response: Thank you for your comment. Please see the summary consideration in response to comments on Question 1.		
The Empire District Electric Company	No	Nameplate data should be sufficient and verification is an overburdon to industry.
Response: Thank you for your comments. The SDT acknowledges that if the correct system operations circumstance exists then the data obtained by performing the Real Power capability verification required by the MOD-024 standard (now incorporated into the MOD-025 standard) for system planning purposes may yield the same results as could be obtained by using equipment nameplate ratings, unit operational data, EMS data, forecast information, etc. required to be provided to the ERO by other standards. Recognize this alternate set of data is collected for other reliability purposes and is not guaranteed to represent actual capability. As such, there is a reliability need to specifically require Real Power capability verification. The SDT also acknowledges it is acceptable to utilize reasonable assumptions when performing long term planning analysis however the SDT also believes it is prudent from a reliability concern to incorporate established unit operational constraints into the planning model when relevant. Units may be derated or constrained for a variety of legitimate long term reasons. Likewise, units derated or constrained today may have restrictions released in the future. Only by performing a Real Power capability verification to determine what the unit is capable of supplying can accuracy of needed reliability data be assured.		
Consolidated Edison Co. of New York	No	Please see response to question 4. In addition, terms such as “identical significant control systems settings” and “similar verified capabilities” are ambiguous. Section 4.4 of Attachment 1 should be removed.
Response: Thank you for your comment. The SDT agrees, and the new standard will require verification of all applicable units once every five years.		
AMEA	No	The MOD-024-2 draft removes the regions and entities like the Planning Coordinator from the decision making ability as to which generators are material to the BES but instead provides a blanket approach that will include generators that are and are not material to the BES.
Response: Thank you for your comment. Response: The GV SDT used the NERC Registration Criteria and believes that it is appropriate for this continent wide standard. Individual Regions are free to propose adjustments if they are deemed necessary, by submitting a request for a variance. **The SDT decided to revise the standard and require the Generator Owner to provide the data to the Planning Coordinator – it is then the Planning Coordinator’s responsibility to share the data with other planning entities. The Planning Coordinator has the ability to review past unit performance to insure that the verification value submitted is reasonable, indicative of past unit performance. There is nothing in the standard to prevent the Planning Coordinator from questioning the submitted data.**		
North Carolina Electric	No	The SDT should not be concerned with administrative details.

Organization	Yes or No	Question 5 Comment
Membership Corporation		
Response: Thank you for your comment. The SDT agrees, and the new standard will require verification of all applicable units.		
IRC Standards Review Committee	No	The SDT should not be concerned with administrative details. The PC should be responsible for requesting verification when verification is needed as opposed to mandating artificial (i.e. one test for all conditions) verification for the sake of artificial verification.
Response: Thank you for your comment. The SDT agrees, and the new standard will require verification of all applicable units with greater flexibility as to when the verification is conducted **The SDT decided to revise the standard and require the Generator Owner to provide the data to the Planning Coordinator – it is then the Planning Coordinator's responsibility to share the data with other planning entities. The Planning Coordinator has the ability to review past unit performance to insure that the verification value submitted is reasonable, indicative of past unit performance. There is nothing in the standard to prevent the Planning Coordinator from questioning the submitted data.**		
Xcel Energy	No	We are in agreement with the concept as long as the caveats that the major components and control systems are identical and that the verified capabilities are similar remain in the wording.
Response: Thank you for your comment. The revised standard will require verification of all applicable units once every five years.

Organization	Yes or No	Question 5 Comment
Transmission/Generation		
Manitoba Hydro	Yes	Can the verification frequency of units be lowered to less than 20% for indentical units. Can it be 10% of identical uinits, as deterioration of unit real capacity is a very slow process unless a failure occurs (and failures are picked up by other standards)
Response: Thank you for your comments. The new standard will require verification for all applicable units on a five year schedule.		
Puget Sound Energy	Yes	However, we encourage this approach to test over a 5 year period for more that just identical units as discussed in our response to question 1. A 5 year cycle for testing is adequate.
Response: Thank you for your comment. The GV SDT agrees, and the combined standard's cycle is five years.		
ITC Holdings	Yes	None
NERC Standards Review Subcommittee	Yes	Please revise 4.4 of Attachment 14.4. Alternatively for multiple units installed at the same site where the units have identical designs, identical major components, identical significant control system settings and similar "tested" verified capabilities "per MOD-024": 4.4.1 Verify approximately 20 percent of all such units annually with all units being verified over a five year period. 4.4.2 Verify at least one unit each year if fewer than five units meet the criteria in 4.4.
Response: Thank you for your comments. The revised standard will require verification for all applicable units on a five year schedule.		
E.ON U.S.	Yes	The language of 4.4 isn't clear -E.ON U.S. suggests revising to "If 5 or more units are at a single site, verify....". Does "approximately 20 percent" imply rounding to the closest whole number? If 2 identical units are at the same site - no annual test is required but both units need to be verified within a 5 year interval?
Response: Thank you for your comment. The revised standard will require verification for all applicable units on a five year schedule.		

6. The SDT believes that every Resource Planner and Planning Coordinator does not necessarily perform studies involving generating unit verified capability at the same time each year nor do they necessarily need current verified information at the same time. The SDT has developed Requirement R2 that requires the Resource Planner and Planning Coordinator to provide a schedule for receiving verified information that best fits the schedule and needs for performing studies. Do you agree with this approach? If not, please explain.

Summary Consideration: The majority of respondents supported having the Resource Planner/Planning Coordinator provide a schedule. One respondent suggested a 5 year periodicity. The SDT, based on this comment and others around the need for this standard, has combined the real and reactive power verifications in the proposed draft of MOD-025. The SDT has also dropped the planning entities (both the Resource Planner and the Planning Coordinator) from the applicability of this standard since the periodicity was revised to 5 years and no longer requires the RP or PC to provide a schedule for verifications.

Organization	Yes or No	Question 6 Comment
Generators Supporting Elimination of MOD-024		NA. This standard is not needed for reliability.
Response: Thank you for your comment. Please see the summary response to the comments submitted for Question 1.		
PacifiCorp	No	: Scheduling of generator capability verification should be set by the generator owner and generator operator within the five year cycle suggested in the Item 5 comments.
Response: Thank you for your comment. The SDT aggress with PacifiCorp on a 5 year cycle. The proposed next draft on MOD-024 combines MOD-024 with MOD-025 reactive power verification. Both the real and reactive power will be scheduled and verified at the same time.		
FirstEnergy	No	It is unclear if R2 is intended to be a one-time submission of temperature adjustment information and schedule by the RP and PC or if this is something that is required each and every time the RP and PC would "seek" the data. Requirement R2 brings into question if the GO is simply holding verification data until requested to provide by an entity who "seeks" the data. Also, as written the RP and PC could provide conflicting temperature data and schedule expectations that would needlessly overburden the GO. As described in our item 4 in our Q9 response, FE suggests that R1 is ambiguous in regards to who the GO is to provide data to on an annual or every 5 year basis. FE suggests the team modify requirement R1 or Attachment 2 to clarify the intended recipients for either annual or 5-year generation verification data. In our opinion the GO should automatically provide the data to the intended recipients. Additionally, we propose the team to set a firm expectation that summer and winter verifications would be

Organization	Yes or No	Question 6 Comment
		provide to the appropriate entities within 90 days of the conclusion of the applicable summer or winter peak period. In regards to temperature adjustment, the GO should simply provide any applicable temperature adjustment data used for the data provided and respond to inquiries from data recipients as needed and upon request.If the team elects to accept FE's proposed changes it is our opinion that R2 can be removed from the standard.
Response: Thank you for your comments. The SDT removed the requirement for the planning entity to provide the Generator Owner with a temperature adjustment. The revised standard now requires the Generator Owner to record the ambient temperature and any adjustment to the temperature and provide this information to the Planning Coordinator. **The revised standard clearly states that the Generator Owner must provide the data to the Planning Coordinator and requires verification of each unit once every five years.** **The revised standard does not require separate winter and summer verifications.** **The SDT revised the standard to require that the data be submitted to the Planning Coordinator within 90 days of conducting verification.** **The SDT did remove Requirement R2 in support of your suggestion.**		
Luminant	No	Luminant believes the test results should be submitted within 30 days of completion of the annual verification. Luminant submits the following modification to Requirements R1 and R2 to address this issue. R1. Each Generator Owner shall verify the summer and winter Real Power generation capability for each of its units in accordance with MOD-024-02 Attachment 1, Verification of Sumer and Winter Generating Unit Capability,and record and submit the verification information via MOD-024-02 Attachment 2, One-line Diagram, Table and Summary for Verification Information Reporting (or similar diagram and form), to the Resoruce Planner and Planning Coordinator within 30 calendar days of the completion of the Real Power capability verification. R2. Each Resourc Planner and Planning Coordinator that seeks verified generating unit Real Power capability data shall provide each Generator Owner: - the desired temperature to which the data is to be adjusted - the calendar dates that encompass the summer period and winter period.
Response: Thank you for your comments. The SDT considered Luminant's recommendation and has modified the standard to require submission of data within 90 days of the verification. Since the data is intended for use in planning studies, the need for the data within 30 days is not clear. **Please see the revised standard – the drafting team made significant changes including the removal of Requirement R2.**		
Public Service Electric and Gas Company	No	N/A as MOD-024 should be retired as demonstrated by PSE&G response to Question 1.

Organization	Yes or No	Question 6 Comment
Response: Thank you for your comment. Please see the summary consideration of comments on Question 1.		
Consumers Energy	No	Testing is arranged around scheduled unit outages. Unit ratings can be normalized to specific temperatures/conditions so results can be sent at any time.
Response: Thank you for your comment. The revised standard is written in such a way as to allow for the GO to conduct the verification at a time that is convenient to the GO, and requires the GO to record the ambient temperature and any adjustments to that temperature. The revised standard does not have any requirements for the planning entities.		
North Carolina Electric Membership Corporation	No	The concept that regular period-specific verification is not necessary. If the SDT is insistent on such a schedule established by the RP/PC, we would ask the SDT to consider circumstances where the same GO owns generators in multiple operating areas thus having to comply with varying requirements by multiple PCs. This would potentially result in the GO having to comply with different schedules of these multiple PCs which could be very difficult for the GO to comply with.
Response: Thank you for your comment. Agree. The revised standard is written in such a way as to allow for the GO to conduct the verification at a time that is convenient to the GO. The revised standard does not have any requirements for the planning entities.		
E.ON U.S.	No	The fundamental concept is correct; but, rather than ambient temperature, seasonal back pressure is much more appropriate to use for corrective factors. (e.g. with temperatures - is it wet bulb/dry bulb; humidity or not; how clean are the condenser/cooling tower?) All of these factors are satisfied by correcting to back-pressure conditions).
Response: Thank you for your comment. The standard does not preclude the GO from including condenser back pressure. The revised standard requires the Generator Owner to record the ambient temperature at the time of verification and to record any adjustments to the temperature.		
AMEA	No	The MOD-024-2 draft removes the regions and entities like the Planning Coordinator from the decision making ability as to which generators are material to the BES but instead provides a blanket approach that will include generators that are and are not material to the BES.
Response: Thank you for your comment. The SDT followed the compliance registration guidelines in establishing section 4.2 Facilities. **The SDT decided to revise the standard and require the Generator Owner to provide the data to the Planning Coordinator – it is then the Planning Coordinator's responsibility to share the data with other planning entities. The Planning Coordinator has the ability to review past unit performance to insure that the verification value submitted is reasonable, indicative of past unit performance. There is nothing in the standard to prevent the Planning Coordinator from questioning the submitted data.**		

Organization	Yes or No	Question 6 Comment
IRC Standards Review Committee	No	The SRC believes with the concept that regular period-specific verification is not necessary, but does not agree with the SDT's requirement. Rather the SRC would propose that R1 and R2 be replaced by the following 3 requirements: R.1. Each Planning Coordinator that requires validation of a Generator Owner's reported generator capability for use in a NERC-mandated assessment shall submit a request to the Generator Owner specifying the applicable conditions. These conditions may include such parameters as: o Gross or Net data o Time (season) required o Boundary conditions (temperature, wind if appropriate) R.2. Each Generator Owner shall verify the Real Power generating capability for each of its units in accordance with requests from their Planning Coordinator. R.3. The Planning Coordinator shall distribute the verified data to the Resource Planners that request the data, or are known by the PC to use that data. Note: CAISO does not support the proposed R3.
Response: Thank you for your comments. As a result of reviewing other responses the SDT has revised the standard to eliminate the Applicability to the PC and has required that the data be submitted to the Planning Coordinator.		
Dynegy Inc	No	The Transmission Planner also needs this generator data. These planning entities should not be required to provide the desired temperature to which the data needs to be adjusted. Generator Owners should simply adjust the actual test data using average temperature data from a location near the plant. This provision has been incorporated in the related RFC Regional Standard MOD-024-RFC-01.
Response: Thank you for your comments. Agree – all of the planning entities need the data. The SDT decided to revise the standard and require the Generator Owner to provide the data to the Planning Coordinator – it is then the Planning Coordinator's responsibility to share the data with other planning entities. **The revised standard does not require the planning entities to provide temperature adjustments to the Generator Owners – in response to suggestions from stakeholders, this requirement was removed. The revised standard requires the Generator Owner to record the ambient temperature at the time of verification and to record any adjustments made to that temperature.**		
Bauer	No	This standard is not consistent with the NERC functional model in that it requires the submission of information is not consistent with the role of the Resources Planner. The Resource Planner's role is to

Organization	Yes or No	Question 6 Comment
		develop a long term plan for resource adequacy of specific loads within a Resource Planners area. The information furnished under this requirement would be valid for less than one year. Forecast reservoir operations are notoriously inaccurate at more than 9 months. The forecast seasonal variation is relevant for TOP and BA functions. Resource Planners would interested in average seasonal variations and any physical changes to generator capability (e.g. de-rating, up-rating, etc).
Response: Thank you for your comments. The Functional Model assigns all three of the planning functional entities, including the Resource Planner, with the responsibility for collecting data from the Generator Owner. The SDT modified the standard and now requires the Generator Owner to provide the verification data just to the Planning Coordinator. The Planning Coordinator is responsible for sharing data with other planning entities. **The frequency of verification has been changed to once every five years which more closely fits the planning entities.**		
We Energies	No	To the extent there are multiple reporting requirements for generator capacity data, a standard timeframe for reporting the information should be developed in order to minimize the potential for conflicting data on the same generator from being used for similar modeling purposes. In addition, to the extent that generator capability data will be adjusted based upon ambient conditions, the requirement to verify the summer gross Real Power generating capability only during the summer period is overly restrictive. Current standards for generator testing allows the results from any period of time to be used as long as the results are adjusted based upon ambient conditions at the time of the test to the ambient conditions that would exist during the summer.
Response: Thank you for your comments. Please see the revised standard. The SDT simplified the standard's requirements by giving the Generator Owner greater latitude on 'when' to conduct its verifications. Several commenters provided sound reasons for granting the Generator Owner latitude in conducting tests or using historical data as an alternative to a test on a schedule that permits the Generator Owner to collect the data more efficiently than under the originally proposed MOD-024. The concept of having the Generator Owner conduct the verifications in accordance with various schedules set by planning entities was not carried over into the next draft of MOD-024 (now integrated into MOD-025). **The revised standard does not require seasonal (summer and winter) verifications – rather the revised standard requires verifications once every five years.**		
Exelon Generation Co LLC	No	Using real time data from EMS would allow planners to have access to dat for anytime of year and system conditions elimiating the need to schedule testing.
Response: Thank you for your comment. The SDT recognized this and debated this issue at length. The revised standard allows the use of historical data provided that data meets specific criteria.		
Independent Electricity System	No	We agree with the RPs and PCs to specify the schedule for receiving verified information to suit their needs.

Organization	Yes or No	Question 6 Comment
Operator		However, we have concerns with the applicability which relates to the purpose of the standard. a. The purpose of the existing MOD-024-1 is: “To ensure accurate information on generator gross and net Real Power capability is available for steady-state models used to assess Bulk Electric System reliability.” This implies that the data is also used for accurate modeling of the BES which the TPs, TOPs and RCs use to assess transmission system performance. The purpose of the proposed MOD-024-2 appears to have been changed somewhat: “To ensure that planning entities have accurate generator Real Power capability modeling data used in system planning studies.” This change was not mentioned in the SAR for the project (posted for comment in April 2007). We have two concerns with this change and the corresponding requirements: (i) The data is not only used for planning, it is also used for operational planning and near-term adequacy assessments (ii) If the intent of the existing standard is to continue, then the data is used for transmission reliability assessment as well. Other applicable entities need to be added. We suggest the SDT to assess the intended users of the generator’s real power capability data. Is the data used for resource adequacy assessment only, or is it also used for system model for transmission reliability/adequacy assessment? If it is the former, then RPs and PCs would be the only users. If it’s the latter, then TPs, TOPs, and RCs can be the other users.b. In the Background Information section of the comment form, the SDT indicates that it “has taken the approach that the Transmission Planner needs to communicate the conditions under which the Generator Owner is to provide verified values.” The proposed requirement does not include TPs. We wonder if the Background Information quoted the incorrect entities, or the standard is missing the TP as an applicable entity.
Response: Thank you for your comments. The SDT removed the reference to Transmission Planner from the Standard. It is the SDT’s view that the RP, and TP can obtain any data that they need from the Planning Coordinator. Each Reliability Coordinator and Transmission Operator is required to have a data specification that it issues to the entities required to submit data – and if the RC or TOP needs data from the GO, this is a mechanism for the RC or TOP to receive data from the GO. The data used by the TOP and RC for real-time monitoring must be more accurate than the data used for planning studies. There are other requirements in other standards that require the Generator Owner or Generator Operator to keep the Transmission Operator informed of generator availability, changes to output, etc. **The purpose of the standard has not changed. The SDT views steady state models as a type of planning model.**		
GO/GOP	No	We do not agree with this approach. Validation should be performed during a period which is mutually agreed upon by both the GO and TOP to take into account seasonality. For the other periods, validations should not be required.

Organization	Yes or No	Question 6 Comment
Response: Thank you for your comment. Please see the revised standard. The SDT simplified the standard's requirements by giving the Generator Owner greater latitude on 'when' to conduct its verifications. Several commenters provided sound reasons for granting the Generator Owner latitude in conducting tests or using historical data as an alternative to a test on a schedule that permits the Generator Owner to collect the data more efficiently than under the originally proposed MOD-024. The concept of having the Generator Owner conduct the verifications in accordance with various schedules set by planning entities was not carried over into the next draft of MOD-024 (now integrated into MOD-025).		
Puget Sound Energy	No	While R2 allows flexibility in determining when the data is submitted, the Resource Planner/Planning Coordinator may not need this information each year. If that is the case, this annual requirement imposes an unnecessary burden on Planners and Generators to provide this information more frequently than necessary.
Response: Thank you for your comment. The STD has combined MOD-024 and 025 and moved the real power test to a 5 year periodicity in support of your suggestion.		
American Electric Power	Yes	
American Transmission Company	Yes	
Bonneville Power Administration	Yes	
Calpine Corporation	Yes	
Duke Energy	Yes	
Electric Market Policy	Yes	
Florida Municipal Power Agency and Some Members	Yes	
Hydro-Quebec TransEnergie (HQT)	Yes	
Long island power Authority	Yes	
Northeast Power Coordinating	Yes	

Organization	Yes or No	Question 6 Comment
Council		
Pepco Holdings, Inc	Yes	
Progress Energy	Yes	
SERC Generation Subcommittee (GS)	Yes	
SERC Planning Standards Subcommittee	Yes	
South Carolina Electric and Gas	Yes	
The Empire District Electric Company	Yes	
Xcel Energy	Yes	
Cowlitz County PUD	Yes	As long as it does not conflict with operational constraints of the generation plant.
Response: The SDT agrees. Thank you for your comment. The revised standard gives the Generator Owner more latitude in determining when to conduct its verifications.		
ERCOT ISO	Yes	ERCOT ISO supports this aspect of the proposal. The verification methodology and timing should be left to the discretion of the relevant NERC functional entities. As noted by the SDT, the needs for different Resource Planners and Planning Coordinators may vary. The Standard should enable the relevant entities to respect those needs, including the timing of the verification tests. By simply stating these entities should provide a schedule, the proposal provides adequate flexibility to respect regional differences. To accommodate the potential need for ad hoc testing, the requirement should provide for testing pursuant to the contemplated schedules “or as requested by the RP or PC”.
Response: The SDT agrees. Thank you for your comments. The revised standard gives the Generator Owner more latitude in determining when to conduct its verifications.		

Organization	Yes or No	Question 6 Comment
Indiana Municipal Power Agency	Yes	IMPA agrees with this approach as long as it is for only receiving the verified information and not allowing these entities to specify any type of testing period or requirements outside of this standard.
Response: The SDT agrees. Thank you for your comment. The revised standard gives the Generator Owner more latitude in determining when to conduct its verifications.		
Consolidated Edison Co. of New York	Yes	In addition, different regions of the country may have summer or winter peaking periods and will schedule tests accordingly.
Response: The SDT agrees. Thank you for your comment. The revised standard gives the Generator Owner more latitude in determining when to conduct its verifications and eliminates the requirement to conduct both summer and winter verifications.		
ITC Holdings	Yes	None
NERC Standards Review Subcommittee	Yes	R2 should be redacted to include variables and not be so constrained to temperature since there might be other variables besides temperature. These variables would be specified at the Planning Coordinator and Resource Planner discretion.
Response: The SDT agrees. Thank you for your comments. The drafting team removed Requirement R2 from the revised standard (MOD-024 now merged into MOD-025).		
Manitoba Hydro	Yes	State clearly who provides a schedule to whom. Is it Planning coordinator will provide a schedule to Resource planner for verified capability information of units? We would prefer that the requirement be to complete the testing at the required frequency, and to delete the requirement for creation and submission of a plan.
Response: The SDT agrees. Thank you for your comment. The revised standard gives the Generator Owner more latitude in determining when to conduct its verifications.		
Arizona Public Service Co.	Yes	The need for verification should also be left on the Planning Coordinator.
Response: The SDT agrees. Thank you for your comment. The revised standard requires verification of all applicable units once every five years.		
Southern Company Transmission/Generation	Yes	We agree with this requirement.

Organization	Yes or No	Question 6 Comment
Response: The SDT agrees. Thank you for your comment.		

7. Are you aware of any regional variances that would be required for this standard?

Summary Consideration: An overwhelming majority of responders believe there are no regional variances that would be required for this standard. A few responders suggested that winter validation would not be necessary or that the annual testing requirement was too frequent. The SDT addressed both in the revisions to MOD-024. The language specifying both summer and winter validations was not included in the revised standard and the testing periodicity was changed to once every five years. MOD-024 was combined with MOD-025.

Organization	Yes or No	Question 7 Comment
American Transmission Company	No

Pepco Holdings, Inc	No	
Progress Energy	No	
SERC Planning Standards Subcommittee	No	

Organization	Yes or No	Question 7 Comment
South Carolina Electric and Gas	No	
The Empire District Electric Company	No	
ERCOT ISO	No	As discussed above, ERCOT ISO believes that there may be regional differences in the planning and operational studies where this information provides value. However, if the Standard is drafted to prescribe the reliability “end” result or obligation, and it provides for adequate flexibility with respect to how the means implemented by the relevant entities to comply with the obligation, there should not be a need for regional differences. Revising the Standard in accordance with this general principle and the specific comments provided herein should affect this result and obviate, or at least mitigate to a great extent, the need for regional variances.
Response: Thank you for your comments. The SDT believes the reliability end result and flexibility exists in the standard to allow for implementation by all regional entities. The standard is focused on providing data for planning studies, not necessarily for operational studies.		
NERC Standards Review Subcommittee	No	N/A
Public Service Electric and Gas Company	No	N/A as MOD-024 should be retired as demonstrated by PSE&G response to Question 1.
Response: Thank you for your comment. Please see the summary consideration of the comments submitted in response to Question 1.		
ITC Holdings	No	None
E.ON U.S.	No	Summer peaking regional requirements are different than winter peaking regional requirements
Response: Thank you for your comment. The SDT believes it has provided the flexibility for the MW capabilities to be adjusted to temperatures expected in each area to satisfy regional needs.		
American Electric Power	No	There are no additional variations known beyond those variations already accommodated in the draft standard.
Response: Thank you for your comment.		

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 7 Comment</th></tr>
<tr><td>Electric Market Policy</td><td>No</td><td>We are not aware of any regional variances, but are aware that regional standards are under development.</td></tr>
<tr><td colspan="3">Response: Thank you for your comment. The SDT is aware that regional standards are under development. Some parts have been taken from those regional standards as useful and have been made part of the MOD-024-2 Draft.</td></tr>
<tr><td>GO/GOP</td><td>Yes</td><td>Different regions have different peak seasons depending on the climate.</td></tr>
<tr><td colspan="3">Response: Thank you for your comment. The SDT believes it has provided the flexibility for the MW capabilities to be adjusted to temperatures expected in each area to satisfy regional needs.</td></tr>
<tr><td>FirstEnergy</td><td>Yes</td><td>Our preference is that RFC retire their regional standard for Real Power verification (MOD-024-RFC-01) upon completion of this continent-wide standard. However, if RFC believes their standard is still needed after this NERC standard is completed, then there may be potential regional variances required as follows:
1. The threshold for periodicity of verification for RFC is 85 MVA; NERC is proposing 75 MVA. The gap between 75 and 85 MVA would need to be addressed.
2. RFC explicitly allows for testing, including commissioning tests for new units, in lieu of operational tracking.
3. The applicability for RFC is the Generator Operator while NERC proposes applicability to the Generator Owner.
4. RFC explicitly allows for exemptions and delays in verifications when system conditions or generator issues prevent verification.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. It is expected that regional standards would be revised if necessary to account for differences between them and the NERC standard - or retired if no longer needed.
The applicability in the revised standard (MOD-024 was merged into MOD-025) uses the same thresholds as those used in the compliance registration criteria.
The SDT believes the current draft does not preclude the GO from doing either operational tracking or staged testing as long as the required data is taken.
The SDT considered both the GO and GOP and originally chose the GOP as well. The applicability was changed to GO under advisement from NERC, to align with the Functional Model.
The revised standard requires verification of applicable units once every five years – eliminating the concept of a fixed schedule for verifications.</td></tr>
</table>

Organization	Yes or No	Question 7 Comment
Manitoba Hydro	Yes	Regions with considerable hydraulic generation require verification of unit output that will be modified by calculation for rated head output for comparison. Exempting run of river plants removes this need for exemption.
Response: Thank you for your comment. After discussions with the Integration of Variable Generation Task Force, IVGTF, the SDT has modified the standard to require verification of the real power capability for all generator technologies. Consideration of modifications for rated head output will be reviewed.		
Electric Power Supply Association (EPSA)	Yes	See answer to question 9.
Response: Thank you for your comment. Please see the response to comments on Question 9.		
Xcel Energy	Yes	Some Regional Entities have developed their own requirements as directed under MOD-024-1. These would presumably take precedence over MOD-024-2. Some RTO's (e.g. MISO) have their own requirements for capability verification.
Response: Thank you for your comment. NERC's MOD-024-2, if approved or combined into MOD-025-2, may necessitate revisions to some regional standards if they are less restrictive than the NERC Standard. RTO's should review their requirements for consistency as well.		
AMEA	Yes	The current MOD-024-1 allows the regions to determine which generators must provide the requied data. Regions like SERC have developed regional supplemental standards that identifies such generators. The draft MOD-024-2 contradicts SERC's regional supplemental standards and totally removes SERC and other regions from the decision making process.
Response: Thank you for your comment. The revised standard duplicates the language of the compliance registry criteria. Regions are free to include other facilities if they see fit, by requesting a variance		
SERC Generation Subcommittee (GS)	Yes	The SERC Region is a summer peaking load region. Since unit capability (excluding hydro) is either independent of seasonal differences or will exhibit increased capacity for non summer periods, winter validation is not necessary. This would apply to summer peaking entities or regions.
Response: Thank you for your comment. The SDT has incorporated the proposed real power verification requirements into the revised MOD-025. In that revised standard, the SDT eliminated the need for seasonal verification. As envisioned, only a periodic verification would be required and other data would be calculated based on that one.		

Organization	Yes or No	Question 7 Comment
Southern Company Transmission/Generation	Yes	The SERC Region is a summer peaking load region. Since unit capability (excluding hydro) is either independent of seasonal differences or will exhibit increased capacity for non summer periods, winter validation is not necessary.
Response: Thank you for your comment. The SDT has incorporated the proposed real power verification requirements into the revised MOD-025. In that revised standard, the SDT eliminated the need for seasonal verification. As envisioned, only a periodic verification would be required and other data would be calculated based on that one.		
Puget Sound Energy	Yes	The WECC may want to continue using a 5 year cycle for testing. From the WECC experience testing annually for most units would be unnecessarily frequent.
Response: Thank you for your comment. The GVSDT agrees. In the proposed revisions to MOD-024 (now integrated into MOD-025) the real power verification frequency would be on a five year cycle, in support of your suggestion.		

8. Are you aware of any conflicts between the proposed standard and any regulatory function, rule, order, tariff, rate schedule, legislative requirement, or agreement?

Summary Consideration: An overwhelming majority of respondents were not aware of any conflicts. A few specific conflicts were identified such as with regional standards which will have to be revised when the NERC standard is approved, a maximum hydraulic flow rate by licensing issue with some hydros and a diesel generator law in Kansas. A couple of general conflicts were suggested such as with TOP-002 and CIP standards but the drafting team could not specifically identify those conflicts.

Organization	Yes or No	Question 8 Comment
Generators Supporting Elimination of MOD-024		NA. This standard is not needed for reliability.
Response: Thank you for your comment. Please see the summary consideration of comments in response to Question 1.		
ERCOT ISO		See response to Question 7 - if the Standard provides adequate flexibility with respect to the means for complying with the reliability end prescribed by the requirements, this should mitigate any potential conflict.
Response: Thank you for your comment. The SDT believes the reliability end result and flexibility exists in the standard to allow for implementation by all regional entities.		
American Transmission Company	No

Organization	Yes or No	Question 8 Comment
SERC Planning Standards Subcommittee	No	
South Carolina Electric and Gas	No	
Southern Company Transmission/Generation	No	
Xcel Energy	No	
Manitoba Hydro	No	MAPP was requiring unit capability tests in MRO region prior to MOD-024 NERC standard. The overlap with FAC-008 and FAC-009 should be carefully examined to avoid confusion.
Response: Thank you for your comment. FAC-008 and FAC-009 reference facility ratings while MOD-024 proposes capability verification. The SDT is constantly vigilant of potential confusion or conflicts however if there is confusion on a specific point please bring it to our attention.		
NERC Standards Review Subcommittee	No	N/A
Public Service Electric and Gas Company	No	N/A as MOD-024 should be retired as demonstrated by PSE&G response to Question 1.
Response: Thank you for your comment. Please see the summary consideration of comments submitted in response to Question 1.		
American Electric Power	No	No known conflicts.
Response: Thank you for your comment.		
ITC Holdings	No	None
Response: Thank you for your comment.		
Northeast Power Coordinating Council	No	The collection of this data is already addressed through tariffs, Market Rules, and Interconnection Agreements. The Standard should be retired. Although data can be reliability related sufficient data is collected as dictated by other standards. NERC staff should coordinate and ensure that the collection of this

Organization	Yes or No	Question 8 Comment
		data is incorporated in existing standards projects.
Response: Thank you for your comments. Tariffs, Market Rules, and Interconnection agreements are independent of the reliability obligations being addressed by this standard. Please see the summary consideration of comments submitted in response to Question 1.		
E.ON U.S.	No	This information requires some duplicate reporting. For example, the Kentucky Public Service Commission requires resource adequacy planning and reporting of the same data.
Response: Thank you for your comment. The GV SDT agrees, some coordination may be required by the GO and various organized markets to avoid conflicts.		
PacifiCorp	Yes	: Again, water resource impacts on hydroelectric facility capability have not been addressed sufficiently by the proposed standard and may result in conflict with other regulatory standards. Please provide clarification on expectations for data collection at hydro facilities when water resources do not support operation at unit capability.
Response: Thank you for your comment. The revised standard (MOD-024 is now incorporated into MOD-025) Attachment 1, 2.2 allows for a one hour test at any time during the year and for adjustments to the data for expected resource conditions.		
Pepco Holdings, Inc	Yes	As noted in Question 1, this data is already being collected under other standards and in various organized markets. Coordination will be required to avoid conflicts
Response: Thank you for your comment. The GV SDT agrees, some coordination may be required by the GO and various organized markets to avoid conflicts. The SDT reviewed the requirements identified by stakeholders as potentially redundant with the proposed standard, and found no conflicts.		
IRC Standards Review Committee	Yes	Certain Regional Entities are currently developing or have developed standards to comply with MOD-024-1 and close coordination will be necessary to ensure that no compliance conflicts are created with the approval of this updated standard.
Response: Thank you for your comment. It will be up to the Regional Entities to review their standards to be sure they are not in conflict with the NERC's standard (MOD-024 now integrated into MOD-025) when it is approved.		
The Empire District Electric Company	Yes	I am aware the state of Kansas has a current law that forbids units that start on Diesel fuel. This could cause some issues with smaller generators in the state of Kansas.
Response: Thanks for your comment. The law, as referenced, may be more restrictive but does not appear to conflict with MOD-024-2 (now integrated		

Organization	Yes or No	Question 8 Comment
into MOD-025-2) as proposed.		
Cowlitz County PUD	Yes	Maximum hydraulic flow constraints by operation license can legally prevent maximum name plate capacity verification tests.
Response: Thank you for your comment. The standard does not require maximum name plate capacity verifications.		
AMEA	Yes	Since SERC's supplemental standards have not yet been approved by FERC I consider them proposed standards. The current MOD-024-1 allows the regions to determine which generators must provide the requied data. Regions like SERC have developed regional supplemental standards that identifies such generators. The draft MOD-024-2 contradicts SERC's regional supplemental standards and totally removes SERC and other regions from the decision making process.The draft MOD-024-2 conflicts with the new CIP standards regarding the size of significant generators.
Response: Thank you for your comments. FERC did not approve the current MOD-024 Standard calling it a fill-in-the-blank standard and directed that it be re-written as a continent wide standard. Regional standards may have to be revised. Regions would still be allowed to include requirements that are not included in the NERC version. The GV SDT does not believe there is a conflict with the CIP Standards as written. If you could be more specific as to the nature of the potential conflict the SDT will review it.		
Indiana Municipal Power Agency	Yes	This standard conflicts with the RFC approved standard, MOD-024-RFC-01. The NERC draft version of MOD-024 has the Generator Owner submitting reports to the proper entities. This conflicts with the RFC standard which has the Generator Operator submitting the reports to the proper entities. IMPA believes that NERC should resolve this issue by having the RFC standard agree with the NERC MOD-024 standard and the Functional Model. The SDT may not be able to resolve this issue, but it needs to be resolved or two different entities could be in non-compliance in the RFC region if a report is not submitted.
Response: Thank you for your comments. The RFC standard does not appear to have been approved by the NERC BOT or by FERC. Regional Standards may have to be revised to be in compliance with the NERC Standard once it is approved. **Note that the SDT consulted with the Functional Model, and it is the Generator Owner that is responsible for providing data on its units.**		
Bauer	Yes	This standard conflicts with TOP-002
Response: Thank you for your comment. The GV SDT does not believe there is a conflict with TOP-002. Please see the summary consideration of comments submitted in response to Question 1.		

9. Do you have any other questions or concerns with the proposed standard that have not been addressed? If yes, please provide a reference to the section, requirement or subrequirement that you believe should be changed, added or deleted and the rationale for your proposal.

Summary Consideration: Many of the respondents made numerous suggestions for edits or changes that would provide clarity to the standard. The SDT has reviewed all comments, provided explanations and made the following edits to the revised standard (MOD-024 was merged into MOD-025):

- Edited Requirement and attachment language.
- The Generator Owner record the ambient temperature at the time of the verification and documents any adjustment to that temperature.
- The Generator Owner submits verified data within 90 days to the Planning Coordinator.
- The standard does not reference seasonal requirements.
- The revised standard does not require staged tests, and only requires verification once every five years.
- Flexibility has been given to modify the attachment-2 diagram (refer to MOD-025-1).
- Requirement R2 was not carried forward into the revised standard.
- The threshold was modified, and now includes two aspects – first the change must be expected to last at least six months, and second the change must be at least 10% of the last verified capability.
- Lower VRF defined for each Requirement.
- 5 Year verification cycle specified.
- Modified the applicability section of the standard to more closely align with the criteria in the compliance registry.

Organization	Yes or No	Question 9 Comment
Generators Supporting Elimination of MOD-024		NA. This standard is not needed for reliability.
Response: Thank you for your comment. Please see the summary consideration of comments submitted in response to Question 1.		
American Electric Power	No	

Organization	Yes or No	Question 9 Comment
Exelon Generation Co LLC	No	
Hydro-Quebec TransEnergie (HQT)	No	
IRC Standards Review Committee	No	
Long island power Authority	No	
Northeast Power Coordinating Council	No	
Pepco Holdings, Inc	No	
Puget Sound Energy	No	
South Carolina Electric and Gas	No	
The Empire District Electric Company	No	
Public Service Electric and Gas Company	No	N/A as MOD-024 should be retired as demonstrated by PSE&G response to Question 1.
Response: Thank you for your comment. Please see the summary consideration of comments submitted in response to Question 1.		
ITC Holdings	No	None
Oglethorpe Power Corporation	Yes	
PacifiCorp	Yes	: Suggest language in Section 2.2 to read “the resource planner will assess the stated winter generating capability based on a test hour of generation corrected for actual vs forecasted water elevations and flows.”
Response: Thank you for your comment. The GV SDT agrees that clarification is necessary and eliminated the identified language in the combined		

Organization	Yes or No	Question 9 Comment
MOD-024 and MOD-025 standard.		
Dynegy Inc	Yes	1. Applicability 4.1- Transmission Planner needs to be added as a Functional Entity. All Planning related entities (i.e. Planni ng Coordinator, Resource Planner and Transmission Planner) need the maximum demonstrated capability of generating units for inclusion in their planning models. 2. Requirement R2- Adjustment of generating verification data should not be dependent on a request from a planning entity. This data should be adjusted to an average temperature in all cases and recorded on Attachment 2. 3. Attachment 1, Item 3.4.5- Modify this item to correspond to recommended changes in Requirement R2 (see above comment #2). 4. Attachment 1, Item 4.5- The phrase “does not run with the periodicity described in 4.1 through 4.4” “ is ambiguous. No “periods” are included in Items 4.1 through 4.4 in Attachment 1. The intent of this provision needs to be clarified.
Response: Thank you for your comments. The SDT believes that the Planning Coordinator is the most appropriate entity to receive the data. The Planning Coordinator works cooperatively with Resource Planners and Transmission Planners. The SDT removed the need for the planning entity to provide the Generator Owner with a temperature adjustment. The revised standard has the Generator Owner record the ambient temperature at the time of the verification and documents any adjustment to that temperature. **The phrase “does not run . . .” is not used in the revised standard.**		
Electric Market Policy	Yes	1. Requirement R1 states to “submit” the Real Power generating capability: however Requirement R2 appears to suggest that the data be submitted only when requested by the Resource Planner and/or Planning Coordinator. Therefore, we suggest you remove the words “and submit” from R1. 2. Requirement R2 - the first bullet should be revised to indicate “desired condition” to which the data is to be adjusted.2. “Summer period” and “summer season” appear to be used interchangeably in Attachment 1. The same comment applies for winter.
Response: Thank you for your comments. The revised standard is clear that the Generator Owner must submit its verified data within 90 days of the date of verification to its Planning Coordinator. **The revised standard does not reference summer period or summer season - or does it reference winter periods or winter seasons.**		
Southern Company Transmission/Generation	Yes	1. The subject standard should not require annual staged full load capability demonstration for verifying MW capability. There are many factors such as system load, economic dispatch, etc that determine if a unit is

Organization	Yes or No	Question 9 Comment
		expected to be called to full load. This is especially true for the smaller (<75 MVA) units. 2. The requirement for ambient temperature monitoring during the verification period is unreasonable. The ambient temperature is not needed for unit operation, and may not be tracked, and in some cases may not be reliable. In these cases, either inaccurate data would be collected or added investment would be required. (The official ratings mentioned above are based on performance data taken at or adjusted to specified ambient conditions.) 3. Allowances for different reporting format from that in attachment 2 should be permitted. We prefer a tabular reporting method due to the number of units in our fleet. An allowance for tabular reporting of the same information as indicated in attachment 2 should be permitted. 4. In Paragraph 3 of Page 5, we recommend replacing “Number” with “Paragraph”. 5. The following comments relate to Attachment 2: a. On Page 7 we recommend the following: o moving the “Date of Report” and the associated blank line to the same line as “Unit No”. o changing “Auxiliary Transformer(s)” below point A to “Unit Auxiliary Transformer(s)” o changing “Auxiliary Transformer(s)” below point C to “Station Auxiliary Transformer(s)” o splitting the bus just below the “Point of Interconnection” and eliminating the single line diagram associated with point D. o adjusting single line diagram to fit on the page (displayed on a PC monitor) o change “MW (tertiary load, if any)”, to “MW (GSU tertiary load, if any)” at the bottom of the page b. On Page 8, we recommend the following: o delete the point D measurement line from page 8 c. On Page 9 (Summer Verification Data), we recommend the following: o Insert a blank line between the “Date of Verification...” line and the “Verification End Time...” line.- in other words, make the summer and winter verification forms identical with respect to the Date of Verification, Verification Start Time, Verification End Timed. On Page 9 & 10 (Summer and Winter Verification Data), we recommend the following: o specify if the Aux Power (MW*) column in the table is “the sum of the auxiliary loads shown

Organization	Yes or No	Question 9 Comment
		on page 7” 6. R2 is not a requirement as currently written. It is a choice that the RP or PC makes. If he seeks verfied data, then he must provide certain things to the GO. If he chooses to not seek verified data, then he is not required to do anything. This means that M2 is wrong. The RP and PC should not be required to have evidence if they chose not to seek the data. 7. R1 requires the GO to submit information but it does not indicate to whom the data should be submitted. 8. R3: The threshhold for reporting a change in MW output is too high. A change of 10 to 50 MW in a generator's output could have an impact to system stability. The threshhold should be 10 MW. 9. Paragraph 2.4 in Att 1: The first word grouping is not a sentence and reads awkwardly. It is suggested that the words "an acceptable value can be obtained" be place in front of the words "by making a temperature". 10. Paragraph 3.4.2 in Att 1: Replace the word "since" with "if" for better clarity. 11. Paragraph 3.4.4 in Att 1: Move the words "in Attachment 2" to the position just after the word "flows". This will make it clear that the sentence refers to flows in Attachments 2 rather than units in Attachment 2.

Response: Thank you for your comments.

1. **The revised standard does not require staged tests, and only requires verification once every five years.**
2. **The SDT feels that the ambient temperature could significantly affect the performance of some units, especially combustion units and should be recorded and averaged for the one hour test.**
3. **Flexibility has been given to modify the diagram which could include adding a table if all of the required data is included. The SDT modified the diagram to incorporate some of your suggestions. As a note, point D was meant for units that may have part of their aux load supplied from a different bus than the point of interconnection such as on some units that have had large emissions control retrofits. Although this load would not be subtracted from the gross/net load capability of the unit, it should relieve the confusion of where it should be grouped.**
4. **The revisions made to Attachment 1 did not include carrying forward the language proposed for modification.**
5. **The SDT agrees with several of your suggestions for clarity of Attachments 1 and 2 and adopted several of your suggestions. The SDT adopted those suggestions that seem most likely to have widespread applicability.**
6. **Requirement R2 was not carried forward into the revised standard.**
7. **Requirement R1 was modified to clarify that the Generator Owner must provide the data to the Planning Coordinator.**
8. **The threshold was modified, and now includes two aspects – first the change must be expected to last at least six months, and second the change must be at least 10% of the last verified capability.**

Organization	Yes or No	Question 9 Comment
9. Paragraph 2.4 in Att 1: The phrase proposed for revision is not included in the revised standard. **10. And Paragraph 3.4.2 in Att 1: this has been replaced with the following for improved clarity:** **a. If metering does not exist to measure specific reactive auxiliary load(s), provide an engineering estimate and associated calculations.** **11. Paragraph 3.4.4 in Att 1: The phrase proposed for clarification is not used in the revised standard.**		
Indiana Municipal Power Agency	Yes	A clarification under number five, the effective date is needed. Under effective date, both sentences need to be clarified. Is the effective date the first day of the first calendar quarter after or part of the six months after applicable regulatory approval. For example, if regulatory approved is received on June 28, 2011 and then six months after is December 28, 2011, is the standard effective on January 1, 2012 (first day of the first calendar quarter after six months) or a date in the six months (before December 28, 2011).
Response: Thank you for your comments. The SDT took the basic wording for "Effective Date", common in other standards, and applied it to this standard. The effective date is the first calendar day of the first quarter one calendar year after regulatory approvals. So, if FERC approved the standard in January of 2012, the first calendar day of the first quarter one calendar year after regulatory approvals would be April 1, 2013.		
Cowlitz County PUD	Yes	Ambient temperature correction calculation requirements may incur significant compliance costs with little return for the effort. Will the Planner be asking for operation output vs. ambient temperatures way beyond normal levels? If the required ambient temperature is beyond the operational testing ability (i.e. 500 year high), how will the engineering analysis be established and verified?
Response: Thank you for your comments. The revised standard does not include the requirement for the planning entities to give the Generator Owner a temperature adjustment – instead the Generator Owner is required to document the temperature at the time of the verification and note any adjustments made to that temperature.		
SERC Generation Subcommittee (GS)	Yes	Assuming this standard is not retired, the first bullet item under R2 should be deleted. If it is not, it should be revised as follows: o The data is to be adjusted for conditions normally experienced for summer and winter peak periods, as applicable. Industry guidance is needed on how to adjust recorded test data in Requirement R2 and Section 3.4.5 on Attachment 1. Section 3.4.5 should be expanded to allow for adjusting of data for factors other than ambient air temperature. It's unclear what is being sought by "adjusting" data to a desired temperature. For steam turbines, ambient air temperature may not impact output nearly as much as coolant temperature, when the machine is not air cooled.
Response: Thank you for your comments. As you implied, generator ratings could vary significantly with ambient temperature. Combustion turbines may also be significantly affected by ambient temperatures. Affects on other units may not be as significant so some engineering judgment and/or historical data may be required to estimate a change in capability due to changes in coolant temperature and how those coolant temperatures change		

Organization	Yes or No	Question 9 Comment
with ambient temperature. The SDT believes that the GO is the best qualified to adjust unit output for temperatures other than that at the time of the test. The objective is to give the planning entities the best estimate of Unit real power capability for the desired ambient temperatures used in planning studies. The revised standard requires the Generator Owner to document the ambient temperature at the time of the verification and to document any adjustments made to that temperature. The revised standard does not include any requirement for any planning entity to give the Generator Owner a temperature adjustment.		
Bonneville Power Administration	Yes	Attachment 2 needs modification: Attachment 2 should have a measurement point on their diagram for the gross generator output, and the table should specify what values to use in the calculation of each column (Gross capability power = new point F, Aux power = A+B+C+D, Net Power = F-A-B-C-D) Because this standard is paired with MOD-025(reactive), BPA believes they should be commented together.
Response: Thanks for your comments. The SDT agrees that some modifications were needed on Attachment 2 and has modified accordingly. After thorough consideration of all responses, the SDT is proposing to merge the requirements for MOD-024 with the requirements for MOD-025, to obtain real power verification data at the same time as reactive power verification data. To perform the reactive power verification it is necessary to go to the rated real power operating point. Therefore, recording and reporting both the real and reactive power data as part of the MOD-025 verification only makes sense. **Note that in the revised standard, the attachment does collect gross real and gross reactive generator capability.**		
Calpine Corporation	Yes	Combined cycle power plants are often built with peaking capability such as steam injection for power augmentation. The term "normal operation" should be defined and include a statement that peaking capability is included only if the unit routinely operates in this mode. Combined cycle plants are sensitive to a variety of ambient conditions in addition to temperature, such as relative humidity. The standard should be revised to include other ambient data required by the generator to adjust output.
Response: Thank you for your comments. The SDT does not believe that "normal operation" needs to be defined. **The SDT felt that ambient temperature had the most significant impact on unit capability. Adjustments made to the ambient temperature must be documented.**		
Progress Energy	Yes	COMMENT 1-The first bullet item under R2 should be revised as follows: o the desired temperature to which the data is to be adjusted for conditions normally experienced for summer and winter periods. COMMENT 2- R3 should be revised as follows:"Each Generator Owner shall report to its Resource Planner and Planning Coordinator any change that is greater than 50 MW in the gross Real Power generating capability of any unit compared with the last verification submittal that is expected to last more than six months. The Generator Owner shall make such report within 15 calendar days of the determination that the

Organization	Yes or No	Question 9 Comment
		change in capability is expected to last more than 6 months." COMMENT 3- For Attachment 1, Section 4.3, in “For each individual generating units...” change “units” to “unit”. COMMENT 4- Attachment 2, Requirement 3 provides for the RP and PC to provide the GO “the desired temperature to which the data is to be adjusted”. Attachment 2 provides a blank to record that value for adjustment in each of the Summer and Winter Verification Data sections stated as: “The recorded MW values were adjusted for the following average temperature conditions:” We suggest removing the word "average" which is inconsistent with R3. COMMENT 5- In Footnote 1, revise as follows for clarification: 1- If the winter verification is based on Summer data, provide only the date of the “summer” verification “used” not the start and end times. COMMENT 6- The standard does not address validation of initial Real Power Capability for new units.
Response: Thank you for your comments. **The SDT removed Requirement R2 from the revised standard.** **The revised standard requires the Generator Owner to report any change affecting its last verified Real Power or Reactive Power capability by more than 10% if that change is expected to last for more than six months. In the revised standard, the data is only reported to the Planning Coordinator, with the expectation that the Planning Coordinator will share that data with other planning entities.** **The typographical error does not exist in the revised standard.** **The term, ‘average’ is not used in the revised standard.** **The revised standard does not require and does not reference summer or winter verifications.** **The intent of this standard is to verify data previously provided under the MOD standards.**		
Electric Power Supply Association (EPSA)	Yes	EPSA agrees with many of the SDT’s findings in its review of current verification and data reporting practices. Entities that use generator real power capability data already receive and depend on the necessary data. The SDT’s review confirms that capability data is often already being provided due to existing requirements that should reduce the frequency for real power capability testing set forth in MOD-024. While planners have asserted the need for the data to improve modeling accuracy - the SDT review of different planning models finds that they have inconsistent needs and don’t facilitate a standard that supports reliability. EPSA respectfully requests that the SDT recognize the following objectives in crafting a standard that is responsive to FERC’s directives in Order No. 693 (see 1310): 1. MOD-24 should not preempt or duplicate the real power verification procedures that already exist in the

Organization	Yes or No	Question 9 Comment
		organized markets. 2. the frequency of real power verification in the organized market regions is driven by the annual capacity markets. System planning is a longer-term endeavor and as such real power verification for system planning purposes does not require the same annual frequency or level of precision. Thus, annual verification should not be required for any units, but rather all units should verify their real power capability on a longer cycle - i.e., the five (5) year cycle currently proposed for certain smaller and low capacity factor units. A longer verification cycle reduces the need for unnecessary fuel burn and the uniformity results in better clarity as well as ease of implementation for Generator Operators.(note below) The SDT in its review also found that enhanced communication between entities will best facilitate the exchange of generator capability data. Further, it is worth noting that the Transmission Operator (TOP), Reliability Coordinator (RC), Balancing Authority (BA) and Regional Transmission Organization (RTO) / Independent System Operator (ISO) have access to a unit's real time output through their Energy Management System (EMS). The EMS provides updated information on a real-time basis, making further testing and reporting under MOD-24 duplicative and unnecessary. In addition, the GOP is required by other reliability standards to report unit de-rates to the TOP, RC, BA or ISO immediately after they occur, again making more frequent testing and data reporting under MOD-24 unnecessary. In addition, several existing Standards require the GOP to provide data related to generating unit capability status. Note: The capacity factor limitation simply may not be implementable if a unit has a capacity factor that fluctuates from year (i.e., if a 25 MVA unit has a CF less than 5% in years 1&2, but then exceeds 5% in year 3, then it needed to be tested annually and is non-compliant).
Response: Thank you for your comments. While there is no intent to duplicate requirements that may exist within markets, some duplication may exist – the data addressed in the proposed standard is needed for reliability. **Several commenters indicated that a five-year cycle for verification should still provide reliable data for system models, and the drafting team adopted the five-year cycle in the revised standard.** **The drafting team reviewed all of the standards and requirements identified as potentially having requirements redundant with those in the proposed MOD-024 (now merged with MOD-025) and did not find any duplication.**		
ERCOT ISO	Yes	ERCOT ISO believes R1 should clearly state to whom the Generator Owner of the Attachment 1 and Attachment 2 data should be submitted.
Response: Thank you for your comment. The revised standard clearly states that the Generator Owner must provide the data to the Planning Coordinator.		

Organization	Yes or No	Question 9 Comment
FirstEnergy	Yes	FirstEnergy offers the following additional suggestions and comments: 1. We question the applicability to the Generator Owner (GO) instead of the Generator Operator (GOP). We believe the standard should apply to the GOP because the operation of the unit (operational verification and testing) impacts reliability more directly than ownership. In addition multiple ownership confuses responsibility and compliance. Only one GOP will operate a unit and perform the required verification, testing and data reporting. 2. The proposed requirements in this standard do not specifically allow for testing in lieu of operational tracking. We suggest the team add testing as an explicit alternative. 3. Several terms used in this standard should be defined to alleviate any varying interpretations; we suggest the following definitions: a. Summer/Winter Peak Period - For the summer season, the Peak Period extends from the first day of June to the last day of August. For the winter peak season, the Peak Period extends from the first day of December to the last day of February. b. Peak Period Hours - The four summer hours ending at 3 PM, 4 PM, 5 PM and 6 PM. The four winter hours ending 8 AM, 9 AM, 7 PM and 8 PM. c. Capacity Factor (expressed as a percent) - Is the net actual energy generation (MW-hours) divided by the product of the period (hours) and the net max capacity rating (MW) 4. R1 - It is not clear to whom the GO must submit this information. We suggest that the SDT add language in R1 that states the GO be required to submit verification information "as requested, in accordance with a predetermined schedule and format specified by a requesting Resource Planner, Planning Coordinator, or Transmission Planner". 5. R2 - First Bullet - The phrase "The desired temperature" is too broad; we suggest a change to "The desired ambient temperature". 6. R2 - If R2 is retained (see proposal to remove in our response to Q6), FE suggests the phrase "that seeks" be replaced with "having a reliability need for" since as written could have the unintended meaning that any RP or PC could request information of a particular generator unit owner. 7. R3 - Regarding the 50MW level, it should be clear that this would be for situations where the MW level decreased by more than 50 MW. Significant increases in MW levels could violate interconnection agreements and be used by an entity to sidestep the required studies for facility uprates 8. Att. 2 - Diagram - The transformer downstream from the GSU should be the Start-Up Transformer, not Aux Transformer as currently shown.9. In the background information provided by the SDT on pg.2 it states "... the

Organization	Yes or No	Question 9 Comment
		SDT has taken the approach that the Transmission Planner needs to communicate the conditions under which the Generator Owner is to provide verified values..". It is not clear how this standard requires the TP to communicate the conditions. Was it the SDT's intent to say the PC or RP needs to communicate the conditions as stated in R2?
Response: Thank you for your comments. 1. **After consulting with the Functional Model Working Group, the SDT was directed to make the GO responsible for reporting the data.** 2. **Although not explicitly stated, operational tracking has always been considered a permissible means of testing. This is clearer in the revised standard (now merged with MOD-025).** 3. **The following terms are not used in the revised standard:** o **Summer/Winter Peak Period** o **Peak Period Hours** o **Capacity Factor** 4. **The revised standard clearly states that the verified data must be provided to the Generator Owner's Planning Coordinator.** 5. **Requirement R2 from the initial draft of MOD-024-2 is not included in the second draft of the standard (now incorporated into MOD-025).** 6. **Requirement R2 from the initial draft of MOD-024-2 is not included in the second draft of the standard.** 7. **The 50 MW level was modified so that instead of having a MW level to trigger the reporting requirement, a change of 10% to the last verified capability that is expected to last at least six months is the trigger for reporting the change to the Planning Coordinator.** 8. **The SDT agrees that there are many different configurations in use, which is why the standard specifically allows for customization of the diagram.**		
American Transmission Company	Yes	For R1, R2, & R3, we propose a Violation Risk Factor of "Lower" and a Time Horizon of "Operations Planning, Long-Term Planning". We propose "Lower" for the VRF because more accurate real power capability values will be assured by this requirement, but reasonably accurate values are likely without this requirement. We propose "Operations Planning, Long-Term Planning" for the TH because RCs and TOPs will use this data in their operations planning studies and PCs and TPs will use this data in their transmission planning studies. For R2, replace "desired temperature to which the data" with "desired ambient coolant temperature to which the summer and winter data" for added clarity. In Attachment 1, 3.2; replace "ambient air temperature" with "ambient coolant (air, water, etc.) temperature" because the capability of different types of generators is affected by the temperature of different cooling medium. In addition, consideration may need to be given to the average pressure level of generating units

Organization	Yes or No	Question 9 Comment
		that use hydrogen for equipment cooling. Requirement 1: ATC believes that some additional clarity is needed as to those entities that will receive the information. Suggestion: "...submit to the Resource Planner and/or Planning Coordinator the information view MOD-024-2 Attachment 2..." General Comment:It should be made clear that a GO validating and reporting a change in a unit's gross Real Power capability, in particular an increase in output, to comply with this standard, does not enable or give a GO the right to inject said incremental output onto the transmission system. Any MW increase (regardless of duration or ambient conditions) must be formally considered via separate mechanisms for study and verification of the BES's ability to reliably support any such increase beyond that previously approved and included in a generation-transmission interconnection agreement.
Response: Thank you for your comments. **The SDT has proposed a "Lower" VRF for both Requirement R1 and Requirement R2 in the revised standard (now merged with MOD-025). The team did not adopt the suggestion to include both Operations Planning and Long-term Planning because the intent of the data in this standard is for use in long-range planning studies. The data is not provided to any operating entities.** **Several commenters had objections to various aspects of Requirement R2 and the drafting team has not included this requirement in the revised standard.** **The SDT feels that it is up to the GO to provide the adjusted unit capability for a specific ambient temperature and coolant pressures or temperatures. The SDT agrees that clarity was needed on who should receive the data, and the revised standard is clear that the data must be provided to the Planning Coordinator.**		
Duke Energy	Yes	Industry guidance is needed on how to adjust recorded test data in Requirement R2 and Section 3.4.5 on Attachment 1. It's unclear what is being sought by "adjusting" data to a desired temperature. Ambient air temperature may not impact output nearly as much as coolant temperature, when the machine is not air cooled. Also, Section 3.4.5 should be expanded to allow for adjusting of data for factors other than ambient air temperature (e.g. steam leaks, condenser cooling water temperature, out of service reheaters, condenser fouling, turbine blade wear....). Planners need to model to the unit's expected sustained capability. If tests are conducted under degraded plant or equipment conditions the test results need to be adjusted. Otherwise planners could plan the system for less than the full capability of the unit, which would yield a non-conservative result. Guidance is needed on how to report (i.e. actual data, adjusted data and a prognosis for sustained capability that may be achieved). The test should represent the actual condition of the equipment. If it is degraded then the unit would have less capability. However capability could be restored during a repair or outage, and demonstrated with another test.

Organization	Yes or No	Question 9 Comment
Response: Thank you for your comments. **Requirement R2 was not carried over into the next version of the standard. The SDT recognizes that ambient temperature affects some units more than others. The SDT also feels that it would be unreasonable to expect the Planning Coordinator to be able to convert coolant temperature to ambient temperature as that is best understood by the GO. In the revised standard the Generator Owner is required to document the ambient temperature at the time of the verification and any adjustments made to that temperature.** **The SDT agrees that accurate model data is needed and is attempting to capture the most relevant data with this standard. The SDT added a “remarks” section to the attachment so the Generator Owner can document any special conditions that should be considered when interpreting the verification data.**		
Consolidated Edison Co. of New York	Yes	MOD-024-2 requires bi-annual testing, while at the same time exempted intermittent units (e.g. wind generators) and stations with multiple units (section 4.4). A reliability standard should support reliability; therefore, all units should be tested at the same frequency. The DT should consider a reliability standard that has an annual test requirement only that tests all generation units, regardless of type (including intermittent units or stations with multiple units). A region can also develop bi-annual requirements for a summer and winter test if they see a reliability benefit and/or have a market requirement. Concerning R1: The requirement does not specifically state who should receive the generator unit capability data. The PC? The RP?
Response: Thank you for your comments. After thorough consideration of all responses, the SDT has proposed requiring the Generator Owner to verify real power capability data at the same time as reactive power capability data, and proposed merging MOD-024 requirements with MOD-025. In the revised standard, both verifications occur with the same five year re-verification cycle. **The SDT decided to revise the standard and require the Generator Owner to provide the data to the Planning Coordinator – it is then the Planning Coordinator’s responsibility to share the data with other planning entities. The Planning Coordinator has the ability to review past unit performance to insure that the verification value submitted is reasonable, indicative of past unit performance. There is nothing in the standard to prevent the Planning Coordinator from questioning the submitted data.**		
North Carolina Electric Membership Corporation	Yes	R2 is not a requirement as currently written. It is a choice that the RP or PC makes. If he seeks verfied data, then he must provide certain things to the GO. If he chooses to not seek verified data, then he is not required to do anything. This means that M2 is wrong. The RP and PC should not be required to have evidence if they chose not to seek the data. This situation can be fixed by revising R2 to read: "Each Resource Planner and Planning Coordinator shall request verified generating unit Real Power capability data and shall provide each Generator Owner..." R1 requires the GO to submit information but it does not indicate to whom the data should be submitted. We recommend that R1 be changed to read: "Each Generator Owner shall verify the summer and winter Real

Organization	Yes or No	Question 9 Comment
		Power generating capability for each of its units in accordance with MOD-024-2 Attachment 1 - Verification of Summer and Winter Generating Unit Capability and record and submit the information to its Resource Planner and Planning Coordinator via MOD-024-2 Attachment 2 - One-line Diagram, Table and Summary for Verification Information Reporting." Paragraph 2.4 in Att 1: The first word grouping is not a sentence and reads awkwardly. It is suggested that the words "an acceptable value can be obtained" be place in front of the words "by making a temperature". Paragraph 3.4.2 in Att 1: Replace the word "since" with "if" for better clarity. Paragraph 3.4.4 in Att 1: Move the words "in Attachment 2" to the position just after the word "flows". This will make it clear that the sentence refers to flows in Attachments 2 rather than units in Attachment 2.
Response: Thank you for your comments. The SDT did not carry Requirement R2 into the revised standard. **Requirement R1: The revised standard clearly states that the verified data must be provided to the Planning Coordinator. The Planning Coordinator is responsible for sharing its data with other planning entities.** Paragraph 2.4 in Att 1: **The revised standard does not require seasonal (summer and winter) verifications – rather the revised standard requires verifications once every five years.** **Paragraph 3.4.2 in Att 1: this has been replaced with the following for improved clarity:** o **If metering does not exist to measure specific reactive auxiliary load(s), provide an engineering estimate and associated calculations.** **Paragraph 3.4.4 in Att 1: The phrase proposed for clarification is not used in the revised standard.**		
SERC Planning Standards Subcommittee	Yes	R2 is not a requirement as currently written. It is a choice that the RP or PC makes. If he seeks verfied data, then he must provide certain things to the GO. If he chooses to not seek verified data, then he is not required to do anything. This means that M2 is wrong. The RP and PC should not be required to have evidence if they chose not to seek the data. This situation can be fixed by revising R2 to read: "Each Resource Planner and Planning Coordinator shall request verified generating unit Real Power capability data and shall provide each Generator Owner..." R1 requires the GO to submit information but it does not indicate to whom the data should be submitted. We recommend that R1 be changed to read: "Each Generator Owner shall verify the summer and winter Real Power generating capability for each of its units in accordance with MOD-024-2 Attachment 1 - Verification of Summer and Winter Generating Unit Capability and record and submit the information to its Resource Planner and Planning Coordinator via MOD-024-2 Attachment 2 - One-line Diagram, Table and Summary for Verification Information Reporting." R3: The threshhold for reporting a change in MW output is too high. A change of 10 to 50 MW in a generator's

Organization	Yes or No	Question 9 Comment
		output could have an impact to system stability. The threshhold should be a 10 MW change or greater. Paragraph 2.4 in Att 1: The first word grouping is not a sentence and reads awkwardly. It is suggested that the words "an acceptable value can be obtained" be place in front of the words "by making a temperature". Paragraph 3.4.2 in Att 1: Replace the word "since" with "if" for better clarity. Paragraph 3.4.4 in Att 1: Move the words "in Attachment 2" to the position just after the word "flows". This will make it clear that the sentence refers to flows in Attachments 2 rather than units in Attachment 2. The comments expressed herein represent a consensus of the views of the above named members of the SERC Planning Standards Subcommittee only and should not be construed as the position of SERC Reliability Corporation, its board or its officers.
Response: Thank you for your comments. The SDT did not carry Requirement R2 into the revised standard. **Requirement R1: The revised standard clearly states that the verified data must be provided to the Planning Coordinator. The Planning Coordinator is responsible for sharing its data with other planning entities.** **Requirement R3: The revised standard does not use a MW threshold as a trigger for reporting a change to verified capabilities – the revised standard uses a threshold of 10% change from the last verified data that is expected to last at least six months. This should limit the reported changes to just those that will be large enough to impact the validity of the models.** **Paragraph 2.4 in Att 1: The revised standard does not require seasonal (summer and winter) verifications – rather the revised standard requires verifications once every five years.** **Paragraph 3.4.2 in Att 1: this has been replaced with the following for improved clarity:** o **If metering does not exist to measure specific reactive auxiliary load(s), provide an engineering estimate and associated calculations.** **Paragraph 3.4.4 in Att 1: The phrase proposed for clarification is not used in the revised standard.**		
NERC Standards Review Subcommittee	Yes	Requirement R1 - The requirement should be clarified that in the case of Joint-owned-units, the Operator of the unit is responsible for verifying the capability of the unit. For R1, R2, & R3, we propose a Violation Risk Factor of “Lower” and a Time Horizon of “Operations Planning, Long-Term Planning”. We propose “Lower” for the VRF because more accurate real power capability values will be assured by this requirement, but reasonably accurate values are likely without this requirement. We propose “Operations Planning, Long-Term Planning” for the TH because RCs and TOPs will use this data in their operations planning studies and PCs and TPs will use this data in their transmission planning studies.

Organization	Yes or No	Question 9 Comment
		For R2, replace "desired temperature to which the data" with "desired ambient coolant temperature to which the summer and winter data" for added clarity.In Attachment 1, 3.2; replace "ambient air temperature" with "ambient coolant (air, water, etc.) temperature" because the capability of different types of generators is affected by the temperature of different cooling medium. In addition, consideration may need to be given to the average pressure level of generating units that use hydrogen for equipment cooling. Introduction, Section 4.2 - As written, small diesel generators at applicable Generating Facilities could be expected to be tested as part of this standard, even if these small generators are intended only for local site power, and are only capable of reaching a 100 KV interconnection by back-feeding through local site distribution circuits and auxiliary transformers. Based on the MVA metrics provided, it would appear their inclusion is not the intent, but the standard is ambiguous as written. On the Implementation Plan for MOD-024-2 for units that are to be verified every five years, they state the verification "will begin five years after the compliance implementation date for annual units." Wouldn't it make more sense to make them verify in the first year after the MOD-24-02 is adopted or approved and then do it every five years after that? On page 2 of 10, A.5. Effective Date, it seems unclear when they say verification "will begin 30 calendar days following the first summer or winter peak period" . For example, if the summer peak occurs in June and you expect a higher peak in July or August and it doesn't occur, then you would be in violation. The same applies for the winter period. They don't define the summer and winter period. On page 5 of 10, MOD-024-2 Attachment 1. 2. Verify generating unit winter gross Real Power generating capability as follows: 2.1. They don't define the winter period and what the conditions should be for the verification test period. Please Clarify. On page 5 of 10, MOD-024-2 Attachment 1. 2. Verify generating unit winter gross Real Power generating capability as follows: 2.4. "by making a temperature correction to the most recent summer gross Real Power generating capability verification." Under what conditions can temperature corrections be made?

Response: Thank you for your comments. After conferring with the Functional Model Working Group, the SDT was directed to change the applicability to Generator Owner based on roles and responsibilities assigned to the Generator Owner.

The SDT is proposing a Lower VRF for both requirements in the revised standard (MOD-024 now merged into MOD-025). However the team did not adopt the suggestion to propose two different time horizons. The data addressed by this standard is limited to data used in planning studies – the data is not provided to any operating entities, just to the Planning Coordinator in the revised standard. Therefore, only the long-term planning time horizon has been proposed.

Several comments identified issues with Requirement R2 in the first draft of MOD-024-2, and the SDT did not carry R2 into the second draft of the standard.

Organization	Yes or No	Question 9 Comment
The SDT modified the applicability section of the standard to more closely align with the criteria in the compliance registry. **The standard was revised to require verification of each applicable unit once every five years – references to annual verification were not carried over into the revised standard and its implementation plan.** **The revised standard does not include any references to seasonal verifications, and doesn't use the terms, "summer period" or "winter period."** **The SDT intended for the unit capability to be adjusted to that expected under the ambient temperature conditions where the PC would model the system. The SDT feels that it would be unreasonable to expect the PC to be able to convert coolant temperature on individual units to capability expected for an ambient temperature as that is best understood by the GO. It is expected that units will be at the nominal hydrogen pressure at which they would normally run. That pressure would not be expected to change during the duration of the test.**		
Independent Electricity System Operator	Yes	The detailed requirements in Attachment 1 are overly prescriptive. Specifically, the requirements listed in Item 3 are too detailed, and most of them are not needed for reliability. We believe Attachment 1 needs only to specify the sustainability (Items 1 and 2), periodicity (Item 4) and the ambient conditions of the verification (some of Item 3). Using the form and the one-line diagram do not contribute to reliability. A requirement to ask for both gross and net capability would suffice.
Response: Thank you for your comments. The SDT believes that attachment one does not contain requirements but provides clarity to the Requirements of the Standard. The SDT felt that providing the diagram would help to clearly show the power flows of each unit and thus contribute to reliability.		
AMEA	Yes	The draft MOD-024-2 removes the decision making ability of the only entities (PC, regions, etc.) that actually know which generators are material to the BES. Instead the draft uses a blanket approach to basically include all generators 20 MVA and above connected at 100 kV and above. This approach will reduce the reliability of the BES due to distraction caused by the deluge of data from a multitude of generators that are not material to the BES and will exempt material generators that are connected below 100 kV.
Response: Thank you for your comments. To determine which generating units to include in the standard, the SDT has adopted the same criteria as used in the compliance registry. Regions are free to include other facilities if they see fit by submitting a request for a variance		
E.ON U.S.	Yes	The first bullet under R2 should be modified as follows: "the desired temperature and/or backpressure to which the data is to be adjusted."Other criteria may also be required during the test. (e.g. MVARs, etc.) Clarify R3 language that 50MW is the change in unit rating - not any unit greater than 50MW. E.ON U.S. questions whether a 50MW threshold for capability change is less meaningful than using a percent of unit capacity threshold. Is the need to report such changes to NERC consistent with any Regional requirement? On Attachment 2, are data measuring points A,B,C and D to be reported as peak or average (over the

Organization	Yes or No	Question 9 Comment
		verification period) values? MOD-024 and MOD-025 are linked and the STD has decided to revise each standard independently. This makes compliance difficult to maintain and test while the two linked standards are undergoing revision.
Response: Thank you for your comments. **Requirement R2: Several comments identified issues with Requirement R2 in the first draft of MOD-024-2, and the SDT did not carry R2 into the second draft of the standard.** **Requirement R3: The revised standard does not use a MW threshold as a trigger for reporting a change to verified capabilities – the revised standard uses a threshold of 10% change from the last verified data that is expected to last at least six months. This should limit the reported changes to just those that will be large enough to impact the validity of the models.** **As currently drafted the data points are to be reported as average.** **The SDT adopted your suggestion and merged MOD-024 and MOD-025 into a single standard (MOD-025).**		
Manitoba Hydro	Yes	The requirement R1 should be rewritten to include derivation of Summer and Winter ratings for Thermal units, and measured capacity corrected to design net head for Hydraulic units. R3 should be clarified to ensure it is only changes greater than 50MW that must be reported, not "any change for units that are greater than 50MW".
Response: Thank you for your comments. **Requirement R1 no longer includes any references to summer or winter ratings. See the revisions to Attachment 1 for additional clarity with respect to verifications for hydro units.** **Requirement R3: The revised standard does not use a MW threshold as a trigger for reporting a change to verified capabilities – the revised standard uses a threshold of 10% change from the last verified data that is expected to last at least six months. This should limit the reported changes to just those that will be large enough to impact the validity of the models.**		
Bauer	Yes	The requirement will result in continuous reporting by the Generator Owner for its hydro units. The capability of hydro units can vary seasonally by more than 50 MW in less than 6 months. It is unclear what reliability purpose is served by this requirement. As stated in the general comment section, Generation capability is forecast, adjusted, and provided to TOP's and BA's under TOP-002-2.
Response: Thank you for your comment. It is not the intent of the standard for continuous reporting by any units. Please see the revised standard – it requires verification of each applicable unit once every five years. For reporting changes to capabilities, the revised standard includes two thresholds that must be met before the Generator Owner is required to report a change in its capabilities – the change must be expected to last more than six		

Organization	Yes or No	Question 9 Comment
months, and second the change must be 10% or more of the last verified capability. These changes should minimize the number of times a change must be reported. **The SDT feels that the data requested under TOP requirements refers to the short time horizon and would be the proper place to report changes in capability based on water levels. Reporting under this standard would be changes in capability due to other plant constraints and are for a much longer planning time horizon.**		
Arizona Public Service Co.	Yes	This standard is contradictory to new NERC policy of "results-based reliability standards." NERC should not be developing a standard which it will have to withdrawa in a future review. If it is decided to go ahead with the standard, the reliabiltity benefits should be expalined.
Response: Thank you for your comment. The reliability-related need for this standard was justified when the SAR was posted for stakeholder review and comment. Results-based requirements are not limited to requirements for real-time system performance.		
We Energies	Yes	Under requirement R3, we question the necessity of reporting a 50 MW reduction in a unit within 15 calendar days of the determination that the reduction is expected to last more than 6 months. Given the current wording, this requirement would need to be understood by a very broad base of individuals who may not typically be aware of this reporting requirement (e.g. a maintenance supervisor evaluating the impact of damage to a mill) and the current wording is unclear as to when the 15 day clock would begin. Prior to making this a requirement, an evaluation should be done to determine how big of a problem this is currently causing to any system modeling, what the risks are of waiting until the next test date to report the issue, and whether or not the concerns change if a RTO has an annual testing requirement.
Response: Thank you for your comments. For reporting changes to capabilities, the revised standard includes two thresholds that must be met before the Generator Owner is required to report a change in its capabilities – the change must be expected to last more than six months, and second the change must be 10% or more of the last verified capability. These changes should minimize the number of times a change must be reported. **Note that in the revised standard, the periodicity for verifying a unit's capabilities is once every five years.** **The SDT believes that with a five year reporting cycle, reporting changes in capability at the next test date would not be adequate.**		
Luminant	Yes	Upon approval of MOD-024, Verification of Real Power and the companion standard MOD-025, Verification of Reactive Power, the applicability to Generator Owners and/or Generator Operators needs to be removed from FAC-008 and FAC-009. With actual verification of Real and Reactive Power, the FAC-008 and FAC-009 requirements become redundant for generators. Attachment 1 verbage needs to be consistent between the words "period" and "season". They are currently used interchangeably.

Organization	Yes or No	Question 9 Comment
		Attachment 1, section 4.5, needs to be expanded so that when a lessor utilized unit is started up, it does not necessarily have to immediately run a maximum capacity test. The unit could have been brought online for capacity and the BA may not allow it to run at maximum output. Emergency situations may preclude running the test. This type of unit should be tested based on a schedule coordinated with the BA. All references to Attachment 2 should also include the "or similar diagram and form" language.
Response: Thank you for your comments. The requirements in FAC-008 and FAC-009 are aimed at providing facility ratings, which may not be the same as a unit's capabilities. **The SDT also agrees with your edits for period and season, and for references to the diagram. The terms, "period" and "season" are not used in Attachment 1 of the revised standard.** **After thorough consideration of all responses, the SDT is proposing that the Generator Owner provide real power verification data at the same time as reactive power verification data, and is proposing to merge MOD-024;s requirements into MOD-025. With the merging of the two standards we are proposing that the real power verification be completed on the same five year frequency as the reactive power verification. This relaxed frequency of testing should allow most units to be scheduled for testing.** **Verification should be performed. The standard does not require units to run for verification only. The SDT believes it is reasonable to assume that the unit will run for at least one hour at maximum capability during the five year period.** **The attachment includes language clarifying that alterations to the diagram are acceptable provided those alterations still include all required information.**		
GO/GOP	Yes	We believe this standard should be retired in its entirety.
Response: Thank you for your comment. Please see the summary consideration of comments in response to Question 1.		
Xcel Energy	Yes	With regard to Attachment 2, the only ambient condition that is required to be reported is ambient air temperature. This has a significant impact on combustion turbines, but little effect on steam turbines. Condenser cooling water temperature has much more impact on steam turbine capability and we feel this should be recorded for that type of prime mover. Also, we would like to request that a description of the process for performing ambient compensation be included either in Attachment 1 or in a separate Technical Guideline to improve the quality and consistency of the information that is reported.
Response: Thank you for your comments. The SDT agrees that ambient temperature has a more significant impact on combustion turbines than steam turbines. The SDT feels that the GO is uniquely qualified to estimate the expected capability of a unit based on ambient temperature or the expected coolant temperature based on sustained ambient temperatures.		

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. SAR posted for comment (April 20–May 21, 2007).
2. Revised SAR and response to comments posted.
3. Revised SAR and response to comments approved by SC (June 14, 2007).
4. SDT appointed on (August 18, 2007).
5. Draft MOD-026-1 was posted for a 45 day comment period from February 17 – April 2, 2009.

Proposed Action Plan and Description of Current Draft:

This is the first draft of the this standard including Time Horizons, Data Retention, Violation Risk Factors, and Violation Severity Levels. This second posting is for a 45-day comment period.

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Post first draft revision of standard.	April-May 2011
2. Post response to comments and third version draft revision of standard.	July – August 2011
3. Post response to comments and request authorization to ballot the revised standard.	September - October 2011
4. Conduct initial ballot.	November 2011
5. Post response to comments.	December 2011
6. Conduct recirculation ballot.	January 2012
7. BOT adoption.	February 2012
8. File with regulatory authorities.	March 2012

A. Introduction

1. **Title:** Verification of Models and Data for Generator Excitation Control System and Plant Volt/Var Control Functions

2. **Number:** MOD-026-1

3. **Purpose:** To verify that the generator excitation control system and plant volt/var control[1] model (including the power system stabilizer model and the impedance compensator model), and the model parameters used in dynamic simulations accurately represent the generator excitation control systems and plant volt/var control[1] behavior when assessing Bulk Electric System (BES) reliability.

4. **Applicability:**

    4.1. Functional entities

    4.1.1 Generator Owner

    4.1.2 Transmission Planner

    4.2. Facilities:

For the purpose of this standard, the following Facilities are considered, "applicable units." Units or plants with an average capacity factor[2] greater than 5% over the last three calendar years that meet the following:

4.2.1 Generating units connected to the Eastern or Quebec Interconnections with the following characteristics:

- Each generating unit with a gross nameplate rating greater than 100 MVA, connected at the point of interconnection[3] at greater than or equal to 100 kV.
- For each plant with a gross aggregate nameplate rating greater than to 100 MVA, connected at the same point of interconnection at greater than or equal to 100 kV:
    - Each unit with a gross nameplate rating greater than 20 MVA; and
    - The remainder of the plant as an aggregate.

[1] Excitation control system or plant volt/var control system:
a. For individual synchronous machines, the generator excitation control system includes the generator, exciter, voltage regulator and power system stabilizer.
b. For an aggregate generation plant, the volt/var control system includes the voltage regulator & reactive power control system controlling and coordinating plant voltage and associated reactive capable resources.

[2] Once a capacity factor exemption is declared by notifying the Transmission Planner, verification is not required for 10 calendar years from the date eligibility occurs. At the end of this 10 calendar year timeframe, the current average 3 year capacity factor (for years 8, 9, and 10) is examined to determine if the capacity factor exemption can be declared for the next 10 calendar year period. If not eligible for the capacity factor exemption, then model verification must be completed within one year of the date the capacity factor exemption expired with the 10 calendar year periodicity requirement reset based on the verification date.

[3] The common transmission bus voltage level at which the generator step up transformer is connected.

4.2.2 Generating units connected to the Western Interconnection with the following characteristics:

- Each generating unit with a gross nameplate rating greater than 75 MVA, connected at the point of interconnection[3] at greater than or equal to 100 kV.
- For each plant with a gross aggregate nameplate rating greater than 75 MVA, connected at the same point of interconnection with at greater than or equal to 100 kV:
  - Each unit with a gross nameplate greater than 20 MVA; and
  - The remainder of the plant as an aggregate.

4.2.3 Generating units connected to the ERCOT Interconnection with the following characteristics:

- Each generating unit with a gross nameplate rating of greater than 50 MVA, connected at the point of interconnection[3] with rating greater than or equal to 100 kV.
- For each plant with a gross aggregate nameplate rating of greater than 75 MVA, connected at the same point of interconnection at greater than or equal to 100 kV:
  - Each unit with a gross nameplate greater than 20 MVA; and
  - The remainder of the plant as an aggregate.

4.2.4 For all interconnections:

- Any technically justified[4] unit requested by the Planning Coordinator.

5. Effective Date:

5.1. In those jurisdictions where regulatory approval is required:

5.1.1 By the first day of the first calendar quarter, four years following applicable regulatory approval:

- Each Generator Owner shall ensure at least 30% of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2.
- Each responsible entity shall ensure compliance with Requirements R1, and R3 through R6.

5.1.2 By the first day of the first calendar quarter, six years following applicable regulatory approval:

---

[4] A technical justification for verifying each of those units or plant(s) that demonstrates through simulation and/or measured response that the unit or plant affects a stability limit, or evidence that the simulated unit or plant response does not match measured unit or plant response.

- Each Generator Owner shall ensure at least 50% of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2.

5.1.3 By the first day of the first calendar quarter, ten years following applicable regulatory approval:

- Each Generator Owner shall ensure 100% of its applicable units are compliant with Requirement R2.

5.2. In those jurisdictions where no regulatory approval is required:

5.2.1 By the first day of the first calendar quarter, four years following Board of Trustees adoption:

- Each Generator Owner shall ensure at least 30% of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2.
- Each responsible entity shall ensure compliance with Requirements R1, and R3 through R6.

5.2.2 By the first day of the first calendar quarter, six years following Board of Trustees adoption:

- Each Generator Owner shall ensure at least 50% of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2.

5.2.3 By the first day of the first calendar quarter, ten years following Board of Trustees adoption:

- Each Generator Owner shall ensure 100% of its applicable units are compliant with Requirement R2.

6. Consideration for Early Compliance

6.1. Existing excitation control system and plant volt/var control[1] model verification is sufficient for demonstrating compliance for a ten year period from the actual verification date if:

- The Generator Owner has a verified model that is compliant with the applicable regional entity policies, guidelines or criteria existing at the time of model verification (provided the model verification addresses the same unit criteria and the same information as required by this standard), or
- The Generator Owner has an existing verified model that is compliant with the requirements of this standard.

B. Requirements

R1. Each Transmission Planner shall provide the following instructions and data to its Generator Owner within 30 calendar days of receiving the request from its Generator Owner for those instructions and data: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

- Instructions on how to obtain the list of acceptable excitation control system and plant volt/var control function model for use in dynamic simulation.
- Instructions on how to obtain the Transmission Planner's software manufacturer's dynamic excitation control system and plant volt/var control function system model library block diagrams and/or data sheets.
- Any of the Generator Owner's existing unit or plant specific excitation control system and plant volt/var control model data contained in the Transmission Planner's dynamic database from the current in-use models, including generator MVA base.

R2. Each Generator Owner shall provide a verified generator excitation control system and plant volt/var control model (for each of its applicable Facilities) to its Transmission Planner in accordance with the periodicity specified in MOD-026 Attachment 1 to ensure modeling data is accurate for use in simulation software subject to the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

2.1. Each Generator Owner shall perform its verifications with one or more models acceptable to its Transmission Planner that collectively include the following information:

2.1.1. Documentation demonstrating the unit or plant's model response matches the recorded response for a voltage excursion at the generator or plant point of interconnection from either a staged test or a measured system disturbance.

2.1.2. Manufacturer, model number (if available), and type of excitation control and plant volt/var control system installed (such as static, ac brushless, dc rotating, volt/var system).

2.1.3. Generator (or plant equivalent) model structure and data (such as reactance, time constants, saturation factors, rotational inertia, or equivalent data).

2.1.4. Excitation control system and plant volt/var system model structure and data for the closed loop voltage regulator.

2.1.5. Compensation settings (such as droop, line drop, differential compensation), if used.

2.1.6. Model structure and data for power system stabilizer, if so equipped.

R3. Each Generator Owner shall provide a written response that contains either the technical basis for maintaining the current model, a list of future model changes, or a plan to perform model verification[5] to its Transmission Planner within 90 calendar days of receiving notice of one of the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

---

[5] If verification is performed, the 10 year period as outlined in Attachment 1 is reset.

- Written notification, including a technical description from its Transmission Planner of why the excitation control system and plant volt/var control system function model is not “usable” as identified in Requirement R6, Parts 6.1 through 6.3 criteria, or
- Written comments from its Transmission Planner identifying technical concerns with the verification documentation related to the excitation control system and plant volt/var control system function model, or
- Written comments and supporting evidence from its Transmission Planner indicating that the predicted excitation control system and plant volt/var control function model response did not match the recorded response to a transmission system event.

R4. Each Generator Owner shall provide revised model data or plans to perform model verification to its Transmission Planner within 180 calendar days of making changes to the excitation control system and plant volt/var control system that alter the equipment response[6] characteristic. *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

R5. Each Generator Owner shall provide a written response to its Planning Coordinator following receipt of a technically justified request to perform a model review of a unit/plant that meets the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

5.1. Submit within 90 calendar day’s receipt of the technically justified request.

5.2. Either indicate plans to verify the model or identify the source of revised model data such as:

- Discovery of manufacturer test values to replace generic model data.
- Updating data parameters based on a walk down of the equipment.

5.3. Include corrected excitation control system and plant volt/var control function model data.

R6. Each Transmission Planner shall determine if the verified generator excitation control system and plant volt/control model received meets the criteria identified in Requirement R6 Parts 6.1 through 6.3 and provide a written response to the Generator Owner indicating whether the model is useable or not useable; including a technical description if the model is not useable. This written response shall be submitted within 90 calendar days of receiving the excitation control system and plant volt/var control verified model information. *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

[6] Exciter, voltage regulator, plant volt/var or power system stabilizer control replacement including software alterations that alter excitation control system equipment response, plant digital control system addition or replacement, plant digital control system software alterations that alter excitation control system equipment response, plant volt/var function equipment addition or replacement (such as static var systems, capacitor banks, individual unit excitation systems, etc), a change in the voltage control mode (such as going from power factor control to automatic voltage control, etc), exciter, voltage regulator, impedance compensator, or power system stabilizer settings change.

6.1. The excitation control system and plant volt/var control function model can initialize to compute modeling data without error.

6.2. A no-disturbance simulation results in negligible transients.

6.3. For an otherwise stable simulation, a disturbance simulation results in the excitation control and plant volt/var control system model exhibiting positive damping.

C. Measures

M1. Each Transmission Planner shall have evidence to show that it provided requested instructions and data (such as dated electronic mail messages or mail receipts) within 30 calendar days of receiving a request as specified in Requirement R1.

M2. Each Generator Owner shall have evidence (such as a dated electronic mail messages or mail receipts) including the verification report to show that it provided the verified generator excitation control system or plant volt/var control model as specified in Requirement R2.

M3. Each Generator Owner shall have evidence to show that it provided a written response (such as a dated copy of the response, or dated electronic mail messages or mail receipts) containing identified information and submitted within 90 calendar days of receiving any written notification as specified in Requirement R3.

M4. Each Generator Owner shall have evidence to show that it provided a written response (such as a dated copy of the request, or dated electronic mail messages or mail receipts) submitted within 180 calendar days of making system changes specified in Requirement R4.

M5. Each Generator Owner shall have evidence to show that it provided a written response (such as dated electronic mail messages or mail receipts) and submitted within 90 calendar days of receiving the request as specified in Requirement R5.

M6. Each Transmission Planner shall have evidence to show that it provided a written response (such as dated electronic mail messages or mail receipts) within 90 calendar days of receiving the model as specified in Requirement R6.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

Regional Entity

1.2. Data Retention

The Generator Owner and Transmission Planner shall each keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

- The Transmission Planner shall retain the information/data request and provided response evidence of Requirements R1 and R6, Measures M1 and M6 for 3 calendar years from the date the document was provided.
- The Generator Owner shall retain the latest and previous excitation control system and plant volt/var control system model verification evidence of Requirement R2, Measure M2.
- The Generator Owner shall retain the information/data request and provided response evidence of Requirements R3 through R5, and Measures M3 through M5 for 3 calendar years from the date the document was provided.

If a Generator Owner or Transmission Planner is found non-compliant, it shall keep information related to the non-compliance until found compliant or for the time specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes

Compliance Audits

Self-Certifications

Spot Checking

Compliance Violation Investigations

Self-Reporting

Complaints

1.4. Additional Compliance Information

None

2. Violation Severity Levels

R #	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The Transmission Planner provided the instructions and data to the Generator Owner more than 90 calendar days but less than or equal to 120 calendar days of receiving a request.	The Transmission Planner provided the instructions and data to the Generator Owner more than 120 calendar days but less than or equal to 150 calendar days of receiving a request.	The Transmission Planner provided the instructions and data to the Generator Owner more than 150 calendar days but less than or equal to 180 calendar days of receiving a request.	The Transmission Planner failed to provide the instructions and data to the Generator Owner within 181 calendar days of receiving a request.
R2	The Generator Owner provided its verified model(s) to its Transmission Planner after the periodicity timeframe specified in MOD-026 Attachment 1 but less than or equal to 30 calendar days late; OR The Generator Owner provided the Transmission Planner verified model(s) that omitted one of the six Parts identified in Requirement R2, Parts 2.1.1 through 2.1.6.	The Generator Owner provided its verified model(s) to its Transmission Planner more than 30 calendar days but less than or equal to 60 calendar days late as specified by the periodicity timeframe in MOD-026 Attachment 1. OR The Generator Owner provided the Transmission Planner verified model(s) that omitted two of the six Parts identified in Requirement R2, Parts 2.1.1 through 2.1.6.	The Generator Owner provided its verified model(s) to its Transmission Planner more than 60 calendar days but less than or equal to 90 calendar days late as specified by the periodicity timeframe in MOD-026 Attachment 1. OR The Generator Owner provided the Transmission Planner verified model(s) that omitted three of the six Parts identified in Requirement R2, Parts 2.1.1 through 2.1.6.	The Generator Owner failed to provide the verified generator excitation control system or plant volt/var control model(s) or failed to provide the verified model(s) no more than 90 calendar days late to its Transmission Planner in accordance with the periodicity specified in MOD-026 Attachment 1. OR The Generator Owner failed to use model(s) acceptable to the Transmission Planner as specified in Requirement R2, Part 2.1. OR The Generator Owner provided the Transmission Planner verified model(s) that omitted four or more of the six Parts identified in

				Requirement R2, Parts 2.1.1 through 2.1.6.
R3	The Generator Owner provided a written response more than 90 calendar days but less than or equal to 120 calendar days of receiving notice. (R3)	The Generator Owner provided a written response more than 120 calendar days but less than or equal to 150 calendar days of receiving notice. (R3)	The Generator Owner provided a written response more than 150 calendar days but less than or equal to 180 calendar days of receiving notice. (R3)	The Generator Owner failed to provide a written response within 181 calendar days of receiving notice as specified in Requirement R3.. OR The Generator Owner's written response was provided within 181 calendar days of receiving written notice however failed to contain either the technical basis for maintaining the current model, or a list of future model changes, or a plan to perform model verification.
R4	The Generator Owner provided revised model data or plans to perform model verification more than 180 calendar days but less than or equal to 210 calendar days of making changes to the excitation control system or plant volt/var control[1] system that altered the equipment response characteristic. (R4)	The Generator Owner provided revised model data or plans to perform model verification more than 210 calendar days but less than or equal to 240 calendar days of making changes to the excitation control system or plant volt/var control[1] system that altered the equipment response characteristic. (R4)	The Generator Owner provided revised model data or plans to perform model verification more than 240 calendar days but less than or equal to 270 calendar days of making changes to the excitation control system or plant volt/var control[1] system that altered the equipment response characteristic. (R4)	The Generator Owner failed to provide revised model data or failed to provide plans to perform model verification within 271 calendar days of making changes to the excitation control system or plant volt/var control[1] system that altered the equipment response characteristic as specified in Requirement R4.
R5	The Generator Owner provided a written response more than 90 calendar days but less than or equal to 120 calendar days to the Planning Coordinator following receipt of a technically justified request to perform a model review	The Generator Owner provided a written response more than 120 calendar days but less than or equal to 150 calendar days to the Planning Coordinator following receipt of a technically justified request to perform a model review of a	The Generator Owner provided a written response more than 150 calendar days but less than or equal to 180 calendar days to the Planning Coordinator following receipt of a technically justified request to perform a model review of a	The Generator Owner failed to provide a written response to the Planning Coordinator following receipt of a technically justified request to perform a model review of a unit/plant as specified in Requirement R5.

	of a unit/plant. (R5)	unit/plant. (R5)	unit/plant. OD-026 Attachment 1

Excitation Control System or Plant Volt/VAr Model Verification Periodicity

Note that local grid codes may specify shorter time frames.

Facility	Condition	Periodicity
Existing Generating Unit	During the eleven calendar year (January - December) transition period and **no exceptions** apply. **OR** During the ten calendar year (January - December) period and n**o exceptions** apply.	A recorded response for a voltage excursion shall be collected during a ten calendar year (January - December) period from the effective date of this standard with the verified model and documentation transmitted to the Transmission Planner no more than 365 days from the date that the recorded response was collected.
Existing Generating Unit	During the eleven calendar year (January - December) transition period. **OR** During the ten calendar year (January - December) period. **AND** T**he following exception** applies: 1) Multiple units have the same MVA nameplate rating that are ≤ 350 MVA **AND** 2) The same multiple units have identical applicable components and settings **AND** 3) The same multiple units are sited at the same	Not Required (however, perform verification on a different unit each ten calendar year cycle).

Facility	Condition	Periodicity
	physical location **AND** 4) The model for one of these equivalent units has been verified.	
Existing Generating Unit	Installation of new excitation control system equipment.	A recorded response for a voltage excursion shall be collected and the verified model and documentation transmitted to the Transmission Planner no more than 180 days from the new equipment commissioning date..
Existing Generating Unit	Subjected to an activity resulting in an alteration of the response of the excitation control system.	A recorded response for a voltage excursion shall be collected within 365 days of settings or software changes with the verified model and documentation transmitted to the Transmission Planner no more than 180 calendar days from the date that the recorded response was collected.
Existing Generating Unit	Receive written comments including dated electronic or hard copy evidence indicating that the recorded excitation control system response to a Transmission System event did not match the predicted excitation control system model response.	A recorded response for a voltage excursion shall be collected within 365 days of a written response by the Generator Owner committing to perform model verification with the verified model and documentation transmitted to the Transmission Planner no more than 180 calendar days from the date that the recorded response was collected.
Existing Generating Unit	A model verification plan submitted as a result of a review requested by the Planning Coordinator for an existing Generating Unit.	A recorded response for a voltage excursion shall be collected within 365 days of the submission of a plan to perform model verification as a result of a request for a review from the Planning Coordinator with the verified model and documentation specified in transmitted to the Transmission Planner no more than 180 calendar days from the date that the recorded response was collected.

Facility	Condition	Periodicity
New or Existing Generator Unit	Excitation control system model identified as unusable by the Transmission Planner. **OR** Receive written comments detailing technical concerns with the Generator Owner's excitation control system model verification documentation.	A recorded response for a voltage excursion shall be collected within 365 days of a written response by the Generator Owner committing to perform model verification with the verified model and documentation transmitted to the Transmission Planner no more than 180 calendar days from the date that the recorded response was collected.
New Generating Unit	New unit installed	A recorded response for a voltage excursion shall be collected and the verified model and documentation transmitted to the Transmission Planner no more than 180 calendar days of the unit commercial operating date.

A. Introduction

1. **Title:** Verification of Models and Data for Generator Excitation System Functions

2. **Number:** MOD-026-1

3. **Purpose:** To verify that the excitation system model (including power system stabilizer model and impedance compensator model if so installed) and the model parameters used in dynamic simulations that assess Bulk Electric System (BES) reliability accurately represent generator excitation system behavior.

4. **Applicability:**

4.1. Functional entities

4.1.1 Generator Operators of generating facilities:

4.1.1.1 Connected to Eastern or Quebec Interconnections with the following characteristics:

Each unit (including synchronous condensers) ≥ 100 MVA, connected at the point of interconnection at 100 kV or above and with an average Capacity Factor greater than 5% over the last three calendar years.

Each unit (including synchronous condensers) ≥ 20 MVA within a plant ≥ 200 MVA, connected at the point of interconnection at 100 kV or above and with an average Capacity Factor greater than 5% over the last three calendar years.

4.1.1.2 Connected to Western Interconnection with the following characteristics:

Each unit (including synchronous condensers) ≥ 75 MVA, connected at the point of interconnection at 100 kV or above and with an average Capacity Factor greater than 5% over the last three calendar years.

Each unit (including synchronous condensers) ≥ 20 MVA within a plant ≥ 150 MVA, connected at the point of interconnection at 100 kV or above and with an average Capacity Factor greater than 5% over the last three calendar years.

4.1.1.3 Connected to ERCOT Interconnection with the following characteristics:

Each unit (including synchronous condensers) ≥ 50 MVA, connected at the point of interconnection at 100 kV or above and with an average Capacity Factor greater than 5% over the last three calendar years.

Each unit (including synchronous condensers) ≥ 20 MVA within a plant ≥ 100 MVA, connected at the point of interconnection at 100 kV or above and with an average Capacity Factor greater than 5% over the last three calendar years.

4.1.2 Transmission Planners**.**

Proposed Effective Date:

In those jurisdictions where regulatory approval is required:

- By the first day of the first calendar quarter, two years following applicable regulatory approval:
  - Each Generator Operator shall verify at least 10% of its applicable units per Interconnection on a MVA basis.
- By the first day of the first calendar quarter, six years following applicable regulatory approval:
  - Each Generator Operator shall verify at least 50% (this includes the units verified in the first year) of its applicable units per Interconnection on a MVA basis.
- By the first day of the first calendar quarter, eleven calendar years following applicable regulatory approval:
  - Each Generator Operator shall verify 100% of its applicable units.

In those jurisdictions where no regulatory approval is required:

- By the first day of the first calendar quarter, two years following Board of Trustees adoption:
  - Each Generator Operator shall verify at least 10% of its applicable units per Interconnection on a MVA basis.
- By the first day of the first calendar quarter, six years following Board of Trustees adoption:
  - Each Generator Operator shall verify at least 50% (this includes the units verified in the first year) of its applicable units per Interconnection on a MVA basis.
- By the first day of the first calendar quarter, eleven calendar years following Board of Trustees adoption:
  - Each Generator Operator shall verify 100% of its applicable units.

B. Requirements

R1. The Generator Operator shall verify the excitation system model (including power system stabilizer model and impedance compensator model if so installed) which represents generator excitation system behavior in dynamic simulations per the following schedules:

1) For a new or existing unit with a new excitation system, within 180 days of the commercial operation date or new equipment commissioning date, whichever occurs first.

2) For an existing unit, once in a ten calendar year period. If multiple units have the same MVA rating that is ≤ 250 MVA, and if they have identical applicable components and settings and are sited at the same physical location, verification of one unit is sufficient for all units. Verification shall be performed on a different unit each ten calendar year cycle.

3) If verification cannot be performed within the ten year period because a unit has not been on-line, the ten year period shall be extended. It is permissible to wait until the unit is scheduled to operate in order to conduct verification so that sufficient advance notice to make arrangements for verification is available. After verification is performed, the subsequent ten year schedule for the next verification will start.

4) For units that reach an average Capacity Factor greater than 5% over the last three calendar years, and have not been verified within the last ten calendar years, verification shall be performed within the next calendar year. The subsequent ten year schedule will start upon a successful verification.

R2. The Transmission Planner shall provide the Generator Operator a set of model data sheets for the acceptable excitation system models (models cannot be confidential or proprietary) for use in dynamic simulation software, with each data sheet including the excitation system model block diagram structure and data requirements, within 30 calendar days of a request from the Generator Operator.

R3. The Transmission Planner shall provide the Generator Operator the unit specific data contained in the Transmission Planner's dynamic database from the current in-use excitation system model, within 30 calendar days of a request from the Generator Operator.

R4. The Generator Operator shall provide to the Transmission Planner the following unit specific information within 90 calendar days of completion of the excitation system model verification:

1) Manufacturer, model number if available, and type of excitation system (for example: static, ac brushless, dc rotating).

2) Generator model structure and data (reactances, time constants, saturation factors, rotational inertia)

3) Excitation system model structure and data for the closed loop voltage regulator (including main exciter if so equipped).

4) Reactive compensation settings (for example: reactive droop, line drop, differential compensation), if utilized.

5) Model structure and data for power system stabilizer, if so equipped.

R5. The Transmission Planner shall determine if the excitation system model is useable by including the excitation system model in dynamic simulation software and substantiating that:

1) A no-disturbance simulation contains no transients.

2) For an otherwise stable simulation, a disturbance simulation results in the equipment exhibiting positive damping.

R6. The Transmission Planner shall inform the Generator Operator whether the excitation system model is useable or not within 90 calendar days of receipt (R4). If the excitation system model is not useable, the Transmission Planner shall provide the Generator Operator with a description of the problem and any relevant details.

R7. The Generator Operator shall provide a written response within 90 calendar days following notification by the Transmission Planner that the excitation system model is not useable. The Generator Operator's response shall either:

- Indicate what changes will be made to the excitation system model, or
- Provide the technical basis why no changes will be made.

R8. The Generator Operator shall provide to the Transmission Planner documentation demonstrating that the excitation system model's response matches the recorded response for a voltage excursion at the generator from either a staged test or a measured system disturbance (i.e., an ambient event) within 90 calendar days of completion of the excitation system model verification.

R9. The Generator Operator shall make documentation demonstrating that the excitation system model's response matches the recorded response for a voltage excursion at the generator from either a staged test or a measured system disturbance (i.e., an ambient event) available for inspection and technical review to the Reliability Coordinators, Transmission Operators, and Planning Coordinators that have responsibility for the area in which the associated unit is located, within 60 calendar days after receipt of a request.

R10. The Generator Operator shall provide a written response within 90 calendar days after receipt of a Transmission Planner's or a Planning Coordinator's written comments detailing technical concerns with the Generator Operator's excitation system model verification documentation. That written response shall either:

- Indicate what changes will be made to the excitation system model, or
- Provide the technical basis why no changes will be made.

R11. The Generator Operator shall perform a review of its current excitation system model when its Transmission Operator or Reliability Coordinator provides the Generator Operator dated electronic or hard copy evidence that the recorded excitation control system response to a Transmission system event did not match the predicted excitation system model response. Upon review the Generator Operator shall either:

- Provide a dated electronic or hard copy explanation detailing why the current excitation system model is still appropriate within 90 days to the commenter and the Transmission Planner whose area the generating facility is located in, or
- Perform a re-verification in accordance with R4, and R8 within 180 days. Once the re-verification is performed, the 10 year period as outlined in R1 will be reset.

R12. The Generator Operator shall perform a review of its current excitation system model and model parameters each time an activity that may alter the equipment response is performed. An activity that potentially alters the response of the excitation system and/or power system stabilizer includes but is not limited to:

- Exciter, voltage regulator or power system stabilizer control replacement including software alterations that could alter excitation system equipment response
- Plant Digital Control System addition or replacement

- Plant Digital Control System software alterations that could alter excitation system equipment response
- Exciter, voltage regulator, impedance compensator or power system stabilizer settings change

The Generator Operator shall either:

- Provide documentation that the response has not changed to the Transmission Planner within 90 days of completion of an activity that could have altered equipment response, or
- Perform a re-verification in accordance with Requirements R4 and R8 within 180 days. Once the re-verification is performed, the ten year period as outlined in Requirement R1 is reset.

C. Measures

M1. (To be developed.)

Project 2007-09 Generator Verification Implementation Plan

Implementation Plan for MOD-026-1, Verification of Models and Data for Generator Excitation Control System and Plant Volt/Var Control Functions

Approvals Requested

MOD-026-1 - Verification of Models and Data for Generator Excitation Control System and Plant Volt/Var Control Functions

Prerequisite Approvals

None

Revisions to Approved Standards and Definitions

None

Compliance with the Standard

The following entities are responsible for being compliant with all requirements of MOD-026-1:

- Transmission Planner
- Generator Owner

- Facilities

  For the purpose of this standard, the following Facilities are considered, "applicable units." Units or plants with an average capacity[1] factor greater than 5% over the last three calendar years that meet the following:

[1] Once a capacity factor exemption is declared by notifying the Transmission Planner, verification is not required for 10 calendar years from the date eligibility occurs. At the end of this 10 calendar year timeframe, the current average 3 year capacity factor (for years 8, 9, and 10) is examined to determine if the capacity factor exemption can be declared for the next 10 calendar year period. If not eligible for the capacity factor exemption, then model verification must be completed within one year of the date the capacity factor exemption expired with the 10 calendar year periodicity requirement reset based on the verification date.

Generating units connected to the Eastern or Quebec Interconnection with the following characteristics:

- Each generating unit with a gross nameplate rating greater than or equal to 100 MVA, connected at the point of interconnection[2] with rating greater than or equal to 100 kV.
- For each plant with a gross aggregate nameplate rating greater than or equal to 100 MVA, connected at the same point of interconnection with rating greater than or equal to 100 kV:
    - Each unit with a gross nameplate rating greater than or equal to 20 MVA; and
    - The remainder of the plant as an aggregate.

Generating units connected to the Western Interconnection with the following characteristics:

- Each generating unit with a gross nameplate rating greater than or equal to 75 MVA, connected at the point of interconnection[2] with rating greater than or equal to 100 kV.
- For each plant with a gross aggregate nameplate rating greater than or equal to 75 MVA, connected at the same point of interconnection with rating greater than or equal to 100 kV:
    - Each unit with a gross nameplate rating greater than or equal to 20 MVA; and
    - The remainder of the plant as an aggregate.

Generating units connected to the ERCOT Interconnection with the following characteristics:

- Each generating unit with a gross nameplate rating greater than or equal to 50 MVA, connected at the point of interconnection[2] with rating greater than or equal to 100 kV.
- For each plant with a gross aggregate nameplate rating greater than or equal to 75 MVA, connected at the same point of interconnection with rating greater than or equal to 100 kV:
    - Each unit with a gross nameplate rating greater than or equal to 20 MVA; and
    - The remainder of the plant as an aggregate.

For all interconnections:

- Any technically justified[3] unit requested by the Planning Coordinator.

[2] The common transmission bus voltage level at which the generator step up transformer is connected.

Effective Date

In those jurisdictions where regulatory approval is required:

By the first day of the first calendar quarter, four years following applicable regulatory approval:

- Each Generator Owner shall ensure at least 30% of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2.
- Each responsible entity shall ensure compliance with Requirements R1, and R3 through R6.

By the first day of the first calendar quarter, six years following applicable regulatory approval:

- Each Generator Owner shall ensure at least 50% of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2.

By the first day of the first calendar quarter, ten years following applicable regulatory approval:

- Each Generator Owner shall ensure 100% of its applicable units are compliant with Requirement R2.

In those jurisdictions where no regulatory approval is required:

By the first day of the first calendar quarter, four years following Board of Trustees adoption:

- Each Generator Owner shall ensure at least 30% of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2.
- Each responsible entity shall ensure compliance with Requirements R1, and R3 through R6.

By the first day of the first calendar quarter, six years following Board of Trustees adoption:

- Each Generator Owner shall ensure at least 50% of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2.

By the first day of the first calendar quarter, ten years following Board of Trustees adoption:

- Each Generator Owner shall ensure 100% of its applicable units are compliant with Requirement R2.

[3] A technical justification for verifying each of those units or plant(s) that demonstrates through simulation and/or measured response that the unit or plant affects a stability limit, or evidence that the simulated unit or plant response does not match measured unit or plant response.

Justification

This phased implementation supports the ten year cycle for the collection of generator response data necessary for required verifications and typical generating unit outage schedules.

When a Generator Owner has verified its Excitation Control System and Plant Volt/Var Control model(s) in compliance with its regional entity requirements ten years or less prior to the approval date of this Standard, these verifications are deemed sufficient for demonstrating compliance with this Standard for a ten year period from the date of the aforementioned verification.

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. SAR posted for comment (April 20–May 21, 2007).
2. Revised SAR and response to comments posted.
3. Revised SAR and response to comments approved by SC (June 14, 2007).
4. SDT appointed on (August 18, 2007).
5. Initial draft of PRC-024-1 was posted for a 45 day formal comment period (February 17 – April 2, 2009).

Proposed Action Plan and Description of Current Draft:

This is the second draft of the proposed standard including Time Horizons, Data Retention, Violation Risk Factors, and Violation Severity Levels. This second posting of the standard is for a 30-day formal comment period.

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Post first draft revision of standard.	April-May 2011
2. Post response to comments and third version draft revision of standard.	July – August 2011
3. Post response to comments and request authorization to ballot the revised standard.	September - October 2011
4. Conduct initial ballot.	November 2011
5. Post response to comments.	December 2011
6. Conduct recirculation ballot.	January 2012
7. BOT adoption.	February 2012
8. File with regulatory authorities.	March 2012

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

Frequency Excursion – an exceedance of system frequency beyond a continuous operating band; 60±0.5 Hertz.

Voltage Excursion – an exceedance of system voltage beyond a continuous operating band; ±5% of scheduled voltage.

A. Introduction

1. **Title:** Generator Performance During Frequency and Voltage Excursions

2. **Number:** **PRC-024-1**

3. **Purpose:** Ensure generating units remain connected during frequency and voltage excursions and ensure expected generating unit performance during frequency and voltage excursions is communicated to Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners for accurate system modeling.

4. **Applicability:**

   4.1. Generator Owner

5. **Effective Date:**

   5.1. The first day of the first calendar quarter one year following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter one year following Board of Trustees adoption:

   5.1.1 Each Generator Owner shall verify that at least 33% of its applicable units are fully compliant with this standard.

   5.2. The first day of the first calendar quarter two years following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter two years following Board of Trustees adoption:

   5.2.1 Each Generator Owner shall verify that at least 66% of its applicable units are fully compliant with this standard.

   5.3. The first day of the first calendar quarter three years following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter three years following Board of Trustees adoption:

   5.3.1 Each Generator Owner shall verify that 100% of its applicable units are fully compliant with this standard.

B. Requirements

R1. Each Generator Owner that has frequency protective relaying [1] activated to trip its new or existing generating unit shall set such protective relaying not to trip per the following operating conditions and relay settings unless the Generator Owner has documented and communicated a non-protection system equipment limitation in accordance with

[1] Each Generator Owner is not required to have frequency or voltage protective relaying (includes frequency and voltage protective functions for discrete relays, volts per hertz relays evaluated at nominal frequency, multi-function protective devices or protective functions within excitation controls that directly trip or provide tripping signals to the generator based on frequency or voltage inputs) installed or activated on its unit.

Requirement R3 for an existing generating unit.[2] *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*

1.1. When operating within a frequency range of 59.5 Hz to 60.5 Hz, inclusive.

1.2. During the off-nominal frequency excursions specified in PRC-024 Attachment 1.

1.3. By instantaneous under frequency relays set at a frequency higher than 57.8 Hz.

1.4. By instantaneous over frequency relays set at a frequency lower than 62.2 Hz.

1.5. When the transmission system frequency rate of change is less than 2.5 Hz/second.

R2. Each Generator Owner that has voltage protective relaying activated to trip its new or existing unit or generating plant or Facility shall set its protective relaying not to trip as a result of a voltage excursion (at the point of interconnection) caused by an event external to the plant per the following operating conditions and relay settings unless the Generator Owner has documented and communicated a non-protection system equipment limitation in accordance with Requirement R3 for an existing unit or generating plant or generating Facility: *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*

2.1. When operating within 95% to 105% of rated generator terminal voltage and during the transmission system operating conditions defined in PRC-024 Attachment 2, with the following clarifications:

2.1.1. For three-phase transmission system zone 1 faults with Normal Clearing, set voltage relays based on actual fault clearing times, not to exceed 9 cycles.

2.1.2. If a Transmission Planner’s study (based on the location specific voltage recovery characteristics) recommends less stringent voltage relay settings than those in PRC-024 Attachment 2, set voltage relays either to the Transmission Planner’s settings or the settings in PRC-024 Attachment 2.

2.1.3. If a Special Protection System (SPS) or Remedial Action Scheme (RAS) includes tripping a generator after fault initiation, then setting the SPS or RAS relays to trip the generator even if in the “no trip zone” in PRC-024 Attachment 2 is acceptable.

2.1.4. If clearing a system fault necessitates disconnecting a generator, then setting relays to trip the generator even if operating within the “no trip zone” specified in PRC-024 Attachment 2 is acceptable.

R3. Each Generator Owner of an existing generating unit or generating plant or Facility shall document each non-protection system equipment limitation that prevents a generating unit, generating plant, or Facility from meeting the criteria in Requirement R1 or R2 and communicate the documented limitation to its Reliability Coordinator, Planning

[2] To include generators under construction, generators with an executed interconnection agreement or Power Purchase Agreement by the effective date of this standard, or generators with an executed equipment purchase contract and scheduled delivery of major components within 2 years of the effective date of version 1 of this standard.

Coordinator, Transmission Operator and Transmission Planner within 30 calendar days of identifying the limitation to ensure the accuracy of planning studies and system modeling studies. The equipment limitation expires coincident with either of the following conditions:

- The equipment causing the limitation is repaired or replaced with equipment that removes the limitation.
- The generating unit continuous capacity rating increases ≥ 10%.

[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]

R4. Within 90 calendar days of receipt of a written inquiry from the Reliability Coordinator, Planning Coordinator, Transmission Operator, or Transmission Planner regarding an equipment limitation identified in accordance with Requirement R3, the Generator Owner shall provide a written response to the entity that submitted the inquiry.

R5. Each Generator Owner of an existing unit or generating plant or generating Facility shall provide an estimate of that unit's performance during Frequency/Voltage Excursions to the requesting entity (Reliability Coordinator, Planning Coordinator, Transmission Operator or Transmission Planner that monitors or models the associated unit) within 30 calendar days of a written request to ensure the accuracy of planning studies and system modeling studies. The documentation shall include: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

5.1. An estimate of the time duration the existing unit or generating plant or Facility will remain connected as a result of a Frequency Excursion defined by the curves in PRC-024 Attachment 1 and a Voltage Excursion defined by the curves in PRC-024 Attachment 2 or the voltage profile at the Point of Interconnection for the generating unit or generating plant or Facility of the most severe normally-cleared Zone 1 fault described by dynamic simulation provided by the Transmission Planner if this profile is less stringent than the curves in Attachment 2.

5.2. An estimated probability in 25% increments that the existing unit or generating plant or generating Facility will remain connected during a Frequency Excursion defined by the curves in PRC-024 Attachment 1 and a Voltage Excursion defined by the curves in PRC-024 Attachment 2 or the voltage profile at the Point of Interconnection for the generating unit or generating plant or Facility of the most severe normally-cleared Zone 1 fault described by dynamic simulation provided by the Transmission Planner if this profile is less stringent than the curves in Attachment 2.

5.3. Identification of the basis for the estimates developed for 5.1 and 5.2 which may include, but is not limited to: experience, actual event histories, or sound engineering judgment.

R6. Each Generator Owner shall design, build, and maintain its new [3] unit or new generating plant or generating Facility so that it will not trip due to a Frequency Excursion or Voltage Excursion at the Point of Interconnection, caused by an event external to the plant, within the parameters set forth in PRC-024 Attachments 1 and 2 and in accordance with the following conditions and exceptions: *[Violation Risk Factor: High] [Time Horizon: Real-time Operations]*

6.1. (condition) When the unit or generating plant or generating Facility is operating at or above the minimum sustainable generation threshold.

6.1.1. For a generating plant or generating Facility consisting of multiple units with total generation > 75 MVA (gross aggregate rating), when the Facility is producing at least 20% of the Facility's rated capacity and the voltage support equipment is in service.

6.2. (condition) For a new generating plant or generating Facility consisting of multiple units less than 20 MVA each with total Facility generation > 75 MVA (gross aggregate rating), at least 90% of the individual generating units shall remain connected.

6.3. (exception) A unit or generating plant or generating Facility may operate to a less stringent voltage ride-through performance criterion than the duration curve identified in PRC-024 Attachment 2 based on the location specific voltage recovery characteristics as specified by the Transmission Planner.

6.4. (exception) A unit or generating plant or generating Facility may trip if this action is designed as part of a Special Protection System (SPS) or Remedial Action Scheme (RAS).

6.5. (exception) A unit or generating plant or generating Facility may trip if clearing a system fault necessitates disconnecting the unit or generating plant or generating Facility.

6.6. (exception) A unit or generating plant or generating Facility may trip if the Generator Owner has a temporary exemption granted by its Reliability Coordinator based on a documented equipment limitation.

6.7. (exception) A unit or generating plant or generating Facility may trip if the protective functions (such as out of step or loss of field functions) operate due to an impending or actual loss of synchronism or due to instability in power conversion control equipment.

R7. Each Generator Owner shall provide to the Reliability Coordinator, Planning Coordinator, Transmission Operator and Transmission Planner (that monitors or models the associated unit) its generator protection trip settings as specified by Requirements R1

[3] Excluding generators in service prior to the effective date of version 1 of this standard and excluding generators referenced in Footnote 2.

and R2, and documented equipment limitations as specified by Requirement R3 within 30 calendar days of any change to those trip settings or limitations and within 30 calendar days of a written request for the data to ensure the accuracy of planning studies and system modeling. *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*

C. Measures

M1. Each Generator Owner has evidence such as dated setting sheets, calibration sheets, or other documentation, that generator frequency protective relays have been set in accordance with Requirement R1.

M2. Each Generator Owner has evidence such as dated setting sheets, voltage-time curves, calibration sheets, coordination plots or dynamic simulation studies, that generator voltage protective relays have been set in accordance with Requirement R2.

M3. Each Generator Owner has evidence that it has documented and communicated any equipment limitations (Protection System excluded) that resulted in an exception to Requirements R1 or R2 in accordance with Requirement R3 such as a dated email or letter that contains such documentation as study results, experience from an actual event, or manufacturer's advisory.

M4. Each Generator Owner has evidence such as dated e-mails, mail receipts or other evidence that it provided a written response to an inquiry regarding equipment limitations to a requesting entity within 90 calendar days of a request in accordance with Requirement R4.

M5. Each Generator Owner has evidence such as a copy of the performance report and dated e-mails, mail receipts or other documentation that an estimate of the performance of its existing generating unit(s) as a result of a Frequency Excursion or Voltage Excursion has been communicated in accordance with Requirement R5.

M6. Each Generator Owner has evidence such as dated unit output records, trip investigation reports or disturbance monitoring records or a trip report indicating each unit trip did not result from a Frequency Excursion or Voltage Excursion as specified in Requirement R6 or provide an attestation that the generating unit, generating plant or Facility did not trip.

M7. Each Generator Owner has evidence such as dated e-mails, mail receipts or other evidence that it communicated generator protective relay settings or equipment limitations to a requesting entity within 30 calendar days of a request or change in setting(s) in accordance with Requirement R7.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

Regional Entity

1.2. Data Retention

The Generator Owner shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

- The Generator Owner shall retain the latest evidence of Requirement R1 through R7, Measure M1 through M7; and shall retain prior evidence for 3 calendar years or until the next audit, whichever is longer.

If a Generator Owner is found non-compliant, it shall keep information related to the non-compliance until found compliant or for the time period specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes

Compliance Audit

Self-Certification

Spot Checking

Compliance Violation Investigation

0.30	0.450
2.00	0.650
3.00	0.750
600	0.900

Voltage Ride-Through Curve Clarifications

1. The per unit voltage base for these curves is the scheduled operating voltage as measured at the point of interconnection to the Bulk Electric System (BES).
2. The curves depicted apply to a three-phase transmission system zone 1 fault with Normal Clearing.
3. When the cumulative voltage duration at the point of interconnection with the BES is within the voltage boundaries of these curves, the generator voltage protective relaying will not trip the generator.
4. The curves depicted assume system frequency is 60 Hertz.
5. Use the following assumptions if basing voltage protection relay setting calculations on the static case for steady state initial conditions:
    a. All of the units connected to the same transformer are online and operating,
    b. All of the units are at full nameplate real-power output.
    c. Power factor is 0.95 lagging.
    d. Scheduled voltage is measured at the point of interconnection.
6. Calculate voltage protection relay settings to comply with these curves assuming that any additional installed generating plant reactive support equipment (such as static VAr compensators, synchronous condensers, or capacitors) is available and operating normally.
7. Calculate voltage protection relay settings to comply with these curves, accounting for the actual tap settings of transformers between the generator terminals and the point of interconnection.

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

SAR authorized by Standards Committee for development as a reliability standard July 12, 2007.

Standard Drafting Team appointed by Standards Committee September 11, 2007.

Proposed Action Plan and Description of Current Draft:

This is the first draft of the proposed standard and includes requirements with violation risk factors, time horizons and measures; additional compliance elements will be added later. This first posting of the standard is for a 45-day comment period from February 17 through April 2, 2009.

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Post response to comments and second version of standard.	May 4, 2009
2. Post response to comments and request authorization to ballot the revised standard.	To be determined
3. Conduct initial ballot.	To be determined
4. Post response to comments.	To be determined
5. Conduct recirculation ballot.	To be determined
6. BOT adoption.	To be determined
7. File with regulatory authorities.	To be determined

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

None.

A. Introduction

1. **Title:** **Generator Frequency and Voltage Protective Relay Settings**

2. **Number:** PRC-024-1

3. **Purpose:** Ensure that generator frequency and voltage protective relays[1] are set to support transmission system stability during voltage and frequency excursions.

4. **Applicability**

   4.1. Functional entities:

   4.1.1 Generator Owners

   4.2. Facilities:

   4.2.1 Each generating unit (with installed voltage or frequency protective relays) greater than 20 MVA connected to the Bulk Electric System (BES).

   4.2.2 Each unit (with installed voltage or frequency protective relays) at generating plants/facilities consisting of multiple units with total generation > 75 MVA (gross aggregate nameplate rating) at the point of interconnection to the BES.

5. **Effective Dates:** The standard is effective the first day of the first calendar quarter after applicable regulatory approvals (or the standard otherwise becomes effective the first day of the first calendar quarter after NERC BOT adoption in those jurisdictions where regulatory approval is not required).

   Each Generator Owner's unit with installed voltage or frequency protective relays shall be compliant with the standard based on the following phased implementation schedule:

   5.1. No less than 33% of a Generator Owner's units shall be fully compliant with the standard within 1 year of the effective date of the standard.

   5.2. No less than 66% of a Generator Owner's units shall be fully compliant with the standard within 2 years of the effective date of the standard

   5.3. No less than 100% of a Generator Owner's units shall be fully compliant with the standard within 3 years of the effective date of the standard

A. Requirements

R1. Each Generator Owner shall set its installed generator frequency protective relaying not to trip during the following frequency-related operating conditions unless the Generator Owner has documented and reported the unit's limitation in accordance with Requirement R5: *(Violation Risk Factors: High - Units ≥500 MVA; Medium - Units >100 MVA and <500 MVA; Lower - Units ≤100 MVA) (Time Horizon – Operations Planning)*

R1.1. When operating within a frequency range of 59.5 Hz to 60.5 Hz, inclusive.

R1.2. During the off-normal frequency excursions specified in PRC-024-1 Attachment 1.

R1.3. Instantaneous underfrequency relay trip setting shall be set no higher than 57.8 Hz.

R1.4. Instantaneous overfrequency relay trip settings shall be set no lower than 62.2 Hz.

---

[1] Includes voltage and frequency protective functions for discrete relays, multi-function protective devices, voltage regulators, etc.

R2. Each Generator Owner shall set its installed generator over and under voltage (including volts per hertz relays evaluated at nominal frequency) protective relays not to trip during the steady-state and voltage-related operating conditions as follows unless the Generator Owner has documented and reported the unit's limitation in accordance with Requirement R5 of this standard: *(Violation Risk Factors: High - Units ≥500 MVA; Medium - Units >100 MVA and <500 MVA; Lower - Units ≤100 MVA) (Time Horizons – Operations Planning)*

R2.1. When operating within 95% to 105% of rated generator terminal voltage.

R2.2. During the transient voltage excursions measured at the point of interconnection to the BES as specified in PRC-024-1 Attachment 2. The following generator protective relaying settings are acceptable:

R2.2.1. For three-phase transmission system zone one faults with Normal Clearing, relaying may be set based on actual fault clearing times, but not greater than nine cycles.

R2.2.2. Relaying may be set to meet a shorter voltage ride through duration curve as specified by the Transmission Planner based on the location specific voltage recovery characteristics.

R2.2.3. Relaying may be set to trip a generator after fault initiation if this action is intended as part of a Special Protection System (SPS) or Remedial Action Scheme (RAS).

R2.2.4. Relaying may be set to trip a generator if clearing a system fault necessitates disconnecting the generator.

R3. Each Generator Owner shall provide to the Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners (that monitor or model the associated unit) its generator protection trip settings as specified by Requirement R1 and Requirement R2 within 30 calendar days of any change to those trip settings. *(Violation Risk Factor – Lower) (Time Horizon – Operations Planning)*

R4. Each Generator Owner shall provide to the Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners (that monitor or model the associated unit), its generator protection trip settings as specified by Requirement R1 and Requirement R2 within 30 calendar days of a written request for the data. *(Violation Risk Factor – Lower) (Time Horizon – Operations Planning)*

R5. If an existing generator unit[2] cannot meet either Requirement R1 or Requirement R2 due to equipment limitations, such as manufacturer warranty requirements or limitations that endanger the equipment according to published manufacturer instructions, (Protection System excluded), the Generator Owner is granted an exception for that unit from meeting the portion of Requirement R1 or R2 for that limitation once it provides documentation of the equipment limitation(s) to the Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners that monitor or model the associated unit, within 30 days of identifying the equipment limitation. *(Violation Risk Factors: Medium - Units >100 MVA; Lower - Units ≤100 MVA) (Time Horizon – Operations Planning)*

---

[2] Including generators under construction, generators with an executed interconnection agreement or Power Purchase Agreement, or generators with an executed equipment purchase contract and scheduled delivery within 2 years of the effective date of the standard.

The exception for the equipment limitation shall expire coincident with either of the following conditions:

- The equipment causing the limitation is replaced with equipment that removes the technical limitation.
- The equipment causing the limitation is modified or upgraded resulting in an increase of generator nameplate capacity rating greater than 10%.

R6. The Generator Owner shall provide a written response within 90 calendar days of receipt of written comments from a Reliability Coordinator, Planning Coordinator, Transmission Operator or Transmission Planner (that monitors or models the associated unit) regarding the equipment limitation. The response shall indicate whether a change will be made to the equipment limitation or if no change will be made to the equipment limitation, the reason why. *(Violation Risk Factor – Lower) (Time Horizon – Operations Planning)*

B. Measures

M1. Each Generator Owner shall have evidence such as setting sheets, calibration sheets, or other documentation, that generator frequency protective relays have been set in accordance with Requirement R1.

M2. Each Generator Owner shall have evidence such as setting sheets, voltage-time curves, calibration sheets, coordination plots or dynamic simulation studies, that generator voltage protective relays have been set in accordance with Requirement R2.

M3. Each Generator Owner shall have evidence such as dated e-mails, mail receipts or other documentation that generator protective relay settings changes have been communicated to the entities listed in Requirement R3.

M4. Each Generator Owner shall have evidence such as dated e-mails, mail receipts, request received or other documentation that generator protective relay settings have been communicated to the entities listed in Requirement R4.

M5. Each Generator Owner of existing generators that are unable to comply with Requirements R1 or R2 due to equipment limitations (Protection System excluded) shall have evidence such as warranty agreements, insurance agreements, manufacturers documented limitations, engineering analysis or other documentation that explains the equipment limitation of the unit(s).

M6. Each Generator Owner shall have evidence such as dated copy, e-mail receipts or other evidence that it provided a written response to a commenting entity within 90 calendar days of receipt of comments.

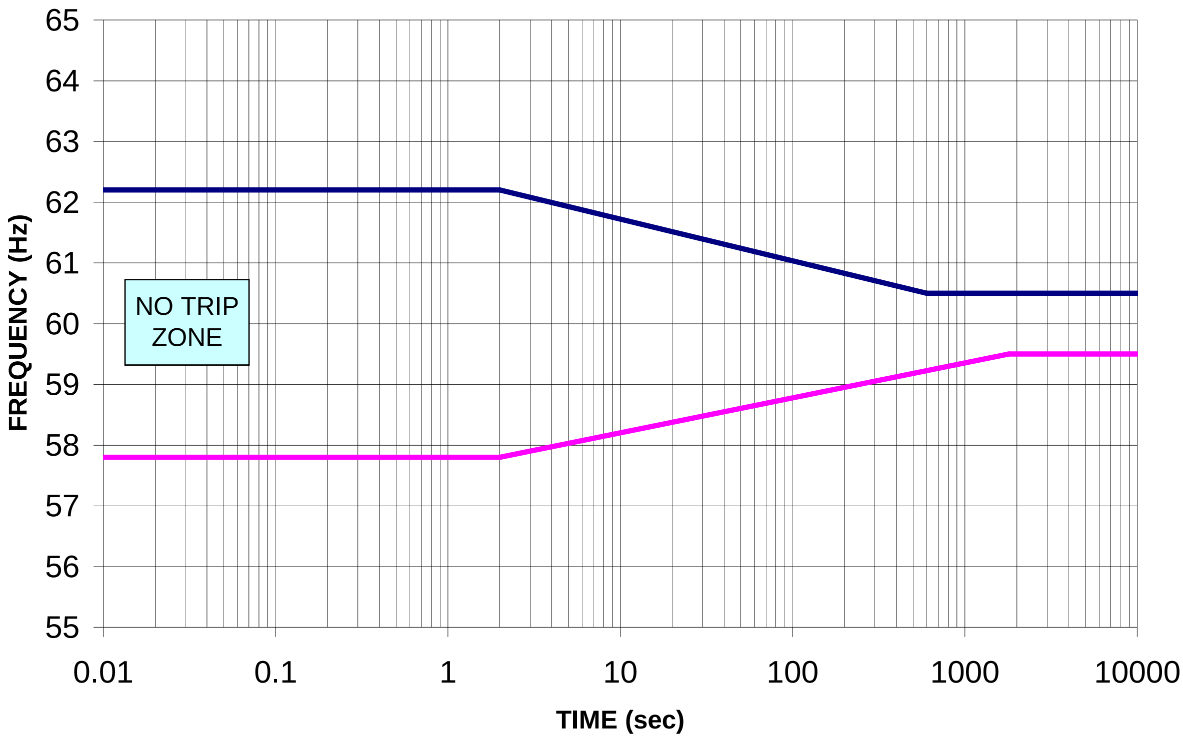
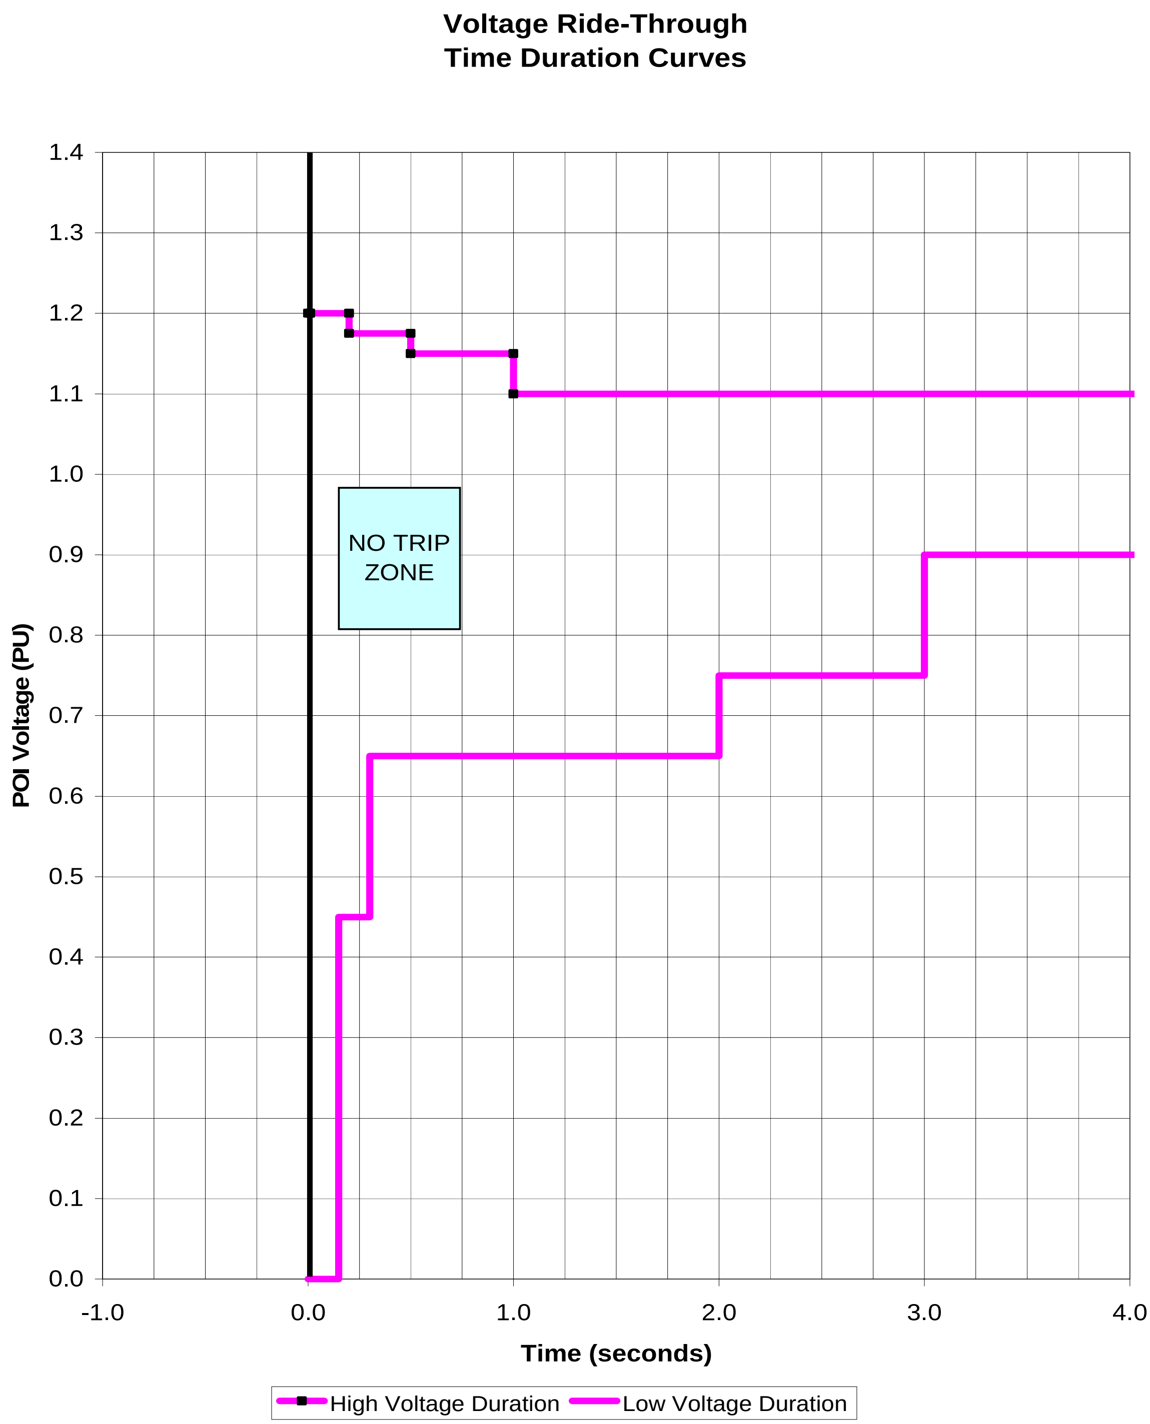
PRC-024-1 — Attachment 1

OFF NOMINAL FREQUENCY CAPABILITY CURVE



Frequency (hertz)	62.2	60.5	57.8	59.5
Time (seconds)	0 to 2	600 to 10,000	0 to 2	1,800 to 10,000

PRC-024-1 — Attachment 2



The following data points would apply to this curve:

HVRT DURATION		LVRT DURATION	
Time	Voltage	Time	Voltage
0.20	1.200	0.15	0.000
0.50	1.175	0.30	0.450
1.00	1.150	2.00	0.650
4.00	1.100	3.00	0.750
		4.00	0.900

Voltage Ride-Through Curve Clarifications

1. The per unit voltage base for this curve is the nominal operating voltage as measured at the point of interconnection to the BES.
2. As long as the cumulative voltage duration at the point of interconnection with the BES is within the voltage boundaries of the curve, the generator voltage protective relaying will not trip the generator.
3. The curve depicted in this Attachment 2 assumes system frequency of 60 Hertz and all of the units connected to the same transformer are on line.

NERC

NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Project 2007-09 Generator Verification Implementation Plan

Implementation Plan for PRC-024-1, Generator Performance During Frequency and Voltage Excursions

Approvals Requested:

PRC-024-1 – Generator Performance During Frequency and Voltage Excursions

Definitions:

Frequency Excursion – an exceedance of system frequency beyond a continuous operating band; 60±0.5 Hertz.

Voltage Excursion – an exceedance of system voltage beyond a continuous operating band; ±5% of scheduled voltage.

Prerequisite Approvals

None

Revisions to Approved Standards and Definitions

None

Compliance with the Standard

The following entities are responsible for being compliant with all requirements of PRC-024-1:

- Generator Owner

Effective Date

The first day of the first calendar quarter one year following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter one year following Board of Trustees adoption:

116-390 Village Blvd.
Princeton, NJ 08540
609.452.8060 | www.nerc.com

- Each Generator Owner shall verify at least 33% applicable units fully compliant with this standard.

The first day of the first calendar quarter two years following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter two years following Board of Trustees adoption:

- Each Generator Owner shall verify at least 66% applicable units fully compliant with this standard.

The first day of the first calendar quarter three years following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter three years following Board of Trustees adoption:

- Each Generator Owner shall verify 100% applicable units fully compliant with this standard

The phasing allows Generator Owners to effect any needed changes to the protective system settings during normally scheduled outages.

According to its Implementation Plan, PRC-006-1, Requirement R4 (see project 2007-01, Underfrequency Load Shedding) does not become effective until PRC-024 becomes effective. Upon the effective date of PRC-024-1, R4 of PRC-006-1, R4 will also go into effect.

Unofficial Comment Form for Generator Verification (Project 2007-09)

Please **DO NOT** use this form to submit comments. Please use the electronic comment form located at the link below to submit comments on the Second Posting of MOD-026-1, Verification of Models and Data for Generator Excitation Control System or Plant Volt/Var Control Functions (Project 2007-09). The electronic comment form must be completed by **August 1, 2011.**

Project 2007-09 Generator Verification

If you have questions please contact Stephen Crutchfield at Stephen.Crutchfield@nerc.net or by telephone at 609-651-9455.

Background Information

The purpose of Project 2007-09 - Generator Verification is:

- To ensure that generators will not trip off-line during specified voltage and frequency excursions or as a result of improper coordination between generator protective relays and generator voltage regulator controls and limit functions (such coordination will include the generating unit's capabilities).

- To ensure that generator models accurately reflect the generator's capabilities and operating characteristics.

The standard drafting team (SDT) for Project 2007-09 Generator Verification based its work on two existing NERC Board approved standards:

- MOD-024-1 — Verification of Generator Gross and Net Real Power Capability.

- MOD-025-1 — Verification of Generator Gross and Net Reactive Power Capability.

And four draft standards developed by the Phase III & IV SDT that were field tested by four Regions from mid 2006 through mid 2007.

- PRC-019-1 — Coordination of Generator Voltage Regulator Controls with Unit
- Capabilities and Protection

- PRC-024-1 — Generator Performance During Frequency and Voltage Excursions

- MOD-026-1 —Verification of Models and Data for Generator Excitation Control System Functions

- MOD-027-1 — Verification of Generator Unit Frequency Response

This is the second posting of standard MOD-026-1 Verification of Models and Data for Generator Excitation Control System Functions for industry review. It should be noted that the title of the standard has been changed from "Verification of Models and Data for Generator Excitation Control System Functions" to "Verification of Models and Data for Generator Excitation Control System or Plant Volt/Var Control Functions" in order to reflect the SDTs inclusion of plants with several small units, in large part to include Variable Energy

Resource plants (discussed in more detail below). The second posting of standard MOD-026-1 Verification of Models and Data for Generator Excitation Control System Functions was developed with consideration of industry response to questions that were posed as part of the Comment Form accompanying the first posting. This posting also includes the initial posting of standard MOD-027-1. Note for the same reason discussed for standard MOD-026-1, standard MOD-027-1 has been re-titled from “Verification of Generator Unit Frequency Response” to “Verification of Models and Data for Turbine/Governor and Load Control or Active Power/Frequency Control Functions”. While there are a few differences between standards MOD-026-1 and MOD-027-1 as detailed below, there are also many similarities. The two standards are similar in both substance and style.

Standard MOD-026-1:
One of the major issues that the SDT presented to industry during the first posting was the functional entity “applicability”. The SDT recognized that assigning responsibility to appropriate entities for a continent wide standard for verifying unit excitation system models would be difficult. In the first posting of the standard, the SDT selected the Generator Operator to be the appropriate entity to be responsible for verifying the model. However, industry feedback from the first posting indicated that the majority of industry participants felt that the Generator Owner was the appropriate entity to assign responsibility. The SDT also consulted with the NERC Functional Model Working Group (FMWG) which felt that the Generator Owner was the appropriate entity to assign model verification responsibility. Therefore, in this second posting of standard MOD-026-1, the responsibility for model verification has been assigned to the Generator Owner. As such, it is up to the Generator Owner and Generator Operator to define contractual arrangements needed to comply with the requirements of this standard.

A significant change incorporated into the second posting of this standard is a proposed process where the Planning Coordinator can request a review of an excitation control system model. Many of the affirmative responses from industry qualified their answer by stating that the process needs to be well defined. As such, the new Requirement (R5) requires the Planning Coordinator to supply technical justification for the request. If upon receipt of this notification the Generator Owner has revised excitation control system model data, then the Generator Owner can supply that data to the Planning Coordinator. An example might be the discovery of unit specific “as-commissioned” manufacturer data which would be more accurate than generic manufacturer data. If better data is not available, or does not address the Planning Coordinator’s dynamic modeling and stability performance needs, then the Planning Coordinator can request the Generator Owner to review the excitation control system model and provide revised data. Since the Generator Owner has already provided updated data to the degree possible without verifying the model, then the Generator Owner would be required to verify the model within the time frame specified in the Periodicity Table (one year to obtain a recorded response of a voltage excursion and submission of the model within 180 days after obtaining the recorded response).

The SDT also asked industry several questions pertaining to the extent facilities are to be verified, including periodicity for model verification. As a baseline, the SDT recognized that the excitation system models and model data are already collected through the processes identified in standards MOD-012 and MOD-013. This information, with few exceptions, already establishes a quality dynamics database. However, as confirmed through field testing, performing verification activities specified in the draft standard will improve the accuracy of exciter models used in dynamic simulation. Major themes expressed by industry and subsequent action taken by the SDT include:

1. The present draft of the standard maintains a base Applicability requiring verification of excitation systems associated with 80% or greater of the connected MVA per Interconnection (refer to Item 5 below). The present draft of the standard does clarify that the connected MVA threshold for plants is to include units connected at the same point of interconnection. For example, if a plant site has generators interconnected to two different transmission voltage levels, the MVA threshold would be applied based on the cumulative MVA of the generators interconnected at each transmission voltage level.
2. The majority of industry agreed with the 5% capacity factor threshold. The application of the capacity factor threshold has been clarified in the new Periodicity Table.
3. The majority of industry agreed with the philosophy of allowing excitation control system verification for a single unit to satisfy compliance for other units if certain conditions are met (such as having the same MVA rating, having identical applicable components and settings, and being sited at the same physical location); which remain unchanged in the present draft of the standard.
4. Based on industry comments and technical justification regarding the nameplate MVA of steam units for existing Combined Cycle plant technology, the SDT raised the threshold MVA nameplate rating from ≤250 MVA to ≤350 MVA.
5. Industry agreed with the general ten year periodicity timeframe proposed. It was pointed out to the SDT that periodicity alone did not constitute a standalone reliability requirement. Therefore, R1 from the previous draft of the standard has been removed and replaced with a Periodicity Table. The Periodicity Table provides the base ten year applicability timeframe for collecting data needed to perform the verification, and adds an additional year to perform the verification analysis. The Periodicity Table also addresses scenarios which could require additional testing and subsequent model re-verification. The Periodicity Table will enable Generator Owners to quickly determine required retest dates for model verification.
6. Several industry responders asked if the standard was applicable to wind generation. As detailed in the Response to Comments document posted on the NERC website, the Applicability section MVA threshold in the first posting of standard MOD-026 resulted in wind powered units not being subject to this standard because individual wind units are not rated greater than 20 MVA. However, since there are an increasing number of wind farms with significantly larger aggregate MVA, their impact on the reliability of the Bulk Electric System cannot be ignored; otherwise, a reliability gap would exist. Therefore, as requested by industry, the SDT discussed the possibility of requiring verification of dynamic models that represent the aggregate of numerous small units and necessary auxiliary equipment required of the technology. This could include plant dynamic voltage control and reactive support of all the units and auxiliary equipment (such as individual WTG response, plant-wide volt/var controller response, and response from separate volt/var regulation devices contained in the plant such as SVC/STATCOM/Synchronous Condenser) contained in any technology generation plant, including a wind farm (plant), that exceeds the aggregate nameplate MVA threshold specified. There are dynamic models that adequately replicate performance for some wind units today. However, there are many existing wind units which do not have publicly available models supplied by the Original Equipment Manufacturer. Generic wind models (i.e., type I, II, III and IV) are in various stages of development. Also, there are ongoing efforts involving Regional Entities and manufactures to close any large gaps that may exist in current generic models. Thus, the SDT believes that generic wind farm

(plant) models will reach an appropriate state of maturity for establishing boundary conditions in Bulk Electric System Studies in advance of the eventual effective date of this standard. Therefore, to mitigate this reliability gap, the Applicability section has been expanded in the second posting of the standard to include a significant MVA percentage of all generation of all technologies. Specifically, based on review of in-service wind farm plant data, that includes approximately 80% of the wind farm plant MVA capacity in each Interconnection, the MVA threshold for plants was decreased from 200 MVA to 100 MVA for the Eastern and Quebec Interconnections, 150 to 75 MVA for the WECC Interconnection, and from 100 to 75 MVA for the ERCOT Interconnection (note – reducing the MVA threshold for plants in ERCOT any further would have exceeded the NERC Compliance Registry criteria. The 75 MVA plant threshold specified includes more than 80% of the wind farms in ERCOT). Additionally, the language makes clear that plant units less than 20 MVA should be verified in aggregate when possible.

The SDT drafted the first posting of the standard with minimal technical specificity so that either traditional staged testing, or ambient monitoring and other future techniques could be refined and utilized while still satisfying the Requirements. The SDT drafted a standard that concentrates on stating "what is required" but without stating "how to accomplish what is required", with peer review processes. Based on industry comments, the present draft of the standard maintains this same philosophy.

Several industry responders pointed out that the first posting version of the draft standard arguably contained non-reliability related requirements, and/or the chronological and procedural style resulted in a cumbersome document that was hard to follow. With this feedback, the SDT refined the standard to contain only reliability related requirements. This effort resulted in the creation of a Periodicity Table which is an attachment to the draft standard but is not a standalone requirement. Also, activities that are expected to occur infrequently, such as the "peer review" process, have been incorporated into Requirement Parts that are not intermingled with the 10 year periodic model verification base tasks. The SDT also combined all information the Generator Owner has to provide the Transmission Planner following successful model verification into a single section (reference requirement R2, Parts 2.1.1 through 2.1.6 of the revised standard). This information also includes the generator model data used in the excitation control system verification process however, the SDT stopped short of requiring generator model data verification. The majority of industry comments indicated a separate SAR would be required for a generator model verification standard.

The SDT discussed if standard MOD-026-1 should also include verification of excitation control systems of synchronous condensers[1]. Synchronous condensers are not currently addressed in the NERC Registry Criteria. Synchronous condensers are not mentioned in the Generation Verification SAR. On an MVA capacity basis, the penetration of Synchronous condensers in North America is extremely low. It is common for Transmission Owners to be the owners of synchronous condensers. As such, the peer review draft requirements would not make sense. There is no peer review requirements incorporated into standard MOD-025 which address steady state modeling thus, the inclusion of synchronous condensers in

[1] Note this does not include hydro generators which can operate in a "synchronous condenser" mode. If this mode of operation is expected, then the model should reflect this operating state.

standard MOD-025 is a better fit. Also, if Transmission Owners decide to pay for synchronous condenser installation and maintenance, which by its very nature does not generate Real Power as a source of revenue, then by default the apparatus is installed for dynamic voltage support; most likely to extend a dynamic voltage security limit. Therefore, the Transmission Owner should be highly motivated to understand and model synchronous condenser dynamic behavior. Therefore, the SDT decided that if there is a need to develop a Reliability Standard to model the expected dynamic behavior of dynamic voltage devices typically owned by Transmission entities, then a more appropriate strategy is to include Synchronous Condensers along with other transmission system dynamic reactive devices (such as SVCs, STATCOMs, etc.) into a separate SAR.

The first posting of the draft standard proposed an implementation plan requiring 10% of a Generator Owner's applicable units to be verified within two years following standard approval, 50% within six years following standard approval, and 100% within eleven years following standard approval. Concern was raised regarding the start up time to establish processes that this standard would require. For this concern, the SDT decided to extend the timeframe following standard approval for the first set of models required to be verified from "after 2 years of regulatory approval, 10% of its applicable units per Interconnection on a MVA basis" to "…four years following applicable regulatory approval….Each Generator Owner shall ensure at least 30% of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2." In addition to allowing entities additional start up time to develop this expertise, the new timeline allows traditional staged testing to be performed concurrent with the planned maintenance outage schedule. The language "being compliant with R1" means that suitable voltage excursion data has to be collected per the Periodicity Table. Entities actually have an additional year to analyze the voltage excursion data to verify the model and communicate the results to the Transmission Planner. Finally, the SDT has accepted the recommendation to allow verification of excitation system model(s) with established Regional Entity procedures and guidelines for demonstrating compliance with this new standard if the verification is completed within 10 years of standard approval (reference the proposed Implementation Plan).

Differences also exist between MOD-026-1 and MOD-027-1:

1) The implementation plan for standard MOD-027-1 is structured to recognize that Generator Owners will either need to install equipment to record the real power output of units during an appropriate frequency excursion or modify the existing recording equipment (such as frequency triggers, recording time, etc.). The proposed implementation plan specifies compliance with R2 at intervals of 25% of applicable units per Interconnection on a MVA basis three years after the effective date, 50% at five years, 75% at seven years, and 100% at nine years. Compliance with R2 as per the Periodicity Table (Table 1), means that beginning on the implementation date, the Generator Owner has 10 years to obtain an appropriate recorded response, and 2 years after obtaining the appropriate recorded response to verify the model (see Item 4 below that discusses exceptions to the aforementioned timeframe).

2) Like the draft standard for verification of excitation control system models, this draft standard allows for both staged tests and for ambient monitoring. However, the SDT expects that the majority of turbine/governor and load control functions will be verified through ambient monitoring. To ensure the impact of outer loop controls is captured and replicated in the model, the standard allows

staged tests where a frequency reference change is applied if the unit is on-line. This type of test is not common. Many units do not have a frequency reference change input where such a signal can be applied. Therefore, the SDT recognized that the Generator Owner's opportunity to verify that the predicted model response matches the recorded response for an appropriate system frequency excursion will often be dependent on its unit being on-line and in an operating state to respond to the system frequency excursion when it occurs. The basis for this strategy is:

a. Large economical units have a higher probability of being on-line in a proper operating state to experience a frequency excursion requiring model verification.
b. Units which are not on-line or not in a proper operating state will not help arrest the frequency excursion. Even if this is not the case, it is better to experience an event for model verification as opposed to relying on a survey that may be inaccurate.

3) In the current draft of MOD-026, the Generator Owner has one year from the capture of a voltage excursion to verify the excitation control system model. This timeframe is based on the SDT's belief that the majority of exciters will be verified using a staged test; and if ambient monitoring is utilized, there will be frequent naturally occurring transmission system voltage excursions. Since the SDT anticipates that the majority of the units' turbine/governor and load control models will be verified utilizing ambient monitoring, it is recognized that it is appropriate to give the Generator Owner time to retrieve captured data. Unlike ambient voltage excursion data needed for excitation control system model verification, the unit must be in an operating state that would allow the unit to respond to the frequency excursion. Also, it is likely that the number of acceptable frequency excursions (from a compliance perspective) will be significantly fewer than the number of acceptable voltage excursions that would occur for model verification. Therefore, the SDT decided to allow the Generator Owner two years for verifying the model. This timeframe allows adequate time to a) realize the event has occurred while the unit was in the proper operating state, and b) to verify the model. This timeframe will also assist the Generator Owner with planning contractor, budget and schedule support if activities are outsourced.

4) A unit has to be on-line and in the proper operating state during a frequency excursion in order to capture an effective real power response for model verification. Therefore, the standard provides time for the Generator Owner to capture and record a response requiring verification, even if it takes longer than ten years to do so. This language, which is contained in the Periodicity Table, is specifically crafted so that extension of the ten year periodicity cycle will only happen if a frequency excursion does not occur with the unit on-line and in the proper operating state. Therefore, the lack of installed and operating recording equipment during a frequency excursion is not a valid excuse for obtaining a ten year timeframe extension.

5) Industry experience has shown that a unit's real power response to a system frequency excursion could be different from one event to the next. Reasons include different unit load levels, prime mover control conditions, operator control mode, and magnitude of the frequency deviation. By contrast, excitation control

system responses to system voltage excursions are much more consistent. Therefore, the main model verification requirement (R2 Part 2.1.1) calls for the turbine/governor and load control model to be “compared to” the recorded response of actual equipment whereas in standard MOD-026-1, the wording is “matches”.

6) In standard MOD-026-1 R3 there is a process where a Transmission Planner can make a written request, including evidence that the excitation control system (or plant volt/var) model response did not match an actual recorded response, to the Generator Owner which essentially requires the Generator Owner to review the model. While there is similar language in standard MOD-027-1 R3, there is the additional stipulation that the Transmission Planner must include supporting evidence of instances where model response did not match an actual recorded response. The reason for this is that the governor response is not consistent enough from one frequency excursion event to the next for several reasons, such as the operating condition of the plant, ambient temperature, the number of coal pulverizes on line, the pre-contingency MW output of the unit, etc. In fact, while the fundamental requirement for verifying the model once every ten years can be satisfied by taking into account only a single frequency excursion, it is strongly recommended that model verification be performed taking into account multiple frequency excursions (if available and assuming the unit was in a proper operating state as required for model verification).

7) The activity specified in Requirement R4 is similar to draft standard MOD-026-1 Requirement, R4 which lists the evidence of compliance that the Generator Owner must maintain whenever certain activities occur that alter the equipment response; resulting in providing either revised model data or re-verifying the model. Unlike excitation control systems, there are many control parameters associated with the turbine/governor and load control system which will not impact equipment performance that is required to be replicated in the dynamic model. Thus, standard MOD-027-1 Requirement R4 is specifically crafted to only include setting changes for droop, and/or dead band, and/or load control mode. Since it is likely that many Generator Owners will rely on the expertise of consultants to make the determination of how modifications to droop, dead band, and/or load control mode translate into modified model parameter values, a time period of 180 days is proposed.

8) In MOD-026-1, the SDT is proposing a process where the Planning Coordinator can request a review of an excitation control system model for a unit not specified in the standard Applicability section. The new MOD-026-1 Requirement (R5) was added in response to industry comments. It requires the Planning Coordinator to supply technical justification that demonstrates either a) the unit affects a stability limit, or b) the simulated unit response does not match a measured unit response (most likely captured during a system disturbance event). However, this process is not being proposed for MOD-027-1. It is extremely unlikely that the turbine/governor and load control or active power/frequency control system will contribute to a stability limit. Also, as already discussed (Item 6), governor response is not consistent from one frequency excursion event to the next. Therefore, the SDT did not feel that such a Requirement in MOD-027-1 was necessary.

9) There is no need for the Transmission Planner to provide the generator MVA base when providing models for turbine/governor and load control or active power/frequency control systems. The MVA base associated with the generator model is already required to be provided per Requirement R1 of standard MOD-026. The MW base information is reflective of turbine capability and is provided as one of the turbine/governor and load control model data parameters specified. The MW base information, depending on the dynamic simulation software provider model requirements, will either be in the form of an actual MW value or a per unit MW value; with the base being the MVA value that is used in the generator steady state model.

10) The Generation Verification SDT is closely following and coordinating with the Frequency Response SDT. It is hoped that the Frequency Response SDT will create a process where frequency excursions meeting certain criteria for each Interconnection are captured. However, though the Frequency Response SDT has discussed this concept and is investigating the use of a tool to help facilitate the identification of appropriate frequency excursions, the process is still evolving. As an interim step, the Generation Verification SDT has included minimum frequency excursion thresholds in the Periodicity Table for each Interconnection that a) are large enough to be expected to exercise turbine/governor and load control functions for the purpose of model verification and b) would be expected to occur 15 times a year or more. If by chance a process identifying frequency excursions that can be utilized in support of standard MOD-027-1 requirements is not developed by the Frequency Response SDT, then such a process will have to be proposed for future revision to standard MOD-027-1 by the Generation Verification SDT.

Compliance Elements for MOD-026-1:

The SDT added Compliance Elements to the second posting of the standard. The VRF's for Requirements R1-R6 are all designated as low risk. All of these Requirements provide for an update of dynamic modeling data for an existing unit. Violation of these requirements would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system, which is consistent with the low risk level guidelines.

The VSLs for Requirement R2 was selected using the metric of "Requirements with Parts that Contribute Equally to the Requirement". All of the items listed in Requirement R2 are required for successful model verification. The remaining VSLs were selected using the metric of "Increments for Tardiness". The Requirements cover activities that are not typical such as peer reviews and instances where there is concern that the model does not reliably reflect actual equipment performance. As such, timeliness of communications is paramount.

You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. The Applicability section of MOD-026 standard is expanded to include plants/facilities comprised of multiple small units such as variable energy resource plants/facilities. Are you aware of other generation configurations/types that should be covered in the Applicability?

   ☐ Yes

   ☐ No

   Comments:

2. The current version of the MOD-026 standard has been re-formatted so that it would be more concise and contain only reliability related requirements. Do you agree there are no omissions from the prior draft due to the re-formatting of the standard?

   ☐ Yes

   ☐ No

   Comments:

3. The SDT discussed if MOD-026-1 should also include verification of excitation control systems of synchronous condensers. Synchronous condensers are not currently addressed in the NERC Registry Criteria. Synchronous condensers are not mentioned in the Generation Verification SAR. On an MVA capacity basis, the penetration of synchronous condensers in North America is extremely low. It is common for Transmission Owners to be the owners of synchronous condensers. As such, the peer review draft requirements would not make sense. Therefore, the team decided that a more appropriate strategy would be to include synchronous condensers with other transmission system dynamic reactive devices (such as SVCs, STATCOMs, etc.) in a separate SAR.

   Do you agree with the proposal to not include the verification of synchronous condensers in MOD-026-1?

   ☐ Yes

   ☐ No

   Comments:

4. Do you have any other questions or concerns with the proposed standards that have not been addressed? If yes, please explain.

   ☐ Yes

   ☐ No

Unofficial Comment Form for Generator Verification (Project 2007-09)

Please **DO NOT** use this form to submit comments. Please use the electronic comment form located at the link below to submit comments on the Second Posting of PRC-024-1 Generator Performance During Voltage and Frequency Excursions (Project 2007-09). The electronic comment form must be completed by **August 1, 2011.**

Project 2007-09 Generator Verification

If you have questions please contact Stephen Crutchfield at Stephen.Crutchfield@nerc.net or by telephone at 609-651-9455.

Background Information

The purpose of Project 2007-09 Generator Verification is:

- To ensure that generators will not trip off-line during specified voltage and frequency excursions or as a result of improper coordination between generator protective relays and generator voltage regulator controls and limit functions (such coordination will include the generating unit's capabilities).

- To ensure that generator models accurately reflect the generator's capabilities and operating characteristics.

The standard drafting team (SDT) for Project 2007-09 Generator Verification based its work on two existing NERC Board approved standards:

- MOD-024-1 — Verification of Generator Gross and Net Real Power Capability.

- MOD-025-1 — Verification of Generator Gross and Net Reactive Power Capability.

And four draft standards developed by the Phase III & IV SDT that were fielded tested by four Regions from mid 2006 through mid 2007.

- PRC-019-1 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection

- PRC-024-1 — Generator Performance During Frequency and Voltage Excursions

- MOD-026-1 —Verification of Models and Data for Generator Excitation Control System Functions

- MOD-027-1 — Verification of Generator Unit Frequency Response

The second posting of standard PRC-024-1 Generator Performance During Voltage and Frequency Excursions was developed with consideration of industry response to questions that were posed as part of the Comment Form accompanying the first posting.

One of the major issues that the SDT presented to industry during the first posting was the consideration of a relay setting standard versus a performance standard. Based on comments from the first posting, the SDT has again carefully reviewed the original SAR and FERC Order 693, and has modified the standard to reflect requirements for relay settings and performance. For existing generators, the requirements for frequency and voltage are centered around relay settings and on communicating to the planning entities the anticipated performance of a generator during a voltage or frequency excursion. The FERC Order stated that generators should either ride through the events, or be modeled as tripping. For new generators, the SDT has modified the standard to include performance requirements.

After considering comments the SDT has kept the applicability to Generator Owners as described in the NERC Compliance Registry Criteria.

The SDT also considered including synchronous condensers as applicable facilities for this standard. We determined that it is not necessary to include synchronous condensers because frequency transients within the scope of this standard are not a serious concern for synchronous condensers, and most synchronous condensers do not have the auxiliary systems that would cause a condenser to trip under the voltage transients defined in this standard.

The requirements for frequency relay settings were based upon reviews of manufacturers' information, existing regional requirements and coordination with the Under Frequency Load Shedding SDT.

The drafting team intends Requirement R5 to address parameters that the generating unit(s) or plant/facility ride through during Frequency/Voltage Excursions. The SDT does not intend the standard to address dynamic instability, transient instability or any form of loss of synchronism.

You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. There are two new terms proposed in this standard. "Frequency Excursion" and "Voltage Excursion". The former defined as an exceedance of system frequency beyond a continuous operating band; 60±0.5 Hertz. The latter defined as an exceedance of system voltage beyond a continuous operating band; ±5% of scheduled voltage. Do you agree with these new terms and their definitions? If not, please explain.

   ☐ Yes

   ☐ No

   Comments:

2. Requirements R1 and R2 detail the required frequency and voltage protective relaying settings for both new and existing units or generating plant/facilities that opt to activate these relays. Does the current draft of these two requirements, including footnote 1, clarify that a Generator Owner is not required to have protective relaying installed or set for these functions? If you do not believe the requirement is clear, please provide alternative language to clarify the intent.

   ☐ Yes

   ☐ No

   Comments:

3. Requirement R4 has been added for owners of existing units or generating plant/facilities to provide an estimate of the performance of the units during frequency and voltage excursions. This information is intended to provide Transmission Planners with information useful in performing planning studies. Do you agree with this approach? If not please explain and provide alternative language.

   ☐ Yes

   ☐ No

   Comments:

4. Requirement R5 requires a Generator Owner's new unit or generating plant/facility to be able to stay on line when exposed to point-of-interconnection frequency or voltage excursions depicted in the curves of Attachment 1 and Attachment 2. Do you believe this requirement is technically achievable for new units or generating plant/facilities? Please provide comments supporting your answer.

   Please provide along with your comment, what you believe the timeframe is needed to implement this requirement.

   ☐ Yes

   ☐ No

   Comments:

5. The voltage ride-through Tables HVRT and LVRT Duration in Attachment 2, specify time duration of up to 600 seconds that a unit or a generating plant/facility should ride through a voltage excursion. Do you agree with this time duration value? If not, please provide an alternative value and supporting information in the comments.

   ☐ Yes

   ☐ No

   Comments:

6. Do you have any other questions or concerns with the proposed standard that have not been addressed? If yes, please explain.

   ☐ Yes

   ☐ No

Standards Announcement

Project 2007-09 Generator Verification
Ballot Pool Windows Open: June 15 – July 15, 2011
Formal Comment Period Open (Two Standards): June 15 – August 1, 2011
Formal Comment Period Open (Three Standards): June 15 – July 15, 2011

Now available at: http://www.nerc.com/filez/standards/http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html

The Generator Verification standard drafting team has posted five standards and their associated implementation plans for a formal comment period. Please read the following announcement carefully, because although the five standards are being posted together they are at different stages in the standards process and in order to facilitate moving forward those standards that reach consensus, the standards are being processed independently.

1. MOD-026-1 and PRC-024-1 Formal Comment Period and Ballot Pool Formation

Two of the standards, MOD-026-1 – Verification of Models and Data for Generator Excitation System Functions, and PRC-024-1– Generator Frequency and Voltage Protective Relay Settings, are posted for a 45-day formal comment period through August 1, 2011. A ballot and non-binding poll of the associated VRFs and VSLs will be conducted for MOD-026-1 and PRC-024-1 beginning on July 22, 2011. Please note that **separate ballot pools are being formed for each standard and non-binding poll**, and the window to join the ballot pool for each standard and each non-binding poll is open through July 15, 2011.

Ballot Pools Open through 8 a.m. EST on July 15, 2011 for MOD-026-1 and PRC-024-1 Ballots and Non-binding Polls

The Standards Committee has authorized posting these standards and their associated implementation plans for a 45-day formal comment period with an initial ballot and concurrent non-binding poll conducted during the last 10 days of that comment period. A separate ballot pool is being formed for each standard and for each non-binding poll in order to allow Registered Ballot Body members to selectively join those ballot pools in which they have an interest. To register an opinion in the non-binding poll for either standard, you must join the ballot poll for that non-binding poll. Each of the four ballot pools will be open through 8 a.m. EST on July 15, 2011.

Instructions for Joining Ballot Pools for MOD-026-1 and PRC-024-1 Ballots and Non-binding Polls

Registered Ballot Body members may join each of the ballot pools to be eligible to vote in the upcoming ballots and non-binding polls at the following page: https://standards.nerc.net/BallotPool.aspx

During the pre-ballot window, members of the ballot pool may communicate with one another by using their "ballot pool list server." (Once the balloting begins, ballot pool members are prohibited from using the ballot pool list servers.) The list servers for this project are:

- MOD-026-1 ballot bp-2007-09_MOD-026-1_in@nerc.com
- MOD-026-1 non-binding poll bp-2007-09_MOD-026-1_NB_in@nerc.com

- PRC-024-1 ballot bp-2007-09_PRC-024-1_in@nerc.com
- PRC-024-1 non-binding poll bp-2007-09_PRC-024-1_NB_in@nerc.com

Instructions for Commenting

Please use this electronic form to submit comments on MOD-026-1 and PRC-024-1. If you experience any difficulties in using the electronic form, please contact Monica Benson at monica.benson@nerc.net. An off-line, unofficial copy of the comment form is posted on the project page: http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html.

2. MOD-025-2, MOD-027-1, and PRC-019-1 Formal Comment Period

Three additional standards have been posted for a 30-day formal comment period:

- MOD-025-2 – Verification of Generator Gross and Net Reactive Power Capability
- MOD-027-1 – Verification of Models and Data for Turbine/Governor and Load Control or Active Power/Frequency Control Functions
- PRC-019-1 – Coordination of Generating Unit or Plant Voltage Regulating Controls with Generating Unit or Plant Capabilities and Protection

Instructions for Commenting

Please use this electronic form to submit comments on MOD-025-2, MOD-027-1, and PRC-019-1. If you experience any difficulties in using the electronic form, please contact Monica Benson at monica.benson@nerc.net. An off-line, unofficial copy of the comment form is posted on the project page: http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html.

Next Steps

Initial ballots of MOD-026-1 and PRC-024-1, and concurrent non-binding polls of the associated VRFs and VSLs, will begin on July 22, 2011 and end at 8 p.m. Eastern on Monday, August 1, 2011. Following the formal comment period for MOD-025-2, MOD-027-1, and PRC-019-1, the drafting team will consider all comments and determine whether to make changes to the standards, implementation plans, or associated VRFs and VSLs.

Background

The purpose of Project 2007-09 - Generator Verification is to ensure that: 1) generators will not trip off-line during specified voltage and frequency excursions or as a result of improper coordination between generator protective relays and generator voltage regulator controls and limit functions (such coordination will include the generating unit's capabilities); and 2) that generator models accurately reflect the generator's capabilities and operating characteristics.

The standard drafting team (SDT) for Project 2007-09 Generator Verification based its work on two existing NERC Board approved standards, MOD-024-1 — Verification of Generator Gross and Net Real Power Capability and MOD-025-1 — Verification of Generator Gross and Net Reactive Power Capability. The drafting team has recently moved the Requirements of MOD-024-1 into MOD-025-2 and recommends retiring MOD-024-1.

The drafting team has also based its work on four draft standards developed by the Phase III & IV SDT that were field tested by four Regions from mid 2006 through mid 2007:

- PRC-019-1 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection
- PRC-024-1 — Generator Performance During Frequency and Voltage Excursions

- MOD-026-1 —Verification of Models and Data for Generator Excitation Control System Functions
- MOD-027-1 — Verification of Generator Unit Frequency Response

Additional details are available on the project web page at http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html.

Standards Process

The Standard Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

For more information or assistance, please contact Monica Benson,
Standards Process Administrator, at monica.benson@nerc.net or at 404-446-2560.

2. MOD-025-2, MOD-027-1, and PRC-019-1 Formal Comment Period

Three additional standards have been posted for a 30-day formal comment period:

- MOD-025-2 – Verification of Generator Gross and Net Reactive Power Capability
- MOD-027-1 – Verification of Models and Data for Turbine/Governor and Load Control or Active Power/Frequency Control Functions
- PRC-019-1 – Coordination of Generating Unit or Plant Voltage Regulating Controls with Generating Unit or Plant Capabilities and Protection

Instructions for Commenting

Please use this electronic form to submit comments on MOD-025-2, MOD-027-1, and PRC-019-1. If you experience any difficulties in using the electronic form, please contact Monica Benson at monica.benson@nerc.net. An off-line, unofficial copy of the comment form is posted on the project page: http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html.

Next Steps

Initial ballots of MOD-026-1 and PRC-024-1, and concurrent non-binding polls of the associated VRFs and VSLs, will begin on July 22, 2011 and end at 8 p.m. Eastern on Monday, August 1, 2011. Following the formal comment period for MOD-025-2, MOD-027-1, and PRC-019-1, the drafting team will consider all comments and determine whether to make changes to the standards, implementation plans, or associated VRFs and VSLs.

Background

The purpose of Project 2007-09 - Generator Verification is to ensure that: 1) generators will not trip off-line during specified voltage and frequency excursions or as a result of improper coordination between generator protective relays and generator voltage regulator controls and limit functions (such coordination will include the generating unit's capabilities); and 2) that generator models accurately reflect the generator's capabilities and operating characteristics.

The standard drafting team (SDT) for Project 2007-09 Generator Verification based its work on two existing NERC Board approved standards, MOD-024-1 — Verification of Generator Gross and Net Real Power Capability and MOD-025-1 — Verification of Generator Gross and Net Reactive Power Capability. The drafting team has recently moved the Requirements of MOD-024-1 into MOD-025-2 and recommends retiring MOD-024-1.

The drafting team has also based its work on four draft standards developed by the Phase III & IV SDT that were field tested by four Regions from mid 2006 through mid 2007:

- PRC-019-1 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection
- PRC-024-1 — Generator Performance During Frequency and Voltage Excursions

- MOD-026-1 —Verification of Models and Data for Generator Excitation Control System Functions
- MOD-027-1 — Verification of Generator Unit Frequency Response

Additional details are available on the project web page at http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html.

Standards Process

The Standard Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

Standards Announcement

Project 2007-09 Generator Verification
Ballot Pool Windows Open: June 15 – July 15, 2011
Formal Comment Period Open (Two Standards): June 15 – August 1, 2011
Formal Comment Period Open (Three Standards): June 15 – July 15, 2011

Now available at: http://www.nerc.com/filez/standards/http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html

The Generator Verification standard drafting team has posted five standards and their associated implementation plans for a formal comment period. Please read the following announcement carefully, because although the five standards are being posted together they are at different stages in the standards process and in order to facilitate moving forward those standards that reach consensus, the standards are being processed independently.

1. MOD-026-1 and PRC-024-1 Formal Comment Period and Ballot Pool Formation

Two of the standards, MOD-026-1 – Verification of Models and Data for Generator Excitation System Functions, and PRC-024-1– Generator Frequency and Voltage Protective Relay Settings, are posted for a 45-day formal comment period through August 1, 2011. A ballot and non-binding poll of the associated VRFs and VSLs will be conducted for MOD-026-1 and PRC-024-1 beginning on July 22, 2011. Please note that **separate ballot pools are being formed for each standard and non-binding poll**, and the window to join the ballot pool for each standard and each non-binding poll is open through July 15, 2011.

Ballot Pools Open through 8 a.m. EST on July 15, 2011 for MOD-026-1 and PRC-024-1 Ballots and Non-binding Polls

The Standards Committee has authorized posting these standards and their associated implementation plans for a 45-day formal comment period with an initial ballot and concurrent non-binding poll conducted during the last 10 days of that comment period. A separate ballot pool is being formed for each standard and for each non-binding poll in order to allow Registered Ballot Body members to selectively join those ballot pools in which they have an interest. To register an opinion in the non-binding poll for either standard, you must join the ballot poll for that non-binding poll. Each of the four ballot pools will be open through 8 a.m. EST on July 15, 2011.

Instructions for Joining Ballot Pools for MOD-026-1 and PRC-024-1 Ballots and Non-binding Polls

Registered Ballot Body members may join each of the ballot pools to be eligible to vote in the upcoming ballots and non-binding polls at the following page: https://standards.nerc.net/BallotPool.aspx

During the pre-ballot window, members of the ballot pool may communicate with one another by using their "ballot pool list server." (Once the balloting begins, ballot pool members are prohibited from using the ballot pool list servers.) The list servers for this project are:

- MOD-026-1 ballot — bp-2007-09_MOD-026-1_in@nerc.com
- MOD-026-1 non-binding poll — bp-2007-09_MOD-026-1_NB_in@nerc.com

- PRC-024-1 ballot   bp-2007-09_PRC-024-1_in@nerc.com
- PRC-024-1 non-binding poll   bp-2007-09_PRC-024-1_NB_in@nerc.com

Instructions for Commenting

Please use this electronic form to submit comments on MOD-026-1 and PRC-024-1. If you experience any difficulties in using the electronic form, please contact Monica Benson at monica.benson@nerc.net. An off-line, unofficial copy of the comment form is posted on the project page: http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html.

2. MOD-025-2, MOD-027-1, and PRC-019-1 Formal Comment Period

Three additional standards have been posted for a 30-day formal comment period:

- MOD-025-2 – Verification of Generator Gross and Net Reactive Power Capability
- MOD-027-1 – Verification of Models and Data for Turbine/Governor and Load Control or Active Power/Frequency Control Functions
- PRC-019-1 – Coordination of Generating Unit or Plant Voltage Regulating Controls with Generating Unit or Plant Capabilities and Protection

Instructions for Commenting

Please use this electronic form to submit comments on MOD-025-2, MOD-027-1, and PRC-019-1. If you experience any difficulties in using the electronic form, please contact Monica Benson at monica.benson@nerc.net. An off-line, unofficial copy of the comment form is posted on the project page: http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html.

Next Steps

Initial ballots of MOD-026-1 and PRC-024-1, and concurrent non-binding polls of the associated VRFs and VSLs, will begin on July 22, 2011 and end at 8 p.m. Eastern on Monday, August 1, 2011. Following the formal comment period for MOD-025-2, MOD-027-1, and PRC-019-1, the drafting team will consider all comments and determine whether to make changes to the standards, implementation plans, or associated VRFs and VSLs.

Background

The purpose of Project 2007-09 - Generator Verification is to ensure that: 1) generators will not trip off-line during specified voltage and frequency excursions or as a result of improper coordination between generator protective relays and generator voltage regulator controls and limit functions (such coordination will include the generating unit's capabilities); and 2) that generator models accurately reflect the generator's capabilities and operating characteristics.

The standard drafting team (SDT) for Project 2007-09 Generator Verification based its work on two existing NERC Board approved standards, MOD-024-1 — Verification of Generator Gross and Net Real Power Capability and MOD-025-1 — Verification of Generator Gross and Net Reactive Power Capability. The drafting team has recently moved the Requirements of MOD-024-1 into MOD-025-2 and recommends retiring MOD-024-1.

The drafting team has also based its work on four draft standards developed by the Phase III & IV SDT that were field tested by four Regions from mid 2006 through mid 2007:

- PRC-019-1 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection
- PRC-024-1 — Generator Performance During Frequency and Voltage Excursions

- MOD-026-1 —Verification of Models and Data for Generator Excitation Control System Functions
- MOD-027-1 — Verification of Generator Unit Frequency Response

Additional details are available on the project web page at http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html.

Standards Process

The Standard Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

Revised: Standards Announcement

Project 2007-09 Generator Verification
Results of Two Initial Ballots and Non-binding Polls

Update now available at: https://standards.nerc.net/Ballots.aspx

Initial ballots of two standards, MOD-026-1 – Verification of Models and Data for Generator Excitation System Functions, and PRC-024-1– Generator Frequency and Voltage Protective Relay Settings, and concurrent, non-binding polls of the associated VRFs and VSLs concluded on Monday, August 1, 2011.

Revised Ballot Results for MOD-026-1 and PRC-024-1

Updated voting statistics for each standard are listed in the table below, and the Ballot Results Web page provides a link to the detailed results.

Standard	Ballot Results	Non-binding Poll Results
MOD-026-1 – Verification of Models and Data for Generator Excitation System Functions	Quorum: 90.25% Approval: 46.53%	88.75% of those who registered to participate provided an opinion or abstention; 56% of those who provided an opinion indicated support for the VRFs and VSLs
PRC-024-1– Generator Performance During Frequency and Voltage Excursions	Quorum: 90.82% Approval: 18.23%	88.35% of those who registered to participate provided an opinion or abstention; 20.79% of those who provided an opinion indicated support for the VRFs and VSLs

Reason for Revisions

We announced the ballot and non-binding poll results on August 5, 2011 and became aware yesterday that one company submitted a vote via e-mail that was not received by the process administrator due to a problem with NERC’s IT systems. The NERC IT department has been made aware of the situation and is researching the cause. We will provide stakeholders with an alternative method of submitting e-mail ballot which will be highlighted in any future ballot announcement. It is important to note that all votes submitted through NERC’s electronic balloting application have been received.

The only time votes are accepted via e-mail is for an entity that has registered someone in a ballot pool who is not in that role. When the ballot pool member is no longer available to cast a ballot for the entity, we make every effort to allow the entity to continue to participate in the ballot pool by manually entering the vote for the person designated as his/her replacement. Our software, in its current format does not update ballot pools when an entity's Registered Ballot Body member changes, which forces us to enter these ballots through the manual process.

We are committed to maintaining an accurate record of this ballot. If you sent your votes via e-mail, please review the attached ballot results to ensure that your votes are included (or view the project page for the updated posted results: http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html).

If you find that your entity's votes were not posted, please call Monica Benson at 404-446-2573. You will need to send verification of any e-mail vote showing that the ballot was sent before the close of the ballot window, which will be forwarded to our IT department for review.

Thank you for your patience and understanding as we make any necessary voting result updates to ensure that accurate voting records are posted.

For more information or assistance, please contact Monica Benson,
Standards Process Administrator, at monica.benson@nerc.net or at 404-446-2560.

Standards Announcement

Project 2007-09 Generator Verification
Results of Two Initial Ballots and Non-binding Polls

Now available at: https://standards.nerc.net/Ballots.aspx

Initial ballots of two standards, MOD-026-1 – Verification of Models and Data for Generator Excitation System Functions, and PRC-024-1– Generator Frequency and Voltage Protective Relay Settings, and concurrent, nonbinding polls of the associated VRFs and VSLs concluded on Monday, August 1, 2011.

Ballot Results for MOD-026-1 and PRC-024-1

Initial ballots of MOD-026-1 – Verification of Models and Data for Generator Excitation Control System Functions, and PRC-024-1– Generator Performance During Frequency and Voltage Excursions and non-binding polls of the VRFs and VSLs associated with each standard concluded on Monday, August 1, 2011.

Voting statistics for each standard are listed in the table below, and the Ballot Results Web page provides a link to the detailed results.

Standard	Ballot Results	Non-binding Poll Results
MOD-026-1 – Verification of Models and Data for Generator Excitation System Functions	Quorum: 89.94% Approval: 47.24 %	88.75% of those who registered to participate provided an opinion or abstention; 56% of those who provided an opinion indicated support for the VRFs and VSLs
PRC-024-1– Generator Performance During Frequency and Voltage Excursions	Quorum: 90.51% Approval: 18.50%	88.35% of those who registered to participate provided an opinion or abstention; 20.79% of those who provided an opinion indicated support for the VRFs and VSLs

Next Steps

The drafting team will consider all comments received (those submitted with a comment form, and make revisions to the standards. If substantive changes are made to the standards, the team will submit its documents for a quality review.

Background

The purpose of Project 2007-09 - Generator Verification is to ensure that: 1) generators will not trip off-line during specified voltage and frequency excursions or as a result of improper coordination between generator protective relays and generator voltage regulator controls and limit functions (such coordination will include the generating unit's capabilities); and 2) that generator models accurately reflect the generator's capabilities and operating characteristics.

The standard drafting team (SDT) for Project 2007-09 Generator Verification based its work on two existing NERC Board approved standards, MOD-024-1 — Verification of Generator Gross and Net Real Power Capability and MOD-025-1 — Verification of Generator Gross and Net Reactive Power Capability. The drafting team has recently moved the Requirements of MOD-024-1 into MOD-025-2 and recommends retiring MOD-024-1.

The drafting team has also based its work on four draft standards developed by the Phase III & IV SDT that were field tested by four Regions from mid 2006 through mid 2007:

- PRC-019-1 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection
- PRC-024-1 — Generator Performance During Frequency and Voltage Excursions
- MOD-026-1 —Verification of Models and Data for Generator Excitation Control System Functions
- MOD-027-1 — Verification of Generator Unit Frequency Response

AZPS believes this question applies to R5. In any event, this requirement does not add anything to the reliable modeling since most GO(s) will be making a guess, and that does not make the simulation any more accurate. Additionally, the requirement for providing this information within 30 days is unreasonable. It should be at least 90 days. There is no reliability reason for requiring this data within 30 days. These are long range planning studies and modeling data is usually submitted on the annual basis.
No
AZPS believes this question applies to R6. There should be an implementation period for the requirement for new units to allow the plants which have been ordered already to not to have to be redesigned.
Yes

The measurement M6 for the new plant is not clear. One does not know how long a time it would take to get a significant event. M6 should be written such that if a unit did not trip for a system event, it will be considered compliant.

Suggest replacing the term “scheduled voltage” with “nominal operating voltage”. Voltage schedules may change over time, whereas “nominal” or “rated” voltages do not. Also, the protective systems are usually set based on voltage excursions above, or below, “rated” or “nominal” voltage.
No
Footnote 1 does make it clear that the Generator Owner is not required to have frequency or voltage protective relaying. However, in the current draft, reference to footnote 1 appears to have been inadvertently omitted following the phrase “voltage protective relaying” in R2.
No
Believe this question is referring to Requirement R5 not R4 as stated in the question. Not sure how useful the R 5.2 probability assessment would be, therefore suggest eliminating that requirement. R 5.1 coupled with the basis requirement in R 5.3 would appear sufficient to quantitatively assess the performance during voltage and frequency excursions. Also, see responses to question #6.
Yes
Believe this question is referring to Requirement R6 not R5 as stated in the question. Yes, it is possible to design a new facility to operate within the requirements identified in this standard. However, it may require specification of equipment with higher than normal overvoltage capabilities. Also, significant analyses would have to be conducted on the behavior of plant control systems (exciter controls, boiler controls, etc.), as well as equipment connected to auxiliary busses (including low voltage motor contactors) to ensure that all systems are designed with appropriate ride-through capabilities. However, it is unclear how this standard would apply to the ride through capability of units connected to the BES, but whose source of auxiliary station service power is from a non-BES interconnection. Would the units also have to ride through expected voltage excursions at the point of interconnection with the station service transformer even if the station service transformer was not fed directly from the BES?
Yes
1) The applicability section from the previous draft of this standard should be re-inserted. Although the SDT chose to remove that section since the standard is intended to apply to all generation facilities that meet Compliance Registry Criteria, adding the specific generation criteria for which this standard applies within the body of the standard provides much more clarity than having to refer to a second document to define applicability. In addition, inserting the full applicability criteria would be consistent with the way Applicable Facilities are identified in Section 4.2 of PRC-019-1. 2) Requirement R 2.1.1 should be re-worded as follows: “For three-phase faults with Normal Clearing on transmission system facilities (lines, busses, transformers, etc.) adjacent to the point of interconnection, set voltage relays to ride through expected fault clearing times, not to exceed 9 cycles.” The use of the term “zone 1 faults” implies that zone 1 relaying schemes are always employed on the transmission system, which may not be the case. Pilot schemes, overcurrent schemes, differential schemes, etc. may be used instead. Also, the unit should stay connected if a fault were to occur on an adjacent bus or transformer rather than just on lines. Also, use of the term “Zone 1 fault” in Requirement R5 needs to be similarly addressed. 3) Requirement R 2.1.1 should also address ride through capability for TPL Category C contingencies (i.e. single line to ground faults with a stuck breaker, or other cause for delayed clearing) since generation units are expected to remain on

line during these contingencies as well. Granted, a three phase fault would be the most severe, however a single line to ground fault with delayed clearing times could also cause unwanted unit tripping, leading to a violation of Reliability Criteria. 4) The SDT in their response to comments on Draft #1 of this standard stated that “Attachment 2 was developed based on a positive sequence model. As such, only balanced voltages should be considered when addressing relay settings.” This is fine for evaluating the response to three phase faults, or other balanced system disturbances. However, if it is critical to the reliability of the BES to not have generators trip off line for voltage excursions associated with three phase faults, then it is equally as important to have them remain on-line for single line to ground faults, which are much more common. During a phase to ground fault at the point of interconnection the faulted phase voltage collapses to zero but the unfaulted phase to ground voltages could rise as high as 80% of the line to line voltage for an effectively grounded system (with a coefficient of grounding = 80%). This is well in excess of the 1.2 p.u. requirement shown in Attachment 2. Generator voltage protection relays respond to actual phase voltages not just positive sequence voltages. As such, for the unit to ride through phase to ground faults at the point of interconnection then the short time 1.2 p.u. overvoltage threshold needs to be raised above 0.8 x 1.73 = 1.38 p.u. 5) The revised language in R3 referring to “the equipment limitation expires coincident with ….” is unclear and confusing. How can the “limitation” expire merely by the generating unit continuous capacity rating being increased > 10%. The Draft #1 version of this standard uses the phrase “the Generator Owner is granted an exception for that unit meeting the portion of R1 or R2 for that limitation once it provides documentation of the equipment limitation(s)…” “This exception for the equipment limitation shall expire coincident with…” The use of the term “exception, or exemption”, makes more sense and is more in line with the intent of this section. As such, the original language from Requirement R5 from Draft #1 should be re-instated. 6) Typically unit connected generator protection packages, which include frequency and voltage protective elements, are supplied by voltage transformers connected on the terminals of the generator rather than on the high side of the generator step-up (GSU) transformer. For frequency elements, the frequency at the terminals of the generator is the same as on the high side of the GSU transformer. So comparison of frequency protective element set points can be made directly with Attachment 1. However, this is not true for voltage. The generator terminal voltage could be higher, or lower, than the system voltage on the high side of the GSU transformer depending on the voltage drop across the transformer, which varies depending on the generator real power output and whether the generator is supplying or absorbing reactive power. Since this standard requires the generation to remain connected for specific voltage criteria as measured at the point of interconnection, but the voltage sensing protection is connected to the generator terminals, some technical guidance (with specific examples) must be provided to allow the Generator Owner to translate these voltage criteria to the voltages seen by the protective relays on the terminals of the generator. Otherwise an incorrect evaluation may result. It is recommended that a Technical Reference Document similar to the “Power Plant and Transmission System Protection Coordination” document developed by the NERC System Protection and Control Subcommittee be produced, or the above mentioned document revised, to provide illustrative examples of how to apply the Attachment 2 POI voltage criteria to voltage sensing protective elements connected to the terminals of the generator. 7) Comments on “Voltage Ride-Through Curve Clarifications” which appears on the last page of the standard: Item#1 - Suggest replacing the term “scheduled operating voltage” with “nominal operating voltage”. Voltage schedules may change over time, whereas “nominal” or “rated” voltages do not. Also, the protective systems are usually set based on voltage excursions above, or below, “rated” or “nominal” voltage. Item #2 - Suggest eliminating item 2. The ride-through curve is to ensure the unit remains on line for voltage excursions up to the limits defined by Attachment 2, regardless of the cause of the voltage excursion. Item #3 – The use of the term “cumulative voltage duration” is confusing since Attachment 2 is made up of a series of discrete allowable voltage magnitudes and durations. Also, the language only mentions voltage protective relaying and not other non-protective equipment, which could cause the unit to trip. Suggest re-wording as follows: “The generator shall remain connected (i.e., “ride-through”) voltage excursions caused by disturbances on the transmission system, when the voltage at the point of interconnection with the BES remains within the boundaries of these curves.” Item #5 d – suggest removing the term “scheduled”, making it read “d. Voltage is measured at the point of interconnection”

Any requirement that requires reporting based on a deviation greater than a specified threshold, that threshold should be included in that requirement, refer to R5 as an example. With those stipulations, those new terms are not needed.
Yes
No
The reference to “R4” in this question should be R5.
No
The refererence to “R5” in this question should be R6.
Yes
Yes
In R3, the SDT should review that generators are not required to provide a remedial plan for an equipment limitation. For the SDT’s consideration is the work done by and for the NPCC UFLS RSDT. It was recommended to retain the more conservative NPCC Frequency Capability Curve for setting generator protection as opposed to the proposed Frequency Capability Curve in PRC-024-1 for the following reasons: 1. Some portions of the NPCC Region have additional stages of UFLS set at lower frequency thresholds below 58 Hz. Adopting the curve in Attachment 1 may impact the effectiveness of the UFLS program from arresting frequency decline in these depressed frequency ranges. 2. As the numbers of distributed generators connected to the system increase, it is expected that overall generator frequency response is expected to be reduced. The distributed generation may also not need to comply with the generation trip thresholds as they may not meet the existing thresholds applicable to Generator Owners in NERC’s Statement of Compliance Registry Criteria. Adopting the proposed PRC-024-1 curve would jeopardize the survival of islands that may contain increasingly larger portions of distributed generation should the frequency decline below 58 Hz. 3. Adopting the proposed PRC-024-1 curve reduces the probability that the UFLS program will successfully arrest declining frequency for system conditions that are not addressed in NPCC’s 2006 UFLS Assessment. 4. Adopting the proposed PRC-024-1 curve would decrease the ability of an island to survive more severe conditions than those considered in the UFLS design (for example, islands with a generation deficiency greater than 25 percent).

Yes
Yes
The applicability in this standard (≥100 MVA) is consistent with the applicability in MOD-027-1. However, the applicability in this standard is not consistent with MOD-025-2 and PRC-019-1. We propose that the SDT revise the applicability to be consistent between all of the standards included in this project.
No

We agree with the frequency excursion defined as +/-0.5Hz. We agree that ±5% is appropriate for normal operating conditions. However, this does not address contingencies or timeframes. The SPP regional criteria allows for a +5% to -10% change from nominal voltage on load serving buses under single contingency conditions. The Voltage Ride-Through Time Duration Curve in Attachment 2 does not appear to correspond with the proposed definition. The Voltage Ride-Through Time Duration Curve in Attachment 2 indicates that at 600 seconds, one would operate within the .95 and 1.05 normal conditions. SPP's regional criteria states that we can operate at a +5% to -10% of nominal voltage on load serving buses during a contingency. FERC pro-forma Generator Interconnection Agreement requirements should also be considered in the development of this definition. We propose that the SDT consider defining continuous. We are unclear if continuous means from zero to infinite.
Yes
No
This question better addresses R5 rather than R4. We propose that the SDT team consider revising the 30 day requirement to provide documentation of the equipment limitation to 90 days in R5. We recommend that 90 days is a more appropriate timeframe for supplying this documentation.
Yes
No
We suggest that the SDT provide the technical justification for this time duration. We do not agree with the time duration of up to 600 seconds. This time duration appears to be significantly long for voltage recovery. From a planning perspective, 15 cycles or 0.25 seconds is standard for voltage recovery. Holding 0.9 from 3 seconds to 600 seconds could be difficult if there is full load on the unit. There may not be enough bandwidth before a loss of field relay occurs. If enough current is provided to the field, it will cause the relay to trip instantaneously. FERC pro-forma Generator Interconnection Agreement requirements should also be considered in the development of the attachment.

New reliability standards should be accompanied by grandfathering provisions for existing generators and an implementation grace period of sufficient length to ensure that manufacturers have enough time to engineer their generators to comply with the standard and that generators for which purchase orders are already in the pipeline will not need to be re-designed. The grandfathering provisions and implementation grace period schedule that were included in FERC Order 661A should be sufficient to achieve those goals if they are incorporated into this standard.

We don't think exceedance is a word. Suggest changing it to "operating outside of a continuous range of 60+/- 0.5 Hz". We don't agree with using the phrase "scheduled voltage" as is staed in the question, but the actual standard uses "rated voltage" with which we do agree.

Synchronous condensers are installed at where they are specifically for voltage/VAR control purposes. The excitation performances of these units are thus known to be impactful to the local areas where they are located. If excitation parametric authenticity is of concern in a dynamic simulation study, then it would seem synchronous condenser performances are particularly of significance to their respective local areas. They should be included in the verification effort.
Yes
We have a number of questions and concerns as follows: • While the Standard uses the word “verified” and “verification” loosely, it is not precisely clear what a GO would have to do to satisfy the verification requirements in R2. Would each of the Time Constants, Forward and/or Feedback Gains, Dead-band Excitation Limits, Saturation Characteristics, etc. to be determined separately each on its own? Or are these parameters taken as a whole so long as their combined effect produces a response characteristic in a simulation that matches the recorded test response during an off-line step-input test? • If a simulation study results in response characteristics that does not match an off-line step input test response, can the GO arbitrarily adjust one or more of the model parametric values to produce a matching response, and send the Transmission Planner these adjusted values as the model data? • We have concern about whether this Standard is cost efficient to the industry. The transient stability dynamic modeling for excitation control was developed under the assumption of limited bandwidth validity and approximations. The other equipment models in the simulation, e.g. generators, prime-mover controls, SVCs, HVDC Converters, etc. are all approximations without any correlated degree of accuracies in comparison to each other. On the other hand, the verification efforts are expected to cost quite a bit to GOs, especially for older units whose vendors/manufacturers may not even be in existence any more.
Individual
Joe Petaski
Manitoba Hydro
No
Yes
No
Manitoba Hydro disagrees with the SDTs decision that a more appropriate strategy would be to include synchronous condensers with other transmission system dynamic reactive devices (such as SVCs, STATCOMs, etc.). The testing of the excitation system of a synchronous condenser is identical to the testing of the excitation system of a generator and will likely be planned, performed, documented and reported on by the same testing team responsible for testing the excitation systems of applicable generators. Placing synchronous condensers in the same category with SVCs,

STATCOMS, etc. introduces an unnecessary hardship to entities. It is suggested that the standard be re-written to include synchronous condensers within the same applicability MVA rating as generators.
Yes
1)For Section 4.2 Facilities, the section should refer to ‘BES Generating Units and Facilities’ instead of restating components of the proposed BES definition. 2)Attachment 1 is not clear. Specifically, -the “Condition” in the first row is not a condition and is not consistent with the remaining rows. -Row 1 suggests that there are no exceptions for submitting a recorded response of a voltage excursion, but Row 2 contradicts this by allowing a single unit to be ‘verified’ and serve as evidence for multiple units meeting the conditions listed. -the wording for the allowance of a representative unit to be verified and submitted as evidence for identical units is not clear. -the periodicity for row 1 suggests that a recorded response for a voltage excursion shall be collected ‘with the verified model’ which is incorrect. -We suggest the following. A statement that precedes the Attachment 1 table should be added that reads ‘For all Existing Generating Units - a recorded response for a voltage excursion shall be collected during a ten calendar year (January - December) period from the effective date of this standard and the documentation transmitted to the Transmission Planner no more than 365 calendar days from the date that the recorded response was collected unless otherwise specified by the table below. For all newly installed Generating Units - a recorded response for a voltage excursion shall be collected and the verified model and documentation transmitted to the Transmission Planner no more than 180 calendar days of the unit in service date unless specified otherwise specified by the table below. ’ Row 1 should then be Facility - Existing Generating Unit, Condition - All existing generating units unless the following exception applies: If multiple units have the same MVA rating that is ≤ 350 MVA, and they have identical applicable components and settings, and they are sited at the same physical location, verification of one representative unit is sufficient for all such units. Verification of a different representative unit should be completed each cycle, Periodicity - not required for any units except one representative unit.

This standard is highly administrative and full of compliance risks not associated with reliability. The purpose of the standard is to ensure that the GO provides an accurate model to the TP and ultimately to the PC. The requirements unnecessarily document the give and take that must occur between the GO and TP to produce a good model. R2, which essentially requires the GO to provide a good model,

is the only requirement needed. Everything else is just documentation related and unnecessary.
Yes
Yes
No
Requirement R4 references inquiries regarding equipment limitations that have been identified in R3. This particular question should apply to R5 instead. If applied to R5, the approach in theory seems reasonable.
Yes
R3 is an unnecessary requirement. Enforcement of R1 and R2 already create a de facto requirement to document limitations. Thus, R3 creates an opportunity for double jeopardy.

The implementation plan call for a certain % of applicable plants to be in compliance over a certain number of years. Since plants may be registered individually, it is unclear what the term applicable plants is referring to in the implementation phase. Oncor takes the position that the reporting requirements for the Generator Owner as specified in R1, R2,R3,R4,R5 & R6 should be to the Planning Authority and not the Transmission Planner in the ERCOT Region. This would align with the current protocols, operating guide and planning guide that require the ERCOT ISO to be the primary interface with Generation Resources. The ERCOT ISO is registered as the Planning Authority. One option would be a regional variance that would point to the Planning Authority or Planning Coordinator in lieu of the Transmission Planner.

Differences between draft 1 and draft 2 of MOD-026 appear to be significant. Without reading through all 134 pages of comments and how the SDT addressed those comments it is too difficult to tell how the requirements were evaluated and if omissions were intentional or not. Suggest that the SDT prepare either a mapping document or a "redline to previous version" to illustrate changes and disposition of such changes to ensure there are no omissions from the prior draft.
Yes
Yes
Requirement R2 Exelon is in agreement that the Generator Owner (GO) should provide the generator excitation control system and plant volt/var control model and any necessary input data; however, the Transmission Planner (TP) should be the entity that is responsible for the model verification. Transmission Planning organizations have the expertise to implement and test the models in software, while the GOs have the necessary access to the equipment in the field. Most GOs do not have the software and the necessary personnel with the expertise to perform the modeling and model testing required by this draft Standard. Typically, TPs currently have existing software programs to run the excitation system models. The overall quality of the verification would be best served by having the TP that has knowledge in the model performance verse the GOs that do not have the current expertise in model performance or dynamic system response evaluations. Exelon also believes that the Standard should specifically define the acceptance criteria. If the acceptance criteria are left up to the GOs, then the TOs may have to deal with multiple acceptance criteria within a single Region. At the same time, a single GO may have to work with multiple TOs, which will lead to inconsistency if definition of the acceptance criteria is left up to the TO. Requirement 2.1.1 The Standard needs to provide specific guidance as to what criteria a voltage excursion from either a staged test or a measured system disturbance should be in regards to performing the verification. In addition, the SDT should provide specific examples of what types of staged tests would be considered acceptable. It is difficult to comment on the potential impact to the generating units (especially a nuclear generating unit) without knowing the criteria.
No
The definitions provided for Frequency Excursion and Voltage Excursion are not consistently applied throughout the Standard. Several of the uses of the term “excursion” (R1.2, R5.1, R5.2, R6, etc…) refer to the graphs in Attachments 1 and 2, which are based on time characteristics. Exelon agrees that 60 HZ +/- 0.5 Hz is reflective of a (normal) continuous operating band; however, the voltage +/- 5% is not necessarily a (normal) continuous operating band of "scheduled voltage". The "scheduled voltage" should be consistent with VAR-001 and VAR-002. VAR-001 Requirement R.4 states: "Each Transmission Operator shall specify a voltage or Reactive Power schedule at the interconnection between the generator facility and the Transmission Owner's facilities to be maintained by each generator." VAR-002 Requirement R.2 states: "[Unless exempted by the Transmission Operator] each Generator Operator shall maintain the generator voltage or Reactive Power output … as directed by the Transmission Operator." Suggest that the definition for Voltage Excursion is revised to state "an exceedance of system voltage beyond (i.e., outside) nominal operating band as determined by the Transmission Operator"
No
Footnote 1 should be added to the Applicability section of the Standard. Suggest that the Applicability section be revised to state "GO shall set applicable protective relaying so as not to impact R1.1, R1.2, R1.3, R1.5, unless exempted by a non-protection system equipment limitation per the exclusion criteria in Requirement R3."
No
This question refers to Requirement R5 not Requirement R4. The "ride through" criteria should not extend beyond currently used critical clearing time (2nd zone of protection or breaker failure) that switchyard breaker failure protection is based on. It is questionable whether nuclear units can survive anything beyond this. Plants with auxiliary power systems fed directly from the nuclear switchyard would be even more questionable as the transient is not shielded by the generator bus.
Yes

Most nuclear units will not be able to meet the time duration of "up to 600 seconds" unless they have an installed Load Tap Changer (LTC). This is due to the NRC required Degraded Voltage relay protection. The purpose of degraded voltage relaying is to protect emergency buses that feed equipment necessary for safe nuclear plant shutdown during an emergency or transient.
Yes
Applicability section and Requirements R.1 and R.2 Most nuclear power plants will not meet the requirements for frequency due to NRC required protection for Reactor Coolant Pumps and Reactor Protection System Motor Generator sets. In addition, most nuclear power plants will not meet the voltage requirements due to NRC required degraded voltage protection. Although a provision for exemption is permitted in R.3, Exelon requests that the SDT communicate with the NRC and with the FERC to ensure a conflict of dual regulation is not imposed on a nuclear generating unit without the necessary evaluation. Requirement R.3 second bullet The equipment limitation expiration should not be dependent on a capacity increase of the generating unit. An equipment limitation may be the result of NRC regulations and not the generating unit capacity.

It is achieveable but signficant analyses must be performed. Undervoltage relay settings must be coordinated with the plant components most sensitive to system wide voltage excursions, particularly voltage drops. In some facilities, a POI voltage dip to 0.95pu would translate to a much larger drop within the local facility such that facility auxiliaries would start tripping due to the lower volatges on the facilities internal buses. The result is that even thogh the HV bus undervolatge relay is set to allow 0.95pu on the system the facility internal distribution may not be able to cope with voltage at that low a level. Nuclear power plants are particularly susceptible to low voltage conditions as unplanned tripping of a nuclear unit is to be avoided as much as possible. Nuclear units are also susceptible to overfrequency excursions as overfrequency causes motors within the plant to run at higher speeds. Nuclear reactor coolant pumps have overspeed limits due to core internals vibration limits that must be analyzed and coordiated with system overfrequency relay settings. These analyses typically take six to twelve months to complete and validate so a 12 to 18 month timeframe should be sufficient to implement the requirement.

No, we are not aware of any. Similar to our comments on MOD-027-1, the Applicability Section of draft MOD-026-1 standard does not contain specific references to variable energy resource plants/facilities. It only covers generating units and plants of certain sizes for the three (and Quebec) Interconnections without any specificity on generator types. Was it an oversight or did the SDT suggest that the “generating units” suffice to generally include all types of energy resources?
We are a bit surprised and disappointed that the SDT asks this question. The posted MOD-026-1 Draft 2 is a clean version, not a redline version from last posted, making it difficult for readers to identify where the previous requirements are contained in the revised draft. We understand that a reformatting may render tracked changes to be convoluted and hence a clean version may be a better option. However, in doing so, the SDT should provide a mapping document to show where the previous requirements are mapped into the revised draft standard. Whether or not any requirements were omitted could have been and should have been identified by the SDT through the mapping process rather than by the commenters.
We do not have an opinion on which standard should contain this as long as synchronous condensers are verified.
Yes
1. We do not agree with some of the requirements. i. R1: Standards should stipulate the “what’s” not the ”how’s”. To avoid the perception that the requirement is prescribing the “how”, we suggest simplifying the language of Requirement R1 by replacing “Instruction on how to obtain” with “Instructions for obtaining”. Further, are all three bullets meant to be complied with or are they listed as options? We understand that the general rule for NERC standards is that those items that must be complied with are labeled as parts (e.g. 1.1, 1.2, etc.) while those that are options or examples that do not need to be complied with are placed in bullets. Please verify this with the Director of Standards Process. ii. R2.1: The phrase “models acceptable to its Transmission Planner” begs the question on what is deemed acceptable and what if the GO disagrees with the TP’s determination. To address the two issues, we suggest adding a requirement for the TP to specify the models requirements (or change the second bullet in R1 to achieve this), and change the wording in R2.1 to “in accordance with the models specified by the TP (or referencing the requirement part that contains the specification). iii. We are not sure why Requirement R5 is needed. First of all, it suggests that a Planning Coordinator may request the GO to perform a model review where the request can be technically justified. We wonder if the requirement really means “Transmission Planner” rather than “Planning Coordinator” since TP as the requester and model user is specified throughout the standard. Secondly, if it is indeed TP that was meant to be the requester, then would this request already been covered by Requirement R3? If not, what are the technical justifications? They are not specified in R5, unlike its R3 counterpart. Please clarify and/or revise the requirement as appropriate. iv. R6 stipulates the criteria that may not be accomplished even if the GO provides an accurate excitation control system and plant volt/var control function model. A computer model may fail to initialize due to reasons other than the submitted excitation control system and plant volt/var control function model itself; a no-disturbance simulation may not result in negligible transients due to other reasons; and finally, a disturbance simulation may not result in the excitation control system and plant volt/var control system model exhibiting positive damping due to other system parameters. System damping is affected by many other dynamic performance contributors such as other generators, system topology, power flow levels, voltage levels, excitation system and power system stabilizer settings, etc. In short, having an accurate excitation control system and plant volt/var control function model does not necessary guarantee or equate to meeting the conditions stipulated in the three sub-requirements. We suggest this requirement be removed. Further, in many jurisdictions the setting and tuning of excitation control systems and associated power system stabilizers, etc. are determined by the Transmission Planners (or Planning Coordinators); the GOs would simply provide the equipment and set them according to the TP’s specification. In this standard, the responsibility is for the GO to verify that the model reflects the actual response of the tested equipment, whose settings have been determined prior by the other responsible entity. 2. In the previous posting, we provided 2 comments which in our view, have not been duly and satisfactorily addressed by the SDT and we would like to reiterate them here: i. We suggested that at a minimum, the generator's basic characteristics such as inertia constant, damping coefficient, saturation parameters, and direct and quadrature axes reactances and time constants), voltage regulators, turbine-governor systems, etc. as stipulated in MOD-013 that support modeling for dynamic simulations should also be verified. A good excitation system model without a valid generator model will not provide the assurance that the

simulation results are valid, which may hurt reliability. In response to this comment, the SDT indicates that: "[it] agrees that appropriate dynamic models are needed for generators, exciters, PSS, and governors. The SDT believes that when testing personnel verify the excitation system model data, they also provide verification of the generator model data. A match between simulation and measured results for the excitation system model is required to indicate that the generator and excitation control system models accurately represent the equipment. The governor model is not verified with the excitation system model since it requires a frequency excursion. Verification of the governor model will be addressed by the MOD-027 standard. Experience indicates verification required by the MOD-026 standard often results in discovery of significant changes to the representation of the generator and exciter, suggesting that model verification provides significant reliability improvement." Generator model parameters need to be verified based on tests conducted during both turbine/governor model verification as well as excitation system model verification. We are however not convinced that those tests that need to be performed during the excitation system model and data verification process, to verify certain portions of the generator model parameters will be conducted as a matter of course. We therefore reiterate our view that the verification of generation model parameters needs to be included within the scope of this standard and we urge the SDT to consider our comments again. ii. We suggested that in some areas on the interconnection, such as those that are sparsely populated, performance of generating units at less than 100 MVA might be critical to reliability. The criteria to allow the TP and PC to identify these units could include: a. A 5% or 10% deviation of any or several of the excitation system's parameters/settings could make an otherwise stable simulation to be unstable; b. Use of generic models for the excitation system or generator would make an otherwise stable simulation to be unstable. c. Other changes or incorrect assumptions for the excitation system or generator would make an otherwise stable simulation to be unstable. The SDT responded that: "After reviewing provided details, the SDT encourages you to review the new process draft (reference Requirement R2) and provide additional comments as appropriate." Requirement R2 does not contain any provision that a TP (or PC) can request for model verification of units that do not meet the Applicability criteria. Throughout the standards, such a provision does not exist. This could leave room for system to exhibit unstable performance for reasons indicated in our previous comments. We urge the SDT to reconsider our proposal.
No
We generally agree with these definitions, but do not see the need to specify the band values, i.e. ±0.5 Hertz and ±5%, in them. The two definitions should stay clear of any specific values, which can be specified in the standard, to remain valid if and when the band values vary.
Yes
No
We believe the SDT meant R5, not R4, unless R4 is a sub-requirement or a part of R3 (which seems to be the case by the way R4 is worded) and a format error resulted in R4 becoming R5. We do not support the provision of such an estimate. First of all, the requirement does not distinguish whether it applies to units that are equipped with frequency/voltage protective relays or otherwise. Secondly, the intent of providing the suggested estimate is to allow Transmission Planners to apply valid or supported assumptions in their planning studies. Given the requirements in Attachments 1 and 2, and Requirement R3 (which, by the way, should be modified as we suggest below), the TPs can apply the following relevant assumptions: a. For units that are equipped with frequency/voltage protective relays, the GO's submitted relay settings will determine when the units will trip; b. For units that are NOT equipped with frequency/voltage protective relays, the units are conservatively assumed to trip when the simulated frequency/voltage goes outside the bounds of Attachments 1 and 2. We do not see what other estimates that can be more relevant and valid than the above. We see that there may be some value in providing these estimates but only in the case of generators not equipped with frequency/voltage protective relays where tripping takes place beyond the no-trip zones of Attachments 1 and 2. For this information to be useful however, the generator's behavior must be predictable. While it may facilitate some "what-if" analysis, it is not clear that using this information would be better than the conservative assumption "b" above. How does the SDT envisage that the Transmission Planner will use this additional information if it cannot be relied upon?
Yes
First of all, we believe the SDT meant R6, not R5. Also see our editorial comments under Q3, above.

We believe this requirement is achievable for most cases. However, provision should be given to the Generator Owners which for specific technical reasons are unable to design a generating units to comply with the requirements. As worded, R6 does not contain this provision.
Yes
1. R3: Please clarify the meaning of the expression “non-protection system equipment”. Does it mean “a limitation imposed by equipment other than the protection system”? Or does it refer to generating units that are NOT equipped with frequency/voltage protective relays? In the latter case, how would the GO determine that the units that are not so equipped are unable to meet the criteria in Requirement R1 or R2? In our view, units that are unable to meet these criteria are those that are equipped with frequency/voltage protective relays and whose trip settings do not meet the criteria specified in R1 and R2 for specific technical reasons that are communicated to the Transmission Planners. For units that are NOT equipped with such protective relays, the suggestion that any of them may be unable to meet the criteria in R1 and R2 could be those which in the past have tripped before the thresholds. However, unless a unit repeatedly trips under like circumstances, isolated incidences do not provide sufficient evidence to arrive at a conclusive determination. And for those units that are NOT equipped with the protective relays and have never tripped before the thresholds, there is no telling whether or not they can meet the criteria. For the above reasons, we suggest the SDT to revise the R3 to convey the requirement that the GOs shall provide the technical reasons for not meeting the R1 and R2 criteria only for those units that ARE equipped with the protective relays and ARE set at different thresholds. 2. As indicated in our comments under Q3, we think R4 is a sub-requirement or part of R3 since R4 mandates the GO to respond to the listed entities within 30 days of receiving a request, and that in the requirement there is no mention of “what” the response should entail. The “what is stipulated in R3. 3. R7: We assess that this requirement duplicates with what we interpret as the intent of a good part of R3, i.e., to provide the listed entities with the settings of the frequency/voltage protective relays. Regardless of whether or not a GO is able to meet R1 and R2, it should be obligated to provide the generator protection trip settings to these other entities for modeling purpose (consistent with our comments under Q3). If a GO sets the protective relays at values that do not meet the R1 and R2 criteria, then it should be obligated to provide the technical limitations that form the basis of the deviation. This requirement thus should come after R1 and R2, and replaces the as written R3 for reasons that we mention in our comments in (1), above.

PE suggests using the term “exceeding” rather than “exceedance”. PE furthermore believes that 60 HZ +/- 0.5 Hz is appropriate but does not agree that +/- 5% for voltage is an appropriate bandwidth for “normal”. Any threshold must agree with VAR-002. Along with a clarification of what a voltage schedule is (i.e. target, bandwith).
No
Requirement R1 subsection 1.5 is not clear as to when rate tripping is acceptable or not. Is it OK to trip at 59.6 Hz if the ROC is > 2.5 Hz or is this ROC trip acceptable only outside the no trip zone.
No
This appears to actually refer to R5. PE submits the comments below with the assumption that this question is directed toward R5: PE agrees with the requirement of R5 in general, but disagrees with the approach to the extent that R5.1 contains two options for GOs’ providing of information regarding

voltage excursions, one of which is problematic. Specifically, the requirements of Attachment 2 are too stringent and cannot be used by the majority of GOs, which leaves the second option as the only feasible method. The second option, provision of a voltage profile “at the Point of Interconnection for the generating unit or generating plant or Facility of the most severe normally-cleared Zone 1 fault described by dynamic simulation provided by the Transmission Planner”, puts the responsibility back on the Transmission Planner. Requirement R5 is intended to aid Transmission Planners in providing information on Generator models needed for Transmission Planning analyses, and yet as it exists the only option for provision of the information is a hindrance to Transmission Planners rather than an aid. PE requests that the SDT simplify the language to merely state that GOs have an obligation to provide information that the TPs request.
No
This appears to actually refer to R6. PE submits the comments below with the assumption that this question is directed toward R6: The ride through voltage profile in attachment 2 is not achievable for either new or existing facilities. The issue is not the relay protection but in the capability of the auxiliary equipment (such as motor contactors, coal feeders, instrument sensors). I do not know of any motor control contactor that will hold in when voltage goes to zero. The energy that is stored in the coil holding the contactor in place is rapid returned into the system during a time of fault. While the short circuit contribution of motors and contactors may last up to .2 seconds the majority of the stored energy is returned in the first 1/5 of the decay curve. The requirements that are specified in this standard are outside the IEEE and ANSI standards associated with manufacturing equipment used in power plants, while manufacturing of equipment to specialized standards MAY be possible the cost would be extremely high and in some cases may not be possible.
No
The ride through capabilities should be within the IEEE and ANSI C84.1-2006 “American National Standard for Electric Power Systems and Equipment – Voltage Ratings (60Hz)”. Standards associated with manufacturing electrical equipment
Yes
Forcing the utility to delay fault clearing (a three phase bolted fault at the point of interconnection causing a zero voltage) will increase the damage to the generation facility caused by the fault. Protective relay schemes have two primary objectives, to clear a fault rapidly to minimize the impact on the Bulk Electric System and to prevent (minimize) the damage to the faulted component and the components close to the faulted component. By forcing utilities to keep a generator feeding a fault of the magnitude implied by attachment 2 of PRC-024 the regulation may increase the costs of maintaining the generator. Additional inspections after a fault may be required to assure no internal damage occurred during the event that would not be required if the generator could be isolated from the fault more rapidly.

Section A Effective Dates: In 5.2.1, replace “30% of its applicable units” with “20% of its applicable units”. There will be a substantial learning curve with this new requirement, therefore the requirements should be less demanding in the earlier years. Section B: Requirement R1: Replace “Each TP shall provide the following INSTRUCTIONS AND DATA to its GO…” with “Each TP shall provide the following DATA to its GO…”. On the first two bullets, remove the phrase “Instructions on how to obtain…” The TP should simply provide this data, and not merely the instructions on how to get it. On the third bullet, replace “Any of the GO's existing … model data“ with “All the GO’s existing … model data…”. Since the TP already has this data, it is more straightforward to simply provide all

relevant data to the GO. Requirement R2: Replace the first sentence with, “Each GO shall provide data which MAY BE USED TO VERIFY the generator excitation control system and plant volt/var control models…” The verification of these models is not determined by the GO, but by the TP in Requirement R6, R6.1, R6.2, and R6.3. In R2.1.1, replace “Documentation demonstrating the … model response matches the recorded response” with “Documentation WHICH MAY BE USED TO DEMONSTRATE that the … model response matches the recorded response”. In R2.1.3, 2.1.4, and 2.1.6 replace “model structure” with “block diagram”. In Requirement R3, replace “90 calendar days” with “180 calendar days”, to allow more time to work through the technical challenges relating to these models. In Requirement R5: Allow 180 days for a response to the PC for the reasons above. This will allow time in the event that the request from the PC lacks the technical rationale or details that are required. Also, in R.5.2, replace “walk down” with “inspection”. Comments on Attachment 1: 1. Remove the note which says, “Note that local grid codes may specify…”. 2. Under “Conditions” for existing generators, it is not clear why there are references to both a ten year period and an eleven year period. Also, replace “Subjected to an activity resulting in an alteration of the response of the excitation control system” with “Changes to control system or parameter values”. 3. Under the exceptions for existing generators, the allowable MVA size should be increased to 500 MVA. 4. Under “Periodicity” for existing generators, in the last three rows covering situations where the recorded response did not match the predicted response, where the PC requests a review, and where the model is identified by the TP as unusable, the GO should be allowed two years (instead of one year) to provide a recorded response for a voltage excursion due to the possible need to take the unit out of service to make control changes, especially where outages are not scheduled on an annual basis. Lastly, staged testing for generator exciter model verification will likely require switching of lines on the transmission system. In cases where the Generator Owner does not own or operate the transmission system, the TO or TOP may understandably be reluctant to switch lines out due to reliability concerns. For this reason, R2 should be modified to provide more incentive for the TO/TOP to coordinate with the GO to do the required testing.
No
The system can operate without problems within +/- 5% of nominal system voltage under normal conditions. Generator capability curves allow for continuous operation between 95% and 105% of rated voltage. Therefore, the operating band for voltage needs to be expanded beyond +/-5%, perhaps as high as +/- 10%.
Yes
No
(We believe the relevant requirement for this question is R5). The estimate of generator performance desired by the RC/PC/TO/TP can be obtained via informal means, including meetings, discussion, and simply working together. Not all information that may be "useful" should be codified by a Requirement in a Standard. Also, R5 and associated Measure M4 refer to a "written request". This would seem to limit the request and response to a hardcopy. Using simply "request" instead of "written request" would allow the use of electronic means as well.
Yes
1. The Applicability of this standard should be specifically stated to be limited to generators connected at 100kv or above, as in the Registry Criteria. 2. The Effective Dates should be increased by one year. 5.1 should be two years, 5.2 should be three years, and 5.3 should be four years. This change would more appropriate for the significant analysis needed to meet these requirements. 3. Requirement R1.5 should be deleted. The rate of change of frequency is not a parameter that is widely available in generator protection schemes on existing units. Requirements 1.1 through 1.4 are sufficient to prevent undesirable operation. 4. Requirement R2.1.1 needs more clarity. Generator voltage relaying is not generally set to trip for system faults. Also, R2.1.2 is unclear as to what "less stringent" means; the reference to the Transmission Planner "settings" should perhaps be changed to "requirements". 5. In R3 and in R7, the allowable times should be 90 days rather than 30 days. This is due to the effort required to perform an adequate investigation. The "Lower" Violation Risk Factors for these two requirements would seem to be consistent with this. In R7, change "written request" to "request". 6. In R2 (second sentence), replace "shall set its protective relaying not to trip … " with, "shall set its

protective relaying to avoid tripping ..."

No
The Applicability section includes Generator Owners and Transmission Planners. If an entity is a Generator Owner, they will meet the NERC Compliance Registry Criteria including MVA criteria. Including phrases in section 4.2 such as “The remainder of the plant as an aggregate”, and “For all interconnections: Any technically justified unit requested by the Planning Authority” is confusing and it seems to be expanding the criteria. For example hydroelectric units that don’t qualify an entity as GO may be captured here. Also, for the aggregate, a GO may not be able to model and verify the aggregate consistent with the method used by TPs.
Yes
Yes
MOD-025 includes synchronous condensers. This doesn’t appear to be consistent with the strategy for MOD-026?
Yes
1. This standard is still not clear in terms of what constitutes verification of the model and what are related obligations of parties involved. Specifically, it is not logical or technically feasible to request GOs to address any problems with “usability” that TPs may have with the excitation control system model applied in their simulation software. Related Requirements are R3 and R6. The GOs provide accurate model data of their systems during the generator interconnection and facility registration process. Detailed base-line testing is done at that time. For subsequent verifications, GOs would use certain software tools, most likely not the same that the TPs are using, to simulate excitation control system response. This simulated response would be compared with actual equipment response. If traces (signatures) match closely enough, the model is verified. The GO would submit required information to the TP as per R2. At this point, the GOs obligations should be over and subsequently, the GOs should not have a compliance obligation to take part in resolving any issues that the TP may have with the “usability” of their models. Any further involvement by the GOs should be in the spirit of good will and professional courtesy among the parties. In conclusion, GOs should not have compliance obligations to resolve issues related to “usability” of models applied in the TPs power system simulation tool. 2. The idea that GOs “own” the models and are responsible for model modifications and verification still remains controversial for a number of reasons: a. GOs have little need for models and many do not have any expertise in modelling. b. Software tools used by GOs or external consultants for commissioning and verification purposes would not be the same as the tools used by TPs c. TPs would have to work on tuning so the whole exercise would not have a particular value in a technical sense. This is supported by the NERC Event Analysis & Information Exchange staff who noted during the first comment period: “Although verification (not validation) of generator equipment settings and testing should be the responsibility of the GO, validation of generator models response to actual system events should be done by the Reliability Coordinator.” Also, NERC’s white paper “Power System Model Validation”, Dec 2010, expands on this view. It implies that the ultimate responsibility for the usability and accuracy of dynamic models and how they perform in relation to the overall system model is the responsibility of the Transmission Planners, Reliability Coordinators or similar entities. 3. We recommend revising the wording in Requirement R2.1.1 for improved clarity. The way it is written, it strongly implies that the method of verification is based on system disturbance (ambient) monitoring: “Documentation demonstrating the unit or plant’s model response matches the recorded response for a Voltage excursion at the generator or plant point of interconnection. 4. Requirement 5 refers to the Planning Coordinator. Is this a typo and supposed to be the Transmission Planner? Also, we recommend revising the wording in Requirement 5 for improved clarity. 5. Attachment 1 Column 6 refers to the Planning Coordinator. Is this a typo and supposed to be the Transmission Planner?
Yes
Yes

No
The requirement R5 (R4 is a typo in the Question) is ambiguous and redundant. What does “estimating” mean? One could infer that the GOs are actually required to do what TPs are normally doing as part of their studies: estimating (assessing, simulating) the performance of units during frequency or voltage excursions. In order to fulfill requirements R1, R2 and R3 of this standard, GOs have to do engineering analysis and studies to develop adequate protection settings and to assess other non-protection systems and equipment. By declaring compliance GOs commit to keeping their units on-line during defined frequency or voltage excursions. In the case that a GO identifies a particular limitation, they would inform the TPs so that this limitation is taken into account in system studies. Hence, the goal of the standard would be fully met without R5. In light of the above, the requirement R5 should be removed. Technically it is of little value, if any, becoming just an unnecessary burden for GOs. In compliance terms it could be a source of perpetual confusion and disputes.
Yes
Frequency and voltage excursions specified in this standard are reasonable and actually less stringent then certain regional or area requirements. Generating facilities designed in line with industry practices and applicable standards should be able to ride through such disturbances. Lastly, it is in GOs best interest to have a robust design for new generating facilities.
Yes
Yes
1. R2 introduces Remedial Action Schemes (RAS) as an alternative description. We recommend keeping to Special Protection System and leaving RAS in the NERC glossary. 2. We recommend a consistent use of the terms Planning Coordinator and Planning Authority. In the Purpose of this standard, Planning Coordinators are referred to. In the NERC glossary, under Planning Coordinator it says “refer to Planning Authority”. The compliance registry list includes a column for Planning Authorities. The NERC Reliability Functional Model version 5 discusses Planning Coordinators only. Is the term Planning Coordinator going to replace Planning Authority?

Section A Effective Dates: In 5.2.1, replace “30% of its applicable units” with “20% of its applicable units”. There will be a substantial learning curve with this new requirement, therefore the requirements should be less demanding in the earlier years. Section B: Requirement R1: Replace “Each TP shall provide the following INSTRUCTIONS AND DATA to its GO…” with “Each TP shall provide the following DATA to its GO…”. On the first two bullets, remove the phrase “Instructions on how to obtain…” The TP should simply provide this data, and not merely the instructions on how to get it. On the third bullet, replace “Any of the GO's existing … model data“ with “All the GO’s existing … model data…”. Since the TP already has this data, it is more straightforward to simply provide all relevant data to the GO. Requirement R2: Replace the first sentence with, “Each GO shall provide data which MAY BE USED TO VERIFY the generator excitation control system and plant volt/var control models…” The verification of these models is not determined by the GO, but by the TP in Requirement R6, R6.1, R6.2, and R6.3. In R2.1.1, replace “Documentation demonstrating the … model response matches the recorded response” with “Documentation WHICH MAY BE USED TO DEMONSTRATE that the … model response matches the recorded response”. In R2.1.3, 2.1.4, and 2.1.6 replace “model structure” with “block diagram”. In Requirement R3, replace “90 calendar days”

with “180 calendar days”, to allow more time to work through the technical challenges relating to these models. In Requirement R5: Allow 180 days for a response to the PC for the reasons above. This will allow time in the event that the request from the PC lacks the technical rationale or details that are required. Also, in R.5.2, replace “walk down” with “inspection”. Comments on Attachment 1: 1. Remove the note which says, “Note that local grid codes may specify…”. 2. Under “Conditions” for existing generators, it is not clear why there are references to both a ten year period and an eleven year period. Also, replace “Subjected to an activity resulting in an alteration of the response of the excitation control system” with “Changes to control system or parameter values”. 3. Under the exceptions for existing generators, the allowable MVA size should be increased to 500 MVA. 4. Under “Periodicity” for existing generators, in the last three rows covering situations where the recorded response did not match the predicted response, where the PC requests a review, and where the model is identified by the TP as unusable, the GO should be allowed two years (instead of one year) to provide a recorded response for a voltage excursion due to the possible need to take the unit out of service to make control changes, especially where outages are not scheduled on an annual basis. Lastly, staged testing for generator exciter model verification will likely require switching of lines on the transmission system. In cases where the Generator Owner does not own or operate the transmission system, the TO or TOP may understandably be reluctant to switch lines out due to reliability concerns. For this reason, R2 should be modified to provide more incentive for the TO/TOP to coordinate with the GO to do the required testing.
No
Yes
No
(We believe the relevant requirement for this question is R5). The estimate of generator performance desired by the RC/PC/TO/TP can be obtained via informal means, including meetings, discussion, and simply working together. Not all information that may be "useful" should be codified by a Requirement in a Standard. Also, R5 and associated Measure M4 refer to a "written request". This would seem to limit the request and response to a hardcopy. Using simply "request" instead of "written request" would allow the use of electronic means as well.
Yes
1. The Applicability of this standard should be specifically stated to be limited to generators connected at 100kv or above, as in the Registry Criteria. 2. The Effective Dates should be increased by one year. 5.1 should be two years, 5.2 should be three years, and 5.3 should be four years. This change would more appropriate for the significant analysis needed to meet these requirements. 3. Requirement R1.5 should be deleted. The rate of change of frequency is not a parameter that is widely available in generator protection schemes on existing units. Requirements 1.1 through 1.4 are sufficient to prevent undesirable operation. 4. Requirement R2.1.1 needs more clarity. Generator voltage relaying is not generally set to trip for system faults. Also, R2.1.2 is unclear as to what "less stringent" means; the reference to the Transmission Planner "settings" should perhaps be changed to "requirements". 5. In R3 and in R7, the allowable times should be 90 days rather than 30 days. This is due to the effort required to perform an adequate investigation. The "Lower" Violation Risk Factors for these two requirements would seem to be consistent with this. In R7, change "written request" to "request". 6. In R2 (second sentence), replace "shall set its protective relaying not to trip ... " with, "shall set its protective relaying to avoid tripping ..."

No
The system can operate without problems within +/- 5% of nominal system voltage under normal conditions. Generator capability curves allow for continuous operation between 95% and 105% of rated voltage. Therefore, the operating band for voltage needs to be expanded beyond +/-5%, perhaps as high as +/- 10%.
Yes
No

The GS is not responding to MOD-026
No
The SERC generation sub-committee (GS) believes that 60 HZ +/- 0.5 Hz is normal but the voltage schedule +/- 5% is not necessarily normal. The normal voltage should be consistent with VAR-002 requirements and defined by the voltage schedule for the unit. Change the verbiage to “… exceedance of system voltage beyond the applicable voltage schedule.”
Yes
The GS recommends that the applicability section be revised from “GO” to “GO’s that have frequency and voltage protection functions activated to trip a new/existing generation unit.” Also, while the GS does, in general, agree with the content of footnote #2 on page 2 (under R1), we believe that this is verbiage is better placed in the implementation plan because it puts commercial considerations into the standard.
No
The ride through criteria should not be anything beyond currently used critical clearing times (2nd zone protection or breaker failure) that switchyard breaker failure protection is based on. It is questionable whether large steam plants can survive anything beyond this. Plants with aux power systems normally fed from the switchyard would be even more questionable as the transient is not shielded by the action of the voltage regulator for the generator.
No
This appears to refer to R6. The proposed bands would need to be considered by new plant designers and incorporated into their design basis if feasible. Specific criteria have not been provided in new plant design guidance provided by EPRI Utility Requirements Document (URD) nor in other industry standards used by new plant designers. The frequency band was considered for some new plant designs and no concerns were identified. However, It is not clear if all or even most of the designers for other nuclear/fossil designs have considered this. The proposed voltage band has caused many concerns and probably is not achievable for existing or new steam plants because electrically powered equipment (motors, MCC components, contactors, etc.) have been and are normally designed for proper operation as follows: The normal voltage boundaries have been specified to be for the steady-state operating conditions based on the ANSI C84.1-2006 “American National Standard for Electric Power Systems and Equipment – Voltage Ratings (60Hz)”as follows: a. Normal Conditions: ±5% Continuous Duration b. Emergency Conditions: ±10% not specified Duration These Criteria are

currently widely used in practice and can be complied with by all types of new generating plants designed with an in-plant voltage regulation capability. In connection with these criteria, all new equipment, both on the transmission system and in new generation plants must be chosen in order to be able to operate and withstand these voltage excursions. For transients, the above should be applied for conditions lasting more than one second. Transient conditions lasting less than one second, can be more severe and the equipment can still ride through it for about 0.5 seconds. A design solution to address severely degraded voltage lasting more than one second, is to utilize expensive voltage regulation devices, normally not utilized in the past at most power generation plants. It's not clear why a plant should be required to withstand any transient beyond that expected by a switchyard fault with one failed breaker (the basis for critical clearing times for second zone or breaker failure protection). An R&D effort should be considered to investigate reasonable steam plant voltage excursion ride through capabilities if a criteria is needed.
No
Comments: The GS proposes that the LVRT portion of the curve between 0.4 secs and 3.0 secs be changed to 0.90 PU voltage. Electrical powered devices at the plant can begin to lose their ride-thru capability in the window of 0.2 to 0.65 seconds (as referenced in the AREVA whitepaper on PRC-024 and based on industry experience)
Yes
During the drafting process, quite a bit of feed back was provided to the SDT about concerns if this became a performance standard and the response was that this is only a relay setting criteria. However, plant performance aspects have been incorporated using the allowed operating bands developed as for use in relay setting coordination. The concerns with this include: • Important Existing nuclear plant settings are inside the published no-trip bands • How quickly plant secondary system motors will decelerate with voltage below ANSI MG-1 criteria. • Why is a voltage ride through criteria beyond existing second zone or breaker failure/critical clearing time design approaches needed? For frequency, the ride-thru criteria should be sufficient for UFLS to perform it's function. Also, the lowest frequency allowed for unit operation must accommodate the turbine blade resonance low frequency requirement for large steam plants (57.5 to 58.5 Hz, depending on the turbine OEM). Similar steam turbine restrictions also apply for the high frequency requirement. For voltage, the ride-thru criteria should be long enough in duration for second zone or breaker failure protection critical clearing time. Voltage recovery to 0.9 PU following critical clearing time is necessary to ensure electrically powered equipment will perform correctly. Nuclear power plant interface requirements are addressed in NERC NUC-001-2. PRC-024 should refer to nuclear plant interface requirements managed under NUC-001-2. “The comments expressed herein represent a consensus of the views of the above named members of the SERC Generation Subcommittee only and should not be construed as the position of SERC Reliability Corporation, its board or its officers.”

Idaho Power - Power Production
Tim Brown
No
We agree with the need to include wind generation in this standard, however the applicability section seems to be overly complicated. We do not see the relevance of the 80% of connected generation as discussed above. We believe that the NERC generator registry/ BES criteria would be clear and appropriate continent wide for this standard and with many other standards. In addition, we believe that Section 4.2.4 is too open-ended. It appears to open the door for the verification of any sized machine that does not match a response, or for other open-ended reasons. Too open-ended and subjective.
No
Yes
The Requirements direct the GO to send responses, data, inquiry to the Transmission Planner. Should this really be to the Transmission Operator? We understand that the TP will ultimately use the data, however, we believe the data and communications should flow through the TOP. Specifying timeframes for both recording data and providing results is cumbersome. More properly, timeframes

and periodicity should be specified only on providing results. If necessary, a limit on the age of the recorded data could be specified. R6.1, R6.2 and R6.3 seems overly prescriptive and of little value. In the process of verifying model data and comparing to recorded results, those 3 conditions are met. If the Transmission Planner has concern about their ability to use the model data in their studies, it is more properly addressed either without specific criteria, or with the specific criteria that the Transmission Planner is unable to reproduce the simulated response contained in the model verification. The requirement of several responses to submit plans to test within 365 days and submit with 180 days (per the periodicity table) seems too long from an system reliability standpoint, particularly where it is the outcome of an observed response to an actual event not matching the predicted response. On the other hand, scheduling a test and model verification within a shorter period of time would be challenging for the GO, particularly those that rely on outside contractors for the model verification work. Any request to verify or retest due to an observed response not matching an actual event should be accompanied by full electronic information (recorded data, simulated output, simulation conditions, model data used by TP). Requirement R1. The first two bullets appear to allow variation between Transmission Planners on acceptable models and software. The list of acceptable models needs to standardized at least across the RRO. In addition, the GO should not need to adjust the model validation and verification work based on the software that the TP uses (what happens when the TP uses multiple software packages?). If the SDT feels there is a need to specify acceptable software, then that should also be standardized. The third bullet should read “All of the Generator Owner’s existing” instead of “Any”. The TP should provide all the information in its database regarding the GO’s facilities, not just “any” piece of it. R2, 2.1. Reference to “models acceptable to its Transmission Planner” is inappropriate, see previous comment. The list of acceptable models needs to be standardized, although situations (rare) where the Generator Owner and Transmission Planner jointly agree to use a model not on the list should be allowed. In particular, the Transmission Planner should not restrict use of any the models on the standardized acceptable list.
No
Basing the voltage excursion definition on scheduled voltage is troublesome, as “scheduled” voltage can change over time, and in some cases, varies seasonally. Protection and limiter settings are not, and should not, be adjusted to address varying schedules. That said, simply using nominal voltage instead of scheduled voltage is probably not the answer either, as it is not unusual to have POI scheduled voltages of 1.05 pu or higher.
Yes
Yes, R1 and R2 do make it clear that the GO does not have to install or set these functions however we believe that the standard should clarify better that the standard is applicable to all “voltage-based” protection functions such as the backup impedance function (21) and the voltage controller (51C) or voltage restrained (51V) Overcurrent functions. These functions may operate if not coordinated properly. We do not believe that was made very clear. Particularly for units that fully compliant with this standard, providing an estimate of unit performance during a frequency or voltage excursion is burdensome and unnecessary. If the event is within the parameters of the standard, the planner can rely on the unit staying on, if not, the planner should model the unit as a trip. In particular, we are unaware of any methodology that would be capable of providing an “estimated probability”. Protection consistently operates as designed and configured.
No
This requirement should not exist. Generator Owners are required to comply will all approved NERC and RRO standards. It is the responsibility of the Generator Owner to see that the plant is built according to specifications which should include all approved NERC Reliability standards governing power plants.
Yes
Yes
In section 2.1.1, we believe that the “three phase transmission system zone 1 fault” should be clarified. Is the zone 1 referring to the generator relay backup zone 1 element? The zone 1 element of the interconnection station line protection relays? Shortest line? Longest line? Another zone 1? Also, the language was a little confusing, is this an if-then statement? Since the voltage ride through curve apparently applies to all conditions (both operating and various fault configuration), reference to the

“three phase transmission system zone 1 fault” implies a limitation to applicability that is not intended, and the reference should be deleted. For R3, because the time horizon for this standard is long-term planning, we believe the 30 day communication requirement is not necessary. We believe 180 days is more in line with other reporting time frames with modeling related standards. We also believe that the equipment limitation expiration section is not needed. A simple statement stating that the when the limitation is no longer valid, the RC, PA, etc should be notified. For R6, we believe it is unnecessary to have different requirements for existing and new units. We do not see the need for performance requirements for new units. We believe this standard should be a relay settings standard, with generator performance being considered in modeling standards. R7 is burdensome to both the Generator Owner and to the receiving entities, and also prone to causing confusion. The entities proposed to receive the protection settings (RC, PC, TO, TP) would face a difficult task to be able to properly interpret the relay settings sent. The Generator Owner is the proper entity to determine the relay settings to remain in compliance with the standard. In addition, the requirement to transmit the settings within 30 days of changes is burdensome and unnecessary. Draft PRC-019-1 properly address the issue of coordinating settings with machine capabilities, and PRC-001 properly addresses the issue coordinating settings with the TO.

Yes
Yes
No
a. This is for requirement 5 not requirement 4 b. We cannot evaluate the performance of units during frequency and voltage excursions at the transmission interface point, only at the generator and 6.9kV bus level where the auxiliary equipment interface exists. Therefore, the frequency and voltage excursion profiles would be different than those submitted by the RC, PC, TO or TP. Also, 30 days is too short to perform a detailed analysis on plant performance during the frequency or voltage excursion. Further evaluation would be required for the transformers, turbine and auxiliary equipment to determine satisfactory operation in the long time periods encompassed in the "No Trip Zones".
No
a. This is for requirement 6 not requirement 5 b. It is uncertain that the requirements, when translated to the 6.9kV AC distribution system and below, can be achieved with the equipment installed in new generating facilities. Most motor specifications do not require demonstrated operability below 75% motor rated terminal voltage or >5% deviation in rated frequency. Additional vendor testing would be required in order to effectively demonstrate equipment design capabilities. Additionally, plant performance has not been evaluated for the entire range of frequencies in the "No Trip Zone". More analysis would have to be performed in order to verify acceptable plant operation in these frequency bands.
No
Due to the excessive duration of the +/- 10% voltage excursion, it is uncertain that many new manufactured turbine generators will be able to meet the V/HZ limits set by the manufacturers. Detailed studies would need to be performed to determine the ability of newer turbine generators to ride through these conditions.

We agree as long as the SDT creates the new SAR to address such devices including Synchronous condensers.
Yes
The applicability of 100 MVA matches MOD027-1 but is inconsistent with MOD025-2 or PRC 019-1. We feel like these should be consistent in every standard included in this project. VSLs for R4 footnote reference needs to be deleted since there is no footnote to reference. We would like to see a more consistent approach to the comment forms and the standard itself. It seems there is room for clean up in the posted standard/comment form.
No
We believe that +-5% is ok for normal operating conditions but this doesn't address contingencies being taken or a time frame. The curve in attachment 2 doesn't seem to correspond with the definition as proposed. We are also unclear about the term continuous. We think this means from 0 to infinite. This graph indicates at 600s one would operate within the .95 and 1.05 normal conditions. SPP's regional criteria shows that during a contingency we can operate at a +5% -10% bandwidth.
No
We agree that R1, with the footnote mentioned, makes it clear that the Generator owner would not be required to have protective relaying installed or set for these functions. As for R2 we feel that footnote 1 should also be referenced in R2.
No
The question should mention R5 and not R4. We feel like the planners shouldn't have to request this data and should be supplied for each unit once and again if the characteristics change. We also feel like 30 days might not be appropriate time to gather such information and would suggest that 90 days would be a better time frame for supplying this data.
Yes
Question should read R6 not R5. We feel that as long as everyone knows about these requirements ahead of time that there shouldn't be an issue with achieving these requirements.
No
We would like to see the technical background/justification of why the timeframe of 600s was chosen. We understand seeing the reasoning to expand it from 4s, but 600s (10 Minutes) seems extremely too long for voltage recovery. From a planning perspective 15 cycles (.25seconds) is standard for voltage recovery. Holding .9 from 3s to 600s could prove difficult if full load on unit and might not be enough bandwidth before you hit a loss of field relay. If enough current is provided to the field it will cause this relay to trip instantaneously. Not sure that taking a 10% hit during this instance will work.
Yes
Would like to see a more consistent approach to the comment forms and the standard. It seems there is room for clean up in the posted standard/comment form.

Synchronous condensers are installed at locations where they are specifically needed for voltage/VAR control purposes. The excitation performances of these units are thus known to be impactful to the local areas where they are located. If excitation parametric authenticity is of concern in a dynamic simulation study, then it would seem synchronous condenser performances are particularly of significance to their respective local areas. They should be included in the verification effort.
Yes
We have a number of questions and concerns as follows: • It is not precisely clear what a GO would have to do to satisfy the verification requirements in R2. Would each of the Time Constants, Forward and/or Feedback Gains, Dead-band Excitation Limits, Saturation Characteristics, etc. to be determined separately each on its own? Or are these parameters taken as a whole so long as their combined effect produces a response characteristic in a simulation that matches the recorded test response during an off-line step-input test? • If a simulation study results in response characteristics that does not match an off-line step input test response, can the GO arbitrarily adjust one or more of the model parametric values to produce a matching response, and send the Transmission Planner these adjusted values as the model data? • We have concern about whether this Standard is cost effective for the industry. The transient stability dynamic modeling for excitation control was traditionally developed under the assumption of limited bandwidth validity and approximations. The other equipment models in the simulation, e.g. generators, prime-mover controls, SVCs, HVDC Converters, etc. are all approximations without any correlated degree of accuracies in comparison to each other. On the other hand, the verification efforts required by this standard are expected to cost quite a bit to GOs, especially for older units whose vendors/manufacturers may not even be in existence any more. • MOD-026 does not account appropriately for the differences between distributed generation and single shaft generation. Aggregate generation that do not have a common excitation and regulator control system (such as wind farms) may pose serious difficulties in meeting system disturbance and / or staged testing. A staged test can be performed for a single shaft unit. However, wind farms may not have a centralized plant or wind farm voltage controller. If that isn’t the case, entities may be forced to actually shock the BES to force a disturbance large enough to force a wind farm response. If this is true, then exceptions need to be made. • In addition, there are concerns about the technical development and accuracy of current wind farm models. It is not certain that all manufacturers have fully developed all of the control system models necessary to meet these standards. Type III and Type IV PSS/E generic standard models have all been benchmarked. What has not been included in these models are the wind farm park voltage controllers. While local turbine model controllers will dominate the short term response, the longer term park voltage controls are not represented. Therefore if the models aren’t available, then model traces can’t accurately match reality. Older wind farms will not have appropriate models. In short, the state of wind farm models hasn’t completely developed to match wind farms and specific exemptions for wind farms need to be added to the standard at a minimum.
Yes
No
The requirement and footnote is not clear in that control algorithms incorporated in plant control systems that effectively limit speed and therefore frequency are not clearly identified as being covered by the standard or not. This does not seem to be covered under R3 which covers equipment limitations either.
Yes
This question seems to be referring to R5 rather than R4.
No
If design standards have not been previously developed or implemented for all plant equipment and therefore the plant itself to not trip during the defined excursions it is uncertain when and if equipment design standards and the equipment itself can become available to achieve the requirements.
Yes
Do not have an alternative value to suggest.

Yes
It is not clear what the basis for the requirement of R3 with regard to a 10% or more increase in capacity would lead to an expiration of an equipment limitation as the change that results in the capacity increase may not be related in any way to the origin of the equipment limitation.

It is Requirement R6 that requires new units to ride through excursions. We believe it is technically feasible to design generating units to reach a high probability of riding through these excursions. However we do not consider the additional expense necessary to meet this objective to be of value to our customers given the infrequency of occurrence of excursions of the magnitude described in this standard. Excursions of this type have occurred on our system and some generating units have tripped due to the excursion, but it has never led to a cascading outage. In addition, we believe new plants should not be considered in violation for a trip during an excursion if the GO can identify the reason for the trip and correct the deficiency. If the standard is made mandatory, we believe that an additional five years should be allowed for new units so that the A/E firms can develop proper design criteria for plant auxiliaries and equipment OEM's to develop designs that can handle the requirements

We appreciate the drafting team's consideration in Section A.6 to allow a unit that has already verified its excitation system to be considered compliant. However, it is not clear how this section helps. How does the Generator Operator demonstrate that it is already compliant when it was not required to retain documentation? Will an attestation by appropriate level of staff be sufficient? Will the regional

entities be willing to validate that they have confirmed regional criteria? This standard is overly administrative by memorializing the interactions between the Generator Operator, Transmission Planner and Planning Coordinator that occur to model the generator's excitation system. Specifically R1, R3, R4 and R5 should be struck. They are purely administrative and present compliance risk to the registered owners without commensurate reliability benefit. For Requirement R6, the portion requiring a written response should be struck as well. Only two requirements are needed to accomplish the purpose of this standard. They are: ne requirement for the Generator Operator to perform the test and one for the Transmission Planner to verify the model is accurate. Requirement R6 creates a situation where a Transmission Planner could be forced to decide between living with an exciter model that needs adjustment and violating the standard. Upon initial examination, the Transmission Planner may determine that the model meets Parts 6.1 through 6.3. Only after months or years of extensive study, it is possible that the Transmission Planner determines that the excitation model could stand some improvements. If they submit a written response one year later, the Transmission Planner may be in violation of Requirement R6. This just represents one of the issues with memorializing the interactions between the Transmission Planner, Planning Coordinator and Generator Operator in the standards. Because the tests to verify the excitation model can be expensive, there should be a demonstrated need to perform a test. Summaries of field test results posted with the second draft of the SAR indicate the costs of these tests could range from $5,000 to $50,000 for a single unit. That does not even include opportunity costs from lost energy sales should the test cause the unit to trip. Thus, if there are no demonstrated modeling deficiencies (i.e. benchmarking reveals model results do not align with actual system results), then no test should be required and the generator operator should be able to wait for a system disturbance appropriate enough to verify its model. Because R3 and R5 give only 90 days to respond to the Planning Coordinator's and Transmission Planner's issues with the excitation model, these requirements could compel tests during a seasonal peak time frame. At a minimum, the Generator Operator should have 180 days to perform the test if that is what is identified as its response to avoid jeopardizing unit tripping during periods of high loads.
Yes
No
The requirement and footnote is not clear in that control algorithms incorporated in plant control systems that effectively limit speed and therefore frequency are not clearly identified as being covered by the standard or not. This does not seem to be covered under R3 which covers equipment limitations either. It is not clear why the exception for R1 and R2 would expire with a capacity up-rate greater than 10% in R3. That implies that the reason for the exception must be fixed with such a capacity up-rate. Was this the SDT's purpose? Why?
No
Requirement R4 is unnecessary and completely administrative. It provides no reliability value. It appears to be an attempt to compel a Generation Owner to be responsive to its Reliability Coordinator, Planning Coordinator, Transmission Operator and Transmission Planner. In fact, it does not compel any real responsiveness as the Generation Owner could simply document their disagreement. It is already in the Generator Owner's best interest to be responsive. Thus, this requirement is not necessary.
No
If design standards have not been previously developed or implemented for all plant equipment and therefore the plant itself to not trip during the defined excursions it is uncertain when and if equipment design standards and the equipment itself can become available to achieve the requirements.
Yes
Yes
It is not clear that this standard is needed. While attempting to eliminate unit tripping from frequency and voltage excursions is a laudable goal, it may not be practical to eliminate all unit tripping for these reasons. Furthermore, it creates the situation where literally every unit trip could become subject to a compliance violation investigation. Before this standard is finalized, NERC needs to assess how it is going to manage compliance enforcement with it. The posting of the ballot is confusing. The

red-line documents are, in fact, clean (i.e. there are no red-lines) documents that do not line up with the “clean” documents. Thus, it is not clear what is being voted on. For example, the “clean” document shows that there are five parts with Requirement R1. The “redline to last posted” document has four subrequirements under the main requirement R1. The basis for the values established in parts 1.1 through 1.5 does not appear to be well documented. We understand from reviewing the documentation that the SDT appears to have reviewed a number of actual events. Documentation of this review would allow us to better understand the drivers for these values. The values in parts 1.1 through parts 1.5 do not appear to be well coordinated with UFLS. For instance, UFLS will actuate at 59.3 Hz per the UFLS standard while many generators could trip at 59.4 Hz that could cause a cascade of units tripping from degrading frequency. Hopefully, the UFLS actuation would prevent a downward spiral of frequency but that coordination is not clear at this point. Requirement R7 is partially redundant with Requirement R3. R3 already requires documentation and communication of equipment limitations. Thus, R7 creates the potential of double jeopardy.

However, an exception should be made for variable energy resources for which models have not yet been fully developed and accepted. Techniques for validation of these devices have not been developed similar to generator excitation model validation tools (EPRI PPPD).
Yes
No
These types of reactive resources should be included if of a sufficient size to impact reliability.
Yes
1) If System Models are poor today, it is probably due to a lack of understanding on what models are required, setpoint control and what changes need to be communicated to Transmission when plant projects are done. Periodic reverifications are probably not the right way to ensure reliability. Instead there should be an event-based revalidation requirement, such as if you replace the control system or recalibrate the control settings on an existing unit, replace the rotating exciter or rewind a generator. An approach where there is an initial validation effort to get today’s models consistent with installed equipment is clearly needed. However, assurance that future models will remain valid requires that there is a program in plant project processes to revalidate when appropriate, and thus a requirement to show that the company has the needed project processes and has followed that process is the right way to approach this. 2) There needs to be a requirement for the entity responsible for actually

inputting the models and data to do so on a timely basis. This should be an annual update of data to be submitted to the interconnected models. As currently written, there is a requirement for the GO/GOP to submit information, but they do not input directly into the interconnected system models. MOD-010, MOD-011, MOD-012 and Mod-013 don't currently ensure that data is incorporated in a timely fashion. 3) Since GO/GOPs do not always have electrical system modeling expertise, nor participate in interconnected system models groups such as the MMWG which sometimes changes how equipment is modeled, there probably needs to be a guide that clearly identifies the steps a GO/GOP needs to take to maintain models up to date. The NATF and EPRI/NAGF are considering a collaboration to do so. 4) Identically designed generation units are identical in control response, independent of site location. New techniques for validation eliminate the impact of the grid on the validation efforts. Thus, credit for sister unit validations should be available independent of the location of a unit. 5) Discussions during the EPRI PPPD users group indicate certain parameters in the models are temperature sensitive, and thus verification and adjustment of models should be done under conditions that reflect normal operating conditions. An on-line voltage step test or DFR data from an event is the best way to perform the validations. It's not clear if validations against off line tests would actually make the models worse, but the industry should be encouraged to do validations on line near full power. 6) R2, 2.1.3 Total unit inertia should be given to include all coupled rotating elements. The way this is currently worded, it could lead generators to only provide the generator H values. 7) Footnote 4 – Delete the phrase "or evidence that the simulated unit or plant response does not match measured unit or plant response". Otherwise this standard could be made applicable to a small unit that has no impact on reliability.
No
We are not sure what is the purpose of the voltage excursion definition in this standard. Is excursion measured versus scheduled voltage, or equipment rating?
Yes
No
Should be R5. We question the value of this requirement, and how the TP use the probabilistic information in any TPL analysis. It's unclear how compliance with planning requirements would be demonstrated. The planner needs to know under what voltage/frequency conditions a unit will trip so that when those conditions are attained in the model the unit will be turned off. Generator owners/operators need to make their best efforts to determine the conditions and provide it to their TP's, updating the information as plant design changes occur or operating history indicates the conditions have changed. Having a time estimate as specified in R5.1 does not provide the voltage/frequency threshold that the planner must know so that the unit can be tripped when those conditions occur in the model, no matter what time those conditions occur.
No
This appears to refer to R6. The proposed bands should be considered by new plant designers and incorporated into their design basis if feasible. Specific criteria have not been provided in new plant design guidance provided by EPRI Utility Requirements Document (URD) nor in other industry standards used by new plant designers. The frequency band was considered for some new plant design basis and no concerns were identified. It's not clear if all or even most of the designers for other nuclear/fossil designs have considered this. The proposed voltage band has caused many concerns and probably is not achievable for existing or new steam plants because electrically powered equipment (motors, MCC components, contactors, etc.) has been and is normally designed for proper operation as follows: The normal voltage boundaries have been specified to be for the steady-state operating conditions based on the ANSI C84.1-2006 "American National Standard for Electric Power Systems and Equipment – Voltage Ratings (60Hz)"as follows: a. Normal Conditions: ±5% Continuous Duration b. Emergency Conditions: ±10% not specified Duration These Criteria are currently widely used in practice and can be complied with by all types of new generating plants designed with an in-plant voltage regulation capability. In connection with these criteria, all new equipment, both on the transmission system and in new generation plants must be chosen in order to be able to operate and withstand these voltage excursions. For transients, the above should be applied for conditions lasting more than one second. Transient conditions lasting more than one second, can be more severe and the equipment can still ride through it. A design solution to address severely degraded voltage lasting more than one second is to utilize expensive voltage regulation devices, normally not utilized at

power generation plants. This standard shouldn’t dictate a solution to the situation where a generator goes offline due to low voltage on the transmission system, because in many cases the generator going offline may not be a problem for the overall transmission system. In situations where it is a problem, a collaborative effort between the Transmission Planner and the Generator Owner would be the best approach (see AREVA white paper that has been provided to the SDT). It's not clear why a plant should be required to withstand any transient beyond that expected by a switchyard fault with one failed breaker (the basis for critical clearing times for second zone or breaker failure protection). An R&D effort should be considered to investigate steam plant ride through capabilities if a criteria is needed.
No
The LVRT portion of the curve between 0.4 seconds and 3.0 seconds should be 0.90 voltage PU. Electrical powered devices at the plant will begin to lose their ride-thru capability in the window of 0.2 to 0.65 seconds (as referenced in the AREVA whitepaper on PRC-024 and based on industry experience).
Yes
During the drafting process, quite a bit of feedback was provided to the SDT about concerns if this became a performance standard and the response was that this is only a relay setting criteria. However, plant performance aspects have been incorporated, using the allowed operating bands developed as a setting coordination. The concerns include: • Existing nuclear plant settings are inside the published no-trip bands • How quickly plant secondary system motors will decelerate with voltage below ANSI MG-1 criteria. • Why is a voltage ride-thru criteria beyond existing second zone or breaker failure/critical clearing time design approaches needed? For frequency, the ride-thru criteria should be long enough in duration for UFLS to perform its function. Also, the lowest frequency allowed for unit operation must accommodate the turbine blade resonance low frequency requirement for large steam plants (57.5 to 58.5 Hz, depending on the turbine OEM). Similar restrictions may also apply for the high frequency requirement. For voltage, the ride-thru criteria should be long enough in duration for second zone or breaker failure protection critical clearing time. Voltage recovery to 0.9 PU following critical clearing time is necessary to ensure electrically powered equipment will perform correctly. Nuclear power plant interface requirements are addressed in NERC Reliability Standard NUC-001-2. PRC-024-1 should allow nuclear power plant interface requirements to be managed under NUC-001-2. (See PowerPoint and AREVA white paper provided to the SDT).

R5 applies to existing units. This requirement seems vague and subjective - recommend clarification. Please clarify the term "less stringent" - do you mean 'in the no-trip zone' or 'outside the no-trip zone. How will the information be used and what are the implicatios if the response is not satisfactory? R6 applies to new units - I have no comments on R6.

Yes
Yes
-R2.1.1 - 'not to exceed 9 cycles' this wording is confusing and needs to be clarified. -Suggest that Requirement R4 be rewritten to add specificity as to what must be included in the required written response, similar to the specificity and clarity included in MOD-026, Requirement R3. -R7 seems to be a duplicate requirement with PRC-001 - Implementation comment - from an implementation perspective it would make it easier if all standards in Project 2007-09 had the same implementation schedule.

Yes
Requirement R1, first bullet. Grammatically, should the word model in the first bullet be models? Requirement R4 requires the Generator Owner to provide revised model data or plans to perform model verification. The way I interprete the wording of Requirement 4 is that the model data or plans to perform model verification are due within 180 calendar days. If the GO provides plans to perform model verification and submits the information on their plans within 180 days, is there any time limit as to when the model verification must be performed? If so I suggest it should be included in the language of the Requirement. If the actual verificatio must be done within 180 days this should be clarified becasue right now it just looks like only the plans have to be submitted within 180 days.
No
WECC is requesting a regional variance to Requirement 1 that reflects the generator performance requirements of the WECC Coordinated Off-Nominal Frequency Load Shedding Plan. WECC's continuouse operations zone is between 59.4 hZ and 60.6 Hz. Therefore, WECC will need a regional definition of Frequency Excursion to be an exceedance of system frequency beyond a continuous operating band of 60±0.6 Hertz.
Yes
No
The question above appears to be referring to R5, not R4. R5 has the requirements for providing estimates of the performance of the units. I have no comments on R5, However, I have the following comment on R4. We agree with the intent of the requirement, but believe that more specificity in what is required in the written response is necessary. As written it could be argued that a simple response from the Generator Owner indicating they received the inquiry was sufficient. Suggest adding detail similar to that included in MOD-026, Requirement 3 that identifies what the response must contain.
For the WECC variance we would need a revised Attachment 1 that also shows the WECC No Trip Zone or an additional Attachment to illustrate the WECC variance No Trip Zone. WECC also requires modified language to R1 and the parts 1.1-1.5 to reflect the WECC variance. Requirements R5 and R6 will need to be modified to identify the appropriate Attachment for the WECC variance.

Generators sized well over 100 MVA with a capacity factor under 5% are numerous in our area of the Eastern Interconnection. These older large generators with a capacity factor below 5% will have a significant impact on electric system performance during stressed conditions with high loads. These

generators must not be excluded from the verification requirement. Generators sized under 100 MVA may also be important, what is the justification for the cutoff from the verification requirement at 100 MVA? The applicability criteria in this standard should be the same as the registry requirements.
Yes
Yes
This standard may lead Generator Owners to violate another NERC Standard; this standard implies in requirement R4 along with footnote 6 that Generator Owners could have 180 days to notify its Transmission Planner that an AVR status has changed. The VAR standards require notification within 30 minutes of a change in AVR status. Requirement R4 is also a direct violation of the ISO/FERC Tariff Section I.3.9 that requires generators to provide information prior to making material changes to equipment characteristics. Allowing generators to make changes such as these without prior review represents a significant reliability concern. MOD 26 needs to clearly state that non-proprietary models need to be provided by Generator Owners, otherwise a major reason (NERC MMG) for model collection will be undermined. As written, the intent of requirement R2.1.1 is unclear. How are stabilizers and excitation limiters to be addressed? How large does the voltage excursion need to be? This requirement needs to be made much more specific. With respect to requirement R1, the standard should allow user models to be provided. The second bullet point implies that models would only be allowed from a list of standard models. User written models may provide more accurate representations of actual equipment installations. However, these models cannot be proprietary and must be able to be distributed. In requirement R5.2 bullet 1 – generator owners should not be providing generic model data. In requirement R5.2 bullet 2 – what constitutes a “walk down” of the equipment? Suggest replacing with “Updating parameters based on actual field verification of equipment settings.” This standard should indicate what constitutes the excitation system and should indicate that it includes a power system stabilizer and limiters. This standard addresses existing generators, but should also address new generators. In regard to the Effective Dates: How is this to be implemented? GOs may have units in multiple control areas. TOs may be in multiple areas. This seems impossible to track and may leave some areas with very little verification for up to ten years after the standard has been approved. The Planning Coordinator should be given the discretion to require and approve a test schedule within it’s area.
No
The term “system voltage” is unclear as to where it is measured. Attachment 2 shows the curve based on voltage at the Point of Interconnection, yet R2.1 refers to voltage at the generator terminals. ISO-NE maintains that the band applies to the voltage as shown in Attachment 2 on the Y axis as the “Point of Interconnection–Voltage (PU). R2.1 should refer to the voltage at the point of interconnection and not the generator terminal voltage. The band shown as .95 p.u to 1.05 p.u. should be widened to at least .90 p.u. to 1.05 p.u. The time duration curve shown in Attachment 2 will need to modified to be consistent with this range for the times at and beyond 600 seconds to be consistent with this change.
Yes
Yes
The RC/PC/TOP/TP functional entities provide for a wide-area view of the transmission system and its operating limitations. These entities need accurate generator characteristics in order to correctly plan the system and to operate it within known limits.
Yes
ISO-NE has frequency data from all generators operating within the New England footprint demonstrating, with the exception of certain nuclear plants and some smaller and very old generating units, that all generators can operate to meet the under-frequency curve depicted by PRC-024 – Attachement 1, and, in fact, can and do meet our more stringent underfrequency requirements. Within the NPCC Region existing requirements for generators have been in place for many years that are more stringent than the underfrequency curve shown here. The NPCC more stringent requirements have been shown by studies to be necessary to support a viable automatic unferfrequency load shedding program. It is our position that generators within NPCC will be required

to continue meeting these more stringent requirements independent of the approval of PRC-024-2. New generating units should meet all the PRC-024-2 requirements at the time of their interconnection or in-service date. No special implementation plan should be afforded these units beyond the regulatory approval date of the standard.
Yes
Although the time duration is acceptable ISO-NE does not agree with the band shown. See our comments on Question 1, above.
Yes
Comments are provided by ISO-NE on the following requirements: R2.1. This requirement specifies when operating (within the band specified) of rated terminal voltage (VT) and during the transmission system operating conditions defined in PRC-024 Attachment 2 .... ISO-NE maintains that the band applies to the voltage as shown in Attachment 2 on the Y axis as the “Point of Interconnection–Voltage (PU). R2.1 should refer to the voltage at the point of interconnection and not the generator terminal voltage. The band shown as .95 p.u to 1.05 p.u. should be widened to at least .90 p.u. to 1.05 p.u. as suggested in our comments on Question 1 above R2.1.1 infers that the standard is to base the voltage relay settings on actual fault clearing times. The standard should be 9 cycles. As the system changes, clearing times may change and then problems with an existing generator who has set its relays to the actual clearing times may be an issue. Changing this requirement would also require a change in the curve shown in Attachment 2. If this comment is ignored, as an alternative ISO-NE suggests that R2.1.1 be modified to state, “For three-phase transmission system zone 1 faults with Normal Clearing, set voltage relays based on actual fault clearing times, plus margin, not to exceed 9 cycles.” This is suggested to direct the setting of relays in a manner that will prevent a relay race that could trip the generator sooner than the actual fault clearing time. R2.1.3 appears to provide a way to get around the intent of the standard. If a generator cannot meet the requirements of the standard, they could put in an SPS to trip the generator and avoid meeting the intent of the standard. This has the potential to lead to a proliferation of SPSs. Notwithstanding the concern over R 2.1.3, R2.1.3 and R2.1.4 should be rewritten as follows: 2.1.3. If a Special Protection System (SPS) or Remedial Action Scheme (RAS) includes tripping a generator after fault initiation, then setting the SPS or RAS relays to trip the generator even if [voltage is] in the “no trip zone” in PRC-024 Attachment 2 is acceptable [provided that the voltages will not enter the trip zone for criteria faults that do not initiate the SPS or RAS]. 2.1.4. If clearing a system fault necessitates disconnecting a generator, then setting relays to trip the generator even if operating [voltage is]within the “no trip zone” specified in PRC-024 Attachment 2 is acceptable. R3 is a significant concern. In the event that a generator has a piece of equipment which prevents it from meeting the requirements of R1 and R2, such as a motor contactor which drops out on voltages in the “No Trip Zone”, there is no requirement to correct the issue. Instead, the generator must only document the limitation. This completely undermines the intent of this standard. There is no point to setting undervoltage relays to meet the curve if other equipment is still going to trip the plant. R5 appears similar to R3 in that the generator is only required to document if it trips in the “No Trip Zone”, rather than correct the issue. Exceptions in 6.1.1 and 6.2 should not be allowed. Each generating unit that is registered based on the NERC Registry Criteria as a single unit, or as part of a generating facility, should comply with PRC-024-2 without exception. In general, R6 and sub-requirements R6.1 through R6.7 introduce a number of conditions and exceptions for new units that are unnecessary and cumbersome to monitor. Some of them represent common sense conditions, such that if they were to occur, an auditor would be able to deem the entity to be in compliance since it is not posiible to comply with the letter of the requirement. However, there are many more cases that could be listed and you will never capture all possibilities here. Overall R6.1 through R6.7 should be deleted. As the system changes, the requirements will change. The machine should be properly designed upon installation to allow the necessary flexibility in the development of the transmission system over time.

Michelle D'Antuono
Ingleside Cogeneration LP
No
Yes

Yes
Yes. There is already a significant body of work underway defining the extent of the Bulk Electric System. This determination should rest with the project team responsible for that effort.
Yes
MOD-026-1 already takes Ingleside Cogeneration LP out of its comfort zone by requiring the ownership and validation of interconnected system performance simulations. This is normally a Transmission Planner or Transmission Operator function, not a Generator Owner. Although we understand the benefit of modeling validations, it is appropriate to begin with only the most critical facilities. If anything, we believe the applicability criteria should be consistent with those generation facilities which have DME installed as required by their Regional Entity. This is a reasonable, in-place means to identify those generators which are important to BES voltage response – and have already the recording equipment needed to validate performance.
No
Ingleside Cogeneration LP agrees that the continuous frequency specification is unambiguous and reasonable. However, the voltage operating specification needs to tie directly to the Transmission Operator's voltage or Reactive Power schedule developed in compliance with VAR-001. We believe this was the drafting team's intent, but the definition does not clearly indicate that this is the case.
No
Requirement R1 from Ingleside Cogeneration's perspective could lead to a double-infraction for the same incident. For example a single improper relay operation for an underfrequency transient would lead to a violation of both R1.2 and R1.3. It should be sufficient to specify that relays must be set in conformance with the off-frequency excursions provided in PRC-024 Attachment 1. Also, there must be some logical limit to the Hz/Second ride-through threshold specified in R1.5. As the requirement is written, even a large-magnitude frequency transient must not cause relays to operate as long as the frequency rate of change is slow. If for example, the interconnection frequency dropped to 55 Hz at a rate lower than 2.5 Hz/Second, R1.5 seems to require that the generator would remain connected to the BES. For the record, R2 seems to be more logically constructed – and lists reasonable exceptions to voltage relay settings. Ingleside Cogeneration LP recommends the drafting team to take a similar approach on R1.
No
Ingleside Cogeneration LP assumes this question actually applies to Requirement R5. It is not clear what extra reliability information will be provided to Transmission Planners as long as Generator Owners confirm that their voltage and frequency settings comply with the performance curves in the attachments. It may be valid to require an estimate of performance if the GO identifies a limitation as allowed under R3. Otherwise, the TP should assume generator relays will operate if the magnitude and duration thresholds defined in the attachments are exceeded.
Yes
Ingleside Cogeneration LP assumes this question actually applies to Requirement R6. The frequency and voltage ride-through specifications are reasonable for new generating facilities in Ingleside Cogeneration LP's view.
Yes
The voltage ride-through specifications are reasonable for new generating facilities in Ingleside Cogeneration LP's view. Existing facilities that cannot meet this specification must be able to document an equipment limitation as allowed in R3.

Brad Jones
Luminant Energy
No
I am not aware of any other generation configurations/types that should be covered in the Applicability portion.
Yes

Yes
No
No
The frequency is acceptable but the voltage band is confusing. The generator operating range is +/-5% from rated at full load. Luminant recommends that the voltage excursion be referenced to generator rated voltage.
No
Recommended that in the Footnote and in R1 indicate generator protective relaying.
No
Note: This appears to be dealing with R5 and not R4. R5 Because of the requirement under R5.3 (identification for basis for estimates of probability of staying on-line, etc), the study would take considerable time to compile. I would recommend that the generator owner be provided 90 calendar days rather that the suggested 30 to submit the results. R5.1 It appears that a frequency and voltage excursion must occur at the same time with the estimated time duration that the unit will remain connected. Was it intended that the "and" be an "or"? Would LVRT dovetail into relay loadability for stressed conditions for low voltage conditions between 45 and 90%? (Generator relay loadability is evaluated at 85% (PRC-023-2).) R5.3 Luminant recommends removing this requirement.
No
Generating units placed in service prior to this standard normally have 30+ years lifespan. During the life span, components targeted for LVRT will experience loss of life (time in use, number of operations, environment, etc) which could result in a failure of an LVRT event at the point of interconnection. Because a study may not be able to locate every component, an increase in reliability or the ability of the plant to ride through a low voltage condition could never be guaranteed above its current level. The same issue exist for new units. If the plant was designed to maintain LVRT conditions, there is no guarantee that the plant's ability to ride through low voltage conditions can be maintained during its life span.
No
The LVRT chart should only be limited by values pertaining to a system fault condition as a result of primary and backup transmission line relaying trip times (usually 0-30 cycles)
Yes
Luminant still believes that the standard should be directed to generator protective relaying only.

SCE believes that the Section 4.2.4 of the Applicability Section should be revised to read "Any technically justified unit requested by the Transmission Planner." We believe that the Transmission Planner is the appropriate functional entity for this role. In addition, SCE believes that Requirement 1 should be revised to allow the Transmission Planner a full 60 days in which to provide the information to the Generator Owner. At various times, Transmission Planners may be inundated with such requests from Generator Owners and may require the extra time in which to respond.

Agree that there are relatively few synchronous condensers installed on the system. Including these devices with other dynamic reactive devices such as SVC's and STATCOMs, rather than in this standard, appears to be a good approach.
Yes
Our comments/concerns are : 1)The wording for Requirement 2.1.4 should be changed to read "Model structure and data for the excitation system, for the plant volt/var system, and for the closed loop voltage regulator". Otherwise, as written, it appears that the required model structure and data only applies to the voltage regulator portion of the equipment. 2)In Requirement R5, the term "technically justified request" needs to be clarified. 3)In Requirement R2.1.3, it should be clarified that "rotational inertia" should include all rotational mass connected to the generator shaft, rather than only the rotational inertia of the generator itself. 4)Units rated 20 MVA will not have a significant impact on system reliability. Only units and aggregate plants capable of > 100 MVA should be included. 5)Sister unit exemptions should be allowed where there is a solid technical support for units built and operated as virtually indistinguishable generators. 6)The SDT should review the requirements in this draft to ensure they do not overlap the requirements in MOD-012 and MOD-013. From our read it appears generator owners will be at serious risk for double jeopardy. 7)The draft uses the term "Point of Interconnection" in several locations, especially R2.1.1. This is not a NERC Glossary term, although the Team used footnote 3 as an internal definition. 8)Footnote 6 should be a set of sub-requirements for R4. 9)Section 6 should be part of the Implementation Plan since it deals with the initial phase-in of the Standard. 10)Footnote 2 should probably be in the Applicability Section, but should not stay as a footnote – it's too important in determining which generators must comply.
No
Voltage Excursion definition should be based on rated system operation voltage which is what the protection is based on, not scheduled voltage which may vary.
Yes
No
Unless written to exclude all auxiliary system equipment which may result in a unit shut down, it will be impossible to determine this probability with any reasonable accuracy. For example, where auxiliary motors would stall and trip off, or contactors drop out would be variable
No
Unless written to exclude all auxiliary system equipment which may result in a unit shut down, it will be impossible to determine with any reasonable accuracy where auxiliary motors would stall and trip off, or contactors drop out.
No
This 90% and 110% ride through times should be longer to handle contingency periods of high voltage during light load conditions or periods where large VAr resources are lost during peak loads. Per our Transmission Planning department high voltages of 110% have been experienced for up to 8hrs.
Yes

1)Comments: Requirement R1.5 is unclear. Are the relays not allowed to trip regardless of frequency if the rate of change is less than 2.5 Hz/sec. If so, the existing generator relays don't have the capability to block for this condition. It would seem undesirable to block for this condition and risk damage to generation. 2)R2.1.3 needs to be more specific. With multiple outlet lines, generators may only be tripped for certain lines or breaker failure conditions. Generators would only be allowed to trip in the "no trip zone" for the specific conditions of the SPS or RAS schemes? 3)R6.2 why are smaller generators allowed to trip 10% of their units? Is this fair to large generators? 4)Do all the requirements of PRC-024-1 apply to all the auxiliary systems, or just the generating unit protection systems? This needs to be made clear for compliance. If applying to all auxiliary systems, guidance will need to be provided on how to meet these standards. 5)For R2 and R6, if clearing a transmission line outlet end of line fault with zone-2 timing exceeds the requirements of Attachment #2, which should be designed for. Does transmission line relays need to be designed to provide performance of Attachment #2 for newly installed facilities?

Yes
Yes
It is possible that the owners of the transmission system dynamic reactive devices (such as synchronous condensers, SVCs, STATCOMs, etc) may not be a NERC registered entity at all. Moreover, it is highly inappropriate to just add equipment not mentioned in the original SAR to the standard. It makes more sense, as SDT suggested, to have a separate SAR to address those transmission system dynamic reactive devices.
Yes
1) We question how field tests can be performed on aggregation based facilities. We recommend removing the requirement for developing models for the aggregation of units < 20 MVA for conventional units. 2) Isn't R2.1.3 already required of the GO in MOD-012 (dynamic data on generators) 3) The timing of R5 requirement (90 days) seems to contradict with the schedule for modeling in Attachment 1 (1 1/2 years) for PC initiated model reviews. 4) The background section indicates that the PC can request a unit not in the applicability scope (page 2, last paragraph), but R5 doesn’t say this. The wording on R5 indicates that the PC can request a review of an existing model. 5) Attachment 1 is difficult to use. Please cross reference the requirement that goes with each row of the periodicity table Attachment 1. Please add row numbers to the table. Please use column 1 to briefly label the conditions that controls the applibility of the row (for example - the row including the exceptions could be labeled SISTER UNITS) 6) It is suggested to review the order in which the requirements are currently numbered. The current R3 seems to be out of place (should occur after the requirement that is currently R6). This will more closely match the flow of how the process will work. 7) VSL for R1 needs work – the requirement specifies 30 days – the VSL doesn’t count it tardy until 90 days. 8) The Sister concept needs to be mentioned in the applicability section 9) The exception rule in Attachment 1 should include Sister units at different geographic sites in addition to those at the same site. 10) The exception rule in Attachment 1 should not be limited to 350MVA – if units are identical, then the sister concept should apply. 11) The first bullet of R1 needs to make "model" plural ("models") for the grammer to be correct. 12) As the requirement of R4 is not a response to a request, we suggest changing the wording of the text in M4 from "show that it provided a written response (...) submitted within 180" to "show that it submitted communication (...) within 180", where (...) is shown to indicate no change to the parenthetical element. 13) As requirement R6 is an evaluation of the verified model by the TP, we suggest changing the wording of the text in R6 from "show that it provided a written response" to "show that it provided an evaulation of the submitted model".
Yes
Yes

1) The footnote is clear, however, the exact meaning of the phrase "non-protective system equipment" limitation in R1 and R2 is not clear. Does this exclude any equipment limitation that is protected by a protective relay? Does this allow tripping using protective relays that are protecting a turbine from underfrequency conditions or a generator or transformer from excessive volts-per-hertz conditions? We feel that a fundamental tenant of reliability includes adequately protecting generating plant equipment from detrimental conditions - a generator owner needs to be allowed to protect its equipment from possible damaging consequences of off-nominal voltage and frequency. 2) We believe examples of “non-protection system equipment” include, but are not limited to, turbine generators, transformers, feed pump systems/controls, boiler control systems, reactor protection systems, emergency diesel generators, AC motors, pumps, fans, AC motor contactors, auxiliary relays, etc. 3) Nuclear stations have an approved Setpoint Methodology which governs the process of determining and documenting setpoints for the equipment at that station. This methodology will incorporate some margin between the expected operating condition and setpoint actuation to help ensure proper operation of the unit but provide the necessary protection as well. How was this considered in the development of this standard?
No
1) This Question is for R5, not R4. 2) We disagree with this approach due to the uncertainty about how to estimate the performance. The detailed dynamic analysis required to make an estimate of a specific units performance is not reasonable to require. The voltage excursion profile needed for an evaluation is that voltage present on the generator bus and plant distribution system auxiliary buses rather than at the point of interconnect. The protective relays and control equipment susceptible to high/low voltage excursions are located on the low voltage side of the generator step up transformer. Does agreeing with the approach mean the philosophical desire to provide the TP with information or mean agreement with the requirement to provide estimations of the voltage excursion ride-through ability? We agree with the philosophical mantra, but we are not sure if a conclusive determination of a unit ride-through capability is possible. Generation Owners need a curve from Transmission that is referenced to the lowside since that is where the relays/equipment are located. 3) Does “estimate of that unit’s performance” only include the estimated time duration of 5.1 and probability of remaining connected in 5.2? Or, does it also include things like the estimated generator terminal voltage, MW, MVars, etc. for the duration of the frequency or voltage excursion? This needs to be clear. 4) The 30 days requirement is much too short. There are a large number of systems and components that would first have to be identified as susceptible to responding to these extreme conditions (especially the voltage conditions). Each of these would then require evaluation, including dynamic analysis for systems and components that respond dynamically over these relatively long time periods. This amounts to major study work on a single unit, much less over many units of many different system configurations and designs having equipment of many different manufacturers and vintages. Also, dynamic studies require accurate system and equipment models to produce valid results and the effort to establish accurate models is no simple task.
No
1) This question is for R6, not R5. 2) We highly doubt that the requirement is technically feasible based on our experience with vendors and the various technical requirements and modifications that would have to be made to make sure that low or high voltage ride thru is possible. Complicating factors include the many different equipment suppliers, limited control of manufacturing standards by the purchasers, and continuing changes in technology must be considered to be able to determine whether or not all plant sub-systems can ride through. The economic impact and technical feasibility of this requirement has not yet been considered by suppliers. 3) Even if this can be achieved, it will require significant changes in the power plant industry. This will include major changes to plant system and equipment design standards (both U.S. and International). This alone will take years to accomplish. Then, manufacturers will have to design, build, and test plant systems and equipment to meet the new requirements. It is impractical to expect a new plant that can meet both the frequency and voltage requirements to be built in less than 10 years after R6 is imposed.
No
1) The 600 seconds for +/- 10% voltage excursion is excessive. GE has published recommended generator permissible V/Hz settings for a stairstep protective solutions of not allowing > 118% V/Hz to exist longer than 2 seconds, and not allowing > 110% V/Hz to exist longer than 45 seconds. The HVRT curve requires allowing 110% V/Hz for 10 minutes, which is much longer. 2) Generators need a generator side excursion curve to even see if this is feasible. 3) We believe a detailed study needs to

be conducted by the industry for typical power plant designs to help determine the feasibility of power plants being able to ride through these extreme voltage conditions. We believe this study will demonstrate that this will not be possible without major re-design of power plant systems and components.
Yes
1) It is recommended to rephrase R4 so that the requirement (shall statement) is first and the conditions (within x of receiving a request) is second as follows: "The Generator Owner shall provide a written response within 90 calendar days of receipt of a written inquiry from the RC, PC, TOP, or TP regarding an equipment limitation identified in accordance with Requirement R3." More response time than 90 days is needed for cases were a written inquiry is given to a GO (with a very large number of units) for all units in one request. 2) We believe that the condition specified in R6.2 should be limited to PV plants and wind farms? 3) Since Requirement R6 provides exceptions to the requirement (6.3 thru 6.7) these exceptions need to be mentioned in Measure M6. (add "unless one of the exceptions 6.3-6.7 apply" to the end of the sentence.) 4) Employing new grid frequency and voltage ride-through requirements may impact the licensing and design basis of nuclear facilities. NUC-001-1 requires coordination between Nuclear Plant Generator Operators and Transmission Entities for the purpose of ensuring nuclear plant safe operation and shutdown. This is achieved through development of Nuclear Plant Interface Requirements (NPLRs) for each nuclear unit that are based on plant-specific Nuclear Plant Licensing Requirements and Bulk Electric System requirements that have been mutually agreed to by the Nuclear Plant Generator Operator and the applicable Transmission Entities. The NPLRs are requirements included in the design basis of the nuclear plant and statutorily mandated for the operation of the plant, including nuclear power plant licensing requirements for 1) Off-site power supply to enable safe shutdown of the plant during an electric system or plant event; and 2) Avoiding preventable challenges to nuclear safety as a result of an electric system disturbance or transient condition is important. It is essential that this process be followed closely in attempting to apply new grid frequency and voltage requirements that are more extreme than those currently addressed in each plant's licensing and design basis. It is fundamental that the safety of nuclear power plants take precedence. 5) R3 states "each" non-protection system equipment limitation where R1 and R2 say "a". Is there a reason for this difference? The feasibility of fully analyzing an existing plant to determine this is extremely questionable. There is no doubt that the cost would be horrendous. 6) We suggest modifying Footnote 2 - add "being built to a completed certified standard design" to this list. If the industry is going to move forward in utilizing standard plant designs to reduce cost and expedite getting plants built, the certified design must be acknowledged. If the equipment to meet this standard can be obtained, which is doubtful, the only way to reasonably attempt to have a design that meets it is to start with these requirements as design criteria at the very beginning. To place requirements such as this on completed standard designs would destroy the use of that concept. 7) The approval of this standard as written will have extreme effects on the construction and operation of generating units which could also affect safety and availability. It would greatly increase the cost and schedule for building generation units and impose a huge cost on existing ones. We believe those developing this reliability standard should be sensitive to such concerns and give them consideration. Has this been done? Is it fully documented and available for review by the industry impacted by the proposal?

American Electric Power
No
Yes
AEP is not aware of any omissions from the prior draft due to the re-formatting of the standard.
Yes
Yes
Standard models may not be available for wind units and wind facilities (which appear to be within scope), particularly aggregate reactive and frequency response controls at the farm level. As a result, it might be difficult to obtain and provide such information.

Yes
Where these definitions appear to be referenced in the standard (R5 and R6), they seem to be at odds with Attachments 1 and 2. Either the attachments should be used and remove the definitions, or instead, the definitions should be used and remove the references to the attachments in R5.1 and R5.2 and R6. We recommend removing the definition of "Frequency Excursion" and retaining Attachment 1 subject to our comments given elsewhere in this document. We recommend keeping the "Voltage Excursion" definition and eliminating Attachment 2 based on our comments elsewhere in our response.
Yes
Although the footnote is worded somewhat awkwardly, it is clear that a Generator Owner is not required to have protective relaying installed or set for these functions. Suggest using "Generator Owners are not required to have… installed or activated on their units".
Yes
A Generator Owner should only be required to report known limitations that might cause their unit to trip. As written, one could be in violation of the standard for some unknown limitation which might exist and that might only be known after an event has occurred. This question seems unrelated to R4 which states the time provided to respond to a written request for information. Rather, it seems to be related instead to R3 or R5.
No
This question references R5, but we believe the team intended to reference R6. The requirement for new units and plants to not trip within the envelope of Attachment 1 is reasonable; the design of turbines involves some off-nominal frequency versus accumulated time criteria and Attachment 1 is being proposed in view of existing design criteria of major manufacturers. While the Standards team has proposed this in view of OEM design criteria, it would be beneficial to obtain input from the OEMs to learn what issues if any they have with this proposal and what changes and/or incremental costs could be incurred to meet the Standard for new or existing generators. The design and ability of auxiliary systems to meet the requirements outlined in Attachment 1 will require review. To not trip within the envelope of the Attachment 2 Voltage Ride-through Time Duration Curves is another matter. No requirement such as this has ever been imposed on generating units in the past and we question the need for it now. The appearance of such graphs seems to have been in response to the performance of wind farms that tripped off-line by protective relays when disturbances occurred on the transmission system. The Attachment 2 VRT curve may thus be an appropriate requirement for wind turbine generators. The applicability to conventional generation, however, is questionable. Further, the curve and the supplemental tables (curve data points) seem to be at odds with the language of R2, e.g. R2.1.1 which states for three-phase transmission system zone 1 faults with Normal Clearing, interpreted to mean as little as 3 cycles up to and not to exceed 9 cycles depending on the transmission relay practice and transmission voltage application. Specific comments on and objections to R6-Attachment 2 are as follows: (1) It is not at all clear that a conventional generating unit could maintain synchronism during POI voltage events within the envelope of Attachment 2. The standard needs to explicitly state that Attachment 2 is not a requirement to maintain synchronism (which is already covered by TPL standards). This point must be made clear within either the text of the requirement or else in a footnote, not just the comment form. (2) Should the SDT retain this requirement, it would be advisable to limit the scope of Attachment 2 in R6 to generator over- and under-voltage relay settings and any unit auxiliary equipment over- and under-voltage protection whose operation could lead to the loss of the unit. However, it is also not at all clear whether auxiliary systems could be designed to withstand voltage disturbances within the envelope of Attachment 2. Further complicating auxiliary systems ride-through, while such a graph may be appropriate for wind farms, it is not appropriate for conventional synchronous generators that have a substantial capability to control the voltage they are subjected to during a system disturbance (unlike most wind farms) and whose critical auxiliary systems are usually (and should be) served from the generator bus (low side of GSU) and are thus insulated to some extent from what may happen on the transmission system. A more appropriate requirement for conventional generation would be to require an automatic over-excitation limiting (OEL) function that is coordinated with over-excitation protection. However, we believe OELs are now standard equipment among excitation equipment suppliers and should not need to be required in a standard. (3) It would be impractical, if not impossible, to test or otherwise verify generator ride-through for POI voltage disturbances within the envelope of Attachment 2. In view of the above considerations, and in the interest of treating all generation types

equitably, we believe a more appropriate approach to generator voltage ride-through would be deference to TPL standards for the types of transmission system disturbances where stability needs to be maintained. This has always been an acceptable criterion for conventional generation ride-through in the past. It is not stated in these terms in this proposed standard and independent review of a random sample of units could demonstrate the units may not meet this R6-Attachment 2 performance requirement though they would meet R2.1.1 and TPL standard requirements. It would be beneficial to state somewhere that any fault or other disturbance on the transmission system for which a conventional generator is expected to survive, a wind farm must also survive without tripping. (A statement such as that may be out of place in this standard and perhaps ought rather to have been included in the new TPL-001-1.) The proposed VRT criteria requires more study and analyses before introducing it so broadly in this standard for other than for wind turbine generators for which it has already been applied. Therefore, for the purposes of the R6 performance requirement, we believe that reference to Attachment 2 should be removed.
No
We agree that a new generating unit reasonably could be required to ride-though 90 percent or 110 percent voltage at the point of interconnection for 600 seconds at nominal frequency. However, this does not take away from the concerns expressed in response to Q4.
Yes
The second point under R3 causes the limitation to expire with rating increases. Is a 10 percent or more rating increase a realistic scenario and common enough to justify attention? 10 percent seems arbitrary and this provision could pose a hindrance to rating increases that may supply other reliability benefits. It may be advisable to remove this point. We believe that R2.1.4 must not allow relay settings to trip a generator within the no-trip zone for other system events that would not disconnect the generator. The phrase "generating plant or Facility" is used in R2, R3, R5 and R6, but not R1.
Individual
Larry Grimm
Texas Reliability Entity
Yes
(1) The implementation period in this standard is far too long. It is unreasonable to allow 11 years for a GO to provide a verified model for 50% of its generation capacity. All generation should comply with Requirement 2 within 3-5 years. (2) The periods allowed for providing correction of identified model deficiencies and updates for system changes are too long. It appears (from Attachment 1) that a GO has almost 2 years to provide a corrected verified model after a request from a TP or an equipment change (per Requirements R3, R4 and R5). This work should be completed within one year to ensure accurate system modeling. (3) It is unclear exactly what is required by Attachment 1, and how the material in the attachment relates to the Requirements. The Attachment appears to contain additional requirements. We suggest moving the required actions described in Attachment 1 into the applicable Requirements, such as the requirements and time periods for recording responses and providing new information to the TP. (4) It is unclear what the 10 and 11 year periods/cycles referenced in the first two rows of Attachment 1 refer to. This needs to be clearly explained somewhere. (5) It is our understanding that this standard is intended to require re-verification of models at least every 10 years, but there is no requirement that clearly sets forth any re-verification requirement or period. (6) Requirement 6 requires the TP to determine if a model is “usable” based only on whether the model is functional, omitting any consideration of whether the model is reasonably accurate. An incorrect model could satisfy 6.1, 6.2 and 6.3. We suggest adding an R6.4 relating to whether the model is reasonably accurate, i.e., whether it reflects actual unit performance. (7) In 4.2.3, in the first bullet, “with rating greater than” should be changed to “at greater than,” which is clearer and consistent with the parallel descriptions in neighboring sections. (8) In the “Consideration for Early Compliance” section, first bullet, “applicable regional entity policies” should be changed to “applicable region policies.” In our region, and perhaps others, there are applicable policies, but they are not “regional entity policies.” (9) Several very informal terms are used that should be replaced with more specific language, such as “walk down” (R5.2) and “local grid codes” (Attachment 1). In R6.2, the term

“negligible transients” in too indefinite and should be replaced by a more objective measure. (10) The terms “unit,” “plant,” and “facility” are used inconsistently in the draft. (11) M4 refers to a “request” and a “response,” but there is no request/response interchange in the associated Requirement R4.
Yes
In the ERCOT Interconnection (ERCOT) there are well-established generator under-frequency relay settings (ERCOT Nodal Operating Guides 2.6.2) that are more stringent than those proposed in this standard. ERCOT also has existing low/high-voltage ride-through requirements (ERCOT Nodal Operating Guides 2.9(2)) that are less stringent than those proposed in the standard. We would prefer to include the existing ERCOT parameters in this standard to apply within the ERCOT Region, rather than having different ERCOT and NERC requirements. We suggest that the drafting team consider adding ERCOT-specific parameters in Attachments 1 and 2, matching the existing ERCOT Nodal Operating Guide requirements, in addition to the stated parameters for the other interconnections.

Yes
Dominion suggests: MOD-026 Section 4.2.4 needs to be removed to be consistent with other standards. MOD-026 Section 2.1.1 “match” should be changed to approximate. The model will never exactly match. MOD-026 Section 2.1.6 remove “structure”. MOD-026 R3 bullet 3 “match” should be changed to approximate. The model will never exactly match. MOD-026 Attachment 1 title is missing “M”. MOD-026 Attachment 1 column “Condition” replace eleven and ten with “eleventh” and “tenth”. MOD-026 Section 4: Applicability should spell out testing exceptions.
Yes
No
The question is confusing because of the phrase “set for these functions.” The language in Requirements R1 and R2 as well as footnote 1 suggest that GOs are not required to have the specific relays “installed or activated on its units. If however, the relays are activated then they are required to be “set” pursuant to the standard.
No
Requirement R4 seems to be duplicative of the obligation to notify the same entities under Requirement R3. Perhaps the language in R4 could be clarified to indicate the distinction.
No
This appears to be a design question that presumably the standard drafting team researched and quantified to provide a basis in framing the curves of Attachment 1 and Attachment 2. If this is true, more documentation should be provided to the ballot body.
Yes
Yes
Dominion suggests the following: Section 3 should capitalize “frequency and voltage excursions”, as they are defined terms. Do not understand R3 bullets. How does increasing your units rating by

≥10% change this? Attachment 2 does not match ±5 voltage schedule per the definition of Voltage Excursion. This curve is not possible. R6 grants new generators exceptions. Where are the exceptions for existing generators? This standard only applies to frequency and voltage excursions within the defined limits. The attachments and requirements go outside of this bound placing much more stringent criteria on the operation of the units. These more stringent criteria may not be possible and should be removed from the standard to align with the definition of applicability. The last sentence of the associated Implementation Plan is confusing. Suggest revising to read: “Upon the effective date of PRC-024-1, R4 of PRC-006-1 will also go into effect.”

Yes
Yes
It is good strategy to include synchronous condensers with other dynamic reactive devices as they all fall under the same category – providing dynamic reactive support.
Yes
R2: The wording for Part 2.1.4 makes it seem that the required model structure and data only applies to the voltage regulator portion of the excitation system. The DRS recommends that R 2.1.4 be reworded to: "Model structure and data for the excitation system, for the plant volt/var system, and for the closed loop voltage regulator." R5: A "technically justified request" needs to be clarified. We suggest using words similar to those used in the slides associated with this project: "A technical justification that demonstrates, through simulation and/or measured response, that the unit or plant affects a stability limit, or evidence that the simulated unit or plant response does not match measured unit or plant response." R2.1.3 : The DRS recommends a clarification to “rotational inertia.” Please consider the following wording: "Generator (or plant equivalent) model structure and data (such as reactance, time constants, saturation factors, rotational inertia (including all rotating components), or equivalent data)."
No
Exceedance implies that the frequency is greater than desired frequency. Since the intent is to identify frequencies greater or less than a specified amount from the desired frequency, replacing the word “exceedance” with “deviation” and “beyond” with “outside” seems more appropriate.
No
It is unclear how an entity can have protective relaying settings for new units. Since "existing units" covers units under construction as specified in footnote 2, "new" implies planned units and thus the associated relaying would also be "planned" not "existing." It appears the word “new” should be deleted from sentence one of R1 and sentence one of R2.
Yes
We assume this pertains to R5 not R4. 30 days is probably not enough time for a GO to determine a suitable estimate. We recommend 90 days.
Yes
Requirement R6 not R5.
Yes
While we agree, a technical basis for this 600 secs. duration (and each breakpoint) would be helpful.
Yes
Under R5, Severe VSL Requirement 55 should be Requirement 5. R7 refers to generator protection trip settings as "specified" in R1 & R2. Settings are not specified in R1 & R2. We recommend using "referred to" instead of "as specified." “The comments expressed herein represent a consensus of the views of the above named members of the [insert the full name of the group] only and should not be construed as the position of SERC Reliability Corporation, its board or its officers.”

LG&E and KU Energy
Brent Ingebrigtson
Yes
Each requirement can be accomplished by itself; but the 90 day vs 60 day vs 180 days on the various 12 requirements will likely create documentation confusion for communication and data retentions. LG&E and KU Energy suggests tha the draft be simplified to enhance coordination amongst requirements by applying a single time frame for completion of the requirements.
Yes
No
Comments: LG&E and KU Energy recommends the wording be changed for R1/R2 to “Each GO shall set the generator frequency protective relaying, if installed, not to trip during the following…” Or, change from “Each GO” to “GO’s that have frequency and voltage protection functions activated to trip a new/existing generation unit.”
No
: LG&E and KU Energy agrees with the approach but recommends 60 days. Moreover, this appears to be R5, not R4.
Yes
: This appears to be R6, not R5 and should be achievable for new units.
No
LG&E and KU Energy agrees with the SERC Generation Subcommittee and proposes that the LVRT portion of the curve between 0.4 secs and 3.0 secs should be 0.90 voltage PU. Electrical powered devices at the plant will begin to loose their ride-thru capability in the window of 0.2 to 0.65 seconds (as referenced in the AREVA whitepaper on PRC-024 and based on industry experience).
Yes
LG&E and KU Energy would prefer to have 60 calendar days on

RFC
Yes
Yes
Yes
Yes
RFC offers the following suggestions regarding the Violation Severity Levels: 1. VSL for R1 – There is a disconnect between the date listed in the VSLs and requirement. The timeframe for the “Lower” VSL starts at 90 calendar days though the requirement states “within 30 calendar days”. Where does an entity fall if they provide instructions 45 calendar days of receiving the request? Based on the current VSLs, they would not even fall under the “Lower” VSL. 2. VSL for R3 – To be consistent with the language in the “Severe” VSL, add the following words to the end of the “Lower”, “Moderate” and “High” VSLs: “…as specified in Requirement R3.” Or conversely remove this language from the “Severe” VSL and replace with “R3”. 3. VSL for R4 – To be consistent with the language in the “Severe” VSL, add the following words to the end of the “Lower”, “Moderate” and “High” VSLs: “…as specified in Requirement R4.” Or conversely remove this language from the “Severe” VSL and replace with “R4”. 4. VSL for R5 - To be consistent with the language in the “Severe” VSL, add the following words to the end of the “Lower”, “Moderate” and “High” VSLs: “…as specified in Requirement R5.” Or conversely remove this language from the “Severe” VSL and replace with “R5”. 5. VSLs for R6 - To be

consistent with the language in the “Severe” VSL, add the following words to the end of the “Lower”, “Moderate” and “High” VSLs: “…as specified in Requirement R6.” Or conversely remove this language from the “Severe” VSL and replace with “R6”.
Yes
Yes
Yes
Yes
For R5, Part 5.1 and 5.2 – suggest adding the word “PRC-024” in front of “Attachment 2” in the last line of the respected Parts.
Yes
Yes
For R3, add the word “generating” in front of the word “Facility” to be consistent with other requirements. The followoing are reccomendations related to the Violation Severity Levels: 1. VSL for R1 – a. The VSL should start off with the following language to be consistent with the language within the requirement: “The Generator Owner that has frequency protective relaying activated to trip its new or existing generating unit failed to…” b. Since there are a number of Parts associated with R1, the SDT may want to consider gradating the VSL rather than making it Binary. 2. VSLs for R2 – a. The VSL should start off with the following language to be consistent with the language within the requirement: “Generator Owner that has voltage protective relaying activated to trip its new or existing unit or generating plant or Facility failed to…” b. There is no reference to any of the Part numbers for R2. Suggest adding references to the Parts to the VSL or since there are a number of Parts associated with R2, the SDT may want to consider gradating the VSL rather than making it Binary. 3. VSLs for R3 a. Suggest not using the language “…prevents compliance with Requirement R1 or R2…” since it is not consistent with the language of the requirement. Suggest stating: “… prevents the Generator Owner from meeting the criteria in Requirement R1 or R2…” 4. VSLs for R5 a. Fix the typo in the “Severe” VSL. Change “R55” to “R5” 5. VSLs for R6 a. The first VSL under the “Severe” suggest referencing “Attachment 1” rather than “Requirement 6.” This will make it consistent with the other “Severe” VSL. b. Suggest adding another VSL which references the GO not following the conditions and exceptions in Parts 6.1 through 6.7. As written, there is currently no reference to the Parts.

FirstEnergy provides the following additional comments and suggestions: 1. Unfortunately as written this standard may require Generator Owners to purchase software to properly analyze voltage excursions to verify their models. This level of expertise historically existed with the TO/TOP, not the Generator. It will be very difficult for the Generators to develop and maintain this expertise for a verification that will only be run once every 10 years. Also, if additional instrumentation is needed to capture this data, nuclear fleets may be challenged to ensure at least 30% of their applicable units will comply with R2 based on refuel outage schedules. 2. Applicability Section 4.2.4 – We do not agree with the Planning Coordinator being able to include additional units. Even though the standard says that the PC would have to show technical justification, it should not be left to their discretion to

add an entity's unit as applicable. A regional entity is the only ultimate authority that can make this decision and the PC should go through its Regional Entity to prove this justification. We suggest removing this section. Furthermore, it states that the technical justification would need to be verified. It is not clear who would make this judgment on the validity of the justification. 3. We are not clear as to what the standard is referring to when it mentions "volt/var control". 4. In requirement 2.1.1, of R2 it states "2.1.1. Documentation demonstrating the unit or plant's model response matches the recorded response for a voltage excursion at the generator or plant point of interconnection from either a staged test or a measured system disturbance." The SDT should specify the magnitude of the voltage excursion referenced in this section. 5. In the SDT notes they make reference to allowance being given for identical (Sister) units but I did not see it anywhere in the standard. Can Generator Owners take credit for Sister units when supplying the model verification? 6. As a general note, the first draft of this standard was reviewed by industry over 2 years ago. It seems like a long time between drafts to expect the industry to review and vote on a standard given that there may be several new personnel in a company that are new to compliance. I would have hoped the team came out with only a comment period at this time. 7. Attachment 1 - General Comment – "M" is missing from title of attachment "OD-026 Attachment. Also. We assume that the mentioned "voltage excursion" is in reference to the proposed definition found in the proposed PRC-024-1. If so, it should be capitalized and added to the front of the standard and balloted with the standard.
Yes
Yes
Although we agree with the requirement, we noticed that the VRF and Time Horizon is missing for R4. We suggest a LOWER VRF and Long-term Planning Time Horizon.
No
Requirement R5 – It may not be feasible for the GO to provide this information in 30 days. We suggest allowing 90 days. Regarding 5.2 and the estimation of the probability, we are not clear as to what is required. The wording is confusing and cannot offer suggestions because we are not sure what the intent is. R5.1 – Some nuclear plants will not be able to run at 95% voltage indefinitely as required as that voltage is lower than each plant's Licensing Basis for degraded grid voltage. We ask that this standard include an exception for nuclear generators that allow them to report what % of grid voltage will force them into a Limiting Condition of Operation if that % voltage is higher than 95%.
Yes
FirstEnergy offers the following additional comments and suggestions: Requirement R3 – It is not clear how this requirement relates to the identified generator equipment limitations. Furthermore we are not clear what "continuous capacity rating" is referring to. We suggest the removal of the second bullet which states "the generator unit continuous capacity rating increases >= 10%". Requirement R3 – This standard does not account for the fact that nuclear plants have equipment other than the generator that potentially will trip the unit at frequencies/ voltages outside of the limits shown in Attachments 1 and 2. Nuclear plant voltage and frequency trip points are set to ensure safety equipment will operated as specified in the plant's License. The standard needs to allow nuclear generators the ability to specify if something other than the generator protective relays dictates where a unit will trip. Under 6.7 (exception) - A unit or generating plant or generating Facility may trip if the protective functions (such as out of step or loss of field functions) operate due to an impending or actual loss of synchronism or due to instability in power conversion control equipment. Maybe this section should include an exception for Volts/Hertz protection. General - The standard should state whether disturbances that include both frequency and voltage excursions are covered under the standard. For example, our Volts/Hertz protection trips in 45 seconds at 110%. The standard calls for a HVRT of 600 seconds at 110%. This current Volts/Hertz setting would not meet the standard.

Modeling wind generation without a developed generic model is a concern. If the generic models are not developed once the standard is effective are exceptions going to be made to accommodate this?
No
The definition for Voltage Excursion provided in the most recent draft of PRC-024-1 is closer to the definition of a voltage deviation. The Voltage Excursion definition should be modified to include a time duration component, e.g. “fast transition” of system voltage beyond the continuous operating band of ±5% of scheduled voltage. Otherwise, a very slow voltage transition could be considered a voltage excursion if it exceeded the voltage band, thereby missing the intent of and time frames set forth in Attachment 2. A similar comment is applicable for Frequency Excursion. A transition time duration is key to the definition of both Voltage Excursion and Frequency Excursion due to the significant impact that these parameters can have on a generating facility.
Yes
Yes
(R4 referenced in the question actually should refer to R5 in the standard)
No
There are going to be certain exceptions to new units or facilities being capable of staying on line under the listed circumstances just as there are current exemptions for existing facilities. Exceptions could be related to VFD (variable frequency drive) operation or motor operation at the plants, which would be true of both existing and new generating plants. There is also a possibility of overcurrent trips during these voltage conditions, tripping would not necessarily be limited to voltage or frequency relays. It would be difficult for Generator Owners to answer this question fully without a thorough

study of how the frequency and voltage excursions will impact generation loads. Generation protective relays do not typically base their protection on transmission system voltages at the point of interconnection.
No
In studying PRC-024 Attachment 2, PacifiCorp believes that the “high voltage duration” curve, which defines the upper edge of the no trip envelope by depicting a 1.10 pu voltage between 1 second and 600 seconds, may potentially conflict with the synchronous generator Inverse-Time V/HZ Relay with Fixed-Time Unit setting recommendations contained in IEEE Std C37-102. For example: At 110% V/Hz, the relay will trip in 291.6 seconds (within the PRC-024-1 No Trip Zone). Additionally, at 109% the setting would be at 1166.4 seconds. PacifiCorp requests that the Standards Drafting Team (“SDT”) further evaluate PRC-024 Attachment 2 to determine if an adjustment to the high voltage duration curve could eliminate this potential conflict.
Yes
In addition to the feedback noted above, the NO votes submitted by PacifiCorp are accompanied with the following comments: (1) Industry practice for generation protective relays is to use the terminal voltage of the generators, not the system voltage or point of interconnection. Generator Owners could provide generation responses and data as contemplated by the standard, but they should not be held responsible for the answers provided without the benefit of associated transmission planning groups. Generator Owners, under this framework, will rely completely on feedback from their associated transmission planning groups in order to provide responses. It concerns PacifiCorp that the draft standard does not address the need for transmission planners to provide the required transmission system response data to Generation Owners in order to make these assessments, or allow for the joint responsibility of transmission planner for the accuracy of the data as it concerns planning studies. (2) PacifiCorp maintains several additional concerns about complying with the standard as drafted: • R1.1.5 – PacifiCorp is not aware of relays used for generator protection that use frequency rate of change to calculate trip points. Generator protection relays use frequency set points and time at certain values, not rate of change of frequency to make tripping decisions. It may not be technically feasible to immediately comply with this sub-requirement of the standard as written. • R2.1.1 - PacifiCorp requests clarification concerning what the SDT has considered a zone 1 fault. PacifiCorp acknowledges that transmission and distribution line relays have zone 1 and zone 2, but the Company does not believe that this is something typically used in the generator protection context. A zone 1 fault needs to be defined somewhere to the extent that it is not clarified in the standard already. • R3 – This requirement was clear in the initial February 2009 draft of PRC-024-1, but the current draft does not clarify that the Generator Owner must upgrade the equipment that is causing a limitation. For example, if an entity upgrades its (synchronous) turbines to increase capacity by greater than 10%, but the voltage limitations still exist because they are related to the generator, which is not upgraded, the exemption would expire under the current language. The SDT should revisit this issue using the initial draft of PRC-024-1 as a guide. • R6 – The failure to include exemptions for new generating plants may have unintended consequences. Some voltage excursions have caused excessive torque on PacifiCorp-owned generators which has caused the controls to trip the units, rather than the relays themselves. If an entity constructs a new plant and cannot document any exemptions due to equipment limitations, such entity may experience future compliance and operational issues. The SDT should revisit this in light of further consideration of potential unintended consequences. . (3) PacifiCorp has concerns that certain references to Attachment 2 in Requirement R2 need to be clarified. Attachment 2 references the generator point of interconnection not the terminal voltage; therefore, clarifications to the proposed language are necessary. As such, the following recommended revisions to Requirement R2 are offered: 2.1 When operating under normal system operating conditons within 95% and 105% of rated generator terminal voltage and during the transmission system conditions define in PRC-024 Attachment 2, with the following clarifications for PRC-024 Attachment 2 are provided: 2.1.1 For three-phase transmission system zone 1 faults with Normal Clearing, set voltage relays transmission system faults should be cleared based on actual fault clearing times, not to exceed 9 cycles. Voltage relays should be set to not trip prior to transmission system fault clearing time. 2.1.2 If a Transmission Planner’s study (based on the location specific voltage recovery characteristics) recommends less stringent voltage relay settings system protection settings than those on PRC-024 Attachment 2, set voltage relays either to the less stringent Transmission Planner’s settings or the setting applicable to in PRC-024 Attachment 2. 2.1.3 Tripping a generator via If a Special Protection System (SPS) or Remedial Action Scheme (RAS) includes tripping

a generator after fault initiation, then setting the SPS or RAS relay to trip the generator even if in the is acceptable in the “no trip zone” in PRC-024 Attachment 2 is acceptable. 2.1.4 If clearing a system fault necessitates disconnecting a generator, this action is acceptable than setting relays to trip the generator even if operating within the “no trip zone” specified in PRC-024 Attachment 2 is acceptable. (4) As drafted, Requirement R1 of proposed PRC-024-1 conflicts with WECC’s Off-Nominal Frequency Load Shedding Plan (“WECC Coordinated Plan”), and could potentially result in negative reliability impacts if enforced in the Western Interconnection. A WECC Regional Variance that includes the WECC Generator underfrequency and overfrequency operation requirements, as identified in the WECC Off-Nominal Load Shedding Plan, must be added to the proposed standard. WECC has developed, implemented, and verified the effectiveness of the WECC Coordinated Plan and any deviations from the requirements of the plan may negatively impact its effectiveness. (5) PacifiCorp believes that the SDT should rewrite Requirement R4 to add specificity as to what must be included in a written response to a submission concerning an equipment limitation, similar to the specificity and clarity included in MOD-026, Requirement R3. (6) PacifiCorp offers one comment on the Violation Severity Limits (“VSLs”) proposed for Requirements R1 and R2 of PRC-024-1, which require that frequency protective relaying (R1) and voltage protective relaying (R2) be set so that they do not trip within the criteria listed in the respective requirements “unless the Generator Owner has documented and communicated a non-protection system limitation in accordance with Requirement R3.” However, the language of the binary Severe VSL for Requirements R1 and R2 only identifies the failure to set protective relaying, without recognizing the exception granted for documenting and communicating a non-protective system limitation. As written, the applicable entity could be compliant with the language of Requirements R1 and R2, but based on the language of the VSLs, they would be non-compliant. The SDT should add this critical clarification to the VSLs. (7) PacifiCorp has a concern that the PRC-024 voltage ride-through requirements identified in Attachment 2 are wholly independent of dynamic reactive power requirements for generators. As an analogy, some European generator interconnection standards and requirements link these two variable. PacifiCorp understands that PRC-024-1 is a generator protection standard; however, the SDT should address the manner in which generator dynamic reactive requirements impact PRC-024-1 Attachment 2. (8) Many European generator interconnection standards and requirements include different voltage ride-through requirements for synchronous and non-synchronous generation. PacifiCorp is concerned that the SDT has inappropriately developed a “one-size fits all” standard applicable to all generation platforms. PacifiCorp recommends that, based on the significant differences between existing and emerging generation platforms, separate voltage ride-through standards be developed for synchronous and non-synchronous (i.e., wind and solar) generation platforms. Different sets of standards will more effectively address such differences in the various generation technologies.

TVA believes that 60 HZ +/- 0.5 Hz is normal but the voltage schedule +/- 5% is not necessarily normal. The normal voltage should be consistent with VAR-002 requirements and defined by the voltage schedule for the unit. Change the verbiage to “... exceedance of system voltage beyond the applicable voltage schedule
Yes
No

The ride through criteria should not be anything beyond currently used critical clearing times (2nd zone protection or breaker failure) that switchyard breaker failure protection is based on. It is questionable whether large steam plants can survive anything beyond this. Plants with aux power systems normally fed from the switchyard would be even more questionable as the transient is not shielded by the action of the voltage regulator for the generator.
No
The proposed bands would need to be considered by new plant designers and incorporated into their design basis if feasible. Specific criteria have not been provided in new plant design guidance provided by EPRI Utility Requirements Document (URD) nor in other industry standards used by new plant designers. The frequency band was considered for some new plant designs and no concerns were identified. However, it is not clear if all or even most of the designers for other nuclear/fossil designs have considered this. The proposed voltage band has caused many concerns and probably is not achievable for existing or new steam plants because electrically powered equipment (motors, MCC components, contactors, etc.) have been and are normally designed for proper operation as follows: The normal voltage boundaries have been specified to be for the steady-state operating conditions based on the ANSI C84.1-2006 “American National Standard for Electric Power Systems and Equipment – Voltage Ratings (60Hz)”as follows: a. Normal Conditions: ±5% Continuous Duration b. Emergency Conditions: ±10% not specified Duration These Criteria are currently widely used in practice and can be complied with by all types of new generating plants designed with an in-plant voltage regulation capability. In connection with these criteria, all new equipment, both on the transmission system and in new generation plants must be chosen in order to be able to operate and withstand these voltage excursions. For transients, the above should be applied for conditions lasting more than one second. Transient conditions lasting less than one second, can be more severe and the equipment can still ride through it for about 0.5 seconds. A design solution to address severely degraded voltage lasting more than one second, is to utilize expensive voltage regulation devices, normally not utilized in the past at most power generation plants. It's not clear why a plant should be required to withstand any transient beyond that expected by a switchyard fault with one failed breaker (the basis for critical clearing times for second zone or breaker failure protection). An R&D effort should be considered to investigate reasonable steam plant voltage excursion ride through capabilities if a criteria is needed.
No
TVA proposes that the LVRT portion of the curve between 0.4 secs and 3.0 secs be changed to 0.90 PU voltage. Electrical powered devices at the plant can begin to lose their ride-thru capability in the window of 0.2 to 0.65 seconds (as referenced in the AREVA whitepaper on PRC-024 and based on industry experience.)
Yes
During the drafting process, quite a bit of feed back was provided to the SDT about concerns if this became a performance standard and the response was that this is only a relay setting criteria. However, plant performance aspects have been incorporated using the allowed operating bands developed as for use in relay setting coordination. The concerns with this include: • Important Existing nuclear plant settings are inside the published no-trip bands • How quickly plant secondary system motors will decelerate with voltage below ANSI MG-1 criteria. • Why is a voltage ride through criteria beyond existing second zone or breaker failure/critical clearing time design approaches needed? For frequency, the ride-thru criteria should be sufficient for UFLS to perform its function. Also, the lowest frequency allowed for unit operation must accommodate the turbine blade resonance low frequency requirement for large steam plants (57.5 to 58.5 Hz, depending on the turbine OEM). Similar steam turbine restrictions also apply for the high frequency requirement. For voltage, the ride-thru criteria should be long enough in duration for second zone or breaker failure protection critical clearing time. Voltage recovery to 0.9 PU following critical clearing time is necessary to ensure electrically powered equipment will perform correctly. Nuclear power plant interface requirements are addressed in NERC NUC-001-2. PRC-024 should refer to nuclear plant interface requirements managed under NUC-001-2.

Applicability to Smaller Units: The proposed standard allows for generators with a capacity factor under 5% rated over 100 MVA to be excluded from verification. There are many older generators that meet this criterion that would be critical during stressed system conditions with high loads. Generators under 100 MVA could also be critical in some local areas. The applicable criterion should be the same as those used in the Compliance Registry. No capacity factor exemptions should be allowed without a technical justification. Also see section 4.2, footnote 2. This is a broad exemption, and as we saw recently during the continent-wide heat wave, almost all units within our control area were operating. The requirement is to test once every 10 years. This is not an excessively onerous requirement.
Yes
The inclusion of all reactive resources as BES Elements covered by a separate standard would be consistent with the current draft of the proposed Bulk Electric System (BES) Definition and Designations being proposed by the BES standard drafting team.
Yes
Requirement R5 – Please define the term “technically justified.” We recommend using wording similar to Comment form paragraph 8) in that definition: “[S]upply technical justification that demonstrates either a) the unit affects a stability limit, or b) the simulated unit response does not match a measured unit response (most likely captured during a system disturbance event).”
No
Requirement 1, paragraph 1.1 requires that units remain connected, 1.1. When operating within a frequency range of 59.5 Hz to 60.5 Hz, inclusive. Yet the definitions of Frequency and Voltage Excursion could be misinterpreted to apply only to trips occurring when the frequency or voltage at the time of trip-out was outside the normal operating range. We do not believe that it was the intent of the drafting team to exempt units which might trip within the normal operating range during an event. Therefore, we propose to change the focus from Excursions outside a normal operating range to variations within and outside that normal operating range, out to specified limits (the operating envelope). We suggest that the term Frequency and Voltage Excursion be re-defined as variations follows: Frequency [delete “Excursion” add “Variation”] – an [delete “exceedance of system” add “unscheduled, excessive variation in BES”] frequency within a planned continuous operating band, e.g., 60±0.5 Hertz, and beyond a planned continuous operating band to specified limits (Attachment 1). Voltage [delete “Excursion” add “Variation”] – an [delete “exceedance of system” add “unscheduled, excessive variation in BES”] voltage within a planned continuous operating band, e.g., 0.95 to 1.00 per unit, and beyond a planned continuous operating band to specified limits (Attachment 2). This definition includes certain types of specified variations: (a) Operation within an allowable normal operating bands, such as voltage variations within an allowed ±5% of scheduled voltage, e.g. from 0.95 to 1.00 per unit. (b) Operation within a modified scheduled operating band voltage change, such as with the range around a scheduled nominal voltage reduction during a brown-out, where the allowed voltage operating band is intentionally reduced, and (c) Operation up to limits specified and/or referenced in MOD-026. For example, voltage variations either within or outside of the scheduled operating band of 0.95 to 1.05 per unit of nominal, e.g., a 328–362 kV operating band around a 345 kV scheduled nominal voltage. We propose to change the Purpose wording (and similar wording elsewhere) as follows: Purpose: Ensure generating units remain connected during frequency and voltage [delete “excursions” and add “variations”] and ensure expected generating unit performance during frequency and voltage [delete “excursions” and add “variations”] is communicated to Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners for accurate system modeling.

Requirement R3. – Delete the word “expires” and replace it with the words “documentation should be renewed” The underlying technical justification for this standard should be supported by a white paper similar to the document available at this link (AREVA PRC-24 White Paper Clean.doc): http://xa.yimg.com/kq/groups/28536519/188315025/name/AREVA%20PRC-24%20White%20Paper%20Clean.doc Requirement R3, bullet 1 allows for an exemption for existing plants subject to equipment failures until “the limitation [limiting equipment] is repaired or replaced.” Similar temporary exemption language should be incorporated in R6 for new units that experience equipment failure-related limitations. The drafting team may also wish to address a requirement for repair or replacement timeliness in both R3 and R6.

We’re not sure these definitions serve a useful purpose, since, later on in the standard, these excursions are defined by the curves in the attachments.
No
The sub-requirements of R2 could be read as prescribing exactly where you have to set this relaying. Often our relay set points originate with the OEM and are based on protecting the Generator and Turbine. The finalized curves that originate here should be used as a means to arrive at those settings, but, as long as the settings do not cause the relaying to operate for the ranges in the finalized curves, the requirements should be satisfied (It shouldn’t have to be stated that you can set them less stringent, if you can not have the relaying entirely).
No
It should be ascertained how and if the TP will use this in TPL-001 analysis. It will be unclear how to demonstrate compliance.
No
This appears to refer to R6. The proposed bands should be considered by new plant designers and incorporated into their design basis if feasible. Specific criteria have not been provided in new plant design guidence provided by EPRI Utility Requirements Document (URD) nor in other industry standards used by new plant designers. The frequency band was considered for some new plant design basis and no concerns were identified. It's not clear if all or even most of the designers for other nuclear/fossil designs have considered this. The proposed voltage band has caused many concerns and probably is not achievable for existing or new steam plants because electrically powered equipment (motors, MCC components, contactors, etc.) has been and is normally designed for proper operation as follows: The normal voltage boundaries have been specified to be for the steady-state operating conditions based on the ANSI C84.1-2006 “American National Standard for Electric Power Systems and Equipment – Voltage Ratings (60Hz)”as follows: a. Normal Conditions: ±5% Continuous Duration b. Emergency Conditions: ±10% not specified Duration These Criteria are currently widely used in practice and can be complied with by all types of new generating plants designed with an in-plant voltage regulation capability. In connection with these criteria, all new equipment, both on the transmission system and in new generation plants must be chosen in order to be able to operate and withstand these voltage excursions. For transients, the above should be applied for conditions lasting more than one second. Transient conditions lasting more than one second, can be more severe and the equipment can still ride through it. A design solution to address severely degraded voltage lasting more than one second, is to utilize expensive voltage regulation devices, normally not utilzed at power generation plants. It's not clear why a plant should be required to withstand any transient beyond that expected by a switchyard fault with one failed breaker (the basis for critical clearing times for second zone or breaker failure protection). An R&D effort should be considered to investigate steam plant ride through capabilities if a criteria is needed.

No
The LVRT portion of the curve between 0.4 secs and 3.0 secs should be 0.90 voltage PU. Electrical powered devices at the plant will begin to loose their ride-thru capability in the window of 0.2 to 0.65 seconds (as referenced in the AREVA whitepaper on PRC-024 and based on industry experience)

The requirement is achievable in concept, however, there is a serious omission in the definition of the requirement. It is not clear how the magnitude of the three phase voltage is defined, for example: average of the individual phase magnitudes, magnitude of the least phase, positive sequence. Also, it should be clearly defined whether the requirement applies to the rms, 60 Hz component, or peak magnitude of the voltage.
Yes
GE has no comment
Yes
Clause 6.1.1 allows an exception from meeting the ride through requirements for voltage support equipment that is not in service. Often such equipment is installed solely for the purpose of acheiving ride through. It is not clear that there are any NERC standards requiring that this equipment be maintained to have a minimum level of availability. As worded, this clause could create a means by which a GO could indefinitely avoid requirements, and subsequent penalties for non-compliance.

If the SDT were to prepare a table showing how the requirements in the prior version were incorporated into the present version and included that in its background information on the standard, this question would be answered.
Yes
The team needs to develop a consistent rationale on synchronous condensers in all of the standards being addressed in Project 2007-09. The team should consider asking the NERC Planning Committee to develop a white paper on the need (or lack of need) for synchronous condenser data.
Yes

1. The capacity factor calculation referenced in 4.2 should refer to a future attachment that the team would develop that explains (a) which reliability standard one would use to for a unit's capacity rating (such as MOD-010) for the calculation and (b) a sample calculation. 2. In 4.2.4, the sentence "Any technically justified unit requested by the Planning Coordinator" should specify (a) the entities that may develop the technical justification, (b) the entity who will evaluate that technical justification and (c) the criteria for judging whether an excluded unit should be included. 3. In R1, first bullet: a. Would the instructions issued by the Transmission Planner on "on how to obtain the list of acceptable excitation control system and plant volt/var control function model for use in dynamic simulation" cover "acceptable" verification via staged tests and "acceptable" verification by a measured system disturbance per R2.1.1. b. Are Transmission Planners the appropriate entity to determine "acceptability" of models or verification since there are about 120 Transmission Planners registered in the Eastern Interconnection? See the comment below regarding R2.1.1 4. R2.1.1 addresses verification via either staged tests or a measured system disturbance. However, the standard leaves the judgment of the acceptability of verification performed by a GO to the Transmission Planner. We suggest that the team include an attachment to the standard that provides guidance for how to perform acceptable verification, covering both staged testing and a measured system disturbance. 5. R5 is unclear. For example, does the 90-day submission period in 5.1 address submissions under 5.2 and 5.3, or does it require that the GO merely acknowledge receipt of the request within 90 days? Since 5.2 addresses plans to verify a model, why would "corrected" data in 5.3 be due within 90 days? 6. Both R3 and R5 require GO action in response to a notification by a Transmission Planner (R3) or a Planning Coordinator (R5). Can a Transmission Planner or Planning Coordinator require a response from a GO for generators that are not yet verified by the GO per the timetable in section 5? If not, it appears that R3 and R5 should be rewritten to recognize this limitation. 7. The July 29 webinar made clear that generator exciter model verification applies to synchronous generators and the plant volt/var control function applies to non-synchronous generators. It would be helpful if this clarification was made in the standard itself, perhaps in the purpose statement.
Yes
Yes
A one-sentence statement should be added stating that the protective relays affected by this standard are only the generator protective relays, not any other relays for the unit and/or facility.
Yes
Yes
No
Typical OEM recommended protective relay settings for generator UV are significantly more stringent than that which is outlined in Attachment 2 of the draft standard. Intuitively, it would seem that a generator and its auxiliary connect loads having the requirements to ride out 0.7 pu voltage for a period of 2 seconds is unrealistic.
Yes
a. Per the July 29 webinar discussion, R2.1.1 needs to be rewritten for clarity. b. The "exception" process in R3 and R4 is too vague as to "who" decides whether this standard applies to a generator. If a GO describes the limitations per R3 and one of the four entities listed in R4 inquires about a specific limitation, and the GO subsequently replies to that entity, is the exception confirmed? Under what circumstances a description of limitations by a GO in R3 would be challenged? Unless the exemption to this standard is made clear, the result will be confusion when the standard is approved.

PPL Electric Utilities
No

The expression, “Units or plants” in para. 4.2 should be changed to “units” to make it clear that a plant with, say, three large fossil units at 90% CF and a standby diesel genset at ~0.1% CF does not need to test the diesel. Also, eliminate the word “to” in the expression in para. 4.2.1, “For each plant with a gross aggregate nameplate rating greater than to 100 MVA”
Yes
Yes
Yes
1. Each requirement can be accomplished by itself; but the 90 day vs 60 day vs 180 days on the various 12 requirements will likely create documentation confusion for communication and data retentions. Suggest that the draft be simplified to enhance coordination amongst requirements by applying a single time frame for completion of the requirements. 2. Paras. R2 and R2.1.1 are not clearly worded. The present R2 text should end after the word “software;” and para. R2.1.1 should state that “Verification consists of developing one or more models that collectively include the following information:” The present R2.1.1 text, “acceptable to the Transmission Planner,” is not included in this suggested revision to make it clear that the R2 Violation Severity Levels later in MOD-026-1 pertain to a GO’s first submittal of a verified model, and the R3 Violation Severity Levels deal with failure to meet follow-up requirements if the Transmission Planner finds the first submittal unacceptable. This distinction is particularly important given the compliance criteria ambiguity discussed in comment #3 below. If on the other hand it was intended that models achieve verified status only after being accepted by the Transmission Planner, the term “verified model(s)” in the R2 Violation Severity Levels should be replaced with, “initial submittal of proposed-verified model(s)”. 3. There is presently no definition of the voltage excursion magnitude and intensity or the recording instrumentation sampling rate required for a valid verification event, nor are there any specifics regarding how closely the model must match the recorded response. The references in MOD-026 provide guidance but not necessarily NERC pass/fail criteria, especially since Transmission Planners may differ in their preferences. Perceived shortcomings in these respects would presumably trigger the Transmission Planner expression of concern described in para. R3, but it would be better to establish the rules up-front rather than addressing the matter only after a GO has attempted to comply with MOD-026. 4. The definition of a “technically justified request” in para. R5 is unclear. Does this term apply only if a model fails to meet the requirements of R6.1-R6.3, or can there be other reasons? In the latter case the wording of the R5 Violation Severity Levels should be modified to start the clock only after agreement has been reached that a request is technically justified. 5. The means by which a walk-down would lead to identification of model parameters in para. 5.2 is not understood.
Yes
1. The question above presents simple +/-0.5 Hz and +/-5% definitions of Frequency Excursions and Voltage Excursions respectively, but the time-related criteria in Attachments 1 and 2 are much more complex and are referenced in R6 as pertaining to the defined terms in question. Part A (Introduction) of this and all NERC standards should include a section dedicated to definition of terms used in the standard, if they are not already included in the NERC Glossary. 2. The need for excursions as severe as those of Att.2 should be confirmed. Anything beyond +/- 4 kV for our 230 kV interconnects (+/-1.74%) would be considered abnormal for our system (PJM).
No
Recommend the wording be changed for R1/R2 to “ Each GO shall set the generator frequency protective relaying, if installed, not to trip during the following…”
No
1. Excursion-estimate requirements for existing units are presented in R5, not R4. Our comments below pertain to R5. 2. The question above cites “frequency and voltage excursions [emphasis added],” the question 4 below deals with “frequency or voltage excursions,” para. R5.1 states “Frequency Excursion…and a Voltage Excursion” and para. R6 references “Frequency Excursion or Voltage Excursion.” The combinations of simultaneous frequency and voltage variations that units must ride-though should be clarified. 3. Preparing the estimates in question appears to constitute a duplication of the excitation and governor model verifications required by MOD-026 and MOD-027. Para. R5 states that the PRC-024 estimates are to be used in modeling studies; but there should be

one, definitive source of modeling data, not two different sources. Para. R5 of PRC-024 should be replaced by a reference to using the tools developed for MOD-026 and MOD-027. 4. In the event that R5 remains as-is, a standard-specific definition of the word “plant” is needed, restricting applicability to NERC-registered generators. A plant consisting of two 750 MW fossil units and a standby 10 MW diesel generator, for example, should not have to model the diesel unit’s behavior. 5. It is necessary in any event to limit the requirement for estimates to that which can reasonably be modeled. Unit auxiliary system buses may drop-out and cause a unit to trip, even if the generator and protective relays can handle any given transient, and dynamic behavior at the 4160V and 460V levels may be impossible to predict for the radical excursions specified in PRC-024.
Yes
1. Excursion-estimate requirements for new units are presented in R6, not R5. Our comments below pertain to R6. 2. Avoiding tripping for 10 minutes of operation at +/- 10% voltage may not be practical, especially if combined with the frequency excursions of Att. 1. 3. See also the final two comments for question 3 above. Preventing (and demonstrating via dynamic analysis the ability to prevent) aux buses from dropping-out at the specified interconnect voltage transients may be especially difficult.
No
Att. 2 extends to 1000 sec in the present draft of PRC-024, with 600 sec at +/- 10% voltage. See our comments above for question 4.
Yes
1. The term “continuous capacity rating” in the second bull-dot item of R3 should be replaced with “Normal Rating or Emergency Rating,” to eliminate ambiguity via use of NERC Glossary-defined terms. 2. The term “non-protection system” in R3 should be replaced with “non-Protection System,” to make it clear that achieving the criteria of R1 and R2 might be prevented by in some cases by OEM controls trip settings, thereby constituting a protection system function (acceptable) that does not involve the Protection System (would be unacceptable). 3. Paras. R5.1 and R5.2 suffer in terms of clarity from consisting of a single sentence that is over 80 words long, with not a single comma or semicolon to guide the reader. NERC standards should make use of normal technical-writing style and punctuation
Group
PPL Supply
Annette Bannon
No
The expression, “Units or plants” in para. 4.2 should be changed to “units” to make it clear that a plant with, say, three large fossil units at 90% CF and a standby diesel genset at ~0.1% CF does not need to test the diesel. Also, eliminate the word “to” in the expression in para. 4.2.1, “For each plant with a gross aggregate nameplate rating greater than to 100 MVA”.
Yes
Yes
Yes
1. Each requirement can be accomplished by itself; but the 90 day vs 60 day vs 180 days on the various 12 requirements will likely create documentation confusion for communication and data retentions. Suggest that the draft be simplified to enhance coordination amongst requirements by applying a single time frame for completion of the requirements. 2. Paras. R2 and R2.1.1 are not clearly worded. The present R2 text should end after the word “software;” and para. R2.1.1 should state that “Verification consists of developing one or more models that collectively include the following information:” The present R2.1.1 text, “acceptable to the Transmission Planner,” is not included in this suggested revision to make it clear that the R2 Violation Severity Levels later in MOD-026-1 pertain to a GO’s first submittal of a verified model, and the R3 Violation Severity Levels deal with failure to meet follow-up requirements if the Transmission Planner finds the first submittal unacceptable. This distinction is particularly important given the compliance criteria ambiguity discussed in comment #3 below. If on the other hand it was intended that models achieve verified

status only after being accepted by the Transmission Planner, the term “verified model(s)” in the R2 Violation Severity Levels should be replaced with, “initial submittal of proposed-verified model(s)”. 3. There is presently no definition of the voltage excursion magnitude and intensity or the recording instrumentation sampling rate required for a valid verification event, nor are there any specifics regarding how closely the model must match the recorded response. The references in MOD-026 provide guidance but not necessarily NERC pass/fail criteria, especially since Transmission Planners may differ in their preferences. Perceived shortcomings in these respects would presumably trigger the Transmission Planner expression of concern described in para. R3, but it would be better to establish the rules up-front rather than addressing the matter only after a GO has attempted to comply with MOD-026. 4. The definition of a “technically justified request” in para. R5 is unclear. Does this term apply only if a model fails to meet the requirements of R6.1-R6.3, or can there be other reasons? In the latter case the wording of the R5 Violation Severity Levels should be modified to start the clock only after agreement has been reached that a request is technically justified. 5. The means by which a walk-down would lead to identification of model parameters in para. 5.2 is not understood.
Yes

Yes
ATC believes that synchronous condensers may have significant impact in the areas where they are installed. Therefore, ATC agrees that they should be added to the NERC Compliance Registration Criteria and that a separate SAR should be established to develop a separate reliability standard for synchronous condensers and other dynamic reactive devices.
Yes
Please give consideration to the following suggestions: 1. In Applicability, 4.2, Include the explanation that “average capacity factor is the average of all the unit or plant output values compared to the gross nameplate rating value” since some have asked how this value is defined and calculated. 2. In Applicability, 4.2.4 - add “Transmission Planner” to this item because Transmission Planners may also have insight and the means to provide technical justification for the inclusion of specific units in their system. 3. In Requirements, R1, bullet 1 - remove this bullet 1, or combine it with bullet 2, because it appears to be redundant with bullet 2, rather than distinctly different. 4. In Requirements, R2.1.4 - replace “model structure and data” with “block diagram and model parameters” for more clarity. 5. In Requirements, R2.1.6 - replace “model structure and data” with “manufacturer, model number, block diagram, and model parameters” for more clarity and specificity. 6. In Requirements, R2.1.6 - add ”and indicate whether the power system stabilizer is planned to be in-service and out-of-service in the planning horizon.” 7. In Requirements, R4 – revise the text from “within 180 days of making changes” to “within 180 prior to making changes” for more clarity.
Yes
Yes
Yes
Yes
Yes
Yes
Please give consideration to the following suggestions: 1. In Requirements, R1, R2, & R3 – include a footnote for the references to “non-protection system equipment” that defines or gives a few examples of this equipment to add clarity. 2. In Requirements, R3 – add the requirement that the GO provides the expected duration of the limitation, if it is known. 3. In Requirements, R5.2 – include a footnote or example of “25% estimated probability increments” to add clarity. 4. In References – include references that provide more technical justification and background for the voltage and frequency limits given in Attachment 1 and Attachment 2. 5. In Attachment 1 - add a “Return to between 59.5 Hz and 60.5 Hz frequency” text box to be consistent with the labeling in Attachment 2. 6. In Attachment 1 – add the title “Curve Data Points” to the Frequency/Time table to be consistent with Attachment 2. 7. In Attachment 2 – modify HVRT and LVRT tables (perhaps combine them into

one more compact table) to be consistent with the table in Attachment 1 and fit on the same page. 8. In Attachment 2, 5a - expand to “Power factor is 0.95 lagging (i.e. supplying reactive power to the system as measured at the generator terminal)” to be more definitive.

Yes
FMPA appreciates the efforts of the SDT to “right-size” the applicability to plants that truly impact the stability response of the system. However, the words used in the draft standard allow a loop-hole to the SDT’s intent. Footnote 4 to the Applicability section states: “(a) technical justification for verifying each of those units or plant(s) that demonstrates through simulation and/or measured response that the unit or plant affects a stability limit, or evidence that the simulated unit or plant response does not match measured unit or plant response”. If a region wishes to include 1 MW generators in the process, all they have to do is show that the unit’s actual response does not match the simulated response without a technical justification to show that the 1MW generator has any impact on the actual stability response of the system. The SDT should change the “or” in footnote 4 to “and” meaning that the technical justification needs to include both an impact to a stability limit AND a difference between actual and simulated response. In addition, for R5 and footnote 4, who judges what is and what is not a “technical justification”? For instance, NPCC in their regional UFLS standard proposed to cause 1 MW generators to register and be included in the standards. Does the region have the final say on technical justification? The staged test in R2.1.2 and Attachment 1 that is required if an actual event does not occur is onerous. FMPA believes this “staged test” is impractical and should be eliminated. Within a ten year period, an actual event is likely to occur resulting in a recorded response. If an actual event does not occur, then, the risk of inaccuracy is small and a “staged test” with associated higher risk should not be required to only marginally improve accuracy.
Yes
No
The term “protective relaying” is confusing in two ways: 1) the footnote is ambiguous as to how it applies; and 2) it calls into question whether this is a “generation Protection System” applicable to PRC-004 and PRC-005 (especially when considering the inconsistent use of “non-protection system equipment” in R3). FMPA suggests the term “safeguard” instead of “protection”, e.g., a “frequency safeguard system” to avoid this ambiguity and with a footnote to make more clear that systems like GE Mark VI’s are or are not included. Similarly in R2, it is unclear what “voltage protective relaying” is. FMPA suggests using the word “safeguard” instead of “protection”. Also, it is unclear whether station service voltage safeguards are included, such as motor contactors. In addition, “external to the plant” as used in several requirements (e.g., R1, R2 and R6) is ambiguous. We assume that this would also mean beyond any radial connection (e.g., generator lead) to the plant and would suggest changing the term to something like: "caused by an event beyond the point at which the plant is radially connected to the transmission system".
No
R4 is missing the VRF and Time Horizon. FMPA recommends “Lower” and “Long-term Planning”.
No
First, FMPA believes the SDT is referring to R6 not R5. Technically, the requirement is inconsistent with the question. The requirement is to design, build and maintain to prevent tripping, it does not say “thou shall not trip”. If a generator is designed, built and maintained to specifications that should not trip, but, a generator trips anyway in a real-life event, is that a violation?
Yes
The bullets in R3 are onerous. The bullets would essentially eliminate the ability to replace like-with-like which would have an impact on spare equipment strategy and stores since existing spares in the

warehouse could not be used. If spares were not available that could meet the new criteria, the GO would be forced to either keep a unit off-line or be non-compliant. FMPA suggests eliminating the bullet, or at most, institute something like a Cyber Security Technical Feasibility Exception (TFE) process. In addition, in the bullets at the end of R3, is the 10% incremental or cumulative over time? E.g., if a GO does a capacity augmentation of 5% one year and then another 5% increase 3 years later, does that trigger the 10%? R6.1.1 is ambiguous, what does "at least 20% of the Facility's rated capacity" imply? Would a single test at full output suffice, or is "book-ending" between minimum and maximum output of the generator implied?

Hydro-Quebec TransEnergie
No
Mostly, HQT's frequency and voltage curves are more stringent for generators, as the area for no trip zone is wider. However, the following points on those curves of attachment 1 and attachment 2 are too stringent and we ask to consider these modifications: • On the frequency curve, for wind or thermal generation only, the no trip zone between 0 and 5 seconds should be limited to an over frequency of 61,7 hz. • On the voltage curve, the no trip zone should be restricted as follow: ♣ Between 1 and 2 seconds, to 0,75 pu, ♣ Between 2 and 3 seconds, to 0,85 pu.
Yes
Yes
The graph of voltage from the interconnexion of Quebec was reflected from the FERC order 661-A which is different from the graph from this standard. Please justify the source of the present standard.

IMPA appreciates the efforts of the SDT on getting the applicability section correct for the plants or units that truly impact the stability response of the BES. However, the standard does contain a loop-hole to the SDT's intent. On page 3 of 16, footnote 4 to the applicabilty section (4.2.4)states: "a technical justification for verifying each of those units or plant(s) that demonstrates through simulation and/or measured response that the unit or plant affects a stability limit, or evidence that the simulated unit or plant response does not match measured unit or plant response". The first or word in that sentence should be replace with the word "and". A technical justification for verifying each of those units and plant(s) that demonstrates through simulation and/or measured response that the unit or plant affects a stability limit should both be required. By requiring both of these items, it might prevent units the size of 1MW from having to perform this standard. In addition, who qualifies what is a technically justified unit or what is a technical justification? Past history as shown that technicaly justifications have been used "losely" by different regions and entities. The Generator Owner should have some means of appealing this request by the Planning Coordinator.
no comment
No

The term "protective relaying" is confusing in a two ways: 1) The footnote needs to clarify how it applies; and 2)the term calls into question whether this is a "generation Protection System" applicable to PRC-004 and PRC-005. It needs to be made more clear that systems like the GE Mark IV and VI control systems are or are not included. R2 is also not clear when using "voltage protective relaying". It is not clear if voltage safeguards on motor contactors are included. The standard also needs to make more clear what "external to the plant" exactly means.
No
This is actually requirement R5. IMPA does not see any value in assigning a standard requirement to a Generator Owner that is just an estimation of performance when it might be a far off estimation of performance compared against actual performance of an existing unit or generating plant. This standard should concentrate on the setting of relays and not have Generator Owners estimate how their unit or generating plant will perform during a Frequency/Voltage Excursion. This standard should also not force Generator Owners to perform studies or model their unit or generating plant since they are not guaranteed or reliable either.
No
This is actually requirement R6. IMPA does not believe this technology is currently achievable for new units or generating plant/facilities on all generation producing fronts. The technology should be in place and proven on all generation fronts before such writing of standard requirements.

CenterPoint Energy
No
(a) CenterPoint Energy agrees with the time duration value of the 0.9 pu voltage level up to 600 seconds and believes this will coordinate with existing undervoltage load shedding systems (UVLS). However, CenterPoint Energy believes there are numerous relays presently set at 2.0 seconds and 3.0 seconds to shed load in a voltage excursion and, therefore, there is not a sufficient margin for coordination at the two second and three second low voltage points in Attachment 2. CenterPoint Energy recommends these two points in Attachment 2 be revised to 2.5 and 3.5 seconds. That is, the data points (Time / Voltage) in the LVRT DURATION table would be as follows: 0.15 / 0.000, 0.30 / 0.450, 2.50 / 0.650, 3.50 / 0.750, and 600 / 0.900. (b) In addition, CenterPoint Energy believes there is insufficient margin at 1.0 seconds for high voltage ride through due to voltage over-shoot following a zone 1 fault. To provide an adequate margin, CenterPoint Energy recommends the 1.0 second high voltage point in Attachment 2 be revised to 1.5 seconds. That is, the data points (Time / Voltage) in the HVRT DURATION table would be as follows: 0.20 / 1.200, 0.50 / 1.175, 1.50 / 1.150, and 600 / 1.100.
Yes
(a) CenterPoint Energy does not agree with limiting the applicability of Requirement 2 to just “voltage protective relaying”. In effect, this would allow possible tripping of generation during off nominal voltage excursions from several other types of relays, such as generator backup over-current and impedance. CenterPoint Energy recommends that this standard be applicable to any generator Protection System relays that operate on voltage and / or current. (b) In Requirement 2.1.1, the fault clearing time should be established at a fixed 9 cycles, instead of site-specific, actual clearing times. R2.1.1 should be written as: “For three-phase transmission zone 1 faults, set generator Protection System relays based on a fault clearing time of 9 cycles”. (c) Requirement 2.1.2 provides for location-

specific criteria that are unnecessary and could have unintended consequences, as such criteria can change over time with additions and modifications of the bulk electric system. CenterPoint Energy believes NERC reliability standards should not include fill-in-the-blank, location-specific criteria and recommends R2.1.2 be deleted.

NERC Staff
Mallory Huggins
No
We are not aware of other units types at this time, but the applicability should be written broadly enough to not preclude applicability to other types of resources that may be connected in the future.
Yes
No
It is most efficient to address synchronous condensers in the same project as generators given that synchronous condensers have many of the same characteristics as generators. Static var compensators (SVCs) and static compensators (STATCOMs) are sufficiently different from generators and synchronous condensers to be appropriately covered in a separate SAR. Despite the low penetration of synchronous condensers in North America, these devices are most likely installed to extend a dynamic voltage security limit as noted by the drafting team. Due to the importance of these devices, validated models should be required for these devices similar to generators. Reliance on other motivations for equipment owners to validate models is inconsistent with requirements for generators and does not provide appropriate assurance that the equipment owners will validate models necessary for system reliability.
Yes
Validation of the voltage and reactive power response of generating units for significant system disturbances indicates that the dynamics database quality is not as robust as noted in the Background Information posted with this standard. As a result NERC staff offers the following three specific comments for improving the quality of the model database: 1) It is not possible to accurately model system voltage and reactive power response with valid models for only 80 percent of the installed system capacity. The standard should be applicable to all units greater than 20 MVA and all plants greater than 75 MVA regardless of interconnection voltage. Per the SDT estimates this will assure accurate modeling for approximately 95 percent of installed capacity. 2) We disagree with the exemption for units with <5% capacity factor for the past three years. Some large, less efficient units may only run during peak load conditions when reactive support may be most critical thereby making valid models critical to system reliability during those conditions. While they should not be exempted from the standard, we do believe it may be appropriate to assign these units lower priority in the implementation plan. 3) The initial completion of validation for all applicable units and periodicity for model verification should be 5 years, not 10 years. The 10 year time is excessive. Any Functional Model entity that requires the models, including Planning Coordinators, Transmission Operators, and Reliability Coordinators, should be permitted under Requirement R3 to provide notification to the Generator Owner that the model is not usable or that the predicted response did not match the recorded response to a transmission system event. Also, Requirement R3 should permit entities to notify the Generator Owner that the model is not usable for any reason. We recommend removing the list referencing Requirement R6, parts 6.1 through 6.3, because it is not and cannot be an all-inclusive list of problems that could make the model not usable (e.g., the model could cause the simulation software to “freeze”). In the first row of the Periodicity Table, transmission of the verified model and documentation to the Transmission Planner should occur within 180 days from the date the recorded response is collected similar to all other rows in the table. There is no apparent basis for the additional time provided in the first row of the table. The violation risk factors associated with Requirements R1 through R6 should be at least medium. Use of invalid models resulting from violation of these standards can produce erroneous results and adversely affect assumptions of the electrical state or capability of the bulk electric system, or the ability to effectively control or restore the bulk electric system, particularly under emergency, abnormal, or restorative conditions. This can result in operating beyond the true stability limits of the system. The models validated by application of this standard are used in both the long-term planning and the operations planning horizon. The time horizon for Requirements R1 through R6 should include the operations planning horizon. In

Requirement R6, part 6.2, the reference to negligible transients is not measurable. We recommend modifying this to ". . . results in a response that varies less than the numerical stability of the program used for the simulation." In Requirement R6, part 6.3, the introductory phrase "For an otherwise stable simulation" is not necessary and a potential source of confusion. We recommend deleting this phrase and starting the sentence with "A disturbance simulation results in . . ." The SDT should consider use of the word validation instead of verification and assure that the terms used in this standard are consistent with other standards.
No
NERC staff believes it is unnecessary to define these terms to achieve the reliability objective of this standard. We further note that the proposed definitions of these terms are in conflict with usage of the phrases frequency excursion and voltage excursion in other standards and a defined glossary term. A review of existing NERC standards and the NERC glossary identifies the following inconsistencies: (1) Standard BAL-003-0.1b "requires a Balancing Authority to analyze its response to frequency excursions as a first step in determining its frequency bias setting." Events identified for use in analyzing and setting requirements for frequency response are associated with frequency deviations of less than ±0.5 Hz, and not necessarily deviating from 60 Hz. (2) Standard EOP-004-1 requires reporting for "any action taken by a Generator Operator, Transmission Operator, Balancing Authority, or Load-Serving Entity that results in sustained voltage excursions equal to or greater than ±10%." (3) Standard PRC-006-1, refers to "system frequency excursions below the initializing set points of the UFLS program." The initializing setpoints of UFLS programs vary by region. (4) The defined term, Disturbance Monitoring Equipment, includes "Dynamic Disturbance Recorders (DDRs), which record incidents that portray power system behavior during dynamic events such as low-frequency (0.1 Hz – 3 Hz) oscillations and abnormal frequency or voltage excursions." We also observe inconsistency within the draft PRC-024-1 which refers to "a Frequency Excursion defined by the curves in PRC-024 Attachment 1 and a Voltage Excursion defined by the curves in PRC-024 Attachment 2," which is in conflict with the proposed definitions. Given the range of contexts in which the phrases frequency excursion and voltage excursion are used we believe it is most appropriate that each standard identify the excursions of interest in the context of that standard, rather than establishing defined terms with specific numerical values.
Yes
Yes
Yes
Yes
Yes
The applicability section should be expanded to address both applicable entities and applicable facilities similar to MOD-025-2 and should apply to individual generating units >20 MVA (gross nameplate rating) and generating plants/Facilities >75 MVA (gross aggregate nameplate rating), regardless of interconnection voltage. The percentage of units that must be compliant in Effective Date sections 5.1.1, 5.2.1, and 5.3.1 should be based on an MVA basis similar to other standards in Project 2007-09, such that the phrase "% of its applicable units" is replaced with "% of its applicable units on an MVA basis." The SDT should consider the implications of Requirement R1, part 1.5, which appears to preclude unit tripping when frequency rate-of-change is less than 2.5 Hz/s, even if the frequency is above 62.2 Hz or below 57.8 Hz. The voltage curves in Attachment 2 should be applicable for any operating condition that falls within the voltage-time curves regardless of the initiating event that causes the voltage excursion. As such, Requirement R2, part 2.1.1 should be removed from the standard. Also, we understand from the webinar that the voltage curves in Attachment 2 represent positive sequence voltage. If voltage relays that sense phase-to-ground or phase-to-phase voltage are set according to this curve, generator tripping could occur for normally cleared unbalanced faults (e.g., the unfaulted phase voltage during a single-line-to-ground may exceed 1.2 per unit on an effectively grounded system). The drafting team must develop curves that can be used directly for setting protective relays to assure that generators remain connected for both balanced and unbalanced faults. System conditions may change more quickly than a Transmission

Planner can identify and convey applicable voltage relay setting requirements to a Generator Owner. We are not aware of any reason a Transmission Planner would require less stringent criteria than Attachment 2. For these reasons, the following items should be deleted: (1) Requirement R2, part 2.1.2; (2) The phrase referring to "the voltage profile at the Point of Interconnection for the generating unit or generating plant or Facility of the most severe normally-cleared Zone 1 fault . . ." in Requirement R5, parts 5.1 and 5.2; (3) Requirement R6, part 6.3; and (4) Note 2 to the Voltage Ride-Through Curve Clarifications. Equipment limitations will not change based on modifications to changes in generating unit capacity. The second sentence in Requirement R3 should be changed from "the equipment limitation expires . . ." to "The waiver for compliance with Requirements R1 and R2 associated with the equipment limitations expires . . ." The conditions in Requirement R6, parts 6.1 and 6.2 could be interpreted to indicate that this requirement only applies to generating plants/Facilities greater than 75 MVA. The standard should be revised to be clear that it also applies to generating units greater than 20 MVA.
Individual
Dan Hansen
GenOn Energy
No
The comment is for R5 for the June 15, 2011 draft. The wording is too open-ended and subjective in scope. Similar to R1 & R2, the requirement should be clearly defined and limited to devices that directly respond to generator voltage or frequency. R3 already requires the information of other control or protective devices. Typically, the Generator Owner does not monitor the interconnection voltage for protection purpose; rather generator terminal voltage is used for generator protection. The modeling is performed by others, but the burden of analysis is being placed upon the Generator Owner to determine performance probability for information not in their possession. 30 days is a short period of time for this analysis when hit cold with a request like this, especially during outage season.
No
Applied to R6 of the June 15, 2011 draft. It does not appear that the SDT has carefully considered the possible impact of Attachment 2 on plant electrical auxiliary motors and contactors. The SDT should ask an power plant engineering company the impact on the electrical auxiliaries of an 800MW coal unit with a scrubber.
No
10 minutes is a long time for some unavoidable configuration of electrical auxiliaries.
Yes
A strong disapproval of the R3 equipment limitation expiration with a generating unit rating increase of 10%. The expiration is unnecessary and is based upon an arbitrary criterion that may be totally unrelated to basis for the limitation. A backwards approach has been taken with the application of Attachment 2, which represents very poor performance of the transmission system for voltage recovery after a fault. This standard will have the affect of permanently defining this as acceptable transmission performance, which should not be the case. This is inequitable since it imposes the lowest common denominator of one segment of the industry and unilaterally transfers the responsibility for that performance upon another seqment (every generating unit on the continent). The Generator Verification team has developed extensive requirement for Generator Owners to provide accurate model data for system studies, but Generator Owners get no benefits in return for their effort and expense. Rather than imposing Attachment 2 on Generator Owners, the more correct way is to require Planning Coordinators, Transmission Operators or Transmission Planners to provide planning study results and voltage recovery profile at the generator terminals (this is where the protection and controls are applied). This will enable Generator Owners correctly apply protection settings as appropriate. Another option is to drive performance improvements on the Transmission

system. Attachment 2 should be set a much higher standard of performance of the transmission system (median or higher), and require the Planning Coordinators, Transmission Operators or Transmission Planners to identify the locations where the higher standard is not attainable and provide the voltage recovery profile.
Group
Bonneville Power Administration
Denise Koehn
No
Yes
Yes
Yes
MOD-026: By making Transmission Planners responsible for generator verification instead of regional entities, it may be more difficult to produce integrated regional models. The standard should also apply to Regional Coordinators to ensure consistent generator verification requirements within regions.
No
R2.1.1 – Please clarify/verify: • That the allowable voltage relay trip time is greater than the normal fault clearing time up to a normal clearing time of 9 cycles; • That tripping is allowed above 9 cycles regardless if it is normal clearing or backup clearing; and, • That for generators in close proximity the normal clearing time is coordinated to ensure it is no greater than what a specific generator was designed to withstand.
No
R3-R4 - Generator Owners may be unwilling to share proprietary information in response to requests from Reliability Coordinators, Planning Coordinators, Transmission Operators, or Transmission Planners, because of manufacturer restrictions or for other reasons. Should the standard anticipate this issue?
R5 - WECC Reliability Subcommittee discussions indicated that protection generation relay performance at the Point of Interconnection was different than if the measurement point is at the low side or high side of the step-up transformer. The NERC Standard should specify the measurement point at the high side of either the generator step up transformer, or at the high side of the collector transformer where multiple small generators are aggregated at a collector substation. Attachment 2 – BPA suggests modifying the diagram to reflect changes to Requirement R2.1.1 above, e.g. to show that allowable voltage relay trip time is greater than the normal fault clearing time if the normal clearing time is less than 9 cycles.
Yes
The proposed standard uses both "zone 1" and "Zone 1", which we assume mean the same thing. What is the source of the Zone 1 determination?

Consideration of Comments on Generator Verification – MOD-026-1 — Project 2007-09

The Generator Verification Drafting Team thanks all commenters who submitted comments on the Second Posting of MOD-026-1, Verification of Models and Data for Generator Excitation Control System or Plant Volt/Var Control Functions. These standards and associated documents were posted for a 45-day public comment period from June 15, 2011 through August 1, 2011. Stakeholders were asked to provide feedback on the standards and associated documents through a special electronic comment form. Also included in this report are comments received from the initial ballots and non-binding polls conducted during the last ten days of the 45-day comment period. There were 66 sets of comments, including comments from approximately 185 different people from approximately 120 companies representing all 10 of the 10 Industry Segments as shown in the table on the following pages.

All comments submitted may be reviewed in their original format on the standard's project page:

http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President of Standards and Training, Herb Schrayshuen, at 404-446-2563 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

Summary Consideration:

The GVSDT asked stakeholders if they believed any additional generation configurations should be considered for applicability under this standard. None of the comments identified other generation configurations/types that should be covered in the applicability. Several commenters recommend making the standard applicability match the compliance registry while other commenters recommend removing the requirement to verify small generator units from the standard applicability. The SDT believes:

- The standard is drafted to provide the proper cost/benefit balance for performing generator verification.
- It is not necessary to have models verified for all units listed in the compliance registry.
- Proposed applicability thresholds will substantially improve the accuracy of the excitation models and associated Reliability based limits determined by dynamic simulation in a cost-effective and time-efficient manner when performing verification.

[1] The appeals process is in the Standard Processes Manual: http://www.nerc.com/files/Appendix_3A_Standard_Processes_Manual_Rev%201_20110825.pdf

The SDT recognizes that the excitation system model and modeling data is already captured by the MOD-012 and MOD-013 required processes. This information, with few exceptions, creates a quality dynamics database. Field Testing initiated by the Phase III-IV SDT has shown that performing the activities specified in the draft standard will improve the accuracy of the exciter model used in dynamic simulation. Utilizing engineering judgment, based in part on recent experience of entities verifying excitation system models, the SDT is proposing to require verification of excitation systems associated with 80% or greater of the connected MVA in each Interconnection. To accomplish this goal, the SDT has proposed MVA thresholds which correspond to at least 80% of the connected MVA in each Interconnection. This concept was overwhelmingly supported by industry in response to the previous posting of the standard.

The SDT also proposes requiring verification of an aggregate plant comprised of several smaller sized units because of the increasing impact renewable generation has on the BES. If there is evidence that the model does not match the performance of the equipment, then R3 provides a mechanism for requiring verification. Concern was raised that the language of R5 could require verification of units with ratings less than the thresholds specified in the registry criteria. The SDT asserts that any unit not included in the standard Applicability and deemed to require verification as justified by the Planning Coordinator must, by definition, satisfy the Registry Criteria threshold established. The standard Applicability would have to explicitly identify units with ratings less than the Registry Criteria threshold established in order for the Planning Coordinator to be able to justify verification of the unit. This is not the case.

A few commenters expressed concern that the standard does not require the Generator Owner to notify the Transmission Owner of new equipment and provide the Transmission Planner preliminary models based on OEM design data. The SDT reminds that the scope of the draft standard is model verification, which can occur only after the equipment is installed. The standard does not address development of the original model during the equipment commissioning process.

Also in response to industry comments, the SDT has inserted a footnote in the standard to make clear that standby generator models are not required to be verified.

The GVSDT asked stakeholders if they believed that synchronous condensers should be applicable under MOD-026. The majority of commenters believe that Synchronous Condensers should not be included in MOD-026. Synchronous condensers are not currently addressed in the NERC Registry Criteria. On an MVA capacity basis, the penetration of Synchronous condensers in North America is extremely low, with many units owned by Transmission Owners. As such, the peer review draft requirements would not make sense. The SDT decided that, with the current structure of the Compliance Registry Criteria, if there is a need to develop a Reliability Standard to model the expected behavior of dynamic voltage devices typically owned by Transmission entities, then a more appropriate strategy is to include Synchronous Condensers along with other transmission system dynamic reactive devices (such as SVCs, STATCOMs, etc.) into a separate SAR. The GVSDT will closely monitor BES SDT efforts to define BES and the correlation of BES elements with the ERO Statement of Compliance Registry Criteria, and make appropriate adjustment as necessary to the Applicability of MOD-026-1 regarding the treatment of Synchronous Condensers.

The GVSDT received many comments concerning various aspects of the standard. As a result of these comments, the SDT has made a number of modifications to the standard including:

1) Correcting several VSL grammatical errors and ensuring consistency between the VSL "increment for tardiness" time period specified and the Requirement language.

2) An additional condition, row 12, was added to Attachment 1 (the Periodicity Table) specifying that validation is not required for an excitation control system or plant volt/var control that does not include an active closed loop voltage regulation function. This condition exempts wind and solar plants that do not have the capability to regulate plant voltage or respond to grid voltage fluctuations other than switching capacitor and reactor banks in and out of service.

3) The format and column information of Attachment 1 has been revised for clarity.

4) The typographical errors in R2.1.1 language has been corrected to clearly state expectation that “the unit or plant’s model response matches the recorded response for a voltage excursion at the generator or plant point of interconnection from either a staged test or a measured system disturbance.”

5) The language of R2.1.4 has been revised to align with the style of R2.1.6.

6) Several commenters expressed concern with the new Requirement R5 added to the standard giving the Planning Coordinator authority to require a model review for a unit not specified in the standard Applicability section. The SDT added this language to the draft standard after considering industry comments to the first posting noting that the Applicability section is a subset of the Compliance Registry criteria. Based on the latest round of industry feedback, the SDT now proposes Applicability Section language allowing the Planning Coordinator to request additional model information (possibly model verification) only if technical justification demonstrates the simulated unit response does not match the measured unit response. Original technical justification language for units that affect a stability limit has been removed from the standard. To emphasize for understanding, the SDT points out only units that meet or exceed the Registry Criteria unit MVA thresholds (> 20 MVA) are subject to Requirement R5. This observation should allay concern the Requirement could be misused inappropriately. In addition, R5 language has been revised for clarity.

7) To clarify concerns regarding calculating unit capacity factor, the SDT has incorporated into the standard the capacity factor calculation specified in Appendix F of the GADS Data Reporting Instructions (which can be obtained from the NERC website).

8) There was some confusion regarding the treatment of small units at plants. The SDT modified the language in the Applicability / Facilities section for clarity and for consistency to the extent possible with the other draft standards in the Generation Verification effort.

As a reminder, the SDT, in its response to industry comments, points out this standard does not address providing notification of equipment changes nor collection of preliminary model data from the equipment manufacturer. The standard addresses verification of models following equipment changes. New equipment models cannot be verified until after the equipment is available.

Index to Questions, Comments, and Responses

1. The Applicability section of MOD-026 standard is expanded to include plants/facilities comprised of multiple small units such as variable energy resource plants/facilities. Are you aware of other generation configurations/types that should be covered in the Applicability? 15

2. The current version of the MOD-026 standard has been re-formatted so that it would be more concise and contain only reliability related requirements. Do you agree there are no omissions from the prior draft due to the re-formatting of the standard? 29

3. The SDT discussed if MOD-026-1 should also include verification of excitation control systems of synchronous condensers. Synchronous condensers are not currently addressed in the NERC Registry Criteria. Synchronous condensers are not mentioned in the Generation Verification SAR. On an MVA capacity basis, the penetration of synchronous condensers in North America is extremely low. It is common for Transmission Owners to be the owners of synchronous condensers. As such, the peer review draft requirements would not make sense. Therefore, the team decided that a more appropriate strategy would be to include synchronous condensers with other transmission system dynamic reactive devices (such as SVCs, STATCOMs, etc.) in a separate SAR. 38

   Do you agree with the proposal to not include the verification of synchronous condensers in MOD-026-1? 38

4. Do you have any other questions or concerns with the proposed standards that have not been addressed? If yes, please explain. 50

END OF REPORT 112

The Industry Segments are:

1 — Transmission Owners
2 — RTOs, ISOs
3 — Load-serving Entities
4 — Transmission-dependent Utilities
5 — Electric Generators
6 — Electricity Brokers, Aggregators, and Marketers
7 — Large Electricity End Users
8 — Small Electricity End Users
9 — Federal, State, Provincial Regulatory or other Government Entities
10 — Regional Reliability Organizations, Regional Entities

1. **The Applicability section of MOD-026 standard is expanded to include plants/facilities comprised of multiple small units such as variable energy resource plants/facilities. Are you aware of other generation configurations/types that should be covered in the Applicability?**

Summary Consideration: None of the comments identified other generation configurations/types that should be covered in the applicability.

Several commenters recommend making the standard applicability match the compliance registry while other commenters recommend removing the requirement to verify small generator units from the standard applicability. The SDT believes:

- **The standard is drafted to provide the proper cost/benefit balance for performing generator verification.**
- **It is not necessary to have models verified for all units listed in the compliance registry.**
- **Proposed applicability thresholds will substantially improve the accuracy of the excitation models and associated Reliability based limits determined by dynamic simulation in a cost-effective and time-efficient manner when performing verification.**

The SDT recognizes that the excitation system model and modeling data is already captured by the MOD-012 and MOD-013 required processes. This information, with few exceptions, creates a quality dynamics database. Field Testing initiated by the Phase III-IV SDT has shown that performing the activities specified in the draft standard will improve the accuracy of the exciter model used in dynamic simulation. Utilizing engineering judgment, based in part on recent experience of entities verifying excitation system models, the SDT is proposing to require verification of excitation systems associated with 80% or greater of the connected MVA in each Interconnection. To accomplish this goal, the SDT has proposed MVA thresholds which correspond to at least 80% of the connected MVA in each Interconnection. This concept was overwhelmingly supported by industry in response to the previous posting of the standard.

The SDT also proposes requiring verification of an aggregate plant comprised of several smaller sized units because of the increasing impact renewable generation has on the BES. If there is evidence that the model does not match the performance of the equipment, then R3 provides a mechanism for requiring verification. Concern was raised that the language of R5 could require verification of units with ratings less than the thresholds specified in the registry criteria. The SDT asserts that any unit not included in the standard Applicability and deemed to require verification as justified by the Planning Coordinator must, by definition, satisfy the Registry Criteria threshold established. The standard Applicability would have to explicitly identify units with ratings less than the Registry Criteria threshold established in order for the Planning Coordinator to be able to justify verification of the unit. This is not the case.

A few commenters expressed concern that the standard does not require the Generator Owner to notify the Transmission Owner of new equipment and provide the Transmission Planner preliminary models based on OEM

design data. The SDT reminds that the scope of the draft standard is model verification, which can occur only after the equipment is installed. The standard does not address development of the original model during the equipment commissioning process.

Finally, in response to industry comments, the SDT has inserted a footnote in the standard to make clear that standby generator models are not required to be verified.

Organization	Yes or No	Question 1 Comment
Beaches Energy Services, Florida Municipal Power Pool, Lakeland Electric, City of Green Cove Springs, City of Vero Beach	Negative	Under Applicability - Facilities. The facilities applicability should be deleted altogether. The Statement of Compliance Registry Criteria already describes the Facilities for which a Generator Owner/Operator must register. Inconsistency with the SCRC will just lead to confusion and chaos with no benefit to BES reliability. As written, the standard could allow a Planning Coordinator to sweep in generation that do not meet the registry criteria simply by showing, as footnote 4 describes "evidence that the simulated unit or plant response does not match measured unit or plant response", without a commensurate technical justification for that unit actually having an impact to the stability response of the system. If such a small generator is truly important, the SCRC already has the ability within it to include such generation under III.c.4: "Any generator, regardless of size, that is material to the reliability of the bulk power system." We see no reason to vary from the SCRC. In R5, who determines whether a request is "technically justified"? "? How are disputes around "technical justification" resolved?

Response: The SDT thanks you for your comment. The SDT believes it is not necessary to have models verified for all units listed in the compliance registry.

The SDT believes proposed applicability thresholds that will substantially improve the accuracy of the excitation models and associated Reliability based limits determined by dynamic simulation in a cost-effective and time-efficient manner when performing verification.

The SDT recognizes that the excitation system model and modeling data is already captured by MOD-012 and MOD-013 required processes. This information, with few exceptions, creates a quality dynamics database.

Field Testing initiated by the Phase III-IV SDT has shown that performing the activities specified in the draft standard will improve the accuracy of the exciter model used in dynamic simulation.

Organization	Yes or No	Question 1 Comment
Utilizing engineering judgment, based in part on recent experience of entities verifying excitation system models, the SDT is proposing to require verification of excitation systems associated with 80% or greater of the connected MVA in each Interconnection. To accomplish this goal, the SDT has proposed MVA thresholds that correspond with at least 80% of the connected MVA in each Interconnection. This concept was overwhelmingly supported by industry in response to the previous posting of the standard. The SDT also proposes requiring verification of an aggregate plant comprised of several smaller sized units because of the increasing impact renewable generation has on the BES. If there is evidence that the model does not match the performance of the equipment, then R3 provides a mechanism for requiring verification. Several commenters expressed concern with the new Requirement added to the standard giving the Planning Coordinator authority to require model review for a unit not specified in the standard Applicability section. The SDT added this language to the draft standard after considering industry comments to the first posting noting that the Applicability section is a subset of the Compliance Registry criteria. Based on the latest round of industry feedback, the SDT now proposes Applicability Section language allowing the Planning Coordinator to request additional model information (possibly model verification) only if technical justification demonstrates the simulated unit response does not match the measured unit response. Original technical justification language for units that affect a stability limit has been removed from the standard. To emphasize for understanding, the SDT points out only units that meet or exceed the Registry Criteria unit MVA thresholds (> 20 MVA) are subject to Requirement R5. This observation should allay concern the Requirement could be misused inappropriately.		
Lakeland Electric	Negative	The Statement of Compliance Registry Criteria already describes the Facilities for which a Generator Owner / Operator must register. Inconsistency with the SCRC will just lead to confusion and chaos with no benefit to BES reliability
Response: The SDT thanks you for your comment. The SDT believes it is not necessary to have models verified for all units listed in the compliance registry. The SDT believes the proposed applicability thresholds will substantially improve accuracy of the excitation models and associated Reliability based limits determined by dynamic simulation in a cost-effective and time-efficient manner when performing verification. Interconnection. To accomplish this goal, the SDT has proposed MVA thresholds that correspond with at least 80% of the connected MVA in each Interconnection. This concept was overwhelmingly supported by industry in response to the previous posting of the standard. **The SDT also proposes requiring verification of an aggregate plant comprised of several smaller sized units because of the increasing impact renewable generation has on the BES.** **If there is evidence that the model does not match the performance of the equipment, then R3 provides a mechanism for requiring verification.**		
Commonwealth of Massachusetts Department of Public Utilities, Northeast Power Coordination Council, Inc., Commonwealth of Massachusetts Dept of Public Utilities	Negative	The Standard allows for generators with a capacity factor under 5% rated over 100 MVA to be excluded from verification. There are many older generators that meet this criterion that would be critical during stressed system conditions with high loads. Generators under 100 MVA could be also be critical in some areas. The applicable criterion should be as in the Compliance Registry. The Standard allows for generators to change equipment and then notify the Transmission Planner of the change.This is unacceptable as it represents a significant relaibility concern. . The Standard still is ambiguous and should contain further definitions and clarification. The standard should include verification of Power System Stabilizers if installed and limiters.
Response: The SDT thanks you for your comment. The 5% capacity factor exemption was selected to achieve a balance between the cost and benefits. The SDT believes that there are a limited number of units greater than 100 MVA with a capacity factor of less than 5%. Also, these units may be excluded from model verification however other standards still require that the data be supplied. **The SDT believes it is not necessary to have models verified for all units listed in the compliance registry.** **The SDT believes proposed applicability thresholds will substantially improve accuracy of the excitation models and associated Reliability based limits determined by dynamic simulation in a cost-effective and time-efficient manner when performing verification.** **The SDT recognizes that the excitation system model and modeling data is already captured by MOD-012 and MOD-013 required processes. Organization	Yes or No	Question 1 Comment
The SDT also proposes requiring verification of an aggregate plant comprised of several smaller sized units because of the increasing impact renewable generation has on the BES. **If there is evidence that the model does not match the performance of the equipment, then R3 provides a mechanism for requiring verification.** **Regarding your comment concerning equipment changes triggering a model verification, this standard does not address providing notification of equipment changes nor collection of preliminary model data from the equipment manufacturer. The standard addresses verification of models following equipment changes. New equipment models cannot be verified until after the equipment is available. Generator Owner development of the original model during the equipment commissioning process – including iterations with transmission entities such as the submittal of preliminary models by the Generator Owner and modifications to preliminary model data should be governed by individual interconnection agreements.** **Regarding your comment concerning power system stabilizer verification, the SDT believes the information required by R2.1.6 will adequately define the PSS behavior for study. If instead your comment pertains to the appropriateness of PSS settings or tuning values used, the SDT believes such concerns are beyond the scope of this standard.** **With respect to limiters, the SDT believes coordination of these devices is addressed by another standard.**		
Public Utility District No. 1 of Lewis County	Negative	Having an engineering staff of one at our small hydro, regulary work takes a full time effort. That means plant engineering is limited. With this standard, as with many ourside consultants will have to be hired to comply at a cost estimated over $100k. Too much for a small plant with nothing to gain from effort. Therefore, I believe the threshhold for compliance should be raised. Standard should recognize that standard models are good enough to protect the BES.
Response: The SDT thanks you for your comment. Based on SDT member experiences, standard compliance cost cited is not accurate for one unit and should be substantially less than estimated. Compliance will demonstrate adequacy and efficacy of existing plant equipment; benefiting both the plant and the BES. The applicability proposed by the SDT represents effort to balance costs and benefits. “Standard” models are not adequate which is why this standard is being developed.		
BC Hydro and Power Authority	No	The Applicability section includes Generator Owners and Transmission Planners. If an entity is a Generator Owner, they will meet the NERC Compliance Registry Criteria including MVA criteria. Including phrases in section 4.2 such as “The remainder of the plant as an aggregate”, and “For all interconnections: Any technically justified unit requested by the Planning Authority” is confusing and it seems to be expanding the criteria. For example hydroelectric units that don’t qualify an entity as GO may be captured here. Also, for the aggregate, a GO may not be able to model and verify the aggregate consistent with the

Organization	Yes or No	Question 1 Comment
		method used by TPs.

Response: The SDT thanks you for your comment. The SDT believes the standard is drafted to provide the proper cost/benefit balance for performing generator verification.

The SDT believes it is not necessary to have models verified for all units listed in the compliance registry.

The SDT believes proposed applicability thresholds will substantially improve accuracy of the excitation models and associated Reliability based limits determined by dynamic simulation in a cost-effective and time-efficient manner when performing verification.

The SDT recognizes that the excitation system model and modeling data is already captured by MOD-012 and MOD-013 required processes. This information, with few exceptions, creates a quality dynamics database.

Field Testing initiated by the Phase III-IV SDT has shown that performing the activities specified in the draft standard will improve the accuracy of the exciter model used in dynamic simulation.

Utilizing engineering judgment, based in part on recent experience of entities verifying excitation system models, the SDT is proposing to require verification of excitation systems associated with 80% or greater of the connected MVA in each Interconnection. To accomplish this goal, the SDT has proposed MVA thresholds that correspond with at least 80% of the connected MVA in each Interconnection. This concept was overwhelmingly supported by industry in response to the previous posting of the standard.

The SDT also proposes requiring verification of an aggregate plant comprised of several smaller sized units because of the increasing impact renewable generation has on the BES.

If there is evidence that the model does not match the performance of the equipment, then R3 provides a mechanism for requiring verification.

Based on the latest round of industry feedback, the SDT now proposes Applicability Section language allowing the Planning Coordinator to request additional model information (possibly model verification) only if technical justification demonstrates the simulated unit response does not match the measured unit response. Original technical justification language for units that affect a stability limit has been removed from the standard. To emphasize for understanding, the SDT points out only units that meet or exceed the Registry Criteria unit MVA thresholds (> 20 MVA) are subject to Requirement R5. This observation should allay concern the Requirement could be misused inappropriately.

The standard Applicability would have to explicitly identify units with ratings less than the Registry Criteria threshold established in order for the Planning Coordinator to be able to justify verification of the unit.

In response to comments received, the phrase, “Remainder of the plant as an aggregate” has been revised with language that is less confusing.

Organization	Yes or No	Question 1 Comment
Idaho Power - Power Production	No	We agree with the need to include wind generation in this standard, however the applicability section seems to be overly complicated. We do not see the relevance of the 80% of connected generation as discussed above. We believe that the NERC generator registry/ BES criteria would be clear and appropriate continent wide for this standard and with many other standards. In addition, we believe that Section 4.2.4 is too open-ended. It appears to open the door for the verification of any sized machine that does not match a response, or for other open-ended reasons. Too open-ended and subjective.
Response: The SDT thanks you for your comment. The SDT believes the standard is drafted to provide the proper cost/benefit balance for performing generator verification. **The SDT believes it is not necessary to have models verified for all units listed in the compliance registry.** **The SDT believes proposed applicability thresholds will substantially improve accuracy of the excitation models and associated Reliability based limits determined by dynamic simulation in a cost-effective and time-efficient manner when performing verification.** **The SDT recognizes that the excitation system model and modeling data is already captured by MOD-012 and MOD-013 required processes. This information, with few exceptions, creates a quality dynamics database.** **Field Testing initiated by the Phase III-IV SDT has shown that performing the activities specified in the draft standard will improve the accuracy of the exciter model used in dynamic simulation.** **Utilizing engineering judgment, based in part on recent experience of entities verifying excitation system models, the SDT is proposing to require verification of excitation systems associated with 80% or greater of the connected MVA in each Interconnection. To accomplish this goal, the SDT has proposed MVA thresholds that correspond with at least 80% of the connected MVA in each Interconnection. This concept was overwhelmingly supported by industry in response to the previous posting of the standard.** **The SDT also proposes requiring verification of an aggregate plant comprised of several smaller sized units because of the increasing impact renewable generation has on the BES.** **If there is evidence that the model does not match the performance of the equipment, then R3 provides a mechanism for requiring verification.** **Regarding your comment concerning Section 4.2.4, the SDT believes, that while this language does allow for additional units to be evaluated, this discretion will be exercised on a limited basis since a technical justification is required. The SDT believes it is necessary to keep this language in the standard for identifying key units that, otherwise, would not be included.**		
PPL Supply	No	The expression, “Units or plants” in para. 4.2 should be changed to “units” to make it clear that a plant with, say, three large fossil units at 90% CF and a standby diesel genset at

Organization	Yes or No	Question 1 Comment
		~0.1% CF does not need to test the diesel. Also, eliminate the word “to” in the expression in para. 4.2.1, “For each plant with a gross aggregate nameplate rating greater than to 100 MVA”.
Response: The SDT thanks you for your comment. The SDT has inserted a footnote in the standard to make clear that standby generator models are not verified. In response to comments received, the phrase, “remainder of the plant as an aggregate” has been revised with language that is less confusing. The wording in 4.2.1 has been corrected. That you for the correction.		
NERC Staff Review Team	No	We are not aware of other units types at this time, but the applicability should be written broadly enough to not preclude applicability to other types of resources that may be connected in the future.
Response: The SDT thanks you for your comment. The SDT believe Standard language is sufficiently broad not to preclude applicability to other types of resources that may be connected to the BES in the future.		
Independent Electricity System Operator	No	No, we are not aware of any. Similar to our comments on MOD-027-1, the Applicability Section of draft MOD-026-1 standard does not contain specific references to variable energy resource plants/facilities. It only covers generating units and plants of certain sizes for the three (and Quebec) Interconnections without any specificity on generator types. Was it an oversight or did the SDT suggest that the “generating units” suffice to generally include all types of energy resources?
Response: The SDT thanks you for your comment. The SDT strove to make standard language technology neutral and purposely avoided identifying specific generating unit technologies. The SDT also proposes requiring verification of an aggregate plant comprised of several smaller sized units because of the increasing impact renewable generation has on the BES.		
Duke Energy	No	However, an exception should be made for variable energy resources for which models have not yet been fully developed and accepted. Techniques for validation of these devices have not been developed similar to generator excitation model validation tools (EPRI PPPD).
Response: The SDT thanks you for your comment. The SDT believes that models have already been developed to an adequate level of detail and are available in the planning tools. Generic models for variable energy resources have been developed in a collaborative industry effort (led by the WECC Dynamic Modeling Working Groups) and should be validated in the absence of available OEM models. Development efforts are underway to provide suitable techniques for validation of variable energy resources.		

Organization	Yes or No	Question 1 Comment
Luminant Energy	No	I am not aware of any other generation configurations/types that should be covered in the Applicability portion.
Response: The SDT thanks you for your comment.		
Consolidated Edison Co. of NY, Inc.	No	Applicability to Smaller Units:The proposed standard allows for generators with a capacity factor under 5% rated over 100 MVA to be excluded from verification. There are many older generators that meet this criterion that would be critical during stressed system conditions with high loads. Generators under 100 MVA could also be critical in some local areas. The applicable criterion should be the same as those used in the Compliance Registry. No capacity factor exemptions should be allowed without a technical justification.Also see section 4.2, footnote 2. This is a broad exemption, and as we saw recently during the continent-wide heat wave, almost all units within our control area were operating. The requirement is to test once every 10 years. This is not an excessively onerous requirement.
Response: The SDT thanks you for your comment. The 5% capacity factor exemption was selected to achieve a balance between the cost and benefits. The SDT believes that there are a limited number of units greater than 100 MVA with a capacity factor of less than 5%. Also, these units may be excluded from model verification however other standards still require that the data be supplied. **The SDT believes the standard is drafted to provide the proper cost/benefit balance for performing generator verification.** **The SDT believes it is not necessary to have models verified for all units listed in the compliance registry.** **The SDT believes proposed applicability thresholds will substantially improve accuracy of the excitation models and associated Reliability based limits determined by dynamic simulation in a cost-effective and time-efficient manner when performing verification.** **The SDT recognizes that the excitation system model and modeling data is already captured by MOD-012 and MOD-013 required processes. 2. The current version of the MOD-026 standard has been re-formatted so that it would be more concise and contain only reliability related requirements. Do you agree there are no omissions from the prior draft due to the re-formatting of the standard?

Summary Consideration: None of the comments identified omissions from the prior draft. One commenter suggested that it would be easier to identify omissions if a mapping document was created. The SDT did not create a mapping document on account extensive changes were made to the standard for which a mapping document would have limited usefulness.

Organization	Yes or No	Question 2 Comment
Independent Electricity System Operator	Negative	We do not agree with the following requirements: i. R1: Standards should stipulate the “what’s” not the “how’s”. To avoid the perception that the requirement is prescribing the “how”, we suggest simplifying the language of Requirement R1 by replacing “Instruction on how to obtain” with “Instructions for obtaining”. Further, are all three bullets meant to be complied with or are they listed as options? We understand that the general rule for NERC standards is that those items that must be complied with are labeled as parts (e.g. 1.1, 1.2, etc.) while those that are options or examples that do not need to be complied with are placed in bullets. Please verify this with the Director of Standards Process. ii. R2.1: The phrase “models acceptable to its Transmission Planner” begs the question on what is deemed acceptable and what if the GO disagrees with the TP’s determination. To address the two issues, we suggest adding a requirement for the TP to specify the models requirements (or change the second bullet in R1 to achieve this), and change the wording in R2.1 to “in accordance with the models specified by the TP (or referencing the requirement part that contains the specification). iii. We are not sure why Requirement R5 is needed. First of all, it suggests that a Planning Coordinator may request the GO to perform a model review where the request can be technically justified. We wonder if the requirement really means “Transmission Planner” rather than “Planning Coordinator” since TP as the requester and model user is specified throughout the standard. Secondly, if it is indeed TP that was meant to be the requester, then would this request already been covered by Requirement R3? If not, what are the technical justifications? They are not specified in R5, unlike its R3 counterpart. Please clarify and/or revise the requirement as appropriate. iv. R6 stipulates the criteria that may not be accomplished even if the GO provides an accurate excitation control system and plant volt/var control function model. A computer model may fail to initialize due to reasons other than the submitted excitation control system and plant volt/var control function model itself; a no-disturbance simulation may

Organization	Yes or No	Question 2 Comment
		not result in negligible transients due to other reasons; and finally, a disturbance simulation may not result in the excitation control system and plant volt/var control system model exhibiting positive damping due to other system parameters. System damping is affected by many other dynamic performance contributors such as other generators, system topology, power flow levels, voltage levels, excitation system and power system stabilizer settings, etc. In short, having an accurate excitation control system and plant volt/var control function model does not necessary guarantee or equate to meeting the conditions stipulated in the three sub-requirements. We suggest this requirement be removed. Further, in many jurisdictions the setting and tuning of excitation control systems and associated power system stabilizers, etc. are determined by the Transmission Planners (or Planning Coordinators); the GOs would simply provide the equipment and set them according to the TP's specification. In this standard, the responsibility is for the GO to verify that the model reflects the actual response of the tested equipment, whose settings have been determined prior by the other responsible entity. v. Generator model parameters need to be verified based on tests conducted during both turbine/governor model verification as well as excitation system model verification. We are however not convinced that those tests that need to be performed during the excitation system model and data verification process, to verify certain portions of the generator model parameters will be conducted as a matter of course. We therefore reiterate our view that the verification of generation model parameters needs to be included within the scope of this standard and we urge the SDT to consider our comments again. vi. The standard does not contain any provision that a TP (or PC) can request for model verification of units that do not meet the Applicability criteria but are deemed to have an impact on reliability. This could leave room for system to exhibit unstable performance for reasons indicated in our previous comments. We urge the SDT to add this provision to fill a potential reliability gap.

Response: The SDT thanks you for your comment. Since the comment contains multiple concerns, the SDT has paraphrased the comment and is responding to each concern separately for easier understanding and review:

#1. Standard shall stipulate the "what's" and not the "how's"; suggest simplifying the language of R1 by replacing "instructions on how to obtain" with "instructions for obtaining".

Response: Requirement 1 does describe the "what". The "what" is that upon request, the Transmission Planner is to provide the Generator Owner data or instructions on how to obtain needed information. Recommended language does not change the meaning of the sentence and the SDT does not believe the revision proposed would improve clarity; so the language was not changed.

#2. Bullet vs. numbers; bullets do not require compliance

Organization	Yes or No	Question 2 Comment
Response: As stated in requirement 1, the three bullets identify instructions and data the Generator Owner can request from the Transmission Planner. The Transmission Planner is only required to provide information requested. The SDT believes standard formatting is correct since the Generator Owner determines what, if any of the information identified is requested from the Transmission Planner. **#3. Not comfortable with the phrase "models acceptable to its transmission planners". Recommend adding a requirement for the Transmission Planner to specify modeling requirements or change the wording in R 2.1 to include "in accordance with models specified by the Transmission Planner".** **Response: Since the Transmission Planner is the user of the models, the models must be acceptable to the Transmission Planner in order to be deemed useful. The first bullet under R1 does require the Transmission Planner to provide instructions on how to obtain the list of acceptable models.** **#4 Why R5 is required? In R5, should it be 'Transmission Planner" rather than "Planning Coordinator". Is this request already covered in R3? If not, what is the technical justification?** **Response: The SDT added requirement R5 because sometimes a planner discovers that a model not covered in the base Applicability, which is a subset of the NERC Registry Criteria, incorrectly represents equipment. Requirement 5 provides a method to validate these models that incorrectly represents equipment and not in the base Applicability but meet the NERC Registry Criteria. This requirement is assigned to the Planning Coordinator to address Generator Owner concern that the Transmission Planner might request a model review without proper justification. The requirement is written to require a higher level of justification for requesting a model review than simply contacting the Generator Owner.** **Several commenters expressed concern with the new Requirement added to the standard giving the Planning Coordinator authority to require model review for a unit not specified in the standard Applicability section. The SDT added this language to the draft standard after considering industry comments to the first posting noting that the Applicability section is a subset of the Compliance Registry criteria. Based on the latest round of industry feedback, the SDT now proposes Applicability Section language allowing the Planning Coordinator to request additional model information (possibly model verification) only if technical justification demonstrates the simulated unit response does not match the measured unit response. Original technical justification language for units that affect a stability limit has been removed from the standard. To emphasize for understanding, the SDT points out only units that meet or exceed the Registry Criteria unit MVA thresholds (> 20 MVA) are subject to Requirement R5. This observation should allay concern the Requirement could be misused inappropriately.** **#5. In R6, having an accurate excitation model does not guarantee meeting requirements R 6.1, 6.2, 6.3 due to the reasons indicated. Suggest that requirement be removed.** **Response: R6.1, R6.2, and R6.3 represent established industry practice for assuring model usability. The positive damping requirement makes the Generator Owner provide a response if a new model introduces negative damping. This requirement recognizes that the equipment must be positively damped during actual operation. Negative damping occurring during simulation indicates incorrect modeling. Initialization errors and oscillation transients without disturbance conditions also indicate incorrect modeling.**		

Organization	Yes or No	Question 2 Comment
#6. How to handle settings provided to GO by TP **Response: The Generator Owner is responsible for tuning the equipment and providing the final model settings to the Transmission Planner. As a specific example, the Transmission Planner may ask the Generator Owner to implement a gain that is proven via a gain margin test to not be implementable. The Generator Owner would report the gain actually implemented on the actual equipment.** **#7. Recommend that the verification of generation model parameters be included as part of this standard.** **Response: The SDT agrees generator parameters such as the inertia constant, damping coefficient, saturation parameters, direct & quadrature axis reactance's, and time constants need to be correctly modeled. Since the phrase, "excitation control system" is an IEEE defined term with specific meaning the SDT contends this term incorporates the generation model parameters by definition. The generation model parameters must be correct to successfully verify the excitation control system model. Note that the governor turbine model verification is addressed by the MOD-027 standard. The SDT recognizes the various control systems interact and expects correct modeling data. The purpose of this standard is model verification and not the development of correct modeling parameters. If model verification is not successful, then the modeling parameters are not correct and the Generator Owner will need to identify and correct bad parameters. This standard intentionally avoids specifying how to correct model parameters with expectation the Generator Owner demonstrates that model data is correct.** **#8. Standard does not contain any provision that a TP can request for model verification of units that are deemed to have an impact on reliability? (R5 addresses this question)** **Response: Requirement 5 provides a clause that allows the Planning Coordinator to require model verification of additional units by providing suitable documented evidence. This task was assigned to the Planning Coordinator instead of the Transmission Provider to provide an extra review layer for any request to verify any additional units.** **Several commenters expressed concern with the new Requirement added to the standard giving the Planning Coordinator authority to require model review for a unit not specified in the standard Applicability section. The SDT added this language to the draft standard after considering industry comments to the first posting noting that the Applicability section is a subset of the Compliance Registry criteria. Based on the latest round of industry feedback, the SDT now proposes Applicability Section language allowing the Planning Coordinator to request additional model information (possibly model verification) only if technical justification demonstrates the simulated unit response does not match the measured unit response. Original technical justification language for units that affect a stability limit has been removed from the standard. To emphasize for understanding, the SDT points out only units that meet or exceed the Registry Criteria unit MVA thresholds (> 20 MVA) are subject to Requirement R5. This observation should allay concern the Requirement could be misused inappropriately.**		
Brazos Electric Power Cooperative, Inc.	Negative	This standard is overly administrative by memorializing the interactions between the Generator Owner, Transmission Planner and Planning Coordinator that occur to model the generator's excitation system. Specifically R1, R3, R4 and R5 should be struck. They are purely administrative and present compliance risk to the registered owners without commensurate reliability benefit. For Requirement R6, the portion requiring a written response should be struck as well. Only two requirements are needed to accomplish the

Organization	Yes or No	Question 2 Comment
		purpose of this standard. They are: one requirement for the Generator Owner to perform the test and one for the Transmission Planner to verify the model is accurate. Requirement R6 creates a situation where a Transmission Planner could be forced to decide between living with an exciter model that needs adjustment and violating the standard. Upon initial examination, the Transmission Planner may determine that the model meets Parts 6.1 through 6.3. Only after months or years of extensive study, it is possible that the Transmission Planner determines that the excitation model could stand some improvements. If they submit a written response one year later, the Transmission Planner may be in violation of Requirement R6. This just represents one of the issues with memorializing the interactions between the Transmission Planner, Planning Coordinator and Generator Owner in the standards. Because the tests to verify the excitation model can be expensive, there should be a demonstrated need to perform a test. Summaries of field test results posted with the second draft of the SAR indicate the costs of these tests could range from $5,000 to $50,000 for a single unit. That does not even include opportunity costs from lost energy sales should the test cause the unit to trip. Thus, if there are no demonstrated modeling deficiencies (i.e. benchmarking reveals model results do not align with actual system results), then no test should be required and the Generator Owner should be able to wait for a system disturbance appropriate enough to verify its model. Because R3 and R5 give only 90 days to respond to the Planning Coordinator's and Transmission Planner's issues with the excitation model, these requirements could compel tests during a seasonal peak time frame. At a minimum, the Generator Owner should have 180 days to perform the test if that is what is identified as its response to avoid jeopardizing unit tripping during periods of high loads.

Response: The SDT thanks you for your comment. Since the comment contains multiple concerns, the SDT has paraphrased the comment and is responding to each concern separately for easier understanding and review:

#1. This standard is overly administrative by memorializing the interactions between the Generator Owner, Transmission Planner and Planning Coordinator that occur to model the generator's excitation system. Specifically R1, R3, R4 and R5 should be struck

Response: The SDT agrees that R2 is the main requirement for model verification. The purpose of requirements R1, R3, R4, and R5 is to provide processes to assure that the information provided per R2 is useful to the user of the information so that the reliability goal of verifying models that are used in BES security limit determination is met.

#2. For Requirement R6, the portion requiring a written response should be struck as well. Only two requirements are needed to accomplish the purpose of this standard. They are: one requirement for the Generator Owner to perform the test and one for the Transmission Planner to verify the model is accurate. Requirement R6 creates a situation where a Transmission Planner could be forced to decide between living with an exciter model that needs adjustment and violating the standard. Upon initial examination, the Transmission Planner may determine that the model meets Parts 6.1 through 6.3. Only after months or years of extensive study, it is possible that the Transmission Planner determines that

Organization	Yes or No	Question 2 Comment
the excitation model could stand some improvements. If they submit a written response one year later, the Transmission Planner may be in violation of Requirement R6 **Response: R6 language references usability testing which can be readily completed by the Transmission Planner. R6 language is not intended to prevent the Transmission Planner from requesting the Generator Owner to verify information if there is evidence that the model is incorrect. The third bullet of R3 mandates that the Generator Owner must respond to evidence from the Transmission Planner that the modeled response does not match the recorded response and this language allows the Transmission Planner, assuming supporting evidence is available, to request a review at any time.** **#3. If there are no demonstrated modeling deficiencies (i.e. benchmarking reveals model results do not align with actual system results), then no test should be required and the Generator Owner should be able to wait for a system disturbance appropriate enough to verify its model. Because R3 and R5 give only 90 days to respond to the Planning Coordinator's and Transmission Planner's issues with the excitation model, these requirements could compel tests during a seasonal peak time frame. At a minimum, the Generator Owner should have 180 days to perform the test if that is what is identified as its response to avoid jeopardizing unit tripping during periods of high loads.** **Response: The SDT believes 90 days is adequate for the Generator Owner to determine if additional information is available to correct the issue or if model verification is required. The requirements do not require model verification in 90 days, only a plan to perform model verification if needed. Per Attachment 1, the Generator Owner then has 365 days to perform the test or collect an ambient event. The 90 day criteria was established to facilitate dialogue between the Transmission Planner and the Generator Owner.**		
Public Service Enterprise Group	No	If the SDT were to prepare a table showing how the requirements in the prior version were incorporated into the present version and included that in its background information on the standard, this question would be answered.
Response: The SDT thanks you for your comment. The SDT did not create a mapping document on account extensive changes were made to the standard for which a mapping document would have limited usefulness.		
Exelon	No	Differences between draft 1 and draft 2 of MOD-026 appear to be significant. Without reading through all 134 pages of comments and how the SDT addressed those comments it is too difficult to tell how the requirements were evaluated and if omissions were intentional or not. Suggest that the SDT prepare either a mapping document or a "redline to previous version" to illustrate changes and disposition of such changes to ensure there are no omissions from the prior draft.
Response: The SDT thanks you for your comment. The SDT did not create a mapping document on account extensive changes were made to the standard for which a mapping document would have limited usefulness.		
Independent Electricity System Operator		We are a bit surprised and disappointed that the SDT asks this question. The posted

Organization	Yes or No	Question 2 Comment
		MOD-026-1 Draft 2 is a clean version, not a redline version from last posted, making it difficult for readers to identify where the previous requirements are contained in the revised draft. We understand that a reformatting may render tracked changes to be convoluted and hence a clean version may be a better option. However, in doing so, the SDT should provide a mapping document to show where the previous requirements are mapped into the revised draft standard. Whether or not any requirements were omitted could have been and should have been identified by the SDT through the mapping process rather than by the commenters.
Response: The SDT thanks you for your comment. The SDT did not create a mapping document on account extensive changes were made to the standard for which a mapping document would have limited usefulness.		
SERC Generation Sub-committee (GS)	Yes	The GS is not responding to MOD-026
American Electric Power	Yes	AEP is not aware of any omissions from the prior draft due to the re-formatting of the standard.

3. The SDT discussed if MOD-026-1 should also include verification of excitation control systems of synchronous condensers. Synchronous condensers are not currently addressed in the NERC Registry Criteria. Synchronous condensers are not mentioned in the Generation Verification SAR. On an MVA capacity basis, the penetration of synchronous condensers in North America is extremely low. It is common for Transmission Owners to be the owners of synchronous condensers. As such, the peer review draft requirements would not make sense. Therefore, the team decided that a more appropriate strategy would be to include synchronous condensers with other transmission system dynamic reactive devices (such as SVCs, STATCOMs, etc.) in a separate SAR.

Do you agree with the proposal to not include the verification of synchronous condensers in MOD-026-1?

Summary Consideration: The majority of commenters agreed with the SDT that synchronous condensers should not be included in MOD-026. Synchronous condensers are not currently addressed in the NERC Registry Criteria. On an MVA capacity basis, the penetration of Synchronous condensers in North America is extremely low, with many units owned by Transmission Owners. As such, the peer review draft requirements would not make sense. The SDT decided that, with the current structure of the Compliance Registry Criteria, if there is a need to develop a Reliability Standard to model the expected behavior of dynamic voltage devices typically owned by Transmission entities, then a more appropriate strategy is to include Synchronous Condensers along with other transmission system dynamic reactive devices (such as SVCs, STATCOMs, etc.) into a separate SAR. The GVSDT will closely monitor BES SDT efforts to define BES and the correlation of BES elements with the ERO Statement of Compliance Registry Criteria, and make appropriate adjustment as necessary to the Applicability of MOD-026-1 regarding the treatment of Synchronous Condensers.

Organization	Yes or No	Question 3 Comment
Manitoba Hydro	Negative	Manitoba Hydro is voting negative for the following reasons: 1)We disagree with the SDTs decision that a more appropriate strategy would be to include synchronous condensers with other transmission system dynamic reactive devices (such as SVCs, STATCOMs, etc.). The testing of the excitation system of a synchronous condenser is identical to the testing of the excitation system of a generator and will likely be planned, performed, documented and reported on by the same testing team responsible for testing the excitation systems of applicable generators. Placing synchronous condensers in the same category with SVCs, STATCOMS, etc. introduces an unnecessary hardship to entities. It is suggested that the standard be re-written to include synchronous condensers within the same applicability MVA rating as generators. 2)Attachment 1 is not clear. Specifically, -the “Condition” in the first row is not a condition and is not consistent with the remaining rows. -Row 1 suggests that there are no exceptions for submitting a recorded response of a voltage excursion, but Row 2 contradicts this by allowing a single unit to be ‘verified’ and

Organization	Yes or No	Question 3 Comment
		serve as evidence for multiple units meeting the conditions listed. -the wording for the allowance of a representative unit to be verified and submitted as evidence for identical units is not clear. -the periodicity for row 1 suggests that a recorded response for a voltage excursion shall be collected 'with the verified model' which is incorrect. -We suggest the following. A statement that precedes the Attachment 1 table should be added that reads 'For all Existing Generating Units - a recorded response for a voltage excursion shall be collected during a ten calendar year (January - December) period from the effective date of this standard and the documentation transmitted to the Transmission Planner no more than 365 calendar days from the date that the recorded response was collected unless otherwise specified by the table below. For all newly installed Generating Units - a recorded response for a voltage excursion shall be collected and the verified model and documentation transmitted to the Transmission Planner no more than 180 calendar days of the unit in service date unless specified otherwise specified by the table below. ' Row 1 should then read 'Facility - Existing Generating Unit, Condition - All existing generating units unless the following exception applies: If multiple units have the same MVA rating that is = 350 MVA, and they have identical applicable components and settings, and they are sited at the same physical location, verification of one representative unit is sufficient for all such units. Verification of a different representative unit should be completed each cycle, Periodicity - not required for any units except one representative unit.' 3)For Section 4.2 "Facilities", the section should refer to 'BES Generating Units and Facilities' instead of restating components of the proposed BES definition.

Response: The SDT thanks you for your comment.

1. Synchronous condensers are not currently addressed in the NERC Registry Criteria. On an MVA capacity basis, the penetration of Synchronous condensers in North America is extremely low. It is common for Transmission Owners to be the owners of synchronous condensers. As such, the peer review draft requirements would not make sense. The MOD-025 standard addresses steady state modeling but does not contain peer review requirements so the GVSDT believes incorporating synchronous condensers into the MOD-025 standard is a better fit. Synchronous condensers do not generate real power as a source of revenue so Transmission Owners paying for synchronous condenser installation and maintenance do so for dynamic voltage support; most likely to extend a dynamic voltage security limit. As such, The Transmission Owner is highly motivated to understand and model synchronous condenser dynamic behavior. Based on this understanding the SDT has decided that:

a. **With the current structure of the Compliance Registry Criteria, if there is a need to develop a Reliability Standard to model the expected behavior of dynamic voltage devices typically owned by Transmission entities, then a more appropriate strategy is to include Synchronous Condensers along with other transmission system dynamic reactive devices (such as SVCs, STATCOMs, etc.) into a separate SAR.**

b. **Both the NERC Board of Trustees and the NERC Standards Committee have endorsed the plan to have the BES SDT during phase 2 of their work under a new SAR (draft version available on the NERC website) to define BES and the correlation of BES elements with the ERO Statement of Compliance Registry Criteria. The GVSDT will closely monitor the progress of the BES SDT and make appropriate adjustment as necessary to the Applicability of MOD-026-1 regarding the treatment of Synchronous Condensers.**

Organization	Yes or No	Question 3 Comment
2. The SDT has revised Attachment 1 to improve clarity. **3. The SDT intentionally established the standard applicability as a subset of generators included in the NERC Registry Criteria. The term “BES Generating Units and Facilities” is not specific enough for compliance. There are regional differences that prevent use of this term in defining standard applicability.**		
Occidental Chemical	Negative	3. The SDT discussed if MOD-026-1 should also include verification of excitation control systems of synchronous condensers. Synchronous condensers are not currently addressed in the NERC Registry Criteria. Synchronous condensers are not mentioned in the Generation Verification SAR. On an MVA capacity basis, the penetration of synchronous condensers in North America is extremely low. It is common for Transmission Owners to be the owners of synchronous condensers. As such, the peer review draft requirements would not make sense. Therefore, the team decided that a more appropriate strategy would be to include synchronous condensers with other transmission system dynamic reactive devices (such as SVCs, STATCOMs, etc.) in a separate SAR. Do you agree with the proposal to not include the verification of synchronous condensers in MOD-026-1? YES Comments: Yes. There is already a significant body of work underway defining the extent of the Bulk Electric System. This determination should rest with the project team responsible for that effort.
Response: The SDT thanks you for your comment. The SDT agrees with your comment and understands both the NERC Board of Trustees and the NERC Standards Committee have endorsed the plan to have the BES SDT during phase 2 of their work under a new SAR (draft version available on the NERC website) to define BES and the correlation of BES elements with the ERO Statement of Compliance Registry Criteria. The GVSDT will closely monitor the progress of the BES SDT and make appropriate adjustment as necessary to the Applicability of MOD-026-1 regarding the treatment of Synchronous Condensers.		
Manitoba Hydro (Greg Parent, S N Fernando, Daniel Prowse)	Negative	1)We disagree with the SDTs decision that a more appropriate strategy would be to include synchronous condensers with other transmission system dynamic reactive devices (such as SVCs, STATCOMs, etc.). The testing of the excitation system of a synchronous condenser is identical to the testing of the excitation system of a generator and will likely be planned, performed, documented and reported on by the same testing team responsible for testing the excitation systems of applicable generators. Placing synchronous condensers in the same category with SVCs, STATCOMS, etc. introduces an unnecessary hardship to entities. It is suggested that the standard be re-written to include synchronous condensers within the same applicability MVA rating as generators.
Response: The SDT thanks you for your comment. The SDT agrees that in a technical sense generator and synchronous condenser excitation system testing have many similarities however there are several factors that prevent clear resolution of this issue. **Synchronous condensers are not currently addressed in the NERC Registry Criteria. On an MVA capacity basis, the penetration of Synchronous condensers in North America is extremely low. It is common for Transmission Owners to be the owners of synchronous condensers. As such, the peer review draft requirements would not make sense. The MOD-025 standard addresses steady state modeling but does not contain peer review**		

Organization	Yes or No	Question 3 Comment
requirements so the GVSDT believes incorporating synchronous condensers into the MOD-025 standard is a better fit. Synchronous condensers do not generate real power as a source of revenue so Transmission Owners paying for synchronous condenser installation and maintenance do so for dynamic voltage support; most likely to extend a dynamic voltage security limit. As such, The Transmission Owner is highly motivated to understand and model synchronous condenser dynamic behavior. Based on this understanding the SDT has decided that: **a. NERC Staff Review Team	No	It is most efficient to address synchronous condensers in the same project as generators given that

Organization	Yes or No	Question 3 Comment
		synchronous condensers have many of the same characteristics as generators. Static var compensators (SVCs) and static compensators (STATCOMs) are sufficiently different from generators and synchronous condensers to be appropriately covered in a separate SAR.Despite the low penetration of synchronous condensers in North America, these devices are most likely installed to extend a dynamic voltage security limit as noted by the drafting team. Due to the importance of these devices, validated models should be required for these devices similar to generators. Reliance on other motivations for equipment owners to validate models is inconsistent with requirements for generators and does not provide appropriate assurance that the equipment owners will validate models necessary for system reliability.

Response: The SDT thanks you for your comment. The SDT believes synchronous condenser model verification will need to be addressed by a standard and the remaining question is "Which standard should address this issue?"

Synchronous condensers are not currently addressed in the NERC Registry Criteria. On an MVA capacity basis, the penetration of Synchronous condensers in North America is extremely low. It is common for Transmission Owners to be the owners of synchronous condensers. As such, the peer review draft requirements would not make sense. The MOD-025 standard addresses steady state modeling but does not contain peer review requirements so the GVSDT believes incorporating synchronous condensers into the MOD-025 standard is a better fit. and maintenance do so for dynamic voltage support; most likely to extend a dynamic voltage security limit. As such, The Transmission Owner is highly motivated to understand and model synchronous condenser dynamic behavior. Based on this understanding the SDT has decided that: **a. With the current structure of the Compliance Registry Criteria, if there is a need to develop a Reliability Standard to model the expected behavior of dynamic voltage devices which could be owned by Transmission entities, then a more appropriate strategy is to include Synchronous Condensers along with other transmission system dynamic reactive devices (such as SVCs, STATCOMs, etc.) into a separate SAR.** **b. Both the NERC Board of Trustees and the NERC Standards Committee have endorsed the plan to have the BES SDT during phase 2 of their work under a new SAR (draft version available on the NERC website) to define BES and the correlation of BES elements with the ERO Statement of Compliance Registry Criteria. The GVSDT will closely monitor the progress of the BES SDT and make appropriate adjustment as necessary to the Applicability of MOD-026-1 regarding the treatment of Synchronous Condensers.**		
Duke Energy	No	These types of reactive resources should be included if of a sufficient size to impact reliability.
Response: The SDT thanks you for your comment. The SDT agrees that in a technical sense generator and synchronous condenser excitation system testing have many similarities however there are several factors that prevent clear resolution of this issue. **The SDT believes synchronous condenser model verification will need to be addressed by a standard and the remaining question is "Which standard should address this issue? Both the NERC Board of Trustees and the NERC Standards Committee have endorsed the plan to have the BES SDT during phase 2 of their work under a new SAR (draft version available on the NERC website) to define BES and the correlation of BES elements with the ERO Statement of Compliance Registry Criteria. The GVSDT will closely monitor the progress of the BES SDT and make appropriate adjustment as necessary to the Applicability of MOD-026-1 regarding the treatment of Synchronous Condensers.**		
Idaho Power - Power Production	No	
Imperial Irrigation District (IID)	Yes	THERE ARE NO SYNCHRONOUS CONDENSERS INSTALLED AND IN SERVICE WITHIN IID FACILITY.
Response: The SDT thanks you for your comment.		
BC Hydro and Power Authority	Yes	MOD-025 includes synchronous condensers. This doesn't appear to be consistent with the strategy for MOD-026?

Organization	Yes or No	Question 3 Comment
Response: The SDT thanks you for your comment. It is true that synchronous condensers are included in the current draft of MOD-025. The MOD-025 standard addresses steady state modeling but does not contain peer review requirements so the GVSDT believes incorporating synchronous condensers into the MOD-025 standard is a better fit.		
SERC Generation Sub-committee (GS)	Yes	The GS is not responding to MOD-026
SPP Reliability Standards Develpment Team	Yes	We agree as long as the SDT creates the new SAR to address such devices including Synchronous condensers.
Response: The SDT thanks you for your comment.		
Dynamics Review Subcommittee	Yes	It is good strategy to include synchronous condensers with other dynamic reactive devices as they all fall under the same category - providing dynamic reactive support.
Response: The SDT thanks you for your comment.		
Public Service Enterprise Group	Yes	The team needs to develop a consistent rationale on synchronous condensers in all of the standards being addressed in Project 2007-09. The team should consider asking the NERC Planning Committee to develop a white paper on the need (or lack of need) for synchronous condenser data.
Response: The SDT thanks you for your comment. Even though Project 2007-09 addresses 5 standards, only two of these standards address verification of generator dynamic models. **Synchronous condensers are not currently addressed in the NERC Registry Criteria. On an MVA capacity basis, the penetration of Synchronous condensers in North America is extremely low. It is common for Transmission Owners to be the owners of synchronous condensers. As such, the peer review draft requirements would not make sense. Therefore the SDT has decided that:** **a. With the current structure of the Compliance Registry Criteria, if there is a need to develop a Reliability Standard to model the expected behavior of dynamic voltage devices typically owned by Transmission entities, then a more appropriate strategy is to include Synchronous Condensers along with other transmission system dynamic reactive devices (such as SVCs, STATCOMs, etc.) into a separate SAR.** **b. Both the NERC Board of Trustees and the NERC Standards Committee have endorsed the plan to have the BES SDT during phase 2 of their work under a new SAR (draft version available on the NERC website) to define BES and the correlation of BES elements with the ERO Statement of Compliance Registry Criteria. The GVSDT will closely monitor the progress of the BES SDT and make appropriate adjustment as necessary to the Applicability of MOD-026-1 regarding the treatment of Synchronous Condensers.**		

Organization	Yes or No	Question 3 Comment
Southern Company	Yes	It is possible that the owners of the transmission system dynamic reactive devices (such as synchronous condensers, SVCs, STATCOMs, etc) may not be a NERC registered entity at all. Moreover, it is highly inappropriate to just add equipment not mentioned in the original SAR to the standard. It makes more sense, as SDT suggested, to have a separate SAR to address those transmission system dynamic reactive devices.
Response: The SDT thanks you for your comment.		
Ingleside Cogeneration LP	Yes	Yes. There is already a significant body of work underway defining the extent of the Bulk Electric System. This determination should rest with the project team responsible for that effort.
Response: The SDT thanks you for your comment. The GVSDT will closely monitor the progress of the BES SDT and make appropriate adjustment as necessary to the Applicability of MOD-026-1 regarding the treatment of Synchronous Condensers.		
Ameren	Yes	Agree that there are relatively few synchronous condensers installed on the system. Including these devices with other dynamic reactive devices such as SVC's and STATCOMs, rather than in this standard, appears to be a good approach.
Response: The SDT thanks you for your comment.		
Consolidated Edison Co. of NY, Inc.	Yes	The inclusion of all reactive resources as BES Elements covered by a separate standard would be consistent with the current draft of the proposed Bulk Electric System (BES) Definition and Designations being proposed by the BES standard drafting team.
Response: The SDT thanks you for your comment.		
American Transmission Company	Yes	ATC believes that synchronous condensers may have significant impact in the areas where they are installed. Therefore, ATC agrees that they should be added to the NERC Compliance Registration Criteria and that a separate SAR should be established to develop a separate reliability standard for synchronous condensers and other dynamic reactive devices.
Response: The SDT thanks you for your comment.

FirstEnergy	Yes	
Independent Electricity System Operator		We do not have an opinion on which standard should contain this as long as synchronous condensers are verified.

4. **Do you have any other questions or concerns with the proposed standards that have not been addressed? If yes, please explain.**

Summary Consideration: As a result of industry comments regarding the SDT's request for questions or concerns that were not covered in the other questions, the SDT has made a number of modifications to the standard including:

1) **Correcting several VSL grammatical errors and ensuring consistency between the VSL "increment for tardiness" time period specified and the Requirement language.**
2) **An additional condition, row 12, was added to Attachment 1 (the Periodicity Table) specifying that validation is not required for an excitation control system or plant volt/var control that does not include an active closed loop voltage regulation function. This condition exempts wind and solar plants that do not have the capability to regulate plant voltage or respond to grid voltage fluctuations other than switching capacitor and reactor banks in and out of service.**
3) **The format and column information of Attachment 1 has been revised for clarity.**
4) **The typographical errors in R2.1.1 language has been corrected to clearly state expectation that the unit model response matches the recorded response for a voltage excursion at the unit's point of interconnection from either a staged test or a measured system disturbance."**
5) **The language of R2.1.4 has been revised to align with the style of R2.1.6.**
6) **Several commenters expressed concern with the new Requirement R5 added to the standard giving the Planning Coordinator authority to require a model review for a unit not specified in the standard Applicability section. The SDT added this language to the draft standard after considering industry comments to the first posting noting that the Applicability section is a subset of the Compliance Registry criteria. Based on the latest round of industry feedback, the SDT now proposes Applicability Section language allowing the Planning Coordinator to request additional model information (possibly model verification) only if technical justification demonstrates the simulated unit response does not match the measured unit response. Original technical justification language for units that affect a stability limit has been removed from the standard. To emphasize for understanding, the SDT points out only units that meet or exceed the Registry Criteria unit MVA thresholds (> 20 MVA) are subject to Requirement R5. This observation should allay concern the Requirement could be misused inappropriately. In addition, R5 language has been revised for clarity.**
7) **To clarify concerns regarding calculating unit capacity factor, the SDT has incorporated into the standard the capacity factor calculation specified in Appendix F of the GADS Data Reporting Instructions (which can be obtained from the NERC website).**

8) There was some confusion regarding the treatment of small units at plants. The SDT modified the language in the Applicability / Facilities section for clarity and for consistency to the extent possible with the other draft standards in the Generation Verification effort.

9) As a reminder the SDT, in its response to industry comments, points out this standard does not address providing notification of equipment changes nor collection of preliminary model data from the equipment manufacturer. The standard addresses verification of models following equipment changes. New equipment models cannot be verified until after the equipment is available.

Organization	Yes or No	Question 4 Comment
Independent Electricity System Operator	Negative	We do not agree with the standard as posted, and we have cast a NO vote. We are unable to support the VRFs and VSLs for the standard/requirements that we reject, and we expect the standard to be materially revised which may result in corresponding changes to the VRFs and VSLs.
Response: The SDT thanks you for your comment. The SDT has revised the standard and believes you may find these changes acceptable and will be able to support the next posting of the standard.		
Sunflower Electric Power Corporation	Negative	We believe that changes are needed for the standard and thus the VSLs and VRFs will require conforming changes.
Response: The SDT thanks you for your comment. The SDT has revised the standard and believes you may find these changes acceptable and will be able to support the next posting of the standard.		
Southern Company Generation	Negative	VSL for R1 needs work - the requirement specifies 30 days - the VSL doesn't count it tardy until 90 days.
Response: The SDT thanks you for your comment. The SDT has corrected the discrepancy identified between Requirement R1 and the associated Lower VSL by changing R1 language to read "within 90 calendar days".		
Western Electricity Coordinating Council	Negative	The timeing requirements in the VSLs for R1 is not in agreement with the timing requirements for providing instructions in Requirement 1. Requirement 1 requires the Transmission Planner to provide instructions within 30 calendar days. However, the Lower VSL starts with a violation for providing the instructions more than 90 days lat but less than 120 days late. What about 31-90 days late. I believe the periods in the four VSLs should be adjusted to start with 31-60 for Lower, 61-90 for Moderate, etc. Other than this issue I support the proposed VRFs and VSLs.

Organization	Yes or No	Question 4 Comment
Response: The SDT thanks you for your comment. The SDT has corrected the discrepancy identified between Requirement R1 and the associated Lower VSL by changing R1 language to read "within 90 calendar days". The 90 calendar day's response period allows sufficient time for communication to occur between the Generator Owner, Transmission Planner and other entities (such as the software vendor or turbine manufacturer) with respect to obtaining information identified in requirement R1. Limiting the R1 response period to 30 days does not provide any benefit.		
MidAmerican Energy Co.	Negative	Neither the standard nor the VSLs are ready to be approved.
Response: The SDT thanks you for your comment. The SDT has revised the standard and believes you may find these changes acceptable and will be able to support the next posting of the standard.		
Liberty Electric Power LLC	Negative	Due to the need for changes to the underlying standard.
Response: The SDT thanks you for your comment. The SDT has revised the standard and believes you may find these changes acceptable and will be able to support the next posting of the standard.		
Texas Reliability Entity	Negative	(1) According to Requirement R1, the TP must provide instructions and data within 30 days of a request. The Lower VSL for R1 starts at 90 days - it should start at 31 days. (2) The Severe VSL for R2 is very awkwardly worded (triple negative?). (3) The VSLs don't reflect all of the actions required in the Requirements and in Attachment 1. For example, the R3 VSLs only refer to the 90 day initial response, and do not address the 365/180 day requirements set forth in the Attachment.
Response: The SDT thanks you for your comment. **(1) The SDT has corrected the discrepancy identified between Requirement R1 and the associated Lower VSL by changing R1 language to read "within 90 calendar days".** **The 90 calendar day's response period allows sufficient time for communication to occur between the Generator Owner, Transmission Planner and other entities (such as the software vendor or turbine manufacturer) with respect to obtaining information identified in requirement R1. Limiting the R1 response period to 30 days does not provide any benefit.** **(2) The SDT has revised the language for the R2 Severe VSL to eliminate the triple negative.** **(3) In the appropriate VSL statements for Requirement R2, reference language for periodicity timeframe has been revised to state, "periodicity timeframe specified in MOD-026 Attachment 1" in order to establish the proper linkage with the time requirements specified in Attachment 1.**		
Sacramento Municipal Utility District	Negative	This vote is cast to correspond with the position on the standard.

Organization	Yes or No	Question 4 Comment
Response: The SDT thanks you for your comment.		
Indiana Municipal Power Agency	Negative	R4 is missing the VRF and Time Horizon. IMPA recommends “Lower” and “Long-term Planning”.
Response: The SDT thanks you for your comment. The SDT has added VRF and Time Horizon information to Requirement R4.		
Lakeland Electric	Negative	What does "external to the plant" mean as used in several of the requirements (e.g., R1, R2, and R6)? Considering R1, many generators have speed protection embedded in control systems (e.g., a GE Mark V or VI), is that included in footnote 1 to the requirement in the phrase: "multi-function protective devices or protective functions within excitation controls that directly trip or provide tripping signals to the generator based on frequency or voltage inputs"? In R2, does "voltage protective relaying" include station service protection, such as motor-contactors? The terms used in R1, R2 and R3 are inconsistent. R1 and R2 refer to "protective relaying", R3 refers to "protection system equipment". R6.1.1 is ambiguous, what does "at least 20% of the Facility's rated capacity" imply? Would a single test at full output suffice, or is "book-ending" the output between minimum and maximum output of the generator implied? R4 is missing the VRF and Time Horizon - would recommend Lower and Long-term Planning.
Response: This comment addresses the draft PRC-024 standard and has been forwarded to the responsible SDT subteam for consideration and response.		
Liberty Electric Power LLC	Negative	This standard should be designed so that a TO needing the information initiates the process with a data request. There is no need to have the GO make the request and then have the TO respond - it adds an extra step and more risk of violation to no purpose.
Response: The SDT thanks you for your comment. The SDT assumes this comment refers to Requirement R1. R1 does not require the Generator Owner to make a request for information from the Transmission Planner. However, since several Generator Owners have expressed a need to obtain data possessed by the Transmission Planner, this requirement simply obligates the Transmission Planner to provide information to the Generator Owner if requested.		
Public Service Electric and Gas Co., PSEG Energy Resources & Trade LLC, PSEG Fossil LLC, Public Service Electric and Gas Co	Negative	This standard has made progress, but there are ambiguities that we addressed in our comments and which the team also addressed on its July 29 Webinar. We recommend that the standard incorporate the suggested comments and the team repost the standard for a round of comments only.

Organization	Yes or No	Question 4 Comment
Response: The SDT thanks you for your comment. The standard is being revised to resolve ambiguities and improve clarity. The SDT will consider incorporating suggested comments. The standard will be posted for comments once the revision process is complete.		
Muscatine Power & Water	Negative	The requirements in this Standards are onerous and burdensome for small Utilities, and we have concern about whether this Standard is cost effective for the industry. The transient stability dynamic modeling for excitation control was traditionally developed under the assumption of limited bandwidth validity and approximations. The other equipment models in the simulation, e.g. generators, prime-mover controls, SVCs, HVDC Converters, etc. are all approximations without any correlated degree of accuracies in comparison to each other. On the other hand, the verification efforts required by this standard are expected to cost quite a bit to Generator Owners, especially for older units whose vendors/manufacturers may not even be in existence any more.
Response: The SDT thanks you for your comment. The SDT has tried to separate Transmission Owner and Generator Owner requirements. Many of the requirements are conditional and may not apply to some or all Generator Owner unit's. The SDT agrees there is a cost associated with this standard however, a need to verify excitation system models has been established and well understood by the technical community. The SDT believes it is not necessary to have models verified for all units listed in the compliance registry. **The SDT believes proposed applicability thresholds will substantially improve accuracy of the excitation models and associated Reliability based limits determined by dynamic simulation in a cost-effective and time-efficient manner when performing verification.** **The SDT recognizes that the excitation system model and modeling data is already captured by MOD-012 and MOD-013 required processes. This information, with few exceptions, creates a quality dynamics database.** **Field Testing initiated by the Phase III-IV SDT has shown that performing the activities specified in the draft standard will improve accuracy of the exciter model used in dynamic simulation.** **Utilizing engineering judgment, based in part on recent experience of entities verifying excitation system models, the SDT is proposing to require verification of excitation systems associated with 80% or greater of the connected MVA in each Interconnection. To accomplish this goal, the SDT has proposed MVA thresholds believed to correspond with at least 80% of the connected MVA in each Interconnection. This concept was overwhelmingly supported by industry in response to the previous posting of the standard.** **The standard does not require models to be valid over a wider bandwidth than what has been accomplished in the past.**		
Northern Indiana Public Service Co.	Negative	The related Standard Drafting subteams held a webinar on July 29 where they fielded numerous questions; issues still need to be addressed
Response: The SDT thanks you for your comment. The SDT has revised the standard and believes you may find these changes acceptable and will be		

Organization	Yes or No	Question 4 Comment
able to support the next posting of the standard.		
	Negative	The proposed standard is deficient in the following areas: I do not support verification exemptions for generating units rated 100 MVA and higher that have a capacity factor of less than 5%. These are the generating units that when dispatched, must be capable of synchronizing to the BES in a timely manner and operating reliably at their rated capability when synchronized to the grid. The proposed wording appears to allow generators to modify control and auxiliary system that would result in a change to the generating unit's capability and then notify the Transmission Planner of the change that has occurred. The order of notification and the actual modification of the generating unit is clearly backwards. The generator owner has a requirement to notify the Transmission Planner prior to modify the generating unit, especially if the modification results in a decrease in any aspect of the unit's capability (MW or MVAR) or its response time. The standard should include a requirement that all performance aspects of a machine Power System Stabilizer and limiter be made to responsible Transmission Planner. The proposed standard is not clear on this basic requirement.
Response: The SDT thanks you for your comment. The 5% capacity factor exemption was selected to achieve a balance between the cost and benefits. SDT believes that there are a limited number of units greater than 100 MVA with a capacity factor of less than 5%. Incremental model improvement for low capacity factor units does not justify the performance cost. This standard deals with modeling the generating unit and does not specify performance such as ability to synchronize in a timely manner for operating reliability. **Regarding changes to control and auxiliary systems, these changes do not affect the excitation system model nor does this standard address them. R4 only addresses changes to excitation control system and pant volt/var control system which will impact model accuracy.** **Regarding the last comment, this standard addresses model verification; in other words, this standard ensures that the model predicted response represents the actual response of the equipment. Per the SAR, this standard is a model verification standard and is not a performance standard.**		
National Association of Regulatory Utility Commissioners	Negative	The NPCC has identified the following issues that need to be resolved: Â· The standard allows for generators to change equipment and then notify the Transmission Planner of the change. This is unacceptable as it represents a significant reliability concern. Â· The standard should include verification of Power System Stabilizers if installed and limiters.
Response: The SDT Thanks you for your comment. Regarding your comment concerning equipment changes triggering model verification, this standard does not address providing notification of equipment changes or collection of preliminary model data from the equipment manufacturer. The standard addresses verification of models following equipment changes. New equipment models cannot be verified until after the equipment is available. **Regarding your comment concerning power system stabilizer verification, the SDT believes the information required by R2.1.6 will adequately define the PSS behavior for study. If instead your comment pertains to the appropriateness of PSS settings or tuning values used, the SDT believes it is**		

Organization	Yes or No	Question 4 Comment
following the intent of the SAR in writing this standard as a model verification standard as opposed to a performance standard.		
Wisconsin Energy Corp.	Negative	Staged testing for generator exciter model verification will likely require switching of lines on the transmission system. In cases where the Generator Owner does not own or operate the transmission system, the TO or TOP may understandably be reluctant to switch lines out due to reliability concerns. For this reason, R2 should be modified to provide more incentive for the TO/TOP to coordinate with the GO to do the required testing.
Response: The SDT thanks you for your comment. Staged testing does not require line switching; and instead simply requires injecting a step change signal value into the voltage regulator summing junction of the unit being tested. This testing has minimal impact on the transmission system and does not require transmission operator action.		
Dominion Resources Services, Dominion Virginia Power	Negative	Section 4.2.4 needs to be removed to be consistent with other standards. Section 2.1.1 “match” should be changed to approximate. The model will never exactly match. Section 2.1.6 remove “structure”. R3 bullet 3 “match” should be changed to approximate. The model will never exactly match. Attachment 1 title is missing “M”. Attachment 1 column “Condition” replace eleven and ten with “eleventh” and “tenth”. Section 4: Applicability should spell out testing exceptions
Response: The SDT thanks you for your comment. Section 4.2.4, as drafted, is necessary to identify applicable facilities covered by this standard. Note that the SDT added this Applicability to the draft standard after considering industry comments to the first posting noting concerns that the Applicability section is a subset of the Compliance Registry criteria. **Regarding comments pertaining to R2.1.1 and R3, the SDT believes use of the term “match” is appropriate because the Webster’s dictionary defines match as something that is equal or similar to another.** **Regarding use of the term “structure” in Section 2.1.6, this language indicates that the “block diagram” is a necessary part of the information provided by the Generator Owner to the Transmission Planner. Note that the same term is also used in Section 2.1.4 as part of the description for the excitation control system and plant volt/var system.** **The typo in the Attachment 1 title has been corrected.** **Attachment 1 has been substantially revised for clarity and thus the issue with “eleven and ten” is no longer an issue in the current draft.** **The SDT believes that the Attachment 1 (Periodicity Table) is an appropriate document for specifying testing periodicity and exemption criteria.**		
Public Utility District No. 1 of Chelan County	Negative	Requirement R1 of the proposed PRC-024-1 reliability standard conflicts with the WECC Off-Nominal Frequency Load Shedding Plan (WECC Coordinated Plan), and could potentially result in negative reliability impacts if enforced in the Western Interconnection. A WECC Regional Variance that includes the WECC Generator underfrequency and overfrequency operation requirements as identified in the WECC

Organization	Yes or No	Question 4 Comment
		Off-Nominal Load Shedding Plan must be added to the proposed standard. WECC has developed, implemented, and verified the effectiveness of the WECC Coordinated Plan and any deviations from the requirements of the plan may negatively impact its effectiveness.
Response: This comment addresses the draft PRC-024 standard and has been forwarded to the responsible SDT subteam for consideration and response.		
ISO New England, Inc.	Negative	Please see detailed commeents submitted. Of specific concern, we are voting negative due to: 1. The standard allows for generators with a capacity factor under 5% rated over 100 MVA to be excluded from verification. There are many older generators that meet this criterion that would be critical during stressed system conditions with high loads. Generators under 100 MVA could also be critical in some areas. The applicable criterion should be as in the Compliance Registry. 2. The standard allows for generators to change equipment and then notify the Transmission Planner of the change. This is unacceptable as it represents a significant reliability concern. 3. The standard still is ambiguous and should contain further definitions and clarification 4. The standard should include verification of Power System Stabilizers if installed and limiters.
Response: The SDT Thanks you for your comment. (1) The 5% capacity factor exemption was selected to achieve a balance between the cost and benefits. The SDT believes that there are a limited number of units greater than 100 MVA with a capacity factor of less than 5%. While these units may be excluded from model verification, other standards still require that the data be supplied. **(2) Regarding your comment concerning equipment changes triggering model verification, this standard does not address providing notification of equipment changes or collection of preliminary model data from the equipment manufacturer. The standard addresses verification of models following equipment changes. New equipment models cannot be verified until after the equipment is available.** **(3) The standard is being revised to resolve ambiguities and improve clarity. The SDT will consider incorporating suggested comments. The standard will be posted for comments once the revision process is complete.** **(4) Regarding your comment concerning power system stabilizer verification, the SDT believes the information required by R2.1.6 will adequately define the PSS behavior for study. If instead your comment pertains to the appropriateness of PSS settings or tuning values used, the SDT believes such concerns are beyond the scope of this standard.**		
SERC Reliability Corporation	Negative	Please see coments of the SERC Dymanics Review Subcommittee.
Response: The SDT thanks you for your comment. Please see the SDT response to the SERC Dynamic Review Subcommittee comment.		
Northeast Utilities	Negative	Opposed with comments: 1) The standard allows for generators with a capacity factor under 5% rated over 100 MVA to be excluded from verification. There are many older generators that meet this criterion that

Organization	Yes or No	Question 4 Comment
		would be critical during stressed system conditions with high loads. Generators under 100 MVA could also be critical in some areas. The applicable criterion should be as in the Compliance Registry. 2) The standard allows for generators to change equipment and then notify the Transmission Planner of the change. This is unacceptable as it represents a significant reliability concern. 3) The standard still is ambiguous and should contain further definitions and clarification 4) The standard should include verification of Power System Stabilizers if installed and limiters.
Response: The SDT Thanks you for your comment. (1) The 5% capacity factor exemption was selected to achieve a balance between the cost and benefits. The SDT believes that there are a limited number of units greater than 100 MVA with a capacity factor of less than 5%. While these units may be excluded from model verification, other standards still require that the data be supplied. **(2) Regarding your comment concerning equipment changes triggering model verification, this standard does not address providing notification of equipment changes or collection of preliminary model data from the equipment manufacturer. The standard addresses verification of models following equipment changes. New equipment models cannot be verified until after the equipment is available.** **(3) The standard is being revised to resolve ambiguities and improve clarity. The SDT will consider incorporating suggested comments. The standard will be posted for comments once the revision process is complete.** **(4) Regarding your comment concerning power system stabilizer verification, the SDT believes the information required by R2.1.6 will adequately define the PSS behavior for study. If instead your comment pertains to the appropriateness of PSS settings or tuning values used, the SDT believes such concerns are beyond the scope of this standard.**		
Oncor Electric Delivery	Negative	Oncor Electric Delivery Company LLC believes that the reporting requirements for the generator owner as specified in R1, R2,R3,R4,R5 & R6 should be to the Planning Authority and not the Transmission Planner in the ERCOT Region. This would blend easily with the current ERCOT Protocols, ERCOT Operating Guides and ERCOT Planning Guide that require ERCOT to be the primary interface with Generation Resources. One option would be a regional variance that would point to the Planning Authority or Planning Coordinator in lieu of the Transmission Planner.
Response: The SDT thanks you for your comment. Regarding the responsibilities assigned to the Transmission Planner in the draft standard, the SDT believes standard language lines up well with the vast majority of entity business practices in effect regarding the interactions between generation and transmission entities when collaborating on generator dynamic models. Since ERCOT is an exception, a regional variance can be considered. Alternatively, the Transmission Planner could delegate the responsibility to another such as its Planning Authority.		
Nebraska Public Power District	Negative	NPPD supports the comments submitted by the Midwest Reliability Organization (MRO) NERC Standards Review Forum (NSRF).
Response: The SDT thanks you for your comment. Please see the SDT response to the MRO-NSFR.		

Organization	Yes or No	Question 4 Comment
Dominion Resources, Inc.	Negative	Dominion submits a negative ballot for the following reasons: Section 4.2.4 needs to be removed to be consistent with other standards. Section 2.1.1 “match” should be changed to approximate. The model will never exactly match. Section 2.1.6 remove “structure”. R3 bullet 3 “match” should be changed to approximate. The model will never exactly match. Attachment 1 title is missing “M”. Attachment 1 column “Condition” replace eleven and ten with “eleventh” and “tenth”. Section 4: Applicability should spell out testing exceptions
Response: The SDT thanks you for your comment. Section 4.2.4, as drafted, is necessary to identify applicable facilities covered by this standard. Note that the SDT added this Applicability to the draft standard after considering industry comments to the first posting noting concerns that the Applicability section is a subset of the Compliance Registry criteria. **Regarding comments pertaining to R2.1.1 and R3, the SDT believes use of the term “match” is appropriate because the Webster’s dictionary defines match as something that is equal or similar to another.** **Regarding use of the term “structure” in Section 2.1.6, this language indicates that the “block diagram” is a necessary part of the information provided by the Generator Owner to the Transmission Planner. Note that the same term is also used in Section 2.1.4 as part of the description for the excitation control system and plant volt/var system.** **The typo in the Attachment 1 title has been corrected.** **Attachment 1 has been substantially revised for clarity and thus the issue with “eleven and ten” is no longer an issue in the current draft.The SDT believes that the Attachment 1 (Periodicity Table) is an appropriate document for specifying testing periodicity and exemption criteria.**		
Cowlitz County PUD	Negative	Cowlitz has concerns this Standard may prove too burdensome. For older generator units, it may prove nearly impossible to ever achieve models that will accurately predict actual generator response. However, the greatest stumbling point and reason for the negative vote is the low 75 MVA name plate applicability that appears to be arbitrary. Please present technical reasons why the Western Interconnection should be treated differently than other interconnections.
Response: The SDT thanks you for your comment. The SDT believes the standard is drafted to provide the proper cost/benefit balance for performing generator verification. **The SDT believes it is not necessary to have models verified for all units listed in the compliance registry.** **The SDT believes proposed applicability thresholds will substantially improve accuracy of the excitation models and associated Reliability based limits determined by dynamic simulation in a cost-effective and time-efficient manner when performing verification.** **The SDT recognizes that the excitation system model and modeling data is already captured by MOD-012 and MOD-013 required processes. This information, with few exceptions, creates a quality dynamics database.**		

Organization	Yes or No	Question 4 Comment
Field Testing initiated by the Phase III-IV SDT has shown that performing the activities specified in the draft standard will improve accuracy of the exciter model used in dynamic simulation. **Utilizing engineering judgment, based in part on recent experience of entities verifying excitation system models, the SDT is proposing to require verification of excitation systems associated with 80% or greater of the connected MVA in each Interconnection. To accomplish this goal, the SDT has proposed MVA thresholds believed to correspond with at least 80% of the connected MVA in each Interconnection. As a result, the WECC MVA threshold to achieve 80% or more of the connected MVA in WECC for individual units and plants is 75 MVA. This concept was overwhelmingly supported by industry in response to the previous posting of the standard.** **The SDT also proposes requiring verification of an aggregate plant comprised of several smaller sized units because of the increasing impact renewable generation has on the BES.** **If there is evidence that the model does not match the performance of the equipment, then R3 provides a mechanism for requiring verification.**		
Constellation Power Source Generation, Inc., Constellation Energy Commodities Group	Negative	Constellation Power Generation is voting negative on MOD-026-1 due to the vague language in Requirement 2.1.1. Constellation Power Generation would like the SDT to revisit this requirement with the knowledge that generation facilities do not have the necessary equipment to capture “the recorded response” of the excitation system and plant voltage/var controls to the level of granularity needed to demonstrate that it followed the “plant’s model response.” Further, generation facilities do not have the proper software to analyze the modeled response, and as such, cannot weigh that response against the recorded response should a facility have the necessary equipment to capture a response to a disturbance.
Response: The SDT thanks you for your comment. The SDT believes proposed applicability thresholds will substantially improve accuracy of the excitation models and associated Reliability based limits determined by dynamic simulation in a cost-effective and time-efficient manner when performing verification. While it is true that many generators do not have necessary expertise, this expertise can be developed or hired. Proper software can be purchased to analyze the modeled response – utility grade dynamic simulation software used by Transmission Planners for regional and inter-regional studies does not have to be purchased. Typically, the expert will install temporary recording equipment for testing.		
MidAmerican Energy Co.	Negative	Comment: Given the number and depth of comments at the NERC webinar, the NERC standard is not clear or enforceable. This will generate the need for interpretations and Compliance Application Notices which cause further confusion and enforcement issues. Technical issues are also present. There are concerns about the technical development and accuracy of current wind farm models. It is not certain that all manufacturers have fully developed all of the control system models necessary to meet these standards. Type III and Type IV PSS/E generic standard models have all been benchmarked. What has not been included in the these model are the wind farm park voltage controllers. While local turbine model controllers will dominate the short term response, the longer term park voltage controls are not represented. Therefore if the models aren’t available, then model traces can’t accurately match reality. Older wind farms or foreign manufacturers may not have appropriate models. In short, the state of wind

Organization	Yes or No	Question 4 Comment
		farm models hasn't completely developed to match wind farms and specific exemptions for wind farms need to be added to the standard at a minimum.

Response: The SDT thanks you for your comment. The SDT believes that required models have already been developed to an adequate level of detail, and are available in the planning tools. Generic models for VER have been developed in a collaborative industry effort (lead by the WECC Dynamic Modeling Working Groups) and should be validated in the absence of available OEM models. These generic models do include a provision for plant-level voltage control (performed by a plant volt/var management system). If plant voltage control is achieved by a device other than a volt/var management system (such as a STATCOM, SVC, etc), verification should also include models of these devices. Finally, An additional condition, row 12, was added to Attachment 1 (the Periodicity Table) specifying that validation is not required for an excitation control system or plant volt/var control that does not include an active closed loop voltage regulation function. This condition exempts wind and solar plants that do not have the capability to regulate plant voltage or respond to grid voltage fluctuations other than switching capacitor and reactor banks in and out of service.

Organization	Yes or No	Question 4 Comment
Ameren Energy Marketing Co., Amerenue	Negative	Comment (1)The wording for Requirement 2.1.4 should be changed to read "Model structure and data for the excitation system, for the plant volt/var system, and for the closed loop voltage regulator". Otherwise, as written, it appears that the required model structure and data only applies to the voltage regulator portion of the equipment.(2)In Requirement R5, the term "technically justified request" needs to be clarified. (3)In Requirement R2.1.3, it should be clarified that "rotational inertia" should include all rotational mass connected to the generator shaft, rather than only the rotational inertia of the generator itself. (4)Units rated 20 MVA will not have a significant impact on system reliability. Only units and aggregate plants capable of > 100 MVA should be included.(5)Sister unit exemptions should be allowed where there is a solid technical support for units built and operated as virtually indistinguishable generators.(6)The SDT should review the requirements in this draft to ensure they do not overlap the requirements in MOD-012 and MOD-013. From our read it appears generator owners will be at serious risk for double jeopardy.(7)The draft uses the term "Point of Interconnection" in several locations, especially R2.1.1. This is not a NERC Glossary term, although the Team used footnote 3 as an internal definition.(8)Footnote 6 should be a set of sub-requirements for R4.(9)Section 6 should be part of the Implementation Plan since it deals with the initial phase-in of the Standard.(10)Footnote 2 should probably be in the Applicability Section, but should not stay as a footnote - it's too important in determining which generators must comply.

Response: The SDT thanks you for your comments.

(1) The SDT has revised R2.1.4 and has included the essence of your suggestion.

(2) The SDT has revised Requirement R5 using a footnote to define the phrase, "technically justified" as the simulated unit or plant response does not match measured unit or plant response.

Organization	Yes or No	Question 4 Comment
(3) The SDT believes that the term rotational inertia is well understood in industry. The term "rotational" infers a mass that is attached to the unit shaft. **(4) The SDT is only proposing verification of units rated 20 MVA at plants which exceed the interconnection established MVA threshold (which is 100 MVA for the Eastern Interconnection). Even with the MVA threshold satisfied, units satisfying sister/proxy unit criteria will not have to be verified, further reducing the number of units actually tested.** **(5) The SDT believes sister/proxy unit criteria established is adequate.** **(6) MOD-012 and MOD-013 requires submission of the latest equipment dynamic model data. MOD-026 requires verification of the equipment dynamic model data.** **(7) Your observation regarding the phrase "point of interconnection" is correct. Please note that this phrase is not capitalized in the standard.** **(8) The SDT believes providing the list associated with Footnote 6 in the Requirement section would make the standard cumbersome to read.** **(9) The SDT believes that Section 6, since it addresses early compliance considerations, is important to require its own "section" in the standard.** **(10) The SDT believes providing the list associated with Footnote 2 in the main body of the standard would make the standard cumbersome to read.**		
Pacific Gas and Electric Company	Negative	As drafted, Requirement R1 of the proposed PRC-024-1 reliability standard conflicts with the WECC Off-Nominal Frequency Load Shedding Plan (WECC Coordinated Plan), and could potentially result in negative reliability impacts if enforced in the Western Interconnection. A WECC Regional Variance that includes the WECC Generator underfrequency and overfrequency operation requirements as identified in the WECC Off-Nominal Load Shedding Plan must be added to the proposed standard. WECC has developed, implemented, and verified the effectiveness of the WECC Coordinated Plan and any deviations from the requirements of the plan may negatively impact its effectiveness. The language of Requirement R2, part 2.1.1 is confusing and needs to be clarified. We suggest that Requirement R4 be rewritten to add specificity as to what must be included in the required written response, similar to the specificity and clarity included in MOD-026, Requirement R3.
Response: This comment addresses the draft PRC-024 standard and has been forwarded to the responsible SDT subteam for consideration and response.		
CPS Energy	Negative	Applicability should be for the "Generator Owner " and not the "Generator Operators".
Response: The SDT thanks you for your comment. The SDT agrees.		
Integrys Energy Group, Inc.	Negative	o While the Standard uses the word "verified" and "verification" loosely, it is not precisely clear what a GO would have to do to satisfy the verification requirements in R2. Would each of the Time Constants, Forward and/or Feedback Gains, Dead-band Excitation Limits, Saturation Characteristics, etc. to be

Organization	Yes or No	Question 4 Comment
		determined separately each on its own? Or are these parameters taken as a whole so long as their combined effect produces a response characteristic in a simulation that matches the recorded test response during an off-line step-input test? o If a simulation study results in response characteristics that does not match an off-line step input test response, can the GO arbitrarily adjust one or more of the model parametric values to produce a matching response, and send the Transmission Planner these adjusted values as the model data? We have concern about whether this Standard is cost efficient to the industry. The transient stability dynamic modeling for excitation control was developed under the assumption of limited bandwidth validity and approximations. The other equipment models in the simulation, e.g. generators, prime-mover controls, SVCs, HVDC Converters, etc. are all approximations without any correlated degree of accuracies in comparison to each other. On the other hand, the verification efforts are expected to cost quite a bit to GOs, especially for older units whose vendors/manufacturers may not even be in existence any more.
Response: The SDT thanks you for your comment. In response to your first question the SDT has drafted the standard with minimal technical specificity so that the actual mechanics of verifying the model could be left up to the experts. The SDT drafted a standard that concentrates on stating "what is required" but without stating "how to accomplish what is required". The standard also includes a peer review process. Based on industry comments, the present draft of the standard maintains this same philosophy. **Regarding your second comment, arbitrary large adjustment of model parameters without a valid technical reason is not appropriate. Minor adjustments to model parameters that are within expected tolerances may be appropriate.** **Regarding your third comment, the SDT has proposed unique MVA thresholds for each Interconnection that correspond to 80% of the Interconnected MVA, which represents a subset of the units identified in the NERC Registry Criteria. This philosophy was adopted because of the standard Field Test results obtained. While Field Test results confirmed that verification of excitation system models resulted in higher quality dynamic data, it was also confirmed that excitation system model verification is expensive and requires a significant amount of manpower to accomplish. The SDT believes that the applicability MVA thresholds established will improvement excitation model accuracy, including Reliability, in both a cost effective and manpower effective manner.**		
Platte River Power Authority	Negative	o The development may include other improvements to the standards deemed appropriate by the drafting team, with the consensus of stakeholders, consistent with establishing high quality, enforceable and technically sufficient bulk power system reliability standards. Requirement R1 mandates the generator off-nominal frequency to requires that the GO to set the protective relays such that they will not trip the generator within the no-trip zones defined by the curves in PRC-024 Attachment 1 without regard for the interconnecting entities' regional off-nominal plan. This may include coordination of load shedding blocks & load restoration blocks and other off-nominal efforts including generation tripping plans that should be left to the interconnecting entity's discretion. Similar to the exception criteria for the voltage excursion of R2.1.2 " If a Transmission Planner's study (based on the location specific voltage recovery characteristics) recommends less stringent voltage relay settings than those in PRC-024 Attachment 2, set the voltage

Organization	Yes or No	Question 4 Comment
		relays either to the Transmission Planner's settings or the settings in PRC-024 Attachment 2" a similar exception should be made where the generator facility interconnects to an entity that has established and incorporated an off-nominal frequency plan. o With respect to the R2.1 requirement, it appears the intent is to not trip the generator and remain interconnected through the voltage excursion. However language for zone 1 faults sets to remove the generator before 9-cycles. o Regarding generator's non-protection system equipment limitations exemption expiration for upgrades of =10%, would the re-exemption status be allowed or does the upgrade require removal of the limitation? o The response content for R4 is ambiguous regarding what the written response should contain. o Other than the R1.1 frequency range of 59.5 Hz and 60.5 Hz, are the other points of the curve of Attachment 1 allowable points for tripping?
Response: This comment addresses the draft PRC-024 standard and has been forwarded to the responsible SDT subteam for consideration and response.		
Occidental Chemical	Negative	4. Do you have any other questions or concerns with the proposed standards that have not been addressed? If yes, please explain. YES Comments: MOD-026-1 already takes Ingleside Cogeneration LP out of its comfort zone by requiring the ownership and validation of interconnected system performance simulations. This is normally a Transmission Planner or Transmission Operator function, not a Generator Owner. Although we understand the benefit of modeling validations, it is appropriate to begin with only the most critical facilities. If anything, we believe the applicability criteria should be consistent with those generation facilities which have DME installed as required by their Regional Entity. This is a reasonable, in-place means to identify those generators which are important to BES voltage response - and have already the recording equipment needed to validate performance.
Response: The SDT thanks you for your comment. The SDT believes that the Generator Owner is in the best position to determine realistic and reasonable model representation of installed equipment. For this reason, the standard gives the Generator Owner authority to determine if the model adequately represents performance of installed equipment. It is not desirable to link this standard with the DME standard under development. Also, the DME standard applies to fault recorders and PMU equipment. Low resolution data is adequate for verification. The SDT agrees that if DME is already in place, especially if it is monitoring the appropriate quantities required for excitation control system verification, then it should be simpler to capture the required data for verification. The applicability section requires verification of units larger than the MVA threshold gross nameplate rating specified for each interconnection and this threshold is intended to emphasize the importance of modeling critical units.		
Manitoba Hydro (Greg Parent, S N Fernando, Daniel Prowse)	Negative	2)Attachment 1 is not clear. Specifically, -the "Condition" in the first row is not a condition and is not consistent with the remaining rows. -Row 1 suggests that there are no exceptions for submitting a recorded response of a voltage excursion, but Row 2 contradicts this by allowing a single unit to be 'verified' and serve as evidence for multiple units meeting the conditions listed. -the wording for the

Organization	Yes or No	Question 4 Comment
		allowance of a representative unit to be verified and submitted as evidence for identical units is not clear. -the periodicity for row 1 suggests that a recorded response for a voltage excursion shall be collected ‘with the verified model’ which is incorrect. -We suggest the following. A statement that precedes the Attachment 1 table should be added that reads ‘For all Existing Generating Units - a recorded response for a voltage excursion shall be collected during a ten calendar year (January - December) period from the effective date of this standard and the documentation transmitted to the Transmission Planner no more than 365 calendar days from the date that the recorded response was collected unless otherwise specified by the table below. For all newly installed Generating Units - a recorded response for a voltage excursion shall be collected and the verified model and documentation transmitted to the Transmission Planner no more than 180 calendar days of the unit in service date unless specified otherwise specified by the table below. ‘ Row 1 should then read ‘Facility - Existing Generating Unit, Condition - All existing generating units unless the following exception applies: If multiple units have the same MVA rating that is = 350 MVA, and they have identical applicable components and settings, and they are sited at the same physical location, verification of one representative unit is sufficient for all such units. Verification of a different representative unit should be completed each cycle, Periodicity - not required for any units except one representative unit.’ 3)For Section 4.2 “Facilities”, the section should refer to ‘BES Generating Units and Facilities’ instead of restating components of the proposed BES definition.
Response: The SDT thanks you for your comment. The SDT has substantially revised Attachment 1. Regarding the last question, The SDT intentionally established the standard applicability as a subset of generators included in the NERC Registry Criteria. The term “BES Generating Units and Facilities” is not specific enough for compliance. There are regional differences that prevent use of this term in defining standard applicability.		
Santee Cooper (Terry Blackwell, James Poston, Lewis Pierce)	Negative	1) On “MOD-026 Attachment 1” under the “Periodicity” column, the method for model verification seems to be the analysis of a “recorded response for a voltage excursion”. It should be made clear that this excursion can be accomplished by either a staged test or a measured system disturbance. In some instances, it would be preferable to schedule staged tests with temporarily installed measurement and recording devices over permanently installing equipment to capture a response to a system disturbance. In each case, the goal of ensuring an accurate model will be accomplished. 2) At our generating facilities, it is very rare that voltage regulator or exciter parameters are changed. This generally occurs at periods much greater than ten years. Certainly, the model parameters must be confirmed after adjustment to any settings that would have an effect on the Volt/Var performance of the units. The accuracy of the model data would not be diminished by removing the ten year periodicity.
Response: The SDT thanks you for your comment. (1) The SDT has substantially revised Attachment 1.		

Organization	Yes or No	Question 4 Comment
(2) The SDT believes that a 10 year periodicity is appropriate to ensure there are not unforeseen modeling issues of actual equipment response to a voltage excursion that would necessitate revising the model for improving the accuracy of predicted equipment response. Also, the 10 year periodicity concept was overwhelmingly approved by industry (reference industry response to Question 2 comments for the first posting).		
Tenaska, Inc.	Negative	1) It is unclear whether such testing will lead to better models and improved reliability given all of the other assumptions made in stability studies 2) It is unclear whether a staged test or actual system disturbance or BOTH are required for “verification”.
Response: The SDT thanks you for your comment. The SDT believes proposed applicability thresholds will substantially improve accuracy of the excitation models and associated Reliability based limits determined by dynamic simulation in a cost-effective and time-efficient manner when performing verification. **The Field Test confirmed model verification will result in accurate models.** **Either a staged test or actual system disturbance data can be used. Both are not required.**		
Ameren Services	Negative	(1)The wording for Requirement 2.1.4 should be changed to read “Model structure and data for the excitation system, for the plant volt/var system, and for the closed loop voltage regulator”. Otherwise, as written, it appears that the required model structure and data only applies to the voltage regulator portion of the equipment.(2)In Requirement R5, the term “technically justified request” needs to be clarified. (3)In Requirement R2.1.3, it should be clarified that “rotational inertia” should include all rotational mass connected to the generator shaft, rather than only the rotational inertia of the generator itself. (4)Units rated 20 MVA will not have a significant impact on system reliability. Only units and aggregate plants capable of > 100 MVA should be included.(5)Sister unit exemptions should be allowed where there is a solid technical support for units built and operated as virtually indistinguishable generators.(6)The SDT should review the requirements in this draft to ensure they do not overlap the requirements in MOD-012 and MOD-013. From our read it appears generator owners will be at serious risk for double jeopardy.(7)The draft uses the term “Point of Interconnection” in several locations, especially R2.1.1. This is not a NERC Glossary term, although the Team used footnote 3 as an internal definition.(8)Footnote 6 should be a set of sub-requirements for R4.(9)Section 6 should be part of the Implementation Plan since it deals with the initial phase-in of the Standard.(10)Footnote 2 should probably be in the Applicability Section, but should not stay as a footnote - it’s too important in determining which generators must comply.
Response: The SDT thanks you for your comments. **(1) The SDT has revised R2.1.4 and has included the essence of your suggestion.** **(2) The SDT has revised Requirement R5 using a footnote to define the phrase, “technically justified” as the simulated unit or plant response does not**		

Organization	Yes or No	Question 4 Comment
match measured unit or plant response. **(3) The SDT believes that the term rotational inertia is well understood in industry. The term "rotational" infers a mass that is attached to the unit shaft.** **(4) The SDT is only proposing verification of units rated 20 MVA at plants which exceed the interconnection established MVA threshold (which is 100 MVA for the Eastern Interconnection). Even with the MVA threshold satisfied, units satisfying sister/proxy unit criteria will not have to be verified, further reducing the number of units actually tested.** **(5) The SDT believes sister/proxy unit criteria established is adequate.** **(6) MOD-012 and MOD-013 requires submission of the latest equipment dynamic model data. MOD-026 requires verification of the equipment dynamic model data.** **(7) Your observation regarding the phrase "point of interconnection" is correct. Please note that this phrase is not capitalized in the standard.** **(8) The SDT believes providing the list associated with Footnote 6 in the Requirement section would make the standard cumbersome to read.** **(9) The SDT believes that Section 6, since it addresses early compliance considerations, is important to require its own "section" in the standard.** **(10) The SDT believes providing the list associated with Footnote 2 in the main body of the standard would make the standard cumbersome to read.**		
PacifiCorp	Negative	(1) Industry practice for generation protective relays is to use the terminal voltage of the generators, not the system voltage or point of interconnection. Generator Owners could provide generation responses and data as contemplated by the standard, but they should not be held responsible for the answers provided without the benefit of associated transmission planning groups. Generator Owners, under this framework, will rely completely on feedback from their associated transmission planning groups in order to provide responses. It concerns PacifiCorp that the draft standard does not address the need for transmission planners to provide the required transmission system response data to Generation Owners in order to make these assessments, or allow for the joint responsibility of transmission planner for the accuracy of the data as it concerns planning studies. (2) PacifiCorp maintains several additional concerns about complying with the standard as drafted: o R1.1.5 - PacifiCorp is not aware of relays used for generator protection that use frequency rate of change to calculate trip points. Generator protection relays use frequency set points and time at certain values, not rate of change of frequency to make tripping decisions. It may not be technically feasible to immediately comply with this sub-requirement of the standard as written. o R2.1.1 - PacifiCorp requests clarification concerning what the SDT has considered a zone 1 fault. PacifiCorp acknowledges that transmission and distribution line relays have zone 1 and zone 2, but the Company does not believe that this is something typically used in the generator protection context. A zone 1 fault needs to be defined somewhere to the extent that it is not clarified in the standard already. o R3 - This requirement was clear in the initial February 2009 draft of PRC-024-1, but the current draft does not clarify that the Generator Owner must upgrade the equipment that is causing a limitation. For example, if an entity upgrades its (synchronous) turbines to increase capacity by greater than 10%, but the voltage

Organization	Yes or No	Question 4 Comment
		limitations still exist because they are related to the generator, which is not upgraded, the exemption would expire under the current language. The SDT should revisit this issue using the initial draft of PRC-024-1 as a guide. o R6 - The failure to include exemptions for new generating plants may have unintended consequences. Some voltage excursions have caused excessive torque on PacifiCorp-owned generators which has caused the controls to trip the units, rather than the relays themselves. If an entity constructs a new plant and cannot document any exemptions due to equipment limitations, such entity may experience future compliance and operational issues. The SDT should revisit this in light of further consideration of potential unintended consequences. . (3) PacifiCorp has concerns that certain references to Attachment 2 in Requirement R2 need to be clarified. Attachment 2 references the generator point of interconnection not the terminal voltage; therefore, clarifications to the proposed language are necessary. As such, the following recommended revisions to Requirement R2 are offered: 2.1 When operating under normal system operating conditions within 95% and 105% of rated generator terminal voltage the following clarifications for PRC-024 Attachment 2 are provided: 2.1.1 For three-phase transmission system zone 1 faults with Normal Clearing, transmission system faults should be cleared based on actual fault clearing times, not to exceed 9 cycles. Voltage relays should be set to not trip prior to transmission system fault clearing time. 2.1.2 If a Transmission Planner's study (based on the location specific voltage recovery characteristics) recommends less stringent system protection settings than those on PRC-024 Attachment 2, set voltage relays either to the less stringent Transmission Planner's settings or the setting applicable to PRC-024 Attachment 2. 2.1.3 Tripping a generator via a Special Protection System (SPS) or Remedial Action Scheme (RAS) is acceptable in the "no trip zone" in PRC-024 Attachment 2. 2.1.4 If clearing a system fault necessitates disconnecting a generator, this action is acceptable within the "no trip zone" specified in PRC-024 Attachment 2. (4) As drafted, Requirement R1 of proposed PRC-024-1 conflicts with WECC's Off-Nominal Frequency Load Shedding Plan ("WECC Coordinated Plan"), and could potentially result in negative reliability impacts if enforced in the Western Interconnection. A WECC Regional Variance that includes the WECC Generator underfrequency and overfrequency operation requirements, as identified in the WECC Off-Nominal Load Shedding Plan, must be added to the proposed standard. WECC has developed, implemented, and verified the effectiveness of the WECC Coordinated Plan and any deviations from the requirements of the plan may negatively impact its effectiveness. (5) PacifiCorp believes that the SDT should rewrite Requirement R4 to add specificity as to what must be included in a written response to a submission concerning an equipment limitation, similar to the specificity and clarity included in MOD-026, Requirement R3. (6) PacifiCorp offers one comment on the Violation Severity Limits ("VSLs") proposed for Requirements R1 and R2 of PRC-024-1, which require that frequency protective relaying (R1) and voltage protective relaying (R2) be set so that they do not trip within the criteria listed in the respective requirements "unless the Generator Owner has documented and communicated a non-protection system limitation in accordance with Requirement R3." However, the language of the binary Severe VSL for Requirements R1 and R2 only identifies the failure to set protective relaying, without recognizing the exception granted for documenting and communicating a non-protective system limitation.

Organization	Yes or No	Question 4 Comment
		As written, the applicable entity could be compliant with the language of Requirements R1 and R2, but based on the language of the VSLs, they would be non-compliant. The SDT should add this critical clarification to the VSLs. (7) PacifiCorp has a concern that the PRC-024 voltage ride-through requirements identified in Attachment 2 are wholly independent of dynamic reactive power requirements for generators. As an analogy, some European generator interconnection standards and requirements link these two variable. PacifiCorp understands that PRC-024-1 is a generator protection standard; however, the SDT should address the manner in which generator dynamic reactive requirements impact PRC-024-1 Attachment 2. (8) Many European generator interconnection standards and requirements include different voltage ride-through requirements for synchronous and non-synchronous generation. PacifiCorp is concerned that the SDT has inappropriately developed a "one-size fits all" standard applicable to all generation platforms. PacifiCorp recommends that, based on the significant differences between existing and emerging generation platforms, separate voltage ride-through standards be developed for synchronous and non-synchronous (i.e., wind and solar) generation platforms. Different sets of standards will more effectively address such differences in the various generation technologies.
Response: This comment addresses the draft PRC-024 standard and has been forwarded to the responsible SDT subteam for consideration and response.

North Carolina Electric Membership Corp., Brazos Electric Power Cooperative, Southwest Transmission Cooperative	Affirmative	While we are voting affirmative for the VSLs and VRFs, conforming changes will be necessary if requirements are modified per our ballot comments.
Response: The SDT thanks you for your comments.		
Old Dominion Electric Coop.	Affirmative	Confirming changes need to be made to the VSL based on changes made in the standard itself.
Response: The SDT thanks you for your comments.		
ACES Power Members	Yes	This standard is highly administrative and full of compliance risks not associated with reliability. The purpose of the standard is to ensure that the GO provides an accurate model to the TP and ultimately to the PC. The requirements unnecessarily document the give and take that must occur between the GO and TP to produce a good model. R2, which essentially requires the GO to provide a good model, is the only requirement needed. Everything else is just documentation related and unnecessary.
Response: The SDT thanks you for your comments. The SDT agrees that R2 is the main requirement for improving reliability. The purpose of requirements R1, R3, R4, and R5 is to provide a peer review process to assure that the information provided per R2 is useful to the user of the information. There are always exceptions however others in the industry believe it is necessary to include these administrative requirements.		
BC Hydro and Power Authority	Yes	1. This standard is still not clear in terms of what constitutes verification of the model and what are related obligations of parties involved. Specifically, it is not logical or technically feasible to request GOs to

Organization	Yes or No	Question 4 Comment
		address any problems with "usability" that TPs may have with the excitation control system model applied in their simulation software. Related Requirements are R3 and R6. The GOs provide accurate model data of their systems during the generator interconnection and facility registration process. Detailed base-line testing is done at that time. For subsequent verifications, GOs would use certain software tools, most likely not the same that the TPs are using, to simulate excitation control system response. This simulated response would be compared with actual equipment response. If traces (signatures) match closely enough, the model is verified. The GO would submit required information to the TP as per R2. At this point, the GOs obligations should be over and subsequently, the GOs should not have a compliance obligation to take part in resolving any issues that the TP may have with the "usability" of their models. Any further involvement by the GOs should be in the spirit of good will and professional courtesy among the parties. In conclusion, GOs should not have compliance obligations to resolve issues related to "usability" of models applied in the TPs power system simulation tool. 2. The idea that GOs "own" the models and are responsible for model modifications and verification still remains controversial for a number of reasons:a. GOs have little need for models and many do not have any expertise in modelling.b. Software tools used by GOs or external consultants for commissioning and verification purposes would not be the same as the tools used by TPsc. TPs would have to work on tuning so the whole exercise would not have a particular value in a technical sense. This is supported by the NERC Event Analysis & Information Exchange staff who noted during the first comment period:"Although verification (not validation) of generator equipment settings and testing should be the responsibility of the GO, validation of generator models response to actual system events should be done by the Reliability Coordinator."Also, NERC's white paper "Power System Model Validation", Dec 2010, expands on this view. It implies that the ultimate responsibility for the usability and accuracy of dynamic models and how they perform in relation to the overall system model is the responsibility of the Transmission Planners, Reliability Coordinators or similar entities. 3. We recommend revising the wording in Requirement R2.1.1 for improved clarity. The way it is written, it strongly implies that the method of verification is based on system disturbance (ambient) monitoring: "Documentation demonstrating the unit or plant's model response matches the recorded response for a Voltage excursion at the generator or plant point of interconnection.4. Requirement 5 refers to the Planning Coordinator. Is this a typo and supposed to be the Transmission Planner? Also, we recommend revising the wording in Requirement 5 for improved clarity.5. Attachment 1 Column 6 refers to the Planning Coordinator. Is this a typo and supposed to be the Transmission Planner?

Response: The SDT thanks you for your comment. Regarding your first comment, the SDT believes that model verification has to be a collaborative effort between the Generator Owner and the Transmission Planner. As owner of the model, the standard is drafted such that the Generator Owner has the final word when collaborating with the Transmission Planner. If the Generator Owner cannot resolve the model "usability" issue, with the Transmission Planners dynamic simulation software, then the Generator Owner simply communicates this fact to the Transmission Planner.

Regarding your second comment, the industry affirmed with the first posting of the draft standard that the Generator Owner should be assigned responsibility for the model. The Generator Owner has direct access to the equipment. The Transmission Planner has the simulation software, but

Organization	Yes or No	Question 4 Comment
does not typically have access to the equipment or have testing capabilities. Therefore, the standard includes several Requirements that facilitate interaction between the Generator Owner and the Transmission Planner. **Regarding your third comment, Requirement R2.1.1 has been revised for clarity. Standard references to the Planning Coordinator are correct. The Planning Coordinator was chosen after considering industry comments to the first posting of the draft standard to require a higher level of justification for requesting a model review for a unit not listed in the Applicability section than simply contacting the generator owner.**		
SERC Generation Sub-committee (GS)	Yes	The GS is not responding to MOD-026
Response: The SDT thanks you for your comment.		
Idaho Power – Power Production	Yes	The Requirements direct the GO to send responses, data, inquiry to the Transmission Planner. Should this really be to the Transmission Operator? We understand that the TP will ultimately use the data, however, we believe the data and communications should flow through the TOP.Specifying timeframes for both recording data and providing results is cumbersome. More properly, timeframes and periodicity should be specified only on providing results. If necessary, a limit on the age of the recorded data could be specified.R6.1, R6.2 and R6.3 seems overly prescriptive and of little value. In the process of verifying model data and comparing to recorded results, those 3 conditions are met. If the Transmission Planner has concern about their ability to use the model data in their studies, it is more properly addressed either without specific criteria, or with the specific criteria that the Transmission Planner is unable to reproduce the simulated response contained in the model verification.The requirement of several responses to submit plans to test within 365 days and submit with 180 days (per the periodicity table) seems too long from an system reliability standpoint, particularly where it is the outcome of an observed response to an actual event not matching the predicted response. On the other hand, scheduling a test and model verification within a shorter period of time would be challenging for the GO, particularly those that rely on outside contractors for the model verification work.Any request to verify or retest due to an observed response not matching an actual event should be accompanied by full electronic information (recorded data, simulated output, simulation conditions, model data used by TP).Requirement R1. The first two bullets appear to allow variation between Transmission Planners on acceptable models and software. The list of acceptable models needs to standardized at least across the RRO. In addition, the GO should not need to adjust the model validation and verification work based on the software that the TP uses (what happens when the TP uses multiple software packages?). If the SDT feels there is a need to specify acceptable software, then that should also be standardized. The third bullet should read "All of the Generator Owner's existing" instead of "Any". The TP should provide all the information in its database regarding the GO's facilities, not just "any" piece of it.R2, 2.1. Reference to "models acceptable to its Transmission Planner" is inappropriate, see previous comment. The list of acceptable models needs to be standardized, although

Organization	Yes or No	Question 4 Comment
		situations (rare) where the Generator Owner and Transmission Planner jointly agree to use a model not on the list should be allowed. In particular, the Transmission Planner should not restrict use of any the models on the standardized acceptable list.

Response: The SDT thanks you for your comment. Regarding your first comment, the SDT selected the Transmission Planner to be the single point of communication for model verification issues. The reason for this is that the Transmission Planner maintains the dynamic database used to performed stability assessments that define BES security boundaries.

Regarding your 2nd comment, Attachment 1 specifies that the final model verification has to be provided either 180 or 365 days after the response of the equipment is captured. The SDT believes that this specificity is required in order to ensure a ten year (or less in some scenarios) periodicity.

Regarding your 3rd comment, the Generator Owner is responsible for verifying the recorded equipment response matches the model's predicted response. The Transmission Planner is only responsible for determining if the model is usable.

Regarding your 4th comment, the SDT expects the Transmission Planner and Generator Owner to work together to resolve any issues with the model. The SDT believes that both entities have common motivation to resolve modeling issues and will share relevant technical data.

Regarding your 5th comment, standardizing a list for the RRO is not possible since Transmission Planners within an RRO may utilize different dynamic simulation software packages.

Regarding your 6th comment, the standard is not written to require use of a specific software package.

Regarding your 7th comment, the word "any" is meant to mean that any unit data can be requested. Once a particular unit's data is requested, the Transmission Planner is required to provide the complete dataset associated with that unit's excitation control system and plant volt/var control model.

Regarding your 8th comment, the Transmission Planner has to maintain a list of acceptable models to ensure that the Generator Owner will not supply a model that is not supported by the Transmission Planners' dynamic simulation software.

Organization	Yes or No	Question 4 Comment
SPP Reliability Standards Develpment Team	Yes	The applicability of 100 MVA matches MOD027-1 but is inconsistent with MOD025-2 or PRC 019-1. We feel like these should be consistent in every standard included in this project. VSLs for R4 footnote reference needs to be deleted since there is no footnote to reference. We would like to see a more consistent approach to the comment forms and the standard itself. It seems there is room for clean up in the posted standard/comment form.

Response: The SDT thanks you for your comment. The Applicability of MOD-026 and MOD-027 is unique because these are the only standards addressing dynamic model verification. The VSL footnote appears earlier in the standard. The SDT believes it is not necessary to have models verified for all units listed in the compliance registry.

The SDT believes proposed applicability thresholds will substantially improve accuracy of the excitation models and associated Reliability based limits

Organization	Yes or No	Question 4 Comment
determined by dynamic simulation in a cost-effective and time-efficient manner when performing verification. **The SDT recognizes that the excitation system model and modeling data is already captured by MOD-012 and MOD-013 required processes. This information, with few exceptions, creates a quality dynamics database.** **Field Testing initiated by the Phase III-IV SDT has shown that performing the activities specified in the draft standard will improve accuracy of the exciter model used in dynamic simulation.** **Utilizing engineering judgment, based in part on recent experience of entities verifying excitation system models, the SDT is proposing to require verification of excitation systems associated with 80% or greater of the connected MVA in each Interconnection. To accomplish this goal, the SDT has proposed MVA thresholds believed to correspond with at least 80% of the connected MVA in each Interconnection. This concept was overwhelmingly supported by industry in response to the previous posting of the standard.** **The SDT has revised the standard in response to industry comments and hope clean up performed is adequate.**		
MRO's NERC Standards Review Forum	Yes	We have a number of questions and concerns as follows: o It is not precisely clear what a GO would have to do to satisfy the verification requirements in R2. Would each of the Time Constants, Forward and/or Feedback Gains, Dead-band Excitation Limits, Saturation Characteristics, etc. to be determined separately each on its own? Or are these parameters taken as a whole so long as their combined effect produces a response characteristic in a simulation that matches the recorded test response during an off-line step-input test? o If a simulation study results in response characteristics that does not match an off-line step input test response, can the GO arbitrarily adjust one or more of the model parametric values to produce a matching response, and send the Transmission Planner these adjusted values as the model data? o We have concern about whether this Standard is cost effective for the industry. The transient stability dynamic modeling for excitation control was traditionally developed under the assumption of limited bandwidth validity and approximations. The other equipment models in the simulation, e.g. generators, prime-mover controls, SVCs, HVDC Converters, etc. are all approximations without any correlated degree of accuracies in comparison to each other. On the other hand, the verification efforts required by this standard are expected to cost quite a bit to GOs, especially for older units whose vendors/manufacturers may not even be in existence any more. o MOD-026 does not account appropriately for the differences between distributed generation and single shaft generation. Aggregate generation that do not have a common excitation and regulator control system (such as wind farms) may pose serious difficulties in meeting system disturbance and / or staged testing. A staged test can be performed for a single shaft unit. However, wind farms may not have a centralized plant or wind farm voltage controller. If that isn't the case, entities may be forced to actually shock the BES to force a disturbance large enough to force a wind farm response. If this is true, then exceptions need to be made. o In addition, there are concerns about the technical development and accuracy of current wind farm models. It is not certain that all manufacturers have fully developed all of the control system models necessary to meet these standards. Type III and Type IV PSS/E generic standard models have all been benchmarked. What has not been

Organization	Yes or No	Question 4 Comment
		included in these models are the wind farm park voltage controllers. While local turbine model controllers will dominate the short term response, the longer term park voltage controls are not represented. Therefore if the models aren't available, then model traces can't accurately match reality. Older wind farms will not have appropriate models. In short, the state of wind farm models hasn't completely developed to match wind farms and specific exemptions for wind farms need to be added to the standard at a minimum.

Response: The SDT thanks you for your comment. In response to your first question, the SDT has drafted the standard with minimal technical specificity so that the actual mechanics of verifying the model is left to the experts. The SDT drafted a standard that states "what is required" without stating "how to accomplish what is required". This standard also includes a peer review process. Based on industry comments, the present draft of the standard maintains this same philosophy.

Regarding your second comment, arbitrary large adjustment of model parameters without a valid technical reason is not appropriate. Minor adjustments to model parameters that are within expected tolerances may be appropriate.

Regarding your third comment, the SDT has proposed unique MVA thresholds for each Interconnection that correspond to 80% of the Interconnected MVA, which represents a subset of the units identified in the NERC Registry Criteria. This philosophy was adopted because of the standard Field Test results obtained. While Field Test results confirmed that verification of excitation system models resulted in higher quality dynamic data, it was also confirmed that excitation system model verification is expensive and requires a significant amount of manpower to accomplish. The SDT believes that the applicability MVA thresholds established will improvement excitation model accuracy, including Reliability, in both a cost effective and manpower effective manner.

Regarding your fourth comment on distributed generators in a plant (such as a Wind Plant), it is reasonable to expect a small signal disturbance (such as switching a static var bank or changing the tap on a load tap changing transformer) test be performed to exercise response of the plant volt/var controls so data recording can be accomplished for validation efforts. The magnitude of the test disturbance will be determined by the nature of the plant control system type (linear closed-loop or semi-discreet with deadband) installed. The specific nature of the stimulus applied is application dependent and will need to be determined by the validation expert, taking into account availability of devices, system strength and other conditions during the test. However, none of these techniques will adversely impact BES reliability.

Regarding your final comment on availability of VER plant-level models, Generic models for VER have been developed in a collaborative industry effort (lead by the WECC Dynamic Modeling Working Group) and should be validated if an OEM model is not available. These generic models include provision for plant-level voltage control using a plant volt/var management system. If plant voltage control is achieved by a device other than a volt/var management system (such as a STATCOM, SVC, etc.), verification should also include the models for these devices.

Electric Market Policy	Yes	Dominion suggests:MOD-026 Section 4.2.4 needs to be removed to be consistent with other standards.MOD-026 Section 2.1.1 "match" should be changed to approximate. The model will never exactly match.MOD-026 Section 2.1.6 remove "structure".MOD-026 R3 bullet 3 "match" should be changed to approximate. The model will never exactly match.MOD-026 Attachment 1 title is missing "M".MOD-026 Attachment 1 column "Condition" replace eleven and ten with "eleventh" and "tenth".MOD-

Organization	Yes or No	Question 4 Comment
		026 Section 4: Applicability should spell out testing exceptions.
Response: The SDT thanks you for your comment. Section 4.2.4, as drafted, is necessary to identify applicable facilities covered by this standard. Note that the SDT added this Applicability to the draft standard after considering industry comments to the first posting noting concerns that the Applicability section is a subset of the Compliance Registry criteria. **Regarding comments pertaining to R2.1.1 and R3, the SDT believes use of the term "match" is appropriate because the Webster's dictionary defines match as something that is equal or similar to another.** **Regarding use of the term "structure" in Section 2.1.6, this language indicates that the "block diagram" is a necessary part of the information provided by the Generator Owner to the Transmission Planner. Note that the same term is also used in Section 2.1.4 as part of the description for the excitation control system and plant volt/var system.** **The typo in the Attachment 1 title has been corrected.** **Attachment 1 has been substantially revised for clarity and thus the issue with "eleven and ten" is no longer an issue in the current draft.** **The SDT believes that the Attachment 1 (Periodicity Table) is an appropriate document for specifying testing periodicity and exemption criteria.**		
Dynamics Review Subcommittee	Yes	R2: The wording for Part 2.1.4 makes it seem that the required model structure and data only applies to the voltage regulator portion of the excitation system. The DRS recommends that R 2.1.4 be reworded to:"Model structure and data for the excitation system, for the plant volt/var system, and for the closed loop voltage regulator." R5: A "technically justified request" needs to be clarified. We suggest using words similar to those used in the slides associated with this project: "A technical justification that demonstrates, through simulation and/or measured response, that the unit or plant affects a stability limit, or evidence that the simulated unit or plant response does not match measured unit or plant response."R2.1.3 : The DRS recommends a clarification to "rotational inertia." Please consider the following wording: "Generator (or plant equivalent) model structure and data (such as reactance, time constants, saturation factors, rotational inertia (including all rotating components), or equivalent data)."
Response: The SDT thanks you for your comments. **(1) The SDT has revised R2.1.4 including the essence of your suggestion.** **(2) The SDT has revised Requirement R5 using a footnote to define the phrase, "technically justified" as the simulated unit or plant response does not match measured unit or plant response.** **(3) The SDT believes that the term rotational inertia is well understood in industry. The term "rotational" infers a mass that is attached to the unit shaft.**		
LG&E and KU Energy	Yes	Each requirement can be accomplished by itself; but the 90 day vs 60 day vs 180 days on the various 12 requirements will likely create documentation confusion for communication and data retentions. LG&E

Organization	Yes or No	Question 4 Comment
		and KU Energy suggests tha the draft be simplified to enhance coordination amongst requirements by applying a single time frame for completion of the requirements.
Response: The SDT thanks you for your comment. The SDT believes it is better for industry to have 180 days to perform model verification activities in lieu of establishing a universal 90 day period to perform all activities required just to achieve timeframe consistency among the Requirements.		
FirstEnergy	Yes	FirstEnergy provides the following additional comments and suggestions:1. Unfortunately as written this standard may require Generator Owners to purchase software to properly analyze voltage excursions to verify their models. This level of expertise historically existed with the TO/TOP, not the Generator. It will be very difficult for the Generators to develop and maintain this expertise for a verification that will only be run once every 10 years. Also, if additional instrumentation is needed to capture this data, nuclear fleets may be challenged to ensure at least 30% of their applicable units will comply with R2 based on refuel outage schedules.2. Applicability Section 4.2.4 - We do not agree with the Planning Coordinator being able to include additional units. Even though the standard says that the PC would have to show technical justification, it should not be left to their discretion to add an entity's unit as applicable. A regional entity is the only ultimate authority that can make this decision and the PC should go through its Regional Entity to prove this justification. We suggest removing this section. Furthermore, it states that the technical justification would need to be verified. It is not clear who would make this judgment on the validity of the justification.3. We are not clear as to what the standard is referring to when it mentions "volt/var control". 4. In requirement 2.1.1, of R2 it states"2.1.1. Documentation demonstrating the unit or plant's model response matches the recorded response for a voltage excursion at the generator or plant point of interconnection from either a staged test or a measured system disturbance."The SDT should specify the magnitude of the voltage excursion referenced in this section.5. In the SDT notes they make reference to allowance being given for identical (Sister) units but I did not see it anywhere in the standard. Can Generator Owners take credit for Sister units when supplying the model verification? 6. As a general note, the first draft of this standard was reviewed by industry over 2 years ago. It seems like a long time between drafts to expect the industry to review and vote on a standard given that there may be several new personnel in a company that are new to compliance. I would have hoped the team came out with only a comment period at this time.7. Attachment 1 - General Comment - "M" is missing from title of attachment "OD-026 Attachment. Also. We assume that the mentioned "voltage excursion" is in reference to the proposed definition found in the proposed PRC-024-1. If so, it should be capitalized and added to the front of the standard and balloted with the standard.
Response: The SDT thanks you for your comment. The responses below are numbered to match the comments. **1. The standard has been written so that either ambient monitoring or a staged testing can be used. The Generator Owner is not required to have the same software used by the TO/TOP. Also, the Generator Owner is not required to maintain testing expertise. It is a Generator Owner decision to**		

Organization	Yes or No	Question 4 Comment
maintain testing expertise or hire a consultant (which could include personnel from its Transmission Planner). A staged test typically involves injecting a step change signal into the voltage regulator. Permanent instrumentation/equipment is not required to be installed for staged testing. A laptop PC can be used to record staged testing data. Nuclear units do not need to wait until a refueling outage to accomplish this test. **2. Several commenters expressed concern with the new Requirement added to the standard giving the Planning Coordinator authority to require model review for a unit not specified in the standard Applicability section. The SDT added this language to the draft standard after considering industry comments to the first posting noting that the Applicability section is a subset of the Compliance Registry criteria. Based on the latest round of industry feedback, the SDT now proposes Applicability Section language allowing the Planning Coordinator to request additional model information (possibly model verification) only if technical justification demonstrates the simulated unit response does not match the measured unit response. Original technical justification language for units that affect a stability limit has been removed from the standard. To emphasize for understanding, the SDT points out only units that meet or exceed the Registry Criteria unit MVA thresholds (> 20 MVA) are subject to Requirement R5. This observation should allay concern the Requirement could be misused inappropriately.** **3. Volt/Var control refers to voltage or var output control at a common coupling point for an entire plant consisting of multiple units, typically comprised of technology that, by itself, does not contain sufficient dynamic var capability (such as wind/solar plants).** **4. The SDT believes specifying a voltage excursion magnitude is prescriptive. The testing expert will determine the voltage excursion magnitude to use during testing. Typically a 1% - 2% voltage excursion will provide adequate results.** **5. Yes, sister unit consideration is included in the Periodicity Table (Attachment 1).** **6. The standard has been revised significantly in response to industry comments and has been sent to ballot to gage the level of industry support existing.** **7. The attachment title has been corrected. The phrase, "voltage excursion" is not a defined term, and does not relate to PRC-024.**		
Public Service Enterprise Group	Yes	1. The capacity factor calculation referenced in 4.2 should refer to a future attachment that the team would develop that explains (a) which reliability standard one would use to for a unit's capacity rating (such as MOD-010) for the calculation and (b) a sample calculation.2. In 4.2.4, the sentence "Any technically justified unit requested by the Planning Coordinator" should specify (a) the entities that may develop the technical justification, (b) the entity who will evaluate that technical justification and (c) the criteria for judging whether an excluded unit should be included.3. In R1, first bullet: a. Would the instructions issued by the Transmission Planner on "on how to obtain the list of acceptable excitation control system and plant volt/var control function model for use in dynamic simulation" cover "acceptable" verification via staged tests and "acceptable" verification by a measured system disturbance per R2.1.1.b. Are Transmission Planners the appropriate entity to determine "acceptability" of models or verification since there are about 120 Transmission Planners registered in the Eastern Interconnection? See the comment below regarding R2.1.14. R2.1.1 addresses verification via either staged tests or a measured system disturbance. However, the standard leaves the judgment of the acceptability of verification performed by a GO to the Transmission Planner. We suggest that the team include an attachment to the standard that provides

Organization	Yes or No	Question 4 Comment
		guidance for how to perform acceptable verification, covering both staged testing and a measured system disturbance.5. R5 is unclear. For example, does the 90-day submission period in 5.1 address submissions under 5.2 and 5.3, or does it require that the GO merely acknowledge receipt of the request within 90 days? Since 5.2 addresses plans to verify a model, why would "corrected" data in 5.3 be due within 90 days? 6. Both R3 and R5 require GO action in response to a notification by a Transmission Planner (R3) or a Planning Coordinator (R5). Can a Transmission Planner or Planning Coordinator require a response from a GO for generators that are not yet verified by the GO per the timetable in section 5? If not, it appears that R3 and R5 should be rewritten to recognize this limitation. 7. The July 29 webinar made clear that generator exciter model verification applies to synchronous generators and the plant volt/var control function applies to non-synchronous generators. It would be helpful if this clarification was made in the standard itself, perhaps in the purpose statement.

Response: The SDT thanks you for your comment. The responses below are numbered to match the comments.

1 To clarify concerns regarding calculating unit capacity factor, the SDT has incorporated into the standard the capacity factor calculation specified in Appendix F of the GADS Data Reporting Instructions (which can be obtained from the NERC website).

2. Several commenters expressed concern with the new Requirement added to the standard giving the Planning Coordinator authority to require model review for a unit not specified in the standard Applicability section. The SDT added this language to the draft standard after considering industry comments to the first posting noting that the Applicability section is a subset of the Compliance Registry criteria. Based on the latest round of industry feedback, the SDT now proposes Applicability Section language allowing the Planning Coordinator to request additional model information (possibly model verification) only if technical justification demonstrates the simulated unit response does not match the measured unit response. Original technical justification language for units that affect a stability limit has been removed from the standard. To emphasize for understanding, the SDT points out only units that meet or exceed the Registry Criteria unit MVA thresholds (> 20 MVA) are subject to Requirement R5. This observation should allay concern the Requirement could be misused inappropriately.

3. a) The list of acceptable models is simply the type of models that the Transmission Planner will accept. This has nothing to do with the methodology used for recording the plant response to a voltage excursion.

3. b) The SDT believes the Transmission Planner is the appropriate entity.

4. Either the staged test or the ambient test can be used to verify the model. The Generator Operator decides which test is used. Restating for emphasis, the list of acceptable models identified in R1 is the list of model structures that can be used to perform the model verification process and does not address "acceptable methodologies" for performing the model verification.

5. After considering industry comments, the SDT has revised R5 for clarity.

6. No, neither the Transmission Planner nor the Planning Coordinator can invoke Requirement R3 for a unit that has not been verified. Requirement R5 is meant to address units otherwise excluded from the standard Applicability standard; so the Transmission Planner or Planning Coordinator can request model verification for otherwise excluded units.

Organization	Yes or No	Question 4 Comment
7. Plant volt/var controls include plant voltage control systems and/or dynamic var devices other than conventional generators. For example, these types of control systems could apply to wind farm units. Wind farm units include both synchronous and asynchronous (often associated with Type I generic models) units. As such, plant volt/var control can be applied to plants that contain synchronous generators, non-synchronous generators, or a combination of both.		
PPL Supply	Yes	1. Each requirement can be accomplished by itself; but the 90 day vs 60 day vs 180 days on the various 12 requirements will likely create documentation confusion for communication and data retentions. Suggest that the draft be simplified to enhance coordination amongst requirements by applying a single time frame for completion of the requirements.2. Paras. R2 and R2.1.1 are not clearly worded. The present R2 text should end after the word "software;" and para. R2.1.1 should state that "Verification consists of developing one or more models that collectively include the following information:"The present R2.1.1 text, "acceptable to the Transmission Planner," is not included in this suggested revision to make it clear that the R2 Violation Severity Levels later in MOD-026-1 pertain to a GO's first submittal of a verified model, and the R3 Violation Severity Levels deal with failure to meet follow-up requirements if the Transmission Planner finds the first submittal unacceptable. This distinction is particularly important given the compliance criteria ambiguity discussed in comment #3 below. If on the other hand it was intended that models achieve verified status only after being accepted by the Transmission Planner, the term "verified model(s)" in the R2 Violation Severity Levels should be replaced with, "initial submittal of proposed-verified model(s)". 3. There is presently no definition of the voltage excursion magnitude and intensity or the recording instrumentation sampling rate required for a valid verification event, nor are there any specifics regarding how closely the model must match the recorded response. The references in MOD-026 provide guidance but not necessarily NERC pass/fail criteria, especially since Transmission Planners may differ in their preferences. Perceived shortcomings in these respects would presumably trigger the Transmission Planner expression of concern described in para. R3, but it would be better to establish the rules up-front rather than addressing the matter only after a GO has attempted to comply with MOD-026.4. The definition of a "technically justified request" in para. R5 is unclear. Does this term apply only if a model fails to meet the requirements of R6.1-R6.3, or can there be other reasons? In the latter case the wording of the R5 Violation Severity Levels should be modified to start the clock only after agreement has been reached that a request is technically justified.5. The means by which a walk-down would lead to identification of model parameters in para. 5.2 is not understood.
Response: The SDT thanks you for your comment. **Regarding your first comment, the SDT believes it is better for industry to have 180 days to perform model verification activities in lieu of establishing a universal 90 day period to perform all activities required just to achieve timeframe consistency among the Requirements.** **Regarding Comment 2, the SDT has revised verbiage in Part 2.1 to emphasis the end goal of verifying the model. The SDT also points out that**		

Organization	Yes or No	Question 4 Comment
standard language proposed is for facilitating verification of the dynamic model, and not development of the dynamic model. **Regarding Comment 3, the standard states "what is required" but not "how to accomplish what is required". The SDT considered ways to quantify a method for evaluating how well the equipment's measured response matches the model's predicted response. However, since a generally accepted technique or criteria for making this quantitative assessment does not exist, the SDT believes that the peer review process incorporated into the standard will ensure model quality. The SDT believes all entities involved with the peer review process have common purpose to develop an accurate excitation control system model. It should be noted that the standard is written so that the Generator Owner "owns' the model, and as such, even with the peer review process described, the Generator Owner has final say on the voltage excursion used, including sampling rate, for model verification as well as determining if the equipment recorded response satisfactorily matches the model's predicted response. The Generator Owner should not be concerned with "acceptance criteria" proposed by a transmission entity.** **Regarding Comment 4, the "technical justification" is not related to Requirements R6.1 – R6.3. These requirements only address if the model is useable by integrating successfully into the Transmission Planner's dynamic simulation software. Additionally, several commenters expressed concern with the new Requirement added to the standard giving the Planning Coordinator authority to require model review for a unit not specified in the standard Applicability section. The SDT added this language to the draft standard after considering industry comments to the first posting noting that the Applicability section is a subset of the Compliance Registry criteria. Based on the latest round of industry feedback, the SDT now proposes Applicability Section language allowing the Planning Coordinator to request additional model information (possibly model verification) only if technical justification demonstrates the simulated unit response does not match the measured unit response. Original technical justification language for units that affect a stability limit has been removed from the standard. To emphasize for understanding, the SDT points out only units that meet or exceed the Registry Criteria unit MVA thresholds (> 20 MVA) are subject to Requirement R5. This observation should allay concern the Requirement could be misused inappropriately.** **Regarding Comment 5, the "walk down" to correct model parameters could be as simple as identifying in the field that equipment gain or limit setting values are incorrectly represented in the model.**		
Florida Municipal Power Agency	Yes	FMPA appreciates the efforts of the SDT to "right-size" the applicability to plants that truly impact the stability response of the system. However, the words used in the draft standard allow a loop-hole to the SDT's intent. Footnote 4 to the Applicability section states: "(a) technical justification for verifying each of those units or plant(s) that demonstrates through simulation and/or measured response that the unit or plant affects a stability limit, or evidence that the simulated unit or plant response does not match measured unit or plant response". If a region wishes to include 1 MW generators in the process, all they have to do is show that the unit's actual response does not match the simulated response without a technical justification to show that the 1MW generator has any impact on the actual stability response of the system. The SDT should change the "or" in footnote 4 to "and" meaning that the technical justification needs to include both an impact to a stability limit AND a difference between actual and simulated response.In addition, for R5 and footnote 4, who judges what is and what is not a "technical justification"? For instance, NPCC in their regional UFLS standard proposed to cause 1 MW generators to register and be included in the standards. Does the region have the final say on technical justification?The staged test in R2.1.2 and Attachment 1 that is required if an actual event does not occur is onerous. FMPA believes

Organization	Yes or No	Question 4 Comment
		this “staged test” is impractical and should be eliminated. Within a ten year period, an actual event is likely to occur resulting in a recorded response. If an actual event does not occur, then, the risk of inaccuracy is small and a “staged test” with associated higher risk should not be required to only marginally improve accuracy.

Response: The SDT thanks you for your comment. Several commenters expressed concern with the new Requirement added to the standard giving the Planning Coordinator authority to require model review for a unit not specified in the standard Applicability section. The SDT added this language to the draft standard after considering industry comments to the first posting noting that the Applicability section is a subset of the Compliance Registry criteria. Based on the latest round of industry feedback, the SDT now proposes Applicability Section language allowing the Planning Coordinator to request additional model information (possibly model verification) only if technical justification demonstrates the simulated unit response does not match the measured unit response. Original technical justification language for units that affect a stability limit has been removed from the standard. To emphasize for understanding, the SDT points out only units that meet or exceed the Registry Criteria unit MVA thresholds (> 20 MVA) are subject to Requirement R5. This observation should allay concern the Requirement could be misused inappropriately. Keep in mind only units identified in the Registry Criteria and not included in the draft standard Applicability Section can be requested to have a model review.

Regarding acceptable methods for capturing equipment response to a voltage excursion, either ambient event data or staged testing is acceptable. When performing staged testing typically a 1% – 2% step change in the voltage reference signal is used (even with the unit synchronized to the BES) and this is widely accepted safe industry practice.

Organization	Yes or No	Question 4 Comment
NERC Staff Review Team	Yes	Validation of the voltage and reactive power response of generating units for significant system disturbances indicates that the dynamics database quality is not as robust as noted in the Background Information posted with this standard. As a result NERC staff offers the following three specific comments for improving the quality of the model database:1) It is not possible to accurately model system voltage and reactive power response with valid models for only 80 percent of the installed system capacity. The standard should be applicable to all units greater than 20 MVA and all plants greater than 75 MVA regardless of interconnection voltage. Per the SDT estimates this will assure accurate modeling for approximately 95 percent of installed capacity.2) We disagree with the exemption for units with <5% capacity factor for the past three years. Some large, less efficient units may only run during peak load conditions when reactive support may be most critical thereby making valid models critical to system reliability during those conditions. While they should not be exempted from the standard, we do believe it may be appropriate to assign these units lower priority in the implementation plan.3) The initial completion of validation for all applicable units and periodicity for model verification should be 5 years, not 10 years. The 10 year time is excessive.Any Functional Model entity that requires the models, including Planning Coordinators, Transmission Operators, and Reliability Coordinators, should be permitted under Requirement R3 to provide notification to the Generator Owner that the model is not usable or that the predicted response did not match the recorded response to a transmission system event. Also, Requirement R3 should permit entities to notify the Generator Owner that the model is not usable for any

Organization	Yes or No	Question 4 Comment
		reason. We recommend removing the list referencing Requirement R6, parts 6.1 through 6.3, because it is not and cannot be an all-inclusive list of problems that could make the model not usable (e.g., the model could cause the simulation software to “freeze”).In the first row of the Periodicity Table, transmission of the verified model and documentation to the Transmission Planner should occur within 180 days from the date the recorded response is collected similar to all other rows in the table. There is no apparent basis for the additional time provided in the first row of the table.The violation risk factors associated with Requirements R1 through R6 should be at least medium. Use of invalid models resulting from violation of these standards can produce erroneous results and adversely affect assumptions of the electrical state or capability of the bulk electric system, or the ability to effectively control or restore the bulk electric system, particularly under emergency, abnormal, or restorative conditions. This can result in operating beyond the true stability limits of the system.The models validated by application of this standard are used in both the long-term planning and the operations planning horizon. The time horizon for Requirements R1 through R6 should include the operations planning horizon.In Requirement R6, part 6.2, the reference to negligible transients is not measurable. We recommend modifying this to “. . . results in a response that varies less than the numerical stability of the program used for the simulation.”In Requirement R6, part 6.3, the introductory phrase “For an otherwise stable simulation” is not necessary and a potential source of confusion. We recommend deleting this phrase and starting the sentence with “A disturbance simulation results in . . .”The SDT should consider use of the word validation instead of verification and assure that the terms used in this standard are consistent with other standards.

Response: The SDT thanks you for your comment. Regarding your opening statement and Comment 1, although the standard does not require verification of modeled excitation control system and plant volt/var response for all units/plants smaller than the MVA nameplate rating thresholds listed in the Applicability section, it is expected that provided models are accurate. If there are reasons to believe that a unit which does not meet the Applicability criteria does not have an adequate model, there is a process proposed that requires the Generator Owner to review the model, and possibly model verification if the review does not identify why the model is not able to correctly predict equipment response.

Regarding Comment 2, the SDT believes requiring verification of small size MVA units and units with a low (< 5%) capacity factor is not practical and would deplete the industry’s limited verification capability for very little reliability benefit as concluded from the field testing data involving 4 regions (WECC, SERC, ERCOT, and the FRCC) initiated by the NERC Phase III-IV SDT and completed July 2007. Units with low capacity factor would seldom be synchronized to the BES during significant events.

Regarding Comment 3, the SDT believes the 10 year period is adequate for both initial verification and repeat verification given that the standard also specifies verification is required when equipment changes are made that would affect the units’ excitation control system response.

Regarding Comment 4, the SDT believes that the single point of contact for model issues detailed in Requirement 3 is correctly identified as the Transmission Planner. It is not reasonable to make the Generator Owner interact with several Functional Model Entities when only one interaction, specifically the Transmission Planner, is necessary. Also, the second bullet paragraph of R3 (…identifying technical concerns with the verification documentation related to the excitation control system and plant volt/var control1 system function model…) allows the Transmission Planner to

Organization	Yes or No	Question 4 Comment
request the Generator Owner provide a response for all reasonable modeling issues that can occur. **Regarding Comment 5, the SDT points out that if any of the Requirement 6 Parts are not achievable, resulting in "software freezing" or countless other issues, then the Transmission Planner will determine that the model is not usable. In other words, the cause of the issue does not matter. What matters is the model does not function correctly to satisfy each of the three tests specified.** **Regarding Comment 6, the reason why the SDT is proposing additional time is because this condition is the one which will recur during the normal, ten year model verification cycle. There is no reason to suspect that the model parameters will need significant adjustment since the last verification performed. The SDT believes that allowing sufficient time to make sure that the last yet critical step of model verification (which is refining the model to make sure that predicted response matches the actual response of the equipment) is performed correctly.** **Regarding Comment 7, the SDT has changed the VRF for R2 and R6 from low to medium. R1 is administrative in nature in making sure that that the Generator Owner has access to data needed to perform model verification per R2. R3 is an administrative peer review requirement. R4 and R5 are also administrative in defining the processes in which a Generator Owner communicates with a transmission entity to either provide updated model data or to commit to verifying the model per R2.** **Regarding Comment 8, since model verification activities typically take months, if not years to perform, the time horizon of "Long Term Planning" is appropriate.** **Regarding Comment 9, the SDT is not aware of any industry practice that takes into account the numerical stability of the simulation program. It is left to the judgment of the expert reviewing the study results to determine if the transients identified are negligible.** **Regarding Comment 10, utilizing a stable simulation is necessary for determining if the model will adversely impact the robustness of any dynamic modeling performed. If an unstable simulation is used as basis, then there is no way to determine the additional negative response of the model when assessing usability.** **Regarding Comment 11, the SDT believes the term "verification" is an appropriate term. The word verify means, "to determine or test the accuracy of" whereas verification means "the act of verifying". Also, since this term is not capitalized, the context does not have to be exactly relevant to other standards.**		
Bonneville Power Administration	Yes	MOD-026: By making Transmission Planners responsible for generator verification instead of regional entities, it may be more difficult to produce integrated regional models.The standard should also apply to Regional Coordinators to ensure consistent generator verification requirements within regions.
Response: The SDT thanks you for your comment. Integrated regional models have been constructed for quite some time with a large number of participants submitting dynamic models. Because this standard will result in enhancing the validity of dynamic models, the SDT believes that this standard will actually enhance the process of creating integrated regional dynamic databases and load flows.		
Westar Energy	Yes	The applicability in this standard (â‰¥100 MVA) is consistent with the applicability in MOD-027-1. However, the applicability in this standard is not consistent with MOD-025-2 and PRC-019-1. We propose

Organization	Yes or No	Question 4 Comment
		that the SDT revise the applicability to be consistent between all of the standards included in this project.

Response: The SDT thanks you for your comment. The Applicability of MOD-026 and MOD-027 is unique because these are the only standards addressing generator dynamic model verification. Therefore, the SDT believes that consistency between the Applicability Sections of these two standards make sense. The SDT also thought it best not to force the Applicability to be the same in the other standards that address distinctly different subject matter.

Organization	Yes or No	Question 4 Comment
Southern Company	Yes	1) We question how field tests can be performed on aggregation based facilities. We recommend removing the requirement for developing models for the aggregation of units < 20 MVA for conventional units. 2) Isn't R2.1.3 already required of the GO in MOD-012 (dynamic data on generators) 3) The timing of R5 requirement (90 days) seems to contradict with the schedule for modeling in Attachment 1 (1 1/2 years) for PC initiated model reviews. 4) The background section indicates that the PC can request a unit not in the applicability scope (page 2, last paragraph), but R5 doesn't say this. The wording on R5 indicates that the PC can request a review of an existing model. 5) Attachment 1 is difficult to use. Please cross reference the requirement that goes with each row of the periodicity table Attachment 1. Please add row numbers to the table. Please use column 1 to briefly label the conditions that controls the applibility of the row (for example - the row including the exceptions could be labeled SISTER UNITS) 6) It is suggested to review the order in which the requirements are currently numbered. The current R3 seems to be out of place (should occur after the requirement that is currently R6). This will more closely match the flow of how the process will work. 7) VSL for R1 needs work - the requirement specifies 30 days - the VSL doesn't count it tardy until 90 days. 8) The Sister concept needs to be mentioned in the applicability section 9) The exception rule in Attachment 1 should include Sister units at different geographic sites in addition to those at the same site. 10) The exception rule in Attachment 1 should not be limited to 350MVA - if units are identical, then the sister concept should apply. 11) The first bullet of R1 needs to make "model" plural ("models") for the grammer to be correct.12) As the requirement of R4 is not a response to a request, we suggest changing the wording of the text in M4 from "show that it provided a written response (...) submitted within 180" to "show that it submitted communication (...) within 180", where (...) is shown to indicate no change to the parenthetical element.13) As requirement R6 is an evaluation of the verified model by the TP, we suggest changing the wording of the text in R6 from "show that it provided a written response" to "show that it provided an evaulation of the submitted model".

Response: The SDT thanks you for your comment. The responses below are numbered to match the comments.

1. **The SDT agrees with this point and has modified the language that inadvertently indicated that mixed plants containing conventional units less than 20MVA had to be tested as an aggregate. The language has been modified to allow, but not require, aggregation by type. This can be accomplished by verifying one unit, then utilizing the sister/proxy unit consideration specified in Attachment 1 for the remaining units of the same type. However, as an option if technically feasible, units can still be tested as an aggregate.**

Organization	Yes or No	Question 4 Comment
		2. The SDT is requiring the Generator Owner to include in the model verification documentation submitted to the Transmission Planner the generator model information, including the model structure and data that was used for verifying the excitation control system (which is a closed loop system). **3. The language in Section 5.1 has been revised for clarity.** **4. The SDT revised the language of R5 to make it clear that the Planning Coordinator, with technical justification, can specify a unit for model review that is not listed in the Applicability Section.** **5. The SDT added applicable Requirement references to the conditions identified in Attachment 1. The SDT believes these additions are sufficient. It should be noted that the use of the terms "sister" or "proxy" unit has deliberately been avoided in the standard since this language is considered "folksy".** **6. The SDT recognizes that the sequencing of the Requirements to the degree that is necessary for any particular unit model is subjective. The SDT believes the current order of standard Requirements is reasonable.** **7. The VSL's have been revised for consistency.** **8. The sister unit concept is more appropriate to include in the Attachment 1 (Periodicity Table) since it is an exemption that can be utilized by the Generator Owner.** **9. The SDT respectfully asserts that the "same physical location" requirement is necessary since this language provides a strong indication of equipment and settings similarity (which can be verified by the same field personnel during a single site walk down). For example, a GO/GOP could own/operate otherwise similar equipment physically located in different geographic locations or regions with different operating procedures/requirements (e.g. having the PSS in-service). To ensure all GO/GOP equipment meets standard intent, the SDT maintains the "same physical location" requirement is necessary.** **10. In response to industry comments received, the SDT raised the MVA threshold for "proxy" units from 250 MVA to 350 MVA to ensure that steam units at sites with multiple combined cycle plants are included. The SDT believes that units rated above the 350 MVA thresholds are critical to BES reliability and should have the excitation control system model verified at least once each decade.** **11. The SDT corrected the use of the term "models" in the first bullet of R1.** **12. The SDT revised the measure to address your comment.** **13. The SDT believes that the word "evaluation" could be taken out of context. The SDT did revise Requirement language to address your concern.**
PacifiCorp	Yes	Modeling wind generation without a developed generic model is a concern. If the generic models are not developed once the standard is effective are exceptions going to be made to accommodate this?

Organization	Yes or No	Question 4 Comment
Response: The SDT thanks you for your comment. Generic models are available and there are efforts, as detailed in the Background Information associated with this posting, that are expected to result in more robust models. Requirement R2.1.1 states that the Generator Owner is required to produce documentation demonstrating the unit or plant's model response matches the recorded response for a voltage excursion at the generator or plant point of interconnection from either a staged test or a measured system disturbance. Since the Generator Owner has the final say in determining if the match is adequate or not, to the extent that non-proprietary models can be used to "match" the recorded response from the actual equipment, then that will be sufficient for compliance with the Requirements.		
Georgia Transmission Corporation	Yes	Should references to Planning Coordinator be changed to Transmission Planner (4.2.4 and R5)? Or, should Planning Coordinator be added as a functional entity?Have software manufacturers agreed to provide their models as described in R1?
Response: The SDT thanks you for your comment. The Planning Coordinator is referenced in the standard, but is not responsible for any of the Requirements and therefore is not listed in the Applicability section. **The software manufacturers with dynamic simulation packages used with the Interconnection dynamic stability databases have agreed to provide their models described in R1.**		
Wisconsin Public Service Corp	Yes	We have a number of questions and concerns as follows: o While the Standard uses the word "verified" and "verification" loosely, it is not precisely clear what a GO would have to do to satisfy the verification requirements in R2. Would each of the Time Constants, Forward and/or Feedback Gains, Dead-band Excitation Limits, Saturation Characteristics, etc. to be determined separately each on its own? Or are these parameters taken as a whole so long as their combined effect produces a response characteristic in a simulation that matches the recorded test response during an off-line step-input test? o If a simulation study results in response characteristics that does not match an off-line step input test response, can the GO arbitrarily adjust one or more of the model parametric values to produce a matching response, and send the Transmission Planner these adjusted values as the model data? o We have concern about whether this Standard is cost efficient to the industry. The transient stability dynamic modeling for excitation control was developed under the assumption of limited bandwidth validity and approximations. The other equipment models in the simulation, e.g. generators, prime-mover controls, SVCs, HVDC Converters, etc. are all approximations without any correlated degree of accuracies in comparison to each other. On the other hand, the verification efforts are expected to cost quite a bit to GOs, especially for older units whose vendors/manufacturers may not even be in existence any more.
Response: The SDT thanks you for your comment. In response to your first question the SDT has drafted the standard with minimal technical specificity so that the actual mechanics of verifying the model could be left up to the experts. The SDT drafted a standard that concentrates on stating "what is required" but without stating "how to accomplish what is required". The standard also includes a peer review process. Based on industry		

Organization	Yes or No	Question 4 Comment
comments, the present draft of the standard maintains this same philosophy. **Regarding your second comment, arbitrary large adjustment of model parameters without a valid technical reason is not appropriate. Minor adjustments to model parameters that are within expected tolerances may be appropriate.** **Regarding your third comment, the SDT has proposed unique MVA thresholds for each Interconnection that correspond to 80% of the Interconnected MVA, which represents a subset of the units identified in the NERC Registry Criteria. This philosophy was adopted because of the standard Field Test results obtained. While Field Test results confirmed that verification of excitation system models resulted in higher quality dynamic data, it was also confirmed that excitation system model verification is expensive and requires a significant amount of manpower to accomplish. The SDT believes that the applicability MVA thresholds established will improvement excitation model accuracy, including Reliability, in both a cost effective and manpower effective manner.**		
Manitoba Hydro	Yes	1)For Section 4.2 Facilities, the section should refer to 'BES Generating Units and Facilities' instead of restating components of the proposed BES definition.2)Attachment 1 is not clear. Specifically, -the "Condition" in the first row is not a condition and is not consistent with the remaining rows. -Row 1 suggests that there are no exceptions for submitting a recorded response of a voltage excursion, but Row 2 contradicts this by allowing a single unit to be 'verified' and serve as evidence for multiple units meeting the conditions listed.-the wording for the allowance of a representative unit to be verified and submitted as evidence for identical units is not clear.-the periodicity for row 1 suggests that a recorded response for a voltage excursion shall be collected 'with the verified model' which is incorrect.-We suggest the following. A statement that precedes the Attachment 1 table should be added that reads 'For all Existing Generating Units - a recorded response for a voltage excursion shall be collected during a ten calendar year (January - December) period from the effective date of this standard and the documentation transmitted to the Transmission Planner no more than 365 calendar days from the date that the recorded response was collected unless otherwise specified by the table below. For all newly installed Generating Units - a recorded response for a voltage excursion shall be collected and the verified model and documentation transmitted to the Transmission Planner no more than 180 calendar days of the unit in service date unless specified otherwise specified by the table below. ' Row 1 should then be Facility - Existing Generating Unit, Condition - All existing generating units unless the following exception applies: If multiple units have the same MVA rating that is â‰¤ 350 MVA, and they have identical applicable components and settings, and they are sited at the same physical location, verification of one representative unit is sufficient for all such units. Verification of a different representative unit should be completed each cycle, Periodicity - not required for any units except one representative unit.
Response: The SDT thanks you for your comment. **(1) The SDT intentionally established the standard applicability as a subset of generators included in the NERC Registry Criteria. The term "BES Generating Units and Facilities" is not specific enough for compliance. There are regional differences that prevent use of this term in defining standard**		

Organization	Yes or No	Question 4 Comment
applicability. **(2) The SDT has significantly revised Attachment 1 to improve clarity.**		
Oncor Electric Delivery Company LLC	Yes	The implementation plan call for a certain % of applicable plants to be in compliance over a certain number of years. Since plants may be registered individually, it is unclear what the term applicable plants is referring to in the implementation phase.Oncor takes the position that the reporting requirements for the Generator Owner as specified in R1, R2,R3,R4,R5 & R6 should be to the Planning Authority and not the Transmission Planner in the ERCOT Region. This would align with the current protocols, operating guide and planning guide that require the ERCOT ISO to be the primary interface with Generation Resources. The ERCOT ISO is registered as the Planning Authority. One option would be a regional variance that would point to the Planning Authority or Planning Coordinator in lieu of the Transmission Planner.
Response: The SDT thanks you for your comment. **The Implementation Plan actually calls for a certain percentage of applicable units on an MVA basis (not plants) to be in compliance over a certain number of years. Specifically for ERCOT, a unit is applicable in the draft standard if: (a) a gross nameplate rating greater than or equal to 50 MVA, connected at the point of interconnection with rating greater than or equal to 100 kV, OR (b) units greater than 20 MVA if it is located at a plant with a gross aggregate nameplate rating greater than or equal to 75 MVA, connected at the same point of interconnection with rating greater than or equal to 100 kV, OR (c) plants (i.e. all the units in each applicable plant) with a gross aggregate nameplate rating greater than 75 MVA comprised of units that have a gross nameplate rating less than or equal to 20 MVA, connected at the same point of interconnection at greater than 100 kV. Regarding the responsibilities assigned to the Transmission Planner in the draft standard, the SDT believes standard language lines up well with the vast majority of entity business practices in effect regarding the interactions between generation and transmission entities when collaborating on generator dynamic models. Since ERCOT is an exception, a regional variance should be considered. Alternatively, the Transmission Planner could delegate the responsibility to another such as its Planning Authority.**		
Exelon	Yes	Requirement R2Exelon is in agreement that the Generator Owner (GO) should provide the generator excitation control system and plant volt/var control model and any necessary input data; however, the Transmission Planner (TP) should be the entity that is responsible for the model verification. Transmission Planning organizations have the expertise to implement and test the models in software, while the GOs have the necessary access to the equipment in the field. Most GOs do not have the software and the necessary personnel with the expertise to perform the modeling and model testing required by this draft Standard. Typically, TPs currently have existing software programs to run the excitation system models. The overall quality of the verification would be best served by having the TP that has knowledge in the model performance verse the GOs that do not have the current expertise in model performance or

Organization	Yes or No	Question 4 Comment
		dynamic system response evaluations.Exelon also believes that the Standard should specifically define the acceptance criteria. If the acceptance criteria are left up to the GOs, then the TOs may have to deal with multiple acceptance criteria within a single Region. At the same time, a single GO may have to work with multiple TOs, which will lead to inconsistency if definition of the acceptance criteria is left up to the TO.Requirement 2.1.1The Standard needs to provide specific guidance as to what criteria a voltage excursion from either a staged test or a measured system disturbance should be in regards to performing the verification. In addition, the SDT should provide specific examples of what types of staged tests would be considered acceptable. It is difficult to comment on the potential impact to the generating units (especially a nuclear generating unit) without knowing the criteria.
Response: The SDT thanks you for your comment. **Generator Owners have access to the equipment, along with access to the equipment's Original Equipment Manufacturer for assistance with technical issues. Historically, the Transmission Planner and Generator Owner entities used to work for the same company, but in today's functional model environment, Transmission Planners could easily work for a different company than the generation entity. As such, the stated access advantages for the generation entity do not transfer to the Transmission Planner. Also, the Transmission Planner has expertise in overall power system simulation analysis but not necessarily expertise in specific excitation control system modeling. While the Transmission Planner can continue to participate in model verification to whatever extent agreements with the generator entity stipulates, the majority of the SDT and industry, based upon comments received, believes that the Generator Owner should be responsible for this activity. Also, the draft standard does not require the Generator entity to perform dynamic simulations to determine Bulk Electric System limits. The generator entity is responsible for ensuring that the excitation system model response matches the response from a recorded voltage excursion. This can be accomplished through software that is much simpler than full dynamic simulation software utilized by Transmission Planners for assessing BES limits. If the Generator Owner determines that it does not want to develop in-house expertise to perform model verification activities, it can choose to hire consultants or continue any arrangements with its Transmission Planner to completely or partially provide this service as required once every ten years – though the task would be delegated, the Generator Owner would ultimately be responsible for compliance with the applicable Requirements.** **Regarding the second half of the comment beginning with a desire for acceptance criteria, the standard states "what is required" but not "how to accomplish what is required". The SDT considered ways to quantify a method for evaluating how well the equipment's measured response matches the model's predicted response. However, since a generally accepted technique or criteria for making this quantitative assessment does not exist, the SDT believes that the peer review process incorporated into the standard will ensure model quality. The SDT believes all entities involved with the peer review process have common purpose to develop an accurate excitation control system model. It should be noted that the standard is written so that the Generator Owner "owns' the model, and as such, even with the peer review process described, the Generator Owner has final say on the voltage excursion used, including sampling rate, for model verification as well as determining if the equipment recorded response satisfactorily matches the model's predicted response. The Generator Owner should not be concerned with "acceptance criteria" proposed by a transmission entity.**		
Dynegy Inc.	Yes	R2.1.1 does not specify the magnitude of the required voltage excursion, i.e. 1%, 2%, etc. Is their a

Organization	Yes or No	Question 4 Comment
		specific required voltage change level?
Response: The SDT thanks you for your comment. No, the standard does not specify a required voltage change level. The SDT drafted a Standard that states "what is required", not "how to accomplish what is required".		
Austin Energy	Yes	ERCOT performs computer modeling based data (RARF) provided by Generators. Please consider allowing an exemption or alternate methods for older unit dynamic data as the information for these older units is not always available. ERCOT has used typical or generic modeling parameters for these units.
Response: The SDT thanks you for your comment. The model can still be verified even if existing dynamic data for older units submitted per the Requirements of MOD-012 and MOD-013 represent typical or generic data.		
Independent Electricity System Operator	Yes	1. We do not agree with some of the requirements.i. R1: Standards should stipulate the "what's" not the "how's". To avoid the perception that the requirement is prescribing the "how", we suggest simplifying the language of Requirement R1 by replacing "Instruction on how to obtain" with "Instructions for obtaining".Further, are all three bullets meant to be complied with or are they listed as options? We understand that the general rule for NERC standards is that those items that must be complied with are labeled as parts (e.g. 1.1, 1.2, etc.) while those that are options or examples that do not need to be complied with are placed in bullets. Please verify this with the Director of Standards Process.ii. R2.1: The phrase "models acceptable to its Transmission Planner" begs the question on what is deemed acceptable and what if the GO disagrees with the TP's determination. To address the two issues, we suggest adding a requirement for the TP to specify the models requirements (or change the second bullet in R1 to achieve this), and change the wording in R2.1 to "in accordance with the models specified by the TP (or referencing the requirement part that contains the specification). 2).iii. We are not sure why Requirement R5 is needed. First of all, it suggests that a Planning Coordinator may request the GO to perform a model review where the request can be technically justified. We wonder if the requirement really means "Transmission Planner" rather than "Planning Coordinator" since TP as the requester and model user is specified throughout the standard. Secondly, if it is indeed TP that was meant to be the requester, then would this request already been covered by Requirement R3? If not, what are the technical justifications? They are not specified in R5, unlike its R3 counterpart. Please clarify and/or revise the requirement as appropriate.iv. 3) R6 stipulates the criteria that may not be accomplished even if the GO provides an accurate excitation control system and plant volt/var control function model. A computer model may fail to initialize due to reasons other than the submitted excitation control system and plant volt/var control function model itself;

Organization	Yes or No	Question 4 Comment
		a no-disturbance simulation may not result in negligible transients due to other reasons; and finally, a disturbance simulation may not result in the excitation control system and plant volt/var control system model exhibiting positive damping due to other system parameters. System damping is affected by many other dynamic performance contributors such as other generators, system topology, power flow levels, voltage levels, excitation system and power system stabilizer settings, etc. In short, having an accurate excitation control system and plant volt/var control function model does not necessary guarantee or equate to meeting the conditions stipulated in the three sub-requirements. We suggest this requirement be removed. Further, in many jurisdictions the setting and tuning of excitation control systems and associated power system stabilizers, etc. are determined by the Transmission Planners (or Planning Coordinators); the GOs would simply provide the equipment and set them according to the TP's specification. In this standard, the responsibility is for the GO to verify that the model reflects the actual response of the tested equipment, whose settings have been determined prior by the other responsible entity.2. 4) In the previous posting, we provided 2 comments which in our view, have not been duly and satisfactorily addressed by the SDT and we would like to reiterate them here:i. We suggested that at a minimum, the generator's basic characteristics such as inertia constant, damping coefficient, saturation parameters, and direct and quadrature axes reactances and time constants), voltage regulators, turbine-governor systems, etc. as stipulated in MOD-013 that support modeling for dynamic simulations should also be verified. A good excitation system model without a valid generator model will not provide the assurance that the simulation results are valid, which may hurt reliability.In response to this comment, the SDT indicates that: "[it] agrees that appropriate dynamic models are needed for generators, exciters, PSS, and governors. The SDT believes that when testing personnel verify the excitation system model data, they also provide verification of the generator model data. A match between simulation and measured results for the excitation system model is required to indicate that the generator and excitation control system models accurately represent the equipment. The governor model is not verified with the excitation system model since it requires a frequency excursion. Verification of the governor model will be addressed by the MOD-027 standard. Experience indicates verification required by the MOD-026 standard often results in discovery of significant changes to the representation of the generator and exciter, suggesting that model verification provides significant reliability improvement."Generator model parameters need to be verified based on tests conducted during both turbine/governor model verification as well as excitation system model verification. We are however not convinced that those tests that need to be performed during the excitation system model and data verification process, to verify certain portions of the generator model parameters will be conducted as a matter of course. We therefore reiterate our view that the verification of generation model parameters needs to be included within the scope of this standard and we urge the SDT to consider our comments again.ii. 5) We suggested that in some areas on the interconnection, such as those that are sparsely populated,

Organization	Yes or No	Question 4 Comment
		performance of generating units at less than 100 MVA might be critical to reliability. The criteria to allow the TP and PC to identify these units could include: a. A 5% or 10% deviation of any or several of the excitation system's parameters/settings could make an otherwise stable simulation to be unstable; b. Use of generic models for the excitation system or generator would make an otherwise stable simulation to be unstable. c. Other changes or incorrect assumptions for the excitation system or generator would make an otherwise stable simulation to be unstable. The SDT responded that: “After reviewing provided details, the SDT encourages you to review the new process draft (reference Requirement R2) and provide additional comments as appropriate.” Requirement R2 does not contain any provision that a TP (or PC) can request for model verification of units that do not meet the Applicability criteria. Throughout the standards, such a provision does not exist. This could leave room for system to exhibit unstable performance for reasons indicated in our previous comments. We urge the SDT to reconsider our proposal.

Response: The SDT thanks you for your comment.

1) Requirement 1 does describe the “what”. The “what” is that upon request, the Transmission Planner is to provide the Generator Owner data or instructions on how to obtain needed information. As stated in requirement 1, the three bullets identify instructions and data the Generator Owner can request from the Transmission Planner. The Transmission Planner is only required to provide information requested. The SDT believes standard formatting is correct since the Generator Owner determines what, if any of the information identified is requested from the Transmission Planner.

2) Response: Several commenters expressed concern with the new Requirement 5 added to the standard giving the Planning Coordinator authority to require model review for a unit not specified in the standard Applicability section. The SDT added this language to the draft standard after considering industry comments to the first posting noting that the Applicability section is a subset of the Compliance Registry criteria. Based on the latest round of industry feedback, the SDT now proposes Applicability Section language allowing the Planning Coordinator to request additional model information (possibly model verification) only if technical justification demonstrates the simulated unit response does not match the measured unit response. Original technical justification language for units that affect a stability limit has been removed from the standard. To emphasize for understanding, the SDT points out only units that meet or exceed the Registry Criteria unit MVA thresholds (> 20 MVA) are subject to Requirement R5. This observation should allay concern the Requirement could be misused inappropriately. Keep in mind only units identified in the Registry Criteria and not included in the draft standard Applicability Section can be requested to have a model review. Conversely, Requirement 3 only applies to units in the base Applicability (a subset of units identified the NERC Registry Criteria). This requirement is assigned to the Planning Coordinator to address generator owner concern that the transmission planner might request a model review without proper justification. The requirement is written to require a higher level of justification for requesting a model review than simply contacting the generator owner.

3) Response: R6.1, R6.2, and R6.3 represent established industry practice for assuring model usability. The positive damping requirement makes the generator owner provide a response if a new model introduces negative damping. This requirement recognizes that the equipment must be positively damped during actual operation. Negative damping occurring during simulation indicates incorrect modeling. Initialization errors and oscillation transients without disturbance conditions also indicate incorrect modeling.

4) Response: The SDT agrees generator parameters such as the inertia constant, damping coefficient, saturation parameters, direct & quadrature axe reactance’s, and time constants need to be correctly modeled. Since the phrase, “excitation control system” is an IEEE defined term with specific

Organization	Yes or No	Question 4 Comment
meaning; the SDT contends this term incorporates the generation model parameters by definition. The generation model parameters must be correct to successfully verify the excitation control system model. Note that the governor turbine model verification is addressed by the MOD-027 standard. The SDT recognizes the various control systems interact and expects correct modeling data. The purpose of this standard is model verification and not the development of correct modeling parameters. If model verification is not successful, then the modeling parameters are not correct and the generator owner will need to identify and correct bad parameters. This standard intentionally avoids specifying how to correct model parameters with expectation the generator owner demonstrates that model data is correct. **5) The SDT regrets that the provided Reference number in the last Consideration of Comments response was incorrect. The SDT added language to the draft standard in Requirement 5 after considering industry comments to the first posting noting that the Applicability section is a subset of the Compliance Registry criteria. Based on the latest round of industry feedback, the SDT now proposes Applicability Section language allowing the Planning Coordinator to request additional model information (possibly model verification) if technical justification demonstrates the simulated unit response does not match the measured unit response. This will include units that meet or exceed the Registry Criteria unit MVA thresholds (> 20 MVA) but are less than the standard's base Applicability (including units > 100MVA for the Eastern Interconnection). In summary, Requirement 5 allows Planning Coordinators to request additional model information, which could include model verification, for units less than 100 MVA that are critical to reliability and have shown that their model does not accurately predict actual equipment response.**		
Wisconsin Electric	Yes	Section A Effective Dates: In 5.2.1, replace "30% of its applicable units" with "20% of its applicable units". There will be a substantial learning curve with this new requirement, therefore the requirements should be less demanding in the earlier years.Section B: Requirement R1: Replace "Each TP shall provide the following INSTRUCTIONS AND DATA to its GO..." with "Each TP shall provide the following DATA to its GO...". On the first two bullets, remove the phrase "Instructions on how to obtain..." The TP should simply provide this data, and not merely the instructions on how to get it. On the third bullet, replace "Any of the GO's existing ... model data" with "All the GO's existing ... model data...". Since the TP already has this data, it is more straightforward to simply provide all relevant data to the GO. Requirement R2: Replace the first sentence with, "Each GO shall provide data which MAY BE USED TO VERIFY the generator excitation control system and plant volt/var control models..." The verification of these models is not determined by the GO, but by the TP in Requirement R6, R6.1, R6.2, and R6.3.In R2.1.1, replace "Documentation demonstrating the ... model response matches the recorded response" with "Documentation WHICH MAY BE USED TO DEMONSTRATE that the ... model response matches the recorded response". In R2.1.3, 2.1.4, and 2.1.6 replace "model structure" with "block diagram". In Requirement R3, replace "90 calendar days" with "180 calendar days", to allow more time to work through the technical challenges relating to these models.In Requirement R5: Allow 180 days for a response to the PC for the reasons above. This will allow time in the event that the request from the PC lacks the technical rationale or details that are required. Also, in R.5.2, replace "walk down" with "inspection". Comments on Attachment 1:1. Remove the note which says, "Note that local grid codes may specify...".2. Under "Conditions" for existing generators, it is not clear why there are references to both a ten year period and an eleven year period. Also, replace "Subjected to an activity resulting in an alteration of the response of the excitation control system" with "Changes to control system or parameter values".3. Under the

Organization	Yes or No	Question 4 Comment
		exceptions for existing generators, the allowable MVA size should be increased to 500 MVA. 4. Under "Periodicity" for existing generators, in the last three rows covering situations where the recorded response did not match the predicted response, where the PC requests a review, and where the model is identified by the TP as unusable, the GO should be allowed two years (instead of one year) to provide a recorded response for a voltage excursion due to the possible need to take the unit out of service to make control changes, especially where outages are not scheduled on an annual basis.Lastly, staged testing for generator exciter model verification will likely require switching of lines on the transmission system. In cases where the Generator Owner does not own or operate the transmission system, the TO or TOP may understandably be reluctant to switch lines out due to reliability concerns. For this reason, R2 should be modified to provide more incentive for the TO/TOP to coordinate with the GO to do the required testing.

Response: The SDT thanks you for your comment.

1. **The SDT considered industry concerns provided in response to the first posting of the standard for this issue and decided to revise the timeframe following standard approval for the first set of models required to be verified from "after 2 years of regulatory approval, 10% of its applicable units per Interconnection on a MVA basis" to "…four years following applicable regulatory approval….Each Generator Owner shall ensure at least 30% of its applicable units per Interconnection on an MVA basis are compliant with Requirement R1." In addition to allowing entities additional start up time to develop this expertise, the revised timeline enables traditional staged testing to be performed concurrent with a scheduled planned maintenance outage. The SDT believes this change allows adequate time for entities to perform model verification activities.**
2. **The SDT believes it is necessary to provide instructions for obtaining the data since a) the SDT anticipates most entities will post the "acceptable list of models" on a website, and b) providing instructions on how to obtain block diagrams or data sheets will help ensure vendor dynamic simulation software data sheets are legally obtained.**
3. **It is acceptable for a Generator Owner to request information for any of its units or plant excitation control systems.**
4. **Requirements R6.1 through R6.3 specifies how a Transmission Planner determines if the model is usable. This determination should not be confused with verifying the model response matches actual equipment response. A model is not considered "usable" if angle drift occurs without a disturbance condition present or if poorly damped oscillations occur when disturbance conditions exist. As required by R2, model verification is ensuring that the predicted model response matches the actual equipment recorded response for a voltage excursion from either a staged test or a measured disturbance (ambient event).**
5. **The phrase "may be used" would undermine the primary reliability related intent of the standard which is to ensure that the predicted model response matches the actual equipment recorded response for a voltage excursion from either a staged test or a measured disturbance (ambient event). Also, the SDT intends to keep the phrase "model structure" since a model structure is a block diagram without parameter values.**
6. **Requirement R3 does not require the Generator Owner to verify the model. Allowing more than 90 days only prolongs the dialog.**

Organization	Yes or No	Question 4 Comment
7. Requirement R5 does not require the Generator Owner to verify the model. Allowing more than 90 days prolongs the process of updating the model which the Planning Coordinator needs to have revised so that accurate BES stability limits can be calculated. The SDT regrets that it could not find the reference to "walk down". **8. Regarding the first two Attachment 1 comments, the Attachment has been revised.** **9. Regarding your Attachment 1 comment pertaining to allowable MVA size, the SDT responded to industry comments by raising the MVA threshold for "proxy" units from 250 MVA to 350 MVA to ensure that steam units at sites with multiple combined cycle plants are included. The SDT believes that units rated above the 350 MVA threshold is critical to BES reliability and should have the excitation control system model verified at least once each decade.** **10. Regarding your second to last Attachment 1 comment, the SDT believes that if any control changes are implemented, they would be performed at the same time a staged testing is conducted (for example, adjusting gain based on the results of a step change voltage test).** **11. Regarding your final Attachment 1 comment, the SDT expects either traditional staged testing or ambient monitoring will be used to collect data for model validation. As such, there is not a need to provide additional incentive to the TO/TOP.**		
We Energies	Yes	Section A Effective Dates: In 5.2.1, replace "30% of its applicable units" with "20% of its applicable units". There will be a substantial learning curve with this new requirement, therefore the requirements should be less demanding in the earlier years. Section B: Requirement R1: Replace "Each TP shall provide the following INSTRUCTIONS AND DATA to its GO..." with "Each TP shall provide the following DATA to its GO...". On the first two bullets, remove the phrase "Instructions on how to obtain..." The TP should simply provide this data, and not merely the instructions on how to get it. On the third bullet, replace "Any of the GO's existing ... model data" with "All the GO's existing ... model data...". Since the TP already has this data, it is more straightforward to simply provide all relevant data to the GO. Requirement R2: Replace the first sentence with, "Each GO shall provide data which MAY BE USED TO VERIFY the generator excitation control system and plant volt/var control models..." The verification of these models is not determined by the GO, but by the TP in Requirement R6, R6.1, R6.2, and R6.3. In R2.1.1, replace "Documentation demonstrating the ... model response matches the recorded response" with "Documentation WHICH MAY BE USED TO DEMONSTRATE that the ... model response matches the recorded response". In R2.1.3, 2.1.4, and 2.1.6 replace "model structure" with "block diagram". In Requirement R3, replace "90 calendar days" with "180 calendar days", to allow more time to work through the technical challenges relating to these models. In Requirement R5: Allow 180 days for a response to the PC for the reasons above. Regarding your final Attachment 1 comment, the SDT expects either traditional staged testing or ambient monitoring will be used to collect data for model validation. As such, there is not need to provide additional incentive to the TO/TOP.**		
Great River Energy	Yes	We appreciate the drafting team's consideration in Section A.6 to allow a unit that has already verified its excitation system to be considered compliant. However, it is not clear how this section helps. How does the Generator Operator demonstrate that it is already compliant when it was not required to retain documentation? Will an attestation by appropriate level of staff besufficient? Will the regional entities be willing to validate that they have confirmed regional criteria?This standard is overly administrative by memorializing the interactions between the Generator Operator, Transmission Planner and Planning Coordinator that occur to model the generator's excitation system. Specifically R1, R3, R4 and R5 should be struck. They are purely administrative and present compliance risk to the registered owners without commensurate reliability benefit. For Requirement R6, the portion requiring a written response should be struck as well. Only two requirements are needed to accomplish the purpose of this standard. They are: ne requirement for theGenerator Operator to perform the test and one for the Transmission Planner to verify the model is accurate.Requirement R6 creates a situation where a Transmission Planner could be forced to decide between living with an exciter model that needs adjustment and violating the standard. Upon initial examination, the Transmission Planner may determine that the model meets Parts 6.1 through 6.3. Only after months or years of extensive study, it is possible that the Transmission Planner determines that the excitation model could stand some improvements. If they submit a written response one year later, the Transmission Planner may be in violation of Requirement R6. This just represents one of the issues with

Organization	Yes or No	Question 4 Comment
		memorializing the interactions between the Transmission Planner, Planning Coordinator and Generator Operator in the standards.Because the tests to verify the excitation model can be expensive, there should be a demonstrated need to perform a test. Summaries of field test results posted with the second draft of the SAR indicate the costs of these tests could range from $5,000 to $50,000 for a single unit. That does not even include opportunity costs from lost energy sales should the test cause the unit to trip. Thus, if there are no demonstrated modeling deficiencies (i.e. benchmarking reveals model results do not align with actual system results), then no test should be required and the generator operator should be able to wait for a system disturbance appropriate enough to verify its model.Because R3 and R5 give only 90 days to respond to the Planning Coordinator's and Transmission Planner's issues with the excitation model, these requirements could compel tests during a seasonal peak time frame. At a minimum, the Generator Operator should have 180 days to perform the test if that is what is identified as its response to avoid jeopardizing unit tripping during periods of high loads.

Response: The SDT thanks you for your comment.

1. **It is beyond the scope of the SDT to specify how an entity will provide evidence if requested to verify a model compliant with the applicable regional entity polices, guidelines, or criteria. It is hoped that documentation and/or correspondence created during the model verification process was compliant with regional entity policies, guidelines, or criteria and maintained by the Generator Owner for use as evidence. The decision to attest or validate regional criteria will have to be determined by the respective region.**
2. **Regarding your comment suggesting that R1 should be struck, the SDT cannot draft a Requirement for a Functional Model Entity without assurance that they have the proper information to satisfy the Requirement. R1 is necessary to ensure the Generator Owner has the proper information to comply with R2.**
3. **Regarding your comment suggesting that R3, R4, and R5 should be struck, the SDT acknowledges that these Requirements are "exception type" Requirements that should rarely be used however the SDT believes striking them from the standard would be detrimental to reliability. Without these Requirements, model accuracy issues may not be resolved for ten years.**
4. **Regarding the comment addressing Requirement 6 language, the Requirement references usability testing only which can be readily completed by the Transmission Planner. R6 language does not prevent the Transmission Planner from requesting the Generator Owner to verify information if there is evidence that the model is incorrect. The third bullet of R3 mandates that the Generator Owner must respond to evidence from the Transmission Planner that the modeled response does not match the recorded response and this language allows the Transmission Planner, assuming supporting evidence is available, to request a review at any time..**
5. **Regarding your comment about the need for model verification, the SDT has proposed unique MVA thresholds for each Interconnection that correspond to 80% of the Interconnected MVA, which represents a subset of the units identified in the NERC Registry Criteria. This philosophy was adopted because of the standard Phase III-IV NERC Field Test results obtained. While Field Test results confirmed that verification of excitation system models resulted in higher quality dynamic data, it was also confirmed that excitation system model verification is expensive and requires a significant amount of manpower to accomplish. The SDT believes that the applicability MVA thresholds established will**

Organization	Yes or No	Question 4 Comment
improvement excitation model accuracy, including Reliability, in both a cost effective and manpower effective manner. **6. Regarding your last comment, please note that the Requirements R3 and R5 only require the Generator Owner to respond to the Transmission Planner within 90 days, and that response could be a plan to verify the model. Once this response is provided, the Generator Owner has one year to collect a voltage excursion and another 180 days to complete model verification based on the current language of Attachment 1.**		
Duke Energy	Yes	1) If System Models are poor today, it is probably due to a lack of understanding on what models are required, setpoint control and what changes need to be communicated to Transmission when plant projects are done. Periodic reverifications are probably not the right way to ensure reliability. Instead there should be an event-based revalidation requirement, such as if you replace the control system or recalibrate the control settings on an existing unit, replace the rotating exciter or rewind a generator. An approach where there is an initial validation effort to get today's models consistent with installed equipment is clearly needed. However, assurance that future models will remain valid requires that there is a program in plant project processes to revalidate when appropriate, and thus a requirement to show that the company has the needed project processes and has followed that process is the right way to approach this.2) There needs to be a requirement for the entity responsible for actually inputting the models and data to do so on a timely basis. This should be an annual update of data to be submitted to the interconnected models. As currently written, there is a requirement for the GO/GOP to submit information, but they do not input directly into the interconnected system models. MOD-010, MOD-011, MOD-012 and Mod-013 don't currently ensure that data is incorporated in a timely fashion.3) Since GO/GOPs do not always have electrical system modeling expertise, nor participate in interconnected system models groups such as the MMWG which sometimes changes how equipment is modeled, there probably needs to be a guide that clearly identifies the steps a GO/GOP needs to take to maintain models up to date. The NATF and EPRI/NAGF are considering a collaboration to do so.4) Identically designed generation units are identical in control response, independent of site location. New techniques for validation eliminate the impact of the grid on the validation efforts. Thus, credit for sister unit validations should be available independent of the location of a unit.5) Discussions during the EPRI PPPD users group indicate certain parameters in the models are temperature sensitive, and thus verification and adjustment of models should be done under conditions that reflect normal operating conditions. An on-line voltage step test or DFR data from an event is the best way to perform the validations. It's not clear if validations against off line tests would actually make the models worse, but the industry should be encouraged to do validations on line near full power.6) R2, 2.1.3 Total unit inertia should be given to include all coupled rotating elements. The way this is currently worded, it could lead generators to only provide the generator H values.7) Footnote 4 - Delete the phrase "or evidence that the simulated unit or plant response does not match measured unit or plant response". Otherwise this standard could be made applicable to a small unit that has no impact on reliability.

Organization	Yes or No	Question 4 Comment

Response: The SDT thanks you for your comment.

1. **The philosophy adopted for the draft standard is based on recently completed NERC sponsored Field Testing. Field Test results confirm excitation system model verification results in higher quality dynamic data. Since excitation system verification is costly and requires significant manpower, the SDT believes the applicability should be a subset of the NERC Registry Criteria and a ten year verification periodicity is appropriate for reliability. Also, the standard includes "event-based" validation requirements to ensure that the model is verified when issues are discovered (Requirement 3, third bullet).**
2. **The results of model verification are required to be transmitted to the Transmission Planner per Requirement 2 and Attachment 1. Sufficient time is provided for the Generator Owner to verify the equipment response matches the predicted response. While the SAR for MOD-026 addresses model verification, which the SDT believes includes the transmittal requirements specified in Attachment 1; it does not address the data submission requirements of MOD-010 and MOD–012.**
3. **Regarding the third comment, the SDT agrees development of model verification guides by credible industry groups such as the NATF and EPRI is a worthy endeavor.**
4. **Regarding the fourth comment, the SDT respectfully asserts that the "same physical location" requirement is necessary since this language provides a strong indication of equipment and settings similarity (which can be verified by the same field personnel during a single site walk down). For example, a GO/GOP could own/operate otherwise similar equipment physically located in different geographic locations or regions with different operating procedures/requirements (e.g. having the PSS in-service). To ensure all GO/GOP equipment meets standard intent, the SDT maintains the "same physical location" requirement is necessary.**
5. **Regarding the fifth comment, the SDT maintains that the standard should state "what is required" and not specify "how to perform what is required". The SDT refrains from entering the debate because both the online and offline step change voltage tests and the ambient event test are adequate for performing model verification.**
6. **Regarding the sixth comment, the SDT believes that the term rotational inertia is well understood in industry. The term "rotational" infers a mass that is attached to the unit shaft.**
7. **Regarding the last comment, several commenters expressed concern with the new Requirement added to the standard giving the Planning Coordinator authority to require model review for a unit not specified in the standard Applicability section. The SDT added this language to the draft standard after considering industry comments to the first posting noting that the Applicability section is a subset of the Compliance Registry criteria. Based on the latest round of industry feedback, the SDT now proposes Applicability Section language allowing the Planning Coordinator to request additional model information (possibly model verification) only if technical justification demonstrates the simulated unit response does not match the measured unit response. Original technical justification language for units that affect a stability limit has been removed from the standard. To emphasize for understanding, the SDT points out only units that meet or exceed the Registry Criteria unit MVA thresholds (> 20 MVA) are subject to Requirement R5. This observation should allay concern the Requirement could be misused inappropriately. Keep in mind only units identified in the Registry Criteria and not included in the draft standard Applicability Section can be requested to have a model review.**

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 4 Comment</th></tr>
<tr><td></td><td></td><td></td></tr>
<tr><td>Western Electricity Coordinating Council</td><td>Yes</td><td>Requirement R1, first bullet. Grammatically, should the word model in the first bullet be models?Requirement R4 requires the Generator Owner to provide revised model data or plans to perform model verification. The way I interprete the wording of Requirement 4 is that the model data or plans to perform model verification are due within 180 calendar days. If the GO provides plans to perform model verification and submits the information on their plans within 180 days, is there any time limit as to when the model verification must be performed? If so I suggest it should be included in the language of the Requirement. If the actual verificatio must be done within 180 days this should be clarified becasue right now it just looks like only the plans have to be submitted within 180 days.</td></tr>
<tr><td colspan="3">Response: The SDT thanks you for your comment.
1. Regarding the first comment, the SDT has corrected the error in R1.
2. Regarding the second comment, the Generator Owner has 180 days to respond, and that response could be a plan to perform model verification. If the Generator Owner plans to perform model verification, then footnote 5 specifies that the ten year periodicity would be reset as detailed in Attachment 1. More specifically, once the Generator Owner states an intention to re-verify the model, Attachment 1 allows up to 365 days to record and collect an ESC response and then is allowed up to 180 days to transmit the verified model and documentation to the Transmission Planner.</td></tr>
<tr><td>ISO New England Inc.</td><td>Yes</td><td>1) This standard may lead Generator Owners to violate another NERC Standard; this standard implies in requirement R4 along with footnote 6 that Generator Owners could have 180 days to notify its Transmission Planner that an AVR status has changed. The VAR standards require notification within 30 minutes of a change in AVR status.Requirement R4 is also a direct violation of the ISO/FERC Tariff Section I.3.9 that requires generators to provide information prior to making material changes to equipment characteristics. Allowing generators to make changes such as these without prior review represents a significant reliability concern.

2) MOD 26 needs to clearly state that non-proprietary models need to be provided by Generator Owners, otherwise a major reason (NERC MMG) for model collection will be undermined.As written, the intent of requirement R2.1.1 is unclear.

3) How are stabilizers and excitation limiters to be addressed? How large does the voltage excursion need to be? This requirement needs to be made much more specific.

4) With respect to requirement R1, the standard should allow user models to be provided. The second bullet point implies that models would only be allowed from a list of standard models. User written models</td></tr>
</table>

Organization	Yes or No	Question 4 Comment
		may provide more accurate representations of actual equipment installations. However, these models cannot be proprietary and must be able to be distributed.In requirement R5.2 bullet 1 - generator owners should not be providing generic model data. In requirement R5.2 bullet 2 - what constitutes a “walk down” of the equipment? 5) Suggest replacing with “Updating parameters based on actual field verification of equipment settings.”This standard should indicate what constitutes the excitation system and should indicate that it includes a power system stabilizer and limiters. 6) This standard addresses existing generators, but should also address new generators.In regard to the Effective Dates: How is this to be implemented? GOs may have units in multiple control areas. TOs may be in multiple areas. This seems impossible to track and may leave some areas with very little verification for up to ten years after the standard has been approved. The Planning Coordinator should be given the discretion to require and approve a test schedule within it’s area.

Response: The SDT thanks you for your comment.

1) The requirements of MOD-026 do not usurp the requirements of other standards. Providing notification of AVR status change is not the same as verifying model data following equipment status change that may affect the model. MOD-026 requires model verification and this cannot be performed until after equipment changes occur and the generator is operating. Also, MOD-026 addresses verification of ECS models that are in service. MOD-026 does not alter requirements for preliminary model data as specified by any Tariffs.

2) Requiring Generator Owners provide models based on an acceptable model list provided by the Transmission Planner is intended to establish usable models. Part of this intention is to address the necessity for non-proprietary models.

3) Generator owners are expected to provide correct stabilizer and excitation limiter data. MOD-026 requires verification of the complete model but does not verify every detail of the model. Limits are difficult to verify using staged or ambient tests. The generator owner and subject matter experts have to determine how to develop correct data.

4) The standard does not prevent user models however the model must be on the list approved by the Transmission Planner. An equipment “walk down” to correct model parameters could be as simple as identifying by observation in the field that equipment gain or limit setting values are incorrectly represented in the model.

5) The standard uses the IEEE term “excitation control system” which includes the PSS, limiters, and generator. The standard requires verification that model data matches equipment performance for the complete voltage control system.

6) The SDT addressed new equipment in Attachment 1 and provided 180 days to complete model verification. Generator owners are required by other standards to provide correct model data so the SDT believes the implementation time frame allows sufficient time to adequately verify the model without impacting Generator Owner ability to develop capabilities and verify models for their other units.

Organization	Yes or No	Question 4 Comment
Ingleside Cogeneration LP	Yes	MOD-026-1 already takes Ingleside Cogeneration LP out of its comfort zone by requiring the ownership and validation of interconnected system performance simulations. This is normally a Transmission Planner or Transmission Operator function, not a Generator Owner. Although we understand the benefit of modeling validations, it is appropriate to begin with only the most critical facilities.If anything, we believe the applicability criteria should be consistent with those generation facilities which have DME installed as required by their Regional Entity. This is a reasonable, in-place means to identify those generators which are important to BES voltage response - and have already the recording equipment needed to validate performance.
Response: The SDT thanks you for your comment. The SDT believes that the Generator Owner is in the best position to determine realistic and reasonable model representation of installed equipment. For this reason, the standard gives the Generator Owner authority to determine if the model adequately represents performance of installed equipment. It is not desirable to link this standard with the DME standard under development. Also, the DME standard applies to fault recorders and PMU equipment. Low resolution data is adequate for verification. The SDT agrees that if DME is already in place, especially if it is monitoring the appropriate quantities required for excitation control system verification, then it should be simpler to capture the required data for verification. The applicability section requires verification of units larger than the MVA threshold gross nameplate rating specified for each interconnection and this threshold is intended to emphasize the importance of modeling critical units.		
Southern California Edison Company	Yes	SCE believes that the Section 4.2.4 of the Applicability Section should be revised to read "Any technically justified unit requested by the Transmission Planner." We believe that the Transmission Planner is the appropriate functional entity for this role.In addition, SCE believes that Requirement 1 should be revised to allow the Transmission Planner a full 60 days in which to provide the information to the Generator Owner. At various times, Transmission Planners may be inundated with such requests from Generator Owners and may require the extra time in which to respond.
Response: The SDT thanks you for your comment. In response to your first comment, the second posting of the standard has proposed a process where the Planning Coordinator can request a review of an excitation control system model for a unit not specified in the standard Applicability section. This requirement was added by the SDT in response to industry asking if a transmission entity should be allowed to identify additional units beyond those identified in the base Applicability. The base Applicability, though expanded in this posting, continues to be a subset of units identified by the NERC Compliance Registry. Also, the time period in Requirement 1 has been increased to 90 days to match the time period in the VSL.		
Ameren	Yes	Our comments/concerns are : 1)The wording for Requirement 2.1.4 should be changed to read “Model structure and data for the excitation system, for the plant volt/var system, and for the closed loop voltage regulator”. Otherwise, as written, it appears that the required model structure and data only applies to the voltage regulator portion of the equipment.2)In Requirement R5, the term “technically justified request” needs to be clarified. 3)In Requirement R2.1.3, it should be clarified that “rotational inertia” should include

Organization	Yes or No	Question 4 Comment
		all rotational mass connected to the generator shaft, rather than only the rotational inertia of the generator itself.4)Units rated 20 MVA will not have a significant impact on system reliability. Only units and aggregate plants capable of > 100 MVA should be included.5)Sister unit exemptions should be allowed where there is a solid technical support for units built and operated as virtually indistinguishable generators.6)The SDT should review the requirements in this draft to ensure they do not overlap the requirements in MOD-012 and MOD-013. From our read it appears generator owners will be at serious risk for double jeopardy.7)The draft uses the term "Point of Interconnection" in several locations, especially R2.1.1. This is not a NERC Glossary term, although the Team used footnote 3 as an internal definition.8)Footnote 6 should be a set of sub-requirements for R4.9)Section 6 should be part of the Implementation Plan since it deals with the initial phase-in of the Standard.10)Footnote 2 should probably be in the Applicability Section, but should not stay as a footnote - it's too important in determining which generators must comply.
Response: The SDT thanks you for your comment. 1) The SDT has revised R2.1.4 incorporating the essence of your suggestion. **2) The SDT has revised Requirement R5 using a footnote to define the phrase, "technically justified" as the simulated unit or plant response does not match measured unit or plant response.** **3) The SDT believes that the term rotational inertia is well understood in industry. The term "rotational" infers a mass that is attached to the unit shaft.** **(4) The SDT is only proposing verification of units rated 20 MVA at plants which exceed the interconnection established MVA threshold (which is 100 MVA for the Eastern Interconnection). Even with the MVA threshold satisfied, units satisfying sister/proxy unit criteria will not have to be verified, further reducing the number of units actually tested.** **(5) The SDT believes sister/proxy unit criteria established is adequate.** **(6) MOD-012 and MOD-013 requires submission of the latest equipment dynamic model data. MOD-026 requires verification of the equipment dynamic model data.** **(7) Your observation regarding the phrase "point of interconnection" is correct. Please note that this phrase is not capitalized in the standard.** **(8) The SDT believes providing the list associated with Footnote 6 in the Requirement section would make the standard cumbersome to read.** **(9) The SDT believes that Section 6, since it addresses early compliance considerations, is important to require its own "section" in the standard.** **(10) The SDT believes providing the list associated with Footnote 2 in the main body of the standard would make the standard cumbersome to read.**		
American Electric Power	Yes	Standard models may not be available for wind units and wind facilities (which appear to be within scope), particularly aggregate reactive and frequency response controls at the farm level. As a result, it might be difficult to obtain and provide such information.

Organization	Yes or No	Question 4 Comment
Response: The SDT thanks you for your comment. Generic models are available and there are efforts, as detailed in the Background Information associated with this posting, that are expected to result in more robust models. Requirement R2.1.1 states that the Generator Owner is required to produce documentation demonstrating the unit or plant's model response matches the recorded response for a voltage excursion at the generator or plant point of interconnection from either a staged test or a measured system disturbance. Since the Generator Owner has the final say in determining if the match is adequate or not, to the extent that non-proprietary models can be used to "match" the recorded response from the actual equipment, then that will be sufficient for compliance with the Requirements.		
Texas Reliability Entity	Yes	(1) The implementation period in this standard is far too long. It is unreasonable to allow 11 years for a GO to provide a verified model for 50% of its generation capacity. All generation should comply with Requirement 2 within 3-5 years.(2) The periods allowed for providing correction of identified model deficiencies and updates for system changes are too long. It appears (from Attachment 1) that a GO has almost 2 years to provide a corrected verified model after a request from a TP or an equipment change (per Requirements R3, R4 and R5). This work should be completed within one year to ensure accurate system modeling.(3) It is unclear exactly what is required by Attachment 1, and how the material in the attachment relates to the Requirements. The Attachment appears to contain additional requirements. We suggest moving the required actions described in Attachment 1 into the applicable Requirements, such as the requirements and time periods for recording responses and providing new information to the TP. (4) It is unclear what the 10 and 11 year periods/cycles referenced in the first two rows of Attachment 1 refer to. This needs to be clearly explained somewhere.(5) It is our understanding that this standard is intended to require re-verification of models at least every 10 years, but there is no requirement that clearly sets forth any re-verification requirement or period. (6) Requirement 6 requires the TP to determine if a model is "usable" based only on whether the model is functional, omitting any consideration of whether the model is reasonably accurate. An incorrect model could satisfy 6.1, 6.2 and 6.3. We suggest adding an R6.4 relating to whether the model is reasonably accurate, i.e., whether it reflects actual unit performance.(7) In 4.2.3, in the first bullet, "with rating greater than" should be changed to "at greater than," which is clearer and consistent with the parallel descriptions in neighboring sections.(8) In the "Consideration for Early Compliance" section, first bullet, "applicable regional entity policies" should be changed to "applicable region policies." In our region, and perhaps others, there are applicable policies, but they are not "regional entity policies."(9) Several very informal terms are used that should be replaced with more specific language, such as "walk down" (R5.2) and "local grid codes" (Attachment 1). In R6.2, the term "negligible transients" in too indefinite and should be replaced by a more objective measure. (10) The terms "unit," "plant," and "facility" are used inconsistently in the draft.(11) M4 refers to a "request" and a "response," but there is no request/response interchange in the associated Requirement R4.
Response: The SDT thanks you for your comment. **Regarding the first comment, in the current draft of the standard, all of the units that meet the Applicability section are required to have their models**		

Organization	Yes or No	Question 4 Comment
verified within 11 years – 50% will be verified within seven years (six years to capture a voltage excursion, and then one year to finish the model verification). Also, the SDT believes, and the majority of industry responders when asked the question in the first posting agree, that the implementation plan provides proper balance between the need to verify excitation control system models and the fact that there are Generator Owners that currently do not have the expertise to perform model verification required. It may not be feasible to rely entirely on consultants to assist the industry with performing unit verification within a short timeframe such as a 5 year period; possibly leading to compliance violations by unfortunate Generator Owners. The 10 year implementation timeframe will provide the industry adequate time to verify the models and data for the excitation control systems and also develop expertise for performing these verifications. **Regarding the second comment, from the time it is decided that model verification is necessary, one year is allowed to capture the recording of the equipment response to an appropriate voltage excursion. One year is not an unreasonable amount of time to perform a staged test or to capture an ambient event. After the event is captured, only 180 days is provided for the completion of model verification.** **Regarding the third comment, the SDT believes that the periodicity of capturing events and subsequently finishing the verification including the documentation is not an activity directly related to the reliability of the BES. The Attachment has been re-worked for clarity in the current draft.** **Regarding the fourth and fifth comment, Attachment 1 has been re-worked for clarity in the current draft.** **Regarding the sixth comment, both the second and third bullets in Requirement 3 allow the Transmission Planner a process to address inaccurate models with the Generator Owner.** **Regarding the seventh comment, the SDT thanks you for catching this oversight and has made the correction.** **Regarding the eight comment, the SDT agrees.** **Regarding the ninth comment, the SDT removed the term “local grid codes”. Regarding the other terms, the SDT feels that they are terms that are well understood by industry.** **Regarding the tenth comment, the SDT used the term “unit” for a single generating unit, the term “plant” for sites with multiple units, and “facility” when appropriate for either a single unit or a plant.** **Regarding the eleventh comment, the SDT thanks you for your observation and has modified M4 appropriately.**		
RFC	Yes	RFC offers the following suggestions regarding the Violation Severity Levels:1. VSL for R1 - There is a disconnect between the date listed in the VSLs and requirement. The timeframe for the “Lower” VSL starts at 90 calendar days though the requirement states “within 30 calendar days”. Where does an entity fall if they provide instructions 45 calendar days of receiving the request? Based on the current VSLs, they would not even fall under the “Lower” VSL.2. VSL for R3 - To be consistent with the language in the “Severe” VSL, add the following words to the end of the “Lower”, “Moderate” and “High” VSLs: “...as specified in Requirement R3.” Or conversely remove this language from the “Severe” VSL and replace with “R3”.3. VSL for R4 - To be consistent with the language in the “Severe” VSL, add the following words to the end of the “Lower”, “Moderate” and “High” VSLs: “...as specified in Requirement R4.” Or conversely

Organization	Yes or No	Question 4 Comment
		remove this language from the "Severe" VSL and replace with "R4".4. VSL for R5 - To be consistent with the language in the "Severe" VSL, add the following words to the end of the "Lower", "Moderate" and "High" VSLs: "...as specified in Requirement R5." Or conversely remove this language from the "Severe" VSL and replace with "R5".5. VSLs for R6 - To be consistent with the language in the "Severe" VSL, add the following words to the end of the "Lower", "Moderate" and "High" VSLs: "...as specified in Requirement R6." Or conversely remove this language from the "Severe" VSL and replace with "R6".
Response: The SDT thanks you for your comment. Regarding your first comment, Requirement 1 has been corrected to specify 90 days instead of 30 days. This resolves the discrepancy between the Requirement and the Lower VSL. **Regarding your remaining comments, the language in the Severe VSL for R3, R4, R5, and R6 was revised to match the format of the other VSLs.**		
Consolidated Edison Co. of NY, Inc.	Yes	Requirement R5 - Please define the term "technically justified." We recommend using wording similar to Comment form paragraph 8) in that definition:"[S]upply technical justification that demonstrates either a) the unit affects a stability limit, or b) the simulated unit response does not match a measured unit response (most likely captured during a system disturbance event)."
Response: The SDT thanks you for your comment. Regarding the last comment, several comments expressed concern with the new Requirement added to the standard giving the Planning Coordinator authority to require model review for a unit not specified in the standard Applicability section. The SDT added this language to the draft standard after considering industry comments to the first posting noting that the Applicability section is a subset of the Compliance Registry criteria. Based on the latest round of industry feedback, the SDT now proposes Applicability Section language allowing the Planning Coordinator to request additional model information (possibly model verification) only if technical justification demonstrates the simulated unit response does not match the measured unit response. Original technical justification language for units that affect a stability limit has been removed from the standard. To emphasize for understanding, the SDT points out only units that meet or exceed the Registry Criteria unit MVA thresholds (> 20 MVA) are subject to Requirement R5. This observation should allay concern the Requirement could be misused inappropriately. Keep in mind only units identified in the Registry Criteria and not included in the draft standard Applicability Section can be requested to have a model review.		
PPL Electric Utilities	Yes	1. Each requirement can be accomplished by itself; but the 90 day vs 60 day vs 180 days on the various 12 requirements will likely create documentation confusion for communication and data retentions. Suggest that the draft be simplified to enhance coordination amongst requirements by applying a single time frame for completion of the requirements.2. Paras. R2 and R2.1.1 are not clearly worded. The present R2 text should end after the word "software;" and para. R2.1.1 should state that "Verification consists of developing one or more models that collectively include the following information:"The present R2.1.1 text, "acceptable to the Transmission Planner," is not included in this suggested revision to make it clear that the R2 Violation Severity Levels later in MOD-026-1 pertain to a GO's first submittal of a verified model, and the R3 Violation Severity Levels deal with failure to meet follow-up requirements if the

Organization	Yes or No	Question 4 Comment
		Transmission Planner finds the first submittal unacceptable. This distinction is particularly important given the compliance criteria ambiguity discussed in comment #3 below. If on the other hand it was intended that models achieve verified status only after being accepted by the Transmission Planner, the term "verified model(s)" in the R2 Violation Severity Levels should be replaced with, "initial submittal of proposed-verified model(s)". 3. There is presently no definition of the voltage excursion magnitude and intensity or the recording instrumentation sampling rate required for a valid verification event, nor are there any specifics regarding how closely the model must match the recorded response. The references in MOD-026 provide guidance but not necessarily NERC pass/fail criteria, especially since Transmission Planners may differ in their preferences. Perceived shortcomings in these respects would presumably trigger the Transmission Planner expression of concern described in para. R3, but it would be better to establish the rules up-front rather than addressing the matter only after a GO has attempted to comply with MOD-026.4. The definition of a "technically justified request" in para. R5 is unclear. Does this term apply only if a model fails to meet the requirements of R6.1-R6.3, or can there be other reasons? In the latter case the wording of the R5 Violation Severity Levels should be modified to start the clock only after agreement has been reached that a request is technically justified.5. The means by which a walk-down would lead to identification of model parameters in para. 5.2 is not understood.

Response: The SDT thanks you for your comment. (1) The SDT believes it is better for industry to have 180 days to perform model verification activities in lieu of establishing a universal 60 day period to perform all activities required just to achieve timeframe consistency among the Requirements.

(2) The SDT believes language is clear following removal of the word "collectively" from the paragraph. The SDT also points out that standard language proposed is for facilitating verification of the dynamic model, and not development of the dynamic model.

(3) The standard states "what is required" but not "how to accomplish what is required". The SDT considered ways to quantify a method for evaluating how well the equipment's measured response matches the model's predicted response. However, since a generally accepted technique or criteria for making this quantitative assessment does not exist, the SDT believes that the peer review process incorporated into the standard will ensure model quality. The SDT believes all entities involved with the peer review process have common purpose to develop an accurate excitation control system model. It should be noted that the standard is written so that the Generator Owner "owns' the model, and as such, even with the peer review process described, the Generator Owner has final say on the voltage excursion used, including sampling rate, for model verification as well as determining if the equipment recorded response satisfactorily matches the model's predicted response. The Generator Owner should not be concerned with "acceptance criteria" proposed by a transmission entity.

(4) The "technical justification" is not related to Requirements R6.1 – R6.3. These requirements only address if the model is useable by integrating successfully into the Transmission Planner's dynamic simulation software. Several comments expressed concern with the new Requirement added to the standard giving the Planning Coordinator authority to require model review for a unit not specified in the standard Applicability section. The SDT added this language to the draft standard after considering industry comments to the first posting noting that the Applicability section is a subset of the Compliance Registry criteria. Based on the latest round of industry feedback, the SDT now proposes Applicability Section language allowing the Planning Coordinator to request additional model information (possibly model verification) only if technical justification demonstrates the simulated

Organization	Yes or No	Question 4 Comment
unit response does not match the measured unit response. Original technical justification language for units that affect a stability limit has been removed from the standard. To emphasize for understanding, the SDT points out only units that meet or exceed the Registry Criteria unit MVA thresholds (> 20 MVA) are subject to Requirement R5. This observation should allay concern the Requirement could be misused inappropriately. Keep in mind only units identified in the Registry Criteria and not included in the draft standard Applicability Section can be requested to have a model review. **(6) The “walk down” to correct model parameters could be as simple as identifying in the field that equipment gain or limit setting values are incorrectly represented in the model.**		
American Transmission Company	Yes	Please give consideration to the following suggestions:1. In Applicability, 4.2, Include the explanation that “average capacity factor is the average of all the unit or plant output values compared to the gross nameplate rating value” since some have asked how this value is defined and calculated.2. In Applicability, 4.2.4 - add “Transmission Planner” to this item because Transmission Planners may also have insight and the means to provide technical justification for the inclusion of specific units in their system.3. In Requirements, R1, bullet 1 - remove this bullet 1, or combine it with bullet 2, because it appears to be redundant with bullet 2, rather than distinctly different.4. In Requirements, R2.1.4 - replace “model structure and data” with “block diagram and model parameters” for more clarity.5. In Requirements, R2.1.6 - replace “model structure and data” with “manufacturer, model number, block diagram, and model parameters” for more clarity and specificity.6. In Requirements, R2.1.6 - add “and indicate whether the power system stabilizer is planned to be in-service and out-of-service in the planning horizon.”7. In Requirements, R4 - revise the text from “within 180 days of making changes” to “within 180 prior to making changes” for more clarity.
Response: The SDT thanks you for your comment. The responses below are numbered to match the comments. **1. To clarify concerns regarding calculating unit capacity factor, the SDT has incorporated into the standard the capacity factor calculation specified in Appendix F of the GADS Data Reporting Instructions (which can be obtained from the NERC website).** **2. Several commenters expressed concern with the new Requirement added to the standard giving the Planning Coordinator authority to require model review for a unit not specified in the standard Applicability section. The SDT added this language to the draft standard after considering industry comments to the first posting noting that the Applicability section is a subset of the Compliance Registry criteria. Based on the latest round of industry feedback, the SDT now proposes Applicability Section language allowing the Planning Coordinator to request additional model information (possibly model verification) only if technical justification demonstrates the simulated unit response does not match the measured unit response. Original technical justification language for units that affect a stability limit has been removed from the standard. To emphasize for understanding, the SDT points out only units that meet or exceed the Registry Criteria unit MVA thresholds (> 20 MVA) are subject to Requirement R5. This observation should allay concern the Requirement could be misused inappropriately.**		

Organization	Yes or No	Question 4 Comment
3. Regarding bullets 1 and 2 in Requirement R1, the information described in each bullet is distinctly different. The first bullet “Instructions on how to obtain the list of acceptable excitation control system and plant volt/var control function model for use in dynamic simulation” is literally just a list of acceptable model types. For many entities, especially those which utilize dynamic simulation software that is widely utilized, this is all the information that they will require. The second bullet, " Instructions on how to obtain the Transmission Planner’s software manufacturer’s dynamic excitation control system and plant volt/var control function system model library block diagrams and/or data sheets”, pertains to the actual block diagrams and/or data sheets (as opposed to only a “list” of model types in bullet 1). The information in the second bullet will likely be required by entities that do not use dynamic simulation software that is widely utilized. **4. The SDT intends to keep the phrase “Model Structure” since a model structure is a block diagram without parameter values.** **5. The language of R2.1.4 has been revised to align with the style of R2.1.6.** **6. Regarding R2.1.6, the SDT does not believe it is appropriate to communicate PSS status as part of a modeling standard.** **7. The SDT believes that the intent of Requirement R4 is captured with the current language. The standard does not address notification regarding equipment changes, nor does it address the transmittal of preliminary model data from the equipment manufacturer; it addresses a requirement for the verification of the model for the “changed out” equipment. The models for the new equipment cannot be verified until the equipment is installed and available.**		
Indiana Municipal Power Agency	Yes	IMPA appreciates the efforts of the SDT on getting the applicability section correct for the plants or units that truly impact the stability response of the BES. However, the standard does contain a loop-hole to the SDT's intent. On page 3 of 16, footnote 4 to the applicabilty section (4.2.4)states: "a technical justification for verifying each of those units or plant(s) that demonstrates through simulation and/or measured response that the unit or plant affects a stability limit, or evidence that the simulated unit or plant response does not match measured unit or plant response". The first or word in that sentence should be replace with the word "and". A technical justification for verifying each of those units and plant(s) that demonstrates through simulation and/or measured response that the unit or plant affects a stability limit should both be required. By requiring both of these items, it might prevent units the size of 1MW from having to perform this standard.In addition, who qualifies what is a technically justified unit or what is a technical justification? Past history as shown that technicaly justifications have been used "losely" by different regions and entities. The Generator Owner should have some means of appealing this request by the Planning Coordinator.
Response: The SDT thanks you for your comment. Several commenters expressed concern with the new Requirement added to the standard giving the Planning Coordinator authority to require model review for a unit not specified in the standard Applicability section. The SDT added this language to the draft standard after considering industry comments to the first posting noting that the Applicability section is a subset of the Compliance Registry criteria. Based on the latest round of industry feedback, the SDT now proposes Applicability Section language allowing the Planning		

Organization	Yes or No	Question 4 Comment
Coordinator to request additional model information (possibly model verification) only if technical justification demonstrates the simulated unit response does not match the measured unit response. Original technical justification language for units that affect a stability limit has been removed from the standard. To emphasize for understanding, the SDT points out only units that meet or exceed the Registry Criteria unit MVA thresholds (> 20 MVA) are subject to Requirement R5. This observation should allay concern the Requirement could be misused inappropriately.

Consideration of Comments on Generator Verification – PRC-024-1 — Project 2007-09

The Generator Verification Drafting Team thanks all commenters who submitted comments on the Second Posting of PRC-024-1 Generator Performance During Voltage and Frequency Excursions. These standards were posted for a 45-day public comment period from June 15, 2011 through August 1, 2011. Stakeholders were asked to provide feedback on the standards and associated documents through a special electronic comment form. Also included in this report are comments received from the initial ballots and non-binding polls conducted during the last ten days of the 45-day comment period. There were 66 sets of comments, including comments from approximately 185 different people from approximately 120 companies representing all 10 of the 10 Industry Segments as shown in the table on the following pages.

All comments submitted may be reviewed in their original format on the standard's project page:

http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President of Standards and Training, Herb Schrayshuen, at 404-446-2563 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

Summary Consideration:

The GVSDT proposed two new definitions for Voltage Excursion and Frequency Excursion. A slight majority agreed with the proposed definitions. The majority of "No" votes disagreed with the voltage excursion portion of the question while there was only one vote disagreeing with the frequency excursion portion. After reviewing all comments the SDT made the following changes:

1. The two new terms proposed in the standard were removed. The voltage and frequency excursion values are now located in the requirements where they apply.

2. Attachment 1 (Off Nominal Frequency Capability Curve) was revised to clarify the "no trip" zone.

3. Attachment 2 (Voltage Ride-Through Time Duration Curves) has been clarified. The per unit voltage base for these curves is the base voltage specified in the system models used by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission Systems at the point of interconnection to the Bulk Electric System (BES). In addition, the

[1] The appeals process is in the Standard Processes Manual: http://www.nerc.com/files/Appendix_3A_Standard_Processes_Manual_Rev%201_20110825.pdf

definition was modified to include the phrase, "voltages in the curve assume minimum phase-to-ground or phase-to-phase voltage for the low voltage duration curve and maximum phase-to-ground or phase-to-phase voltage for the high voltage duration curve."

The GVSDT proposed Requirements R1 and R2 to detail the required frequency and voltage protective relaying settings for both new and existing units or generating plant/facilities that opt to activate these relays. Stakeholders were asked if they believed that the draft of these two requirements, including footnote 1, clarified that a Generator Owner is not required to have protective relaying installed or set for these functions. Stakeholders generally agreed that footnote 1 does clearly state that a Generator Owner is not required to have protective relaying installed or set for frequency or voltage protection. Many of the stakeholders made additional comments beyond the scope of the question regarding the intention of Requirements R1, R2, and R3 and provided clarifying language examples. In response, the SDT made the following changes:

1. The Requirement Parts were revised in Requirement R1. Part 1.5 was moved into the body of R1. The requirement now reads:

   "R1. Each Generator Owner that has generator frequency protective relaying[2] activated to trip its new or existing generating unit or generating plant shall set such protective relaying so that it does not trip within the "no trip zone" of PRC-024 Attachment 1, unless the Generator Owner has documented and communicated each equipment limitation in accordance with Requirement R3 for an existing generating unit. *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*

   1.1. A generating unit or generating plant is allowed to trip within the "no trip zone" if the frequency rate of change is more than 2.5 Hz/sec.

   1.2. A generating unit or generating plant may trip if the protective functions (such as out-of-step or loss-of-field functions) operate due to an impending or actual loss of synchronism or due to instability in power conversion control equipment."

2. Requirement Part 2.1.1 was removed from Requirement R2. The body of the requirement and the remaining Parts were modified to clarify intent. The requirement now reads:

   "R2. Each Generator Owner that has generator voltage protective relaying1 activated to trip its new or existing generating unit or generating plant shall set its protective relaying such that it does not trip as a result of a voltage excursion (at the point of interconnection) that remains within the "no trip zone" of PRC-024 Attachment 2 caused by an event on the transmission system external to the generating plant per the following operating conditions and relay settings, unless the Generator Owner has documented and

[2] Each Generator Owner is not required to have frequency or voltage protective relaying (including but not limited to frequency and voltage protective functions for discrete relays, volts per hertz relays evaluated at nominal frequency, impedance relays, voltage controlled overcurrent relays, multi-function protective devices or protective functions within control systems that directly trip or provide tripping signals to the generator based on frequency or voltage inputs) installed or activated on its unit.

communicated each non-protection system equipment limitation in accordance with Requirement R3 for an existing generating unit2 or generating plant.: [Violation Risk Factor: High] [Time Horizon: Long-term Planning]

2.1. When operating within 95 percent to 105 percent of rated generator terminal voltage and during the transmission system operating conditions defined in PRC-024 Attachment 2, with the following clarifications:

2.1.1. If a Transmission Planner's study (based on the location specific voltage recovery characteristics) allows less stringent voltage relay settings than those required to meet PRC-024 Attachment 2, set voltage relays either to meet the Transmission Planner's voltage recovery characteristics or the characteristics in PRC-024 Attachment 2.

2.1.2. Tripping a generator in accordance with a Special Protection System (SPS) or Remedial Action Scheme (RAS) is acceptable in the "no trip zone" of PRC-024 Attachment 2.

2.1.3. If clearing a system fault necessitates disconnecting a generator, this action is acceptable within the "no trip zone" specified in PRC-024 Attachment 2.

2.1.4. A generating unit or generating plant may trip if the protective functions (such as out-of-step or loss-of-field functions) operate due to an impending or actual loss of synchronism or due to instability in power conversion control equipment."

3. Requirement R3 was changed to clarify the intent of non-protection system limitations and when such limitations must be addressed. The requirement now reads:

"3.1. The Generator Owner shall communicate the documented limitation, or the removal of a previously documented limitation, to its Reliability Coordinator, Planning Coordinator, Transmission Operator and Transmission Planner within 30 calendar days of identifying the limitation to ensure the accuracy of planning studies and system modeling studies. The existing generating unit or generating plant becomes subject to the full extent of Requirements R1 and R2 coincident with either of the following conditions:

- The equipment causing the limitation is repaired or replaced with equipment that removes the limitation.

- The equipment causing the limitation is modified or upgraded resulting in an increase of generator nameplate capacity rating greater than 10 percent (cumulative from the first effective date of this Standard)."

During the Quality Review process prior to the previous posting, a new requirement R4 was added based on the comments of the reviewers. This resulted in requirement numbers being incorrect for Questions 3 and 4. ***The GVSDT will ask these two questions again on the upcoming comment form for the successive ballot.*** A summary of the comments received is in the following paragraphs.

Relating to question 3: The GVSDT added Requirement R5 to allow owners of existing units or generating plant/facilities to provide an estimate of the performance of the units during frequency and voltage excursions. This information was intended to provide Transmission Planners with information useful in performing planning studies. In the comment form, the question erroneously asked about R4 rather than R5. A few commenters made comments regarding R4 while the vast majority commented related to R5.

Several commenters felt that there is no additional reliability gain in Requirement R5. Their comments indicated that the information is not useful and that there is little technical value in this information. A few commenters expressed the opinion that it is very difficult, if not impossible, to predict the consistent response of the balance of (a generating) plant to the system excursions shown in Attachment 1 & 2. Further, several commenters expressed the opinion that it is unlikely that any steam plant will survive for the entire “no trip zones” of the attachments. Other, less frequent, comments included the following:

- R1-R4 adequately fulfill the purpose of the standard.
- Standard requirements should be limited to devices that directly respond to the generator V and F – write standard to exclude all aux system equipment.
- The TP needs only to know when the protective relaying V-t and F-t will trip the unit so the models can switch the generators off when the simulated V and F levels are reached.
- 30 days is too short for a response.

Based on comments received, the GVSDT revised R5 (which is now R4) to:

“R4. Each Generator Owner of an existing generating unit or generating plant shall provide an estimate of that unit’s performance during Frequency/Voltage Excursions to each requesting entity (Reliability Coordinator, Planning Coordinator, Transmission Operator or Transmission Planner that monitors or models the associated generating unit or generating plant) within 60 calendar days of receipt of a written request, to ensure the accuracy of planning studies and system modeling studies. The estimate shall include: [Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]

4.1. An estimate of the time duration the existing generating unit or generating plant will remain connected (considering performance of the auxiliary systems as well as the generator) as a result of a frequency excursion or a voltage excursion defined by the voltage or frequency profile at the point of interconnection described by dynamic simulation provided by the Transmission Planner. If the Generator Owner expects the existing unit, generating plant will remain connected for longer than 10 minutes, the estimate should indicate the existing unit or generating plant is not expected to trip.

4.2. Identification of the bases for the estimates developed for 4.1 which may include, but is not limited to: experience, actual event histories, or sound engineering judgment.”

Relating to Question 4: The question mistakenly referred to Requirement R5 due to changes to the standard made in response to the Quality Review. This error was observed by the stakeholders and the SDT believes the responses accurately reflect the feelings of industry to the intended question. The slight majority of stakeholders agree with the requirement while some stakeholders indicated that they do not feel the requirement is technically achievable. Based on the comments received, no major changes were made to Requirement R6 (now R5).

The GVSDT proposed voltage ride-through tables for High Voltage Ride Through (HVRT) and Low Voltage Ride Through (LVRT) time durations in Attachment 2. These tables a specify time duration of up to 600 seconds that a unit or a generating plant/facility should ride through a voltage excursion. Stakeholders were asked if they agree with the proposed times in the tables. A majority of stakeholders agreed with the time values. Many of those that responded in the negative to the question indicated that they felt the 600 seconds duration was acceptable but had other concerns with the standard. No substantive suggestions were made for revising R6. As a result, the GVSDT did not make any changes to Attachment 2.

Index to Questions, Comments, and Responses

1. There are two new terms proposed in this standard. "Frequency Excursion" and "Voltage Excursion". The former defined as an exceedance of system frequency beyond a continuous operating band; 60±0.5 Hertz. The latter defined as an exceedance of system voltage beyond a continuous operating band; ±5% of scheduled voltage. Do you agree with these new terms and their definitions? If not, please explain. 17

2. Requirements R1 and R2 detail the required frequency and voltage protective relaying settings for both new and existing units or generating plant/facilities that opt to activate these relays. Does the current draft of these two requirements, including footnote 1, clarify that a Generator Owner is not required to have protective relaying installed or set for these functions? If you do not believe the requirement is clear, please provide alternative language to clarify the intent. 30

3. Requirement R4 has been added for owners of existing units or generating plant/facilities to provide an estimate of the performance of the units during frequency and voltage excursions. This information is intended to provide Transmission Planners with information useful in performing planning studies. Do you agree with this approach? If not please explain and provide alternative language. 50

4. Requirement R5 requires a Generator Owner's new unit or generating plant/facility to be able to stay on line when exposed to point-of-interconnection frequency or voltage excursions depicted in the curves of Attachment 1 and Attachment 2. Do you believe this requirement is technically achievable for new units or generating plant/facilities? Please provide comments supporting your answer. 67

   Please provide along with your comment, what you believe the timeframe is needed to implement this requirement. 67

5. The voltage ride-through Tables HVRT and LVRT Duration in Attachment 2, specify time duration of up to 600 seconds that a unit or a generating plant/facility should ride through a voltage excursion. Do you agree with this time duration value? If not, please provide an alternative value and supporting information in the comments. 84

6. Do you have any other questions or concerns with the proposed standard that have not been addressed? If yes, please explain... 98

1. There are two new terms proposed in this standard. "Frequency Excursion" and "Voltage Excursion". The former defined as an exceedance of system frequency beyond a continuous operating band; 60±0.5 Hertz. The latter defined as an exceedance of system voltage beyond a continuous operating band; ±5% of scheduled voltage. Do you agree with these new terms and their definitions? If not, please explain.

Summary Consideration: Stakeholders were evenly divided regarding the proposed definitions. The majority of "No" votes disagreed with the voltage excursion portion of the question while there was only one vote disagreeing with the frequency excursion portion.

After reviewing all comments the SDT made the following changes:

1. **The two new terms proposed in the standard were removed. The voltage and frequency excursion values are now located in the requirements where they apply.**
2. **Attachment 1 (Off Nominal Frequency Capability Curve) was revised to clarify the "no trip" zone.**
3. **Attachment 2 (Voltage Ride-Through Time Duration Curves) has been clarified. The per unit voltage base for these curves is the base voltage specified in the system models used by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission Systems at the point of interconnection to the Bulk Electric System (BES). In addition, the definition was modified to include the phrase, "voltages in the curve assume minimum phase-to-ground or phase-to-phase voltage for the low voltage duration curve and maximum phase-to-ground or phase-to-phase voltage for the high voltage duration curve."**

Organization	Yes or No	Question 1 Comment
Occidental Chemical	Negative	1. There are two new terms proposed in this standard. "Frequency Excursion" and "Voltage Excursion". The former defined as an exceedance of system frequency beyond a continuous operating band; 60Â±0.5 Hertz. The latter defined as an exceedance of system voltage beyond a continuous operating band; Â±5% of scheduled voltage. Do you agree with these new terms and their definitions? If not, please explain. No: Comments: Ingleside Cogeneration LP agrees that the continuous frequency specification is unambiguous and reasonable. However, the voltage operating specification needs to tie directly to the Transmission Operator's voltage or Reactive Power schedule developed in compliance with VAR-001. We believe this was the drafting team's intent, but the definition does not clearly indicate that this is the case.
Response: Thank you for your comments. The two new terms proposed in the standard have been removed. The voltage/frequency excursion values are incorporated in the requirements that they are applied.		

Organization	Yes or No	Question 1 Comment
The voltage excursion (Attachment 2) has been further defined as the per unit voltage base specified in the system models used by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission System at the point of interconnection to the BES.		
Ameren Energy Marketing Co.; Amerenue; Ameren Services	Negative	Comment (1) Voltage Excursion definition should be based on rated system operation voltage which is what the protection is based on, not scheduled voltage which may vary. (2) Unless written to exclude all auxiliary system equipment which may result in a unit shut down, it will be impossible to determine this probability with any reasonable accuracy. For example, where auxiliary motors would stall and trip off, or contactors drop out would be variable.
Response: Thank you for your comments. The two new terms proposed in the standard have been removed. The voltage/frequency excursion values are incorporated in the requirements that they are applied. **With regard to comment 1, R2 has been revised to define that *generator* protective relaying to ride through a system fault (three-phase with clearing time of 9 cycles or less) at the point of interconnection with the unit operating between 95% and 105% of rated voltage. Protective systems at the generator are required to not trip for a voltage excursion at the point of interconnection. The voltage excursion (Attachment 2) has been further defined as the per unit voltage base specified in the system models used by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission System at the point of interconnection to the BES.** **With regard to comment 2, R4 was revised to remove the probability of a unit (including auxiliaries) remaining connected to the system. R4 takes into consideration a voltage recovery profile at the point of interconnection using the dynamic study results from the transmission planner/coordinator. Thank you for your response. The two new terms proposed in the standard have been removed. The voltage/frequency excursion values are incorporated in the requirements that they are applied.**		
Pepco Holdings Incand Affiliates	No	Suggest replacing the term "scheduled voltage" with "nominal operating voltage". Voltage schedules may change over time, whereas "nominal" or "rated" voltages do not. Also, the protective systems are usually set based on voltage excursions above, or below, "rated" or "nominal" voltage.
Response: Thank you for your comments. The two new terms proposed in the standard have been removed. The voltage/frequency excursion values are incorporated in the requirements that they are applied. **The voltage excursion (Attachment 2) has been further defined as the per unit voltage base specified in the system models used by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission System at the point of interconnection to the BES. R2 has been revised to define that *generator* protective relaying to ride through a system fault (three-phase with clearing time of 9 cycles or less) at the point of interconnection with the unit operating between 95% and 105% of rated voltage. Protective systems at the generator are required to not trip for a voltage excursion at the point of interconnection.**		
Northeast Power Coordinating Council	No	Any requirement that requires reporting based on a deviation greater than a specified threshold, that threshold should be included in that requirement, refer to R5 as an example. With those stipulations, those

Organization	Yes or No	Question 1 Comment
		new terms are not needed.
Response: Thank you for your comments. The SDT team agrees with your comment and has removed the new terms. The voltage/frequency excursion values are incorporated in the requirements that they are applied.		
SERC Generation Sub-committee (GS)	No	The SERC generation sub-committee (GS) believes that 60 HZ +/- 0.5 Hz is normal but the voltage schedule +/- 5% is not necessarily normal. The normal voltage should be consistent with VAR-002 requirements and defined by the voltage schedule for the unit. Change the verbiage to "... exceedance of system voltage beyond the applicable voltage schedule."
Response: Thank you for your comments. The two new terms proposed in the standard have been removed. The voltage/frequency excursion values are incorporated in the requirements that they are applied. **The voltage excursion (Attachment 2) has been further defined as the per unit voltage base specified in the system models used by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission System at the point of interconnection to the BES.**		
Idaho Power - Power Production	No	Basing the voltage excursion definition on scheduled voltage is troublesome, as "scheduled" voltage can change over time, and in some cases, varies seasonally. Protection and limiter settings are not, and should not, be adjusted to address varying schedules. That said, simply using nominal voltage instead of scheduled voltage is probably not the answer either, as it is not unusual to have POI scheduled voltages of 1.05 pu or higher.
Response: Thank you for your comments. The voltage excursion (Attachment 2) has been further defined as the per unit voltage base specified in the system models used by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission System at the point of interconnection to the BES. R2 has been revised to define that *generator* protective relaying to ride through a system fault (three-phase with clearing time of 9 cycles or less) at the point of interconnection with the unit operating between 95% and 105% of rated voltage. Protective systems at the generator are required to not trip for a voltage excursion at the point of interconnection.		
SPP Reliability Standards Develpment Team	No	We believe that +-5% is ok for normal operating conditions but this doesn't address contingencies being taken or a time frame. The curve in attachment 2 doesn't seem to correspond with the definition as proposed. We are also unclear about the term continuous. We think this means from 0 to infinite. This graph indicates at 600s one would operate within the .95 and 1.05 normal conditions. SPP's regional criteria shows that during a contingency we can operate at a +5% -10% bandwidth.
Response: Thank you for your comments. **The two new terms proposed in the standard have been removed. The voltage/frequency excursion values are incorporated in the requirements that**		

Organization	Yes or No	Question 1 Comment
they are applied. The voltage excursion (Attachment 2) has been further defined as the per unit voltage base specified in the system models used by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission System at the point of interconnection to the BES. **The standard was not intended to apply to contingency operations.**		
Dynamics Review Subcommittee	No	Exceedance implies that the frequency is greater than desired frequency. Since the intent is to identify frequencies greater or less than a specified amount from the desired frequency, replacing the word “exceedance” with “deviation” and “beyond” with “outside” seems more appropriate.
Response: Thank you for your comments. The two new terms proposed in the standard have been removed. The frequency chart was revised to clarify the “no trip” zone.		
Santee Cooper	No	We’re not sure these definitions serve a useful purpose, since, later on in the standard, these excursions are defined by the curves in the attachments.
Response: Thank you for your comments. The SDT team agrees with your comment and has removed the new terms. The voltage/frequency excursion values are incorporated in the requirements that they are applied.		
NERC Staff Technical Review Team	No	NERC staff believes it is unnecessary to define these terms to achieve the reliability objective of this standard. We further note that the proposed definitions of these terms are in conflict with usage of the phrases frequency excursion and voltage excursion in other standards and a defined glossary term. A review of existing NERC standards and the NERC glossary identifies the following inconsistencies:(1) Standard BAL-003-0.1b “requires a Balancing Authority to analyze its response to frequency excursions as a first step in determining its frequency bias setting.” Events identified for use in analyzing and setting requirements for frequency response are associated with frequency deviations of less than Â±0.5 Hz, and not necessarily deviating from 60 Hz.(2) Standard EOP-004-1 requires reporting for “any action taken by a Generator Operator, Transmission Operator, Balancing Authority, or Load-Serving Entity that results in sustained voltage excursions equal to or greater than Â±10%.”(3) Standard PRC-006-1, refers to “system frequency excursions below the initializing set points of the UFLS program.” The initializing setpoints of UFLS programs vary by region.(4) The defined term, Disturbance Monitoring Equipment, includes “Dynamic Disturbance Recorders (DDRs), which record incidents that portray power system behavior during dynamic events such as low-frequency (0.1 Hz - 3 Hz) oscillations and abnormal frequency or voltage excursions.”We also observe inconsistency within the draft PRC-024-1 which refers to “a Frequency Excursion defined by the curves in PRC-024 Attachment 1 and a Voltage Excursion defined by the curves in PRC-024 Attachment 2,” which is in conflict with the proposed definitions.Given the range of contexts in which the phrases frequency excursion and voltage excursion are used we believe it is most appropriate that each standard identify the excursions of interest in the context of that standard, rather than establishing defined terms with specific numerical values.

Organization	Yes or No	Question 1 Comment
Response: Thank you for your comments. The SDT team agrees with your comment and has removed the new terms. The voltage/frequency excursion values are incorporated in the requirements that they are applied.		
TVA - GO	No	TVA believes that 60 HZ +/- 0.5 Hz is normal but the voltage schedule +/- 5% is not necessarily normal. The normal voltage should be consistent with VAR-002 requirements and defined by the voltage schedule for the unit. Change the verbiage to "... exceedance of system voltage beyond the applicable voltage schedule
Response: Thank you for your comments. The two new terms proposed in the standard have been removed. The voltage/frequency excursion values are incorporated in the requirements that they are applied. **The voltage excursion (Attachment 2) has been further defined as the per unit voltage base specified in the system models used by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission System at the point of interconnection to the BES.**		
Westar Energy	No	We agree with the frequency excursion defined as +/-0.5Hz.We agree that Â±5% is appropriate for normal operating conditions. However, this does not address contingencies or timeframes. The SPP regional criteria allows for a +5% to -10% change from nominal voltage on load serving buses under single contingency conditions. The Voltage Ride-Through Time Duration Curve in Attachment 2 does not appear to correspond with the proposed definition. The Voltage Ride-Through Time Duration Curve in Attachment 2 indicates that at 600 seconds, one would operate within the .95 and 1.05 normal conditions. SPP's regional criteria states that we can operate at a +5% to -10% of nominal voltage on load serving buses during a contingency. FERC pro-forma Generator Interconnection Agreement requirements should also be considered in the development of this definition. We propose that the SDT consider defining continuous. We are unclear if continuous means from zero to infinite.
Response: Thank you for your comments. The two new terms proposed in the standard have been removed. The voltage/frequency excursion values are incorporated in the requirements that they are applied. The voltage excursion (Attachment 2) has been further defined as the per unit voltage base specified in the system models used by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission System at the point of interconnection to the BES. **The standard was not intended to apply to contingency operations.**		
Progress Energy	No	PE suggests using the term "exceeding" rather than "exceedance". PE furthermore believes that 60 HZ +/- 0.5 Hz is appropriate but does not agree that +/- 5% for voltage is an appropriate bandwidth for "normal". Any threshold must agree with VAR-002. Along with a clarification of what a voltage schedule is (i.e. target, bandwith).
Response: Thank you for your comments. The two new terms proposed in the standard have been removed. The voltage/frequency excursion values		

Organization	Yes or No	Question 1 Comment
are incorporated in the requirements that they are applied. **The voltage excursion (Attachment 2) has been further defined as the per unit voltage base specified in the system models used by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission System at the point of interconnection to the BES.**		
PacifiCorp	No	The definition for Voltage Excursion provided in the most recent draft of PRC-024-1 is closer to the definition of a voltage deviation. The Voltage Excursion definition should be modified to include a time duration component, e.g. “fast transition” of system voltage beyond the continuous operating band of Â±5% of scheduled voltage. Otherwise, a very slow voltage transition could be considered a voltage excursion if it exceeded the voltage band, thereby missing the intent of and time frames set forth in Attachment 2. A similar comment is applicable for Frequency Excursion. A transition time duration is key to the definition of both Voltage Excursion and Frequency Excursion due to the significant impact that these parameters can have on a generating facility.
Response: Thank you for your comments. The two new terms proposed in the standard have been removed. The voltage/frequency excursion values are incorporated in the requirements that they are applied. **The voltage excursion (Attachment 2) has been further defined as the per unit voltage base specified in the system models used by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission System at the point of interconnection to the BES. The fast transition is considered with the transmission planner/coordinator performing a dynamic study that provides a voltage recovery profile.**		
Tri-State Generation and Transmission, Inc.	No	We don't think exceedance is a word. Suggest changing it to "operating outside of a continuous range of 60+/-0.5 Hz".We don't agree with using the phrase "scheduled voltage" as is staed in the question, but the actual standard uses "rated voltage" with which we do agree.
Response: The two new terms proposed in the standard have been removed. The voltage/frequency excursion values are incorporated in the requirements that they are applied. **The voltage excursion (Attachment 2) has been further defined as the per unit voltage base specified in the system models used by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission System at the point of interconnection to the BES. Protective systems at the generator are required to not trip for a voltage excursion at the point of interconnection.**		
Exelon	No	The definitions provided for Frequency Excursion and Voltage Excursion are not consistently applied throughout the Standard. Several of the uses of the term “excursion” (R1.2, R5.1, R5.2, R6, etc...) refer to the graphs in Attachments 1 and 2, which are based on time characteristics. Exelon agrees that 60 HZ +/- 0.5 Hz is reflective of a (normal) continuous operating band; however, the voltage +/- 5% is not necessarily a (normal) continuous operating band of "scheduled voltage". The "scheduled voltage" should be consistent with VAR-001 and VAR-002. VAR-001 Requirement R.4 states:"Each Transmission Operator shall specify a

Organization	Yes or No	Question 1 Comment
		voltage or Reactive Power schedule at the interconnection between the generator facility and the Transmission Owner's facilities to be maintained by each generator."VAR-002 Requirement R.2 states:"[Unless exempted by the Transmission Operator] each Generator Operator shall maintain the generator voltage or Reactive Power output ... as directed by the Transmission Operator."Suggest that the definition for Voltage Excursion is revised to state "an exceedance of system voltage beyond (i.e., outside) nominal operating band as determined by the Transmission Operator"
Response: Thank you for your comments. The two new terms proposed in the standard have been removed. The voltage/frequency excursion values are incorporated in the requirements that they are applied. **The voltage excursion (Attachment 2) has been further defined as the per unit voltage base specified in the system models used by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission System at the point of interconnection to the BES.**		
Independent Electricity System Operator	No	We generally agree with these definitions, but do not see the need to specify the band values, i.e. Â±0.5 Hertz and Â±5%, in them. The two definitions should stay clear of any specific values, which can be specified in the standard, to remain valid if and when the band values vary.
Response: Thank you for your comments. The SDT team agrees with your comment and has removed the new terms. The voltage/frequency excursion values are incorporated in the requirements that they are applied.		
Wisconsin Electric	No	The system can operate without problems within +/- 5% of nominal system voltage under normal conditions. Generator capability curves allow for continuous operation between 95% and 105% of rated voltage. Therefore, the operating band for voltage needs to be expanded beyond +/-5%, perhaps as high as +/- 10%.
Response: Thank you for your comments. The voltage chart (Attachment 2) may be more stringent in your region and can be modified.		
We Energies	No	The system can operate without problems within +/- 5% of nominal system voltage under normal conditions. Generator capability curves allow for continuous operation between 95% and 105% of rated voltage. Therefore, the operating band for voltage needs to be expanded beyond +/-5%, perhaps as high as +/- 10%.
Response: Thank you for your comments. The voltage chart (Attachment 2) may be more stringent in your region and can be modified.		
Duke Energy	No	We are not sure what is the purpose of the voltage excursion definition in this standard. Is excursion measured versus scheduled voltage, or equipment rating?
Response: Thank you for your comments. The voltage excursion (Attachment 2) has been further defined as the per unit voltage base specified in the		

Organization	Yes or No	Question 1 Comment
system models used by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission System at the point of interconnection to the BES.		
US Army Corps of Engineers	No	
Western Electricity Coordinating Council	No	WECC is requesting a regional variance to Requirement 1 that reflects the generator performance requirements of the WECC Coordinated Off-Nominal Frequency Load Shedding Plan. WECC's continuouse operations zone is between 59.4 hZ and 60.6 Hz. Therefore, WECC will need a regional definition of Frequency Excursion to be an exceedance of system frequency beyond a continuous operating band of 60Â±0.6 Hertz.
Response: Thank you for your comments. The SDT team discussed this and a regional variance has been added.		
ISO New England Inc.	No	The term “system voltage” is unclear as to where it is measured. Attachment 2 shows the curve based on voltage at the Point of Interconnection, yet R2.1 refers to voltage at the generator terminals. ISO-NE maintains that the band applies to the voltage as shown in Attachment 2 on the Y axis as the “Point of Interconnection-Voltage (PU). R2.1 should refer to the voltage at the point of interconnection and not the generator terminal voltage. The band shown as .95 p.u to 1.05 p.u. should be widened to at least .90 p.u. to 1.05 p.u. The time duration curve shown in Attachment 2 will need to modified to be consistent with this range for the times at and beyond 600 seconds to be consistent with this change.
Response: Thank you for your comments. **R2 has been revised to define that *generator* protective relaying to ride through a system fault (three-phase with clearing time of 9 cycles or less) at the point of interconnection with the unit operating between 95% and 105% of rated voltage. Protective systems at the generator are required to not trip for a voltage excursion at the point of interconnection. A transmission planner can provide a dynamic study that reflects the voltage recovery profile to be used by the generator owner to assess generator protective relay(s) operating characteristics.** **Attachment 2 may be more stringent in your region and can be modified.**		
Ingleside Cogeneration LP	No	Ingleside Cogeneration LP agrees that the continuous frequency specification is unambiguous and reasonable. However, the voltage operating specification needs to tie directly to the Transmission Operator’s voltage or Reactive Power schedule developed in compliance with VAR-001. We believe this was the drafting team’s intent, but the definition does not clearly indicate that this is the case.
Response: Thank you for your comments. **The two new terms proposed in the standard have been removed. The voltage/frequency excursion values are incorporated in the requirements that**		

Organization	Yes or No	Question 1 Comment
they are applied. The voltage excursion (Attachment 2) has been further defined as the per unit voltage base specified in the system models used by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission System at the point of interconnection to the BES.		
Luminant Energy	No	The frequency is acceptable but the voltage band is confusing. The generator operating range is +/- 5% from rated at full load. Luminant recommends that the voltage excursion be referenced to generator rated voltage.
Response: Thank you for your comments. The two new terms proposed in the standard have been removed. The voltage/frequency excursion values are incorporated in the requirements that they are applied. The voltage excursion (Attachment 2) has been further defined as the per unit voltage base specified in the system models used by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission System at the point of interconnection to the BES.		
Ameren	No	Voltage Excursion definition should be based on rated system operation voltage which is what the protection is based on, not scheduled voltage which may vary.
Response: Thank you for your comments. The two new terms proposed in the standard have been removed. The voltage/frequency excursion values are incorporated in the requirements that they are applied. The voltage excursion (Attachment 2) has been further defined as the per unit voltage base specified in the system models used by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission System at the point of interconnection to the BES. **R2 has been revised to define that *generator* protective relaying to ride through a system fault (three-phase with clearing time of 9 cycles or less) at the point of interconnection with the unit operating between 95% and 105% of rated voltage. Protective systems at the generator are required to not trip for a voltage excursion at the point of interconnection.**		
Consolidated Edison Co. of NY, Inc.	No	Requirement 1, paragraph 1.1 requires that units remain connected, 1.1. When operating within a frequency range of 59.5 Hz to 60.5 Hz, inclusive. Yet the definitions of Frequency and Voltage Excursion could be misinterpreted to apply only to trips occurring when the frequency or voltage at the time of trip-out was outside the normal operating range. We do not believe that it was the intent of the drafting team to exempt units which might trip within the normal operating range during an event. Therefore, we propose to change the focus from Excursions outside a normal operating range to variations within and outside that normal operating range, out to specified limits (the operating envelope). We suggest that the term Frequency and Voltage Excursion be re-defined as variations follows: Frequency [delete “Excursion” add “Variation”] - an [delete “exceedance of system” add “unscheduled, excessive variation in BES”] frequency within a planned continuous operating band, e.g., 60Â±0.5 Hertz, and beyond a planned continuous operating band to specified limits (Attachment 1). Voltage [delete “Excursion” add “Variation”] - an [delete “exceedance of system” add “unscheduled, excessive variation in BES”] voltage within a planned continuous operating band, e.g., 0.95 to 1.00 per unit, and beyond a planned continuous operating band to specified limits (Attachment 2). This definition includes certain types of specified variations: (a) Operation within an allowable normal operating bands,

Organization	Yes or No	Question 1 Comment
		such as voltage variations within an allowed Â±5% of scheduled voltage, e.g. from 0.95 to 1.00 per unit. (b) Operation within a modified scheduled operating band voltage change, such as with the range around a scheduled nominal voltage reduction during a brown-out, where the allowed voltage operating band is intentionally reduced, and (c) Operation up to limits specified and/or referenced in MOD-026. For example, voltage variations either within or outside of the scheduled operating band of 0.95 to 1.05 per unit of nominal, e.g., a 328-362 kV operating band around a 345 kV scheduled nominal voltage. We propose to change the Purpose wording (and similar wording elsewhere) as follows: Purpose: Ensure generating units remain connected during frequency and voltage [delete "excursions" and add "variations"] and ensure expected generating unit performance during frequency and voltage [delete "excursions" and add "variations"] is communicated to Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners for accurate system modeling.
Response: Thank you for your comments. The two new terms proposed in the standard have been removed. **Attachment 1 was modified to clearly show the "no trip" zones. The voltage ride-through (Attachment 2) has been further defined as the per unit voltage base specified in the system models used by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission System at the point of interconnection to the BES.** **The standard was not intended to apply to contingency operations.**		
Hydro-Quebec TransEnergie	No	Mostly, HQT's frequency and voltage curves are more stringent for generators, as the area for no trip zone is wider. However, the following points on those curves of attachment 1 and attachment 2 are too stringent and we ask to consider these modifications: o On the frequency curve, for wind or thermal generation only, the no trip zone between 0 and 5 seconds should be limited to an over frequency of 61,7 hz. o On the voltage curve, the no trip zone should be restricted as follow: ï,§ Between 1 and 2 seconds, to 0,75 pu, ï,§ Between 2 and 3 seconds, to 0,85 pu.
		(1) Voltage Excursion definition should be based on rated system operation voltage which is what the protection is based on, not scheduled voltage which may vary. (2) Unless written to exclude all auxiliary system equipment which may result in a unit shut down, it will be impossible to determine this probability with any reasonable accuracy. For example, where auxiliary motors would stall and trip off, or contactors drop out would be variable.
Response: Thank you for your comments. **The frequency chart may be more stringent in your region and can be modified.** **R2 has been revised to define that *generator* protective relaying to ride through a system fault (three-phase with clearing time of 9 cycles or less) at the**		

Organization	Yes or No	Question 1 Comment
point of interconnection with the unit operating between 95% and 105% of rated voltage. Protective systems at the generator are required to not trip for a voltage excursion at the point of interconnection. **R4 was revised to remove the probability of a unit (including auxiliaries) remaining connected to the system. R4 takes into consideration a voltage recovery profile at the point of interconnection using the dynamic study results from the transmission planner/coordinator.**		
PPL Supply	Yes	1. The question above presents simple +/-0.5 Hz and +/-5% definitions of Frequency Excursions and Voltage Excursions respectively, but the time-related criteria in Attachments 1 and 2 are much more complex and are referenced in R6 as pertaining to the defined terms in question. Part A (Introduction) of this and all NERC standards should include a section dedicated to definition of terms used in the standard, if they are not already included in the NERC Glossary.2. The need for excursions as severe as those of Att.2 should be confirmed. Anything beyond +/- 4 kV for our 230 kV interconnects (+/- 1.74%) would be considered abnormal for our system (PJM).
Response: Thank you for your comments. The two new terms proposed in the standard have been removed. The voltage/frequency excursion values are incorporated in the requirements that they are applied. **The voltage excursion (Attachment 2) has been further defined as the per unit voltage base specified in the system models used by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission System at the point of interconnection to the BES. The chart may be more stringent for your region based on the transmission planner specifications.**		
American Electric Power	Yes	Where these definitions appear to be referenced in the standard (R5 and R6), they seem to be at odds with Attachments 1 and 2. Either the attachments should be used and remove the definitions, or instead, the definitions should be used and remove the references to the attachments in R5.1 and R5.2 and R6.We recommend removing the definition of “Frequency Excursion” and retaining Attachment 1 subject to our comments given elsewhere in this document. We recommend keeping the “Voltage Excursion” definition and eliminating Attachment 2 based on our comments elsewhere in our response.
Response: Thank you for your comments. The two new terms proposed in the standard have been removed. The voltage/frequency excursion values are incorporated in the requirements that they are applied. The voltage excursion (Attachment 2) has been further defined as the per unit voltage base specified in the system models used by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission System at the point of interconnection to the BES.		
PPL Electric Utilities	Yes	1. The question above presents simple +/-0.5 Hz and +/-5% definitions of Frequency Excursions and Voltage Excursions respectively, but the time-related criteria in Attachments 1 and 2 are much more complex and are referenced in R6 as pertaining to the defined terms in question. 2. Requirements R1 and R2 detail the required frequency and voltage protective relaying settings for both new and existing units or generating plant/facilities that opt to activate these relays. Does the current draft of these two requirements, including footnote 1, clarify that a Generator Owner is not required to have protective relaying installed or set for these functions? If you do not believe the requirement is clear, please provide alternative language to clarify the intent.

Summary Consideration: Stakeholders agreed that footnote 1 does clearly state that a Generator Owner is not required to have protective relaying installed or set for frequency or voltage protection. Many of the stakeholders made additional comments beyond the scope of the question regarding the intention of Requirements R1, R2, and R3. In response, the SDT made the following changes:

1. The Requirement Parts were revised in Requirement R1. Part 1.5 was moved into the body of R1. The requirement now reads:

> **"R1. Each Generator Owner that has generator frequency protective relaying activated to trip its new or existing generating unit or generating plant shall set such protective relaying so that it does not trip within the "no trip zone" of PRC-024 Attachment 1, unless the Generator Owner has documented and communicated each equipment limitation in accordance with Requirement R3 for an existing generating unit. . [Violation Risk Factor: High] [Time Horizon: Long-term Planning]**
>
> **1.1. A generating unit or generating plant is allowed to trip within the "no trip zone" if the frequency rate of change is more than 2.5 Hz/sec.**
>
> **1.2. A generating unit or generating plant may trip if the protective functions (such as out-of-step or loss-of-field functions) operate due to an impending or actual loss of synchronism or due to instability in power conversion control equipment."**

2. Requirement Part 2.1.1 was removed from Requirement R2. The body of the requirement and the remaining Parts were modified to clarify intent. The requirement now reads:

> **"R2. Each Generator Owner that has generator voltage protective relaying1 activated to trip its new or existing generating unit or generating plant shall set its protective relaying such that it does not trip as a result of a voltage excursion (at the point of interconnection) that remains within the "no trip zone" of PRC-024 Attachment 2 caused by an event on the transmission system external to the generating plant per the following operating conditions and relay settings, unless the Generator Owner has documented and communicated each non-protection system equipment limitation in accordance with Requirement R3 for an existing generating unit2 or generating plant.: [Violation Risk Factor: High] [Time Horizon: Long-term Planning]**

2.1. When operating within 95 percent to 105 percent of rated generator terminal voltage and during the transmission system operating conditions defined in PRC-024 Attachment 2, with the following clarifications:

2.1.1. If a Transmission Planner's study (based on the location specific voltage recovery characteristics) allows less stringent voltage relay settings than those required to meet PRC-024 Attachment 2, set voltage relays either to meet the Transmission Planner's voltage recovery characteristics or the characteristics in PRC-024 Attachment 2.

2.1.2. Tripping a generator in accordance with a Special Protection System (SPS) or Remedial Action Scheme (RAS) is acceptable in the "no trip zone" of PRC-024 Attachment 2.

2.1.3. If clearing a system fault necessitates disconnecting a generator, this action is acceptable within the "no trip zone" specified in PRC-024 Attachment 2.

2.1.4. A generating unit or generating plant may trip if the protective functions (such as out-of-step or loss-of-field functions) operate due to an impending or actual loss of synchronism or due to instability in power conversion control equipment."

3. Requirement R3 was changed to clarify the intent of non-protection system limitations and when such limitations must be addressed. The requirement now reads:

"3.1. The Generator Owner shall communicate the documented limitation, or the removal of a previously documented limitation, to its Reliability Coordinator, Planning Coordinator, Transmission Operator and Transmission Planner within 30 calendar days of identifying the limitation to ensure the accuracy of planning studies and system modeling studies. The existing generating unit or generating plant becomes subject to the full extent of Requirements R1 and R2 coincident with either of the following conditions:

- **The equipment causing the limitation is repaired or replaced with equipment that removes the limitation.**

- **The equipment causing the limitation is modified or upgraded resulting in an increase of generator nameplate capacity rating greater than 10 percent (cumulative from the first effective date of this Standard)."**

Organization	Yes or No	Question 2 Comment
PacifiCorp	Negative	(1) Industry practice for generation protective relays is to use the terminal voltage of the generators, not the system voltage or point of interconnection. Generator Owners could provide generation responses and data as contemplated by the standard, but they should not be held responsible for the answers provided without

Organization	Yes or No	Question 2 Comment
		the benefit of associated transmission planning groups. Generator Owners, under this framework, will rely completely on feedback from their associated transmission planning groups in order to provide responses. It concerns PacifiCorp that the draft standard does not address the need for transmission planners to provide the required transmission system response data to Generation Owners in order to make these assessments, or allow for the joint responsibility of transmission planner for the accuracy of the data as it concerns planning studies. **It is not practical to define the excursions at the generator terminals due to the differences in generator, step-up transformer, and system characteristics. Other voltage ride through standards (e.g. FERC Order 661A and various European standards) all define the voltage profile at the transmission level (where the event occurs).** (2) PacifiCorp maintains several additional concerns about complying with the standard as drafted: o R1.1.5 - PacifiCorp is not aware of relays used for generator protection that use frequency rate of change to calculate trip points. Generator protection relays use frequency set points and time at certain values, not rate of change of frequency to make tripping decisions. It may not be technically feasible to immediately comply with this sub-requirement of the standard as written. **There are several standard generator protection relays (e.g. GE's G-60, Schweitzer's 700G, and Beckwith's M-3425A) in addition to relays that are designed specifically for Aurora Scenario protection that incorporate a frequency rate of change function. R1.1.5 does not require tripping for a frequency rate of change over the stated value, but does allow that tripping even if the frequency magnitude is still within the No Trip Zone.** o R2.1.1 - PacifiCorp requests clarification concerning what the SDT has considered a zone 1 fault. PacifiCorp acknowledges that transmission and distribution line relays have zone 1 and zone 2, but the Company does not believe that this is something typically used in the generator protection context. A zone 1 fault needs to be defined somewhere to the extent that it is not clarified in the standard already. **Part 2.1.1 states "… transmission system zone 1 faults…" The SDT believes this makes it clear that it does not involve the generator or distribution system.** (3) PacifiCorp has concerns that certain references to Attachment 2 in Requirement R2 need to be clarified. Attachment 2 references the generator point of interconnection not the terminal voltage; therefore, clarifications to the proposed language are necessary. As such, the following recommended revisions to Requirement R2 are offered: 2.1 When operating under normal system operating conditions within 95% and 105% of rated generator terminal voltage the following clarifications for PRC-024 Attachment 2 are provided: 2.1.1 For three-phase transmission system zone 1 faults with Normal Clearing, transmission system faults should be cleared based on actual fault clearing times, not to exceed 9 cycles. Voltage relays should be set to not trip prior to transmission system fault clearing time. 2.1.2 If a Transmission Planner's study (based on the location specific voltage recovery characteristics) recommends less stringent system protection settings than those on PRC-024 Attachment 2, set voltage relays either to the less stringent Transmission Planner's settings or the setting applicable to PRC-024 Attachment 2. 2.1.3 Tripping a generator via a Special Protection System (SPS) or Remedial Action Scheme (RAS) is acceptable in the "no trip zone" in PRC-024

Organization	Yes or No	Question 2 Comment
		Attachment 2. 2.1.4 If clearing a system fault necessitates disconnecting a generator, this action is acceptable within the "no trip zone" specified in PRC-024 Attachment 2. **The SDT has revised the wording in the subsections of Requirement R2 to make the intent clearer. Section 2.1.1 has been removed. Section 2.1.3 now says "Tripping a generator via a Special Protection System (SPS) or Remedial Action Scheme (RAS) is acceptable in the "no trip zone" of PRC-024 Attachment 2." Section 2.1.4 now says" If clearing a system fault necessitates disconnecting a generator, this action is acceptable within the "no trip zone" specified in PRC-024 Attachment 2."** (4) As drafted, Requirement R1 of proposed PRC-024-1 conflicts with WECC's Off-Nominal Frequency Load Shedding Plan ("WECC Coordinated Plan"), and could potentially result in negative reliability impacts if enforced in the Western Interconnection. A WECC Regional Variance that includes the WECC Generator underfrequency and overfrequency operation requirements, as identified in the WECC Off-Nominal Load Shedding Plan, must be added to the proposed standard. WECC has developed, implemented, and verified the effectiveness of the WECC Coordinated Plan and any deviations from the requirements of the plan may negatively impact its effectiveness. **The SDT has modified PRC-024 Attachment 1 to accommodate the WECC regional requirements.**
Response: Thank you for your comments. See specific responses above.		
Occidental Chemical	Negative	2. Requirements R1 and R2 detail the required frequency and voltage protective relaying settings for both new and existing units or generating plant/facilities that opt to activate these relays. Does the current draft of these two requirements, including footnote 1, clarify that a Generator Owner is not required to have protective relaying installed or set for these functions? If you do not believe the requirement is clear, please provide alternative language to clarify the intent. No: Comments: Requirement R1 from Ingleside Cogeneration's perspective could lead to a double-infraction for the same incident. For example a single improper relay operation for an underfrequency transient would lead to a violation of both R1.2 and R1.3. It should be sufficient to specify that relays must be set in conformance with the off-frequency excursions provided in PRC-024 Attachment 1. Also, there must be some logical limit to the Hz/Second ride-through threshold specified in R1.5. As the requirement is written, even a large-magnitude frequency transient must not cause relays to operate as long as the frequency rate of change is slow. If for example, the interconnection frequency dropped to 55 Hz at a rate lower than 2.5 Hz/Second, R1.5 seems to require that the generator would remain connected to the BES. For the record, R2 seems to be more logically constructed - and lists reasonable exceptions to voltage relay settings. Ingleside Cogeneration LP recommends the drafting team to take a similar approach on R1.
Response: Thank you for your comments. The SDT has removed the subparts of Requirement R1. The intent of part 1.5 of Requirement R1 was to allow tripping if the rate of change of frequency exceeded 2.5 Hz/sec, even if the absolute frequency were still within the No Trip Zone of PRC-024		

Organization	Yes or No	Question 2 Comment
Attachment 1. The wording has been revised to clarify the intent and incorporated into the body of the Requirement. It now says" Each Generator Owner that has generator frequency protective relaying activated to trip its new or existing generating unit or generating plant or generating Facility shall set such protective relaying not to trip per PRC-024 Attachment 1 unless the Generator Owner has documented and communicated each equipment limitation in accordance with Requirement R3 for an existing generating unit. Additionally, the generator is allowed to trip within the "no trip zone" if the frequency rate of change is more than 2.5 Hz/sec."		
Ameren Energy Marketing Co.; Amerenue; Ameren Services	Negative	4)Requirement R1.5 is unclear. Are the relays not allowed to trip regardless of frequency if the rate of change is less than 2.5 Hz/sec. If so, the existing generator relays don't have the capability to block for this condition. It would seem undesirable to block for this condition and risk damage to generation. **The intent of part 1.5 of Requirement R1 was to allow tripping if the rate of change of frequency exceeded 2.5 Hz/sec, even if the absolute frequency were still within the No Trip Zone of PRC-024 Attachment 1. The wording has been revised to clarify the intent and incorporated into the body of the Requirement. The wording now states: "Additionally, the generator is allowed to trip within the "no trip zone" if the frequency rate of change is more than 2.5 Hz/sec."** (5)R2.1.3 needs to be more specific. With multiple outlet lines, generators may only be tripped for certain lines or breaker failure conditions. Generators would only be allowed to trip in the "no trip zone" for the specific conditions of the SPS or RAS schemes? **The SDT agrees that the generators would be allowed to trip in the no trip zone for the specific condition of a SPS or RAS scheme and believes the existing wording conveys that intent.**
Response: Thank you for your comments. See specific responses above.		
Lower Colorado River Authority; Platte River Authority; Snohomish County PUD No. 1	Negative	o The development may include other improvements to the standards deemed appropriate by the drafting team, with the consensus of stakeholders, consistent with establishing high quality, enforceable and technically sufficient bulk power system reliability standards. Requirement R1 mandates the generator off-nominal frequency to requires that the GO to set the protective relays such that they will not trip the generator within the no-trip zones defined by the curves in PRC-024 Attachment 1 without regard for the interconnecting entities' regional off-nominal plan. This may include coordination of load shedding blocks & load restoration blocks and other off-nominal efforts including generation tripping plans that should be left to the interconnecting entity's discretion. Similar to the exception criteria for the voltage excursion of R2.1.2 " If a Transmission Planner's study (based on the location specific voltage recovery characteristics) recommends less stringent voltage relay settings than those in PRC-024 Attachment 2, set the voltage relays either to the Transmission Planner's settings or the settings in PRC-024 Attachment 2" a similar exception should be made where the generator facility interconnects to an entity that has established and incorporated an off-nominal frequency plan. **The posted curves in PRC-024 Attachment 1 match PRC-006 Attachment 1 expectations for generator tripping. Modifications to PRC-024 Attachment 1 have been made to**

Response: Thank you for your comments. See specific responses above.		
Florida Municipal Power Pool	Negative	Considering R1, many generators have speed protection embedded in control systems (e.g., a GE Mark V or VI), is that included in footnote 1 to the requirement in the phrase: "multi-function protective devices or

Organization	Yes or No	Question 2 Comment
		protective functions within excitation controls that directly trip or provide tripping signals to the generator based on frequency or voltage inputs"? **The SDT agrees and has revised the wording in the footnote to clarify the intent.** In R2, does "voltage protective relaying" include station service protection, such as motor-contactors? **Requirement R2 has been revised to clarify that it is generator protective relaying. Auxiliary systems are not included.** The terms used in R1, R2 and R3 are inconsistent. R1 and R2 refer to "protective relaying", R3 refers to "protection system equipment". **Protective relays are one element in a protection system. The SDT does not believe there is an inconsistency.**
Response: Thank you for your comments. See specific responses above.		
Muscatine Power & Water	Negative	In Requirement 1, Requirement 2 and footnote 1 it is not clear because control algorithms incorporated in plant control systems that effectively limit speed and therefore frequency are not clearly identified as being covered by the standard or not. This does not seem to be covered under Requirement 3, which covers equipment limitations either. **The SDT agrees and has revised the wording in the footnote to clarify the intent.** For Requirement 5, if design standards have not been previously developed or implemented for all plant equipment and therefore the plant itself to not trip during the defined excursions it is uncertain when and if equipment design standards and the equipment itself can become available to achieve the requirements. **The SDT has extended the implementation of Requirement R5 to six years to allow for the development of designs that meet the Requirement.**
Response: Thank you for your comments. See specific responses above.		
Balancing Authority of Northern California NCR11118; Sacramento Municipal Utility District	Negative	We commend the drafting team's efforts with the Verification of Models and Data for Generator Excitation and Control System Functions and Plant Volt/VAr Control Functions. However, the following comments regarding PRC-024-1 are currently prohibiting an affirmative position: Requirement R1 mandates the generator off-nominal frequency to requires that the GO set the protective relays such that they will not trip the generator within the no-trip zones defined by the curves in PRC-024 Attachment 1 without regard for the interconnecting entities' regional off-nominal plan. This may include coordination of load shedding blocks & load restoration blocks and other off-nominal efforts including generation tripping plans that should be left to the interconnecting entity's discretion. Similar to the exception criteria for the voltage excursion of R2.1.2 " If a Transmission Planner's study (based on the location specific voltage recovery characteristics) recommends less stringent voltage relay settings than those in PRC-024 Attachment 2, set the voltage relays either to the

Organization	Yes or No	Question 2 Comment
		Transmission Planner's settings or the settings in PRC-024 Attachment 2" a similar exception should be made where the generator facility interconnects to an entity that has established and incorporated an off-nominal frequency plan. Clarification for allowable tripping options of points on the Attachment 1 curve other than the 59.5 Hz and 60.5 Hz values are necessary. **The posted curves in PRC-024 Attachment 1 match PRC-006 Attachment 1 expectations for generator tripping. Modifications to PRC-024 Attachment 1 have been made to accommodate regional variations in WECC and the Quebec Interconnection.** The language of Requirement R2, part 2.1.1 is confusing and needs to be clarified. According to Attachment 1 capable generators are required to stay connected at a minimum for 9 cycles for the zone 1, three phase faults. Regarding sub-requirement 2.1.1. where: for three-phase transmission system zone 1 faults with Normal Clearing, set voltage relays based on actual fault clearing times, not to exceed 9 cycles. This appears to be addressing clearing times for the transmission elements and is not applicable to the generator owner. As PRC-024-1 is only applicable to the GO, either the applicability needs to be expanded to include the TO or sub-requirement 2.1.1 needs to be struck from PRC-024-1 and considered to be included in another standard. **The wording of Requirement R2, part 2.1.1 had been removed.** Regarding generator's non-protection system equipment limitations exemption expiration for upgrades of =10%, would the re-exemption status be allowed or does the upgrade require removal of the limitation? **The intent is that the Generator Owner would have to replace, repair, or modify any equipment causing a technical limitation if the capacity of the generating unit were increased by 10% or more.**
Response: Thank you for your comments. See specific responses above.		
Pepco Holdings Incand Affiliates	No	Footnote 1 does make it clear that the Generator Owner is not required to have frequency or voltage protective relaying. However, in the current draft, reference to footnote 1 appears to have been inadvertently omitted following the phrase "voltage protective relaying" in R2.
Response: Thank you for your comments. A reference to Footnote 1 has been added to Requirement R2.		
SPP Reliability Standards Develpment Team	No	We agree that R1, with the footnote mentioned, makes it clear that the Generator owner would not be required to have protective relaying installed or set for these functions. As for R2 we feel that footnote 1 should also be referenced in R2.
Response: Thank you for your comments. A reference to Footnote 1 has been added to Requirement R2.		
MRO's NERC Standards Review Forum	No	The requirement and footnote is not clear in that control algorithms incorporated in plant control systems that effectively limit speed and therefore frequency are not clearly identified as being covered by the standard or

Organization	Yes or No	Question 2 Comment
		not. This does not seem to be covered under R3 which covers equipment limitations either.
Response: Thank you for your comments. Footnote 1 has been revised to clarify that "…protective functions within control systems that directly trip the generator…" are included. Requirement R3 discusses the limitations of the generating equipment exclusive of protective functions, whether they are protective relays or protective functions in a control system.		
Electric Market Policy	No	The question is confusing because of the phrase "set for these functions." The language in Requirements R1 and R2 as well as footnote 1 suggest that GOs are not required to have the specific relays "installed or activated on its units. If however, the relays are activated then they are required to be "set" pursuant to the standard.
Response: Thank you for your comments. The SDT agrees that the question could have been worded more clearly, but it appears that you understood the intent.		
Dynamics Review Subcommittee	No	It is unclear how an entity can have protective relaying settings for new units. Since "existing units" covers units under construction as specified in footnote 2, "new" implies planned units and thus the associated relaying would also be "planned" not "existing." It appears the word "new" should be deleted from sentence one of R1 and sentence one of R2.
Response: Thank you for your comments. Requirements R1 and R2 apply to both new and existing units. New units (designed, built and operated after Requirement R5 is implemented) must set any protection system functions that are installed and activated so that they meet these requirements.		
LG&E and KU Energy	No	Comments: LG&E and KU Energy recommends the wording be changed for R1/R2 to "Each GO shall set the generator frequency protective relaying, if installed, not to trip during the following..."Or, change from "Each GO" to "GO's that have frequency and voltage protection functions activated to trip a new/existing generation unit."
Response: Thank you for your comments. The SDT has changed the wording to clarify the intent. Requirement R1 now states, in part: "Each Generator Owner that has generator frequency protective relaying activated to trip its new or existing generating unit or generating plant or generating Facility…". Requirement R2 now states, in part: "Each Generator Owner that has generator voltage protective relaying Error! Bookmark not defined.** **activated to trip its new or existing unit or generating plant or generating Facility…".**		
Santee Cooper	No	The sub-requirements of R2 could be read as prescribing exactly where you have to set this relaying. Often our relay set points originate with the OEM and are based on protecting the Generator and Turbine. The finalized curves that originate here should be used as a means to arrive at those settings, but, as long as the settings do not cause the relaying to operate for the ranges in the finalized curves, the requirements should

Organization	Yes or No	Question 2 Comment
		be satisfied (It shouldn't have to be stated that you can set them less stringent, if you can not have the relaying entirely).
Response: Thank you for your comments. The SDT has defined a "no trip zone" for voltage excursions at the generator's point of interconnection. As with any other exercise in relay coordination, it is up to the Generator Owner to determine how much margin to allow when determining the settings of the protection system.		
Florida Municipal Power Agency	No	The term "protective relaying" is confusing in two ways: 1) the footnote is ambiguous as to how it applies; and 2) it calls into question whether this is a "generation Protection System" applicable to PRC-004 and PRC-005 (especially when considering the inconsistent use of "non-protection system equipment" in R3). FMPA suggests the term "safeguard" instead of "protection", e.g., a "frequency safeguard system" to avoid this ambiguity and with a footnote to make more clear that systems like GE Mark VI's are or are not included.Similarly in R2, it is unclear what "voltage protective relaying" is. FMPA suggests using the word "safeguard" instead of "protection". **The word "safeguard" has specific implications to nuclear plants and is not generally used in industry as a substitute for the word "protection".** Also, it is unclear whether station service voltage safeguards are included, such as motor contactors. **For Requirements R1 and R2, the station service system is not included in the scope. However for new facilities, Requirement R5, states that the facility must ride through the excursions, so the station service system would have to be designed and built to achieve this goal.** In addition, "external to the plant" as used in several requirements (e.g., R1, R2 and R6) is ambiguous. We assume that this would also mean beyond any radial connection (e.g., generator lead) to the plant and would suggest changing the term to something like: "caused by an event beyond the point at which the plant is radially connected to the transmission system". **Requirement R1 does not use the words "external to the plant". Requirements R2 and R6 have been revised and now state, in part: " …caused by an event on the transmission system external to the plant…"**
Response: Thank you for your comments. See specific responses above.		
Bonneville Power Administration	No	R2.1.1 - Please clarify/verify: o That the allowable voltage relay trip time is greater than the normal fault clearing time up to a normal clearing time of 9 cycles; **The SDT agrees.** o That tripping is allowed above 9 cycles regardless if it is normal clearing or backup clearing; and, **The SDT agrees.** o That for generators in close proximity the normal clearing time is coordinated to ensure it is no greater than what a specific generator was designed to withstand. **This standard does not specify requirements for the transmission protection system. This coordination should be accomplished through compliance**

Organization	Yes or No	Question 2 Comment
		with NERC standard PRC-001-1.
Response: Thank you for your comments. See specific responses above.		
Progress Energy	No	Requirement R1 subsection 1.5 is not clear as to when rate tripping is acceptable or not. Is it OK to trip at 59.6 Hz if the ROC is > 2.5 Hz or is this ROC trip acceptable only outside the no trip zone.
Response: Thank you for your comments. The intent is that tripping is allowed if the frequency rate of change exceeds 2.5 Hz/sec even if the absolute frequency is within the "no trip zone" defined in PRC-024 Attachment 1. The wording in Requirement R1 has been revised to clarify the intent. It now states, in part: "…Additionally, the generator is allowed to trip within the "no trip zone" if the frequency rate of change is more than 2.5 Hz/sec."		
Exelon	No	Footnote 1 should be added to the Applicability section of the Standard. Suggest that the Applicability section be revised to state "GO shall set applicable protective relaying so as not to impact R1.1, R1.2, R1.3, R1.5, unless exempted by a non-protection system equipment limitation per the exclusion criteria in Requirement R3."
Response: Thank you for your comments. The SDT disagrees that this wording should be added to the Applicability section.		
Puget Sound Energy	No	Please clarify whether rate of change of frequency relaying is required; or alternatively, if the required setting of not less than 2.5 Hz/sec is only applicable IF rate of change of frequency elements are available and enabled.
Response: Thank you for your comments. The SDT believes that Footnote 1 clearly states that the Generator Owner is not required to install or activate any frequency or voltage protection. This would include rate of change of frequency functions. If the Generator Owner does have frequency rate of change protection installed and activated, then it must be set to meet the Requirement R1.		
Great River Energy	No	The requirement and footnote is not clear in that control algorithms incorporated in plant control systems that effectively limit speed and therefore frequency are not clearly identified as being covered by the standard or not. This does not seem to be covered under R3 which covers equipment limitations either. **Footnote 1 has been revised to clarify that control systems are included if they will trip the generator.** It is not clear why the exception for R1 and R2 would expire with a capacity up-rate greater than 10% in R3. That implies that the reason for the exception must be fixed with such a capacity up-rate. Was this the SDT's purpose? Why? **The SDT has revised Requirement R3 to clarify that the limitation must be eliminated if the equipment causing the limitation is modified or upgraded resulting in an increase in nameplate capacity greater than 10%.**

Organization	Yes or No	Question 2 Comment
Response: Thank you for your comments.		
Ingleside Cogeneration LP	No	Requirement R1 from Ingleside Cogeneration's perspective could lead to a double-infraction for the same incident. For example a single improper relay operation for an underfrequency transient would lead to a violation of both R1.2 and R1.3. It should be sufficient to specify that relays must be set in conformance with the off-frequency excursions provided in PRC-024 Attachment 1. **The SDT has removed the subparts of Requirement R1.** Also, there must be some logical limit to the Hz/Second ride-through threshold specified in R1.5. As the requirement is written, even a large-magnitude frequency transient must not cause relays to operate as long as the frequency rate of change is slow. If for example, the interconnection frequency dropped to 55 Hz at a rate lower than 2.5 Hz/Second, R1.5 seems to require that the generator would remain connected to the BES. **The intent of part 1.5 of Requirement R1 was to allow tripping if the rate of change of frequency exceeded 2.5 Hz/sec, even if the absolute frequency were still within the No Trip Zone of PRC-024 Attachment 1. The wording has been revised to clarify the intent and incorporated into the body of the Requirement which now states, in part: "Additionally, the generator is allowed to trip within the "no trip zone" if the frequency rate of change is more than 2.5 Hz/sec."** For the record, R2 seems to be more logically constructed - and lists reasonable exceptions to voltage relay settings. Ingleside Cogeneration LP recommends the drafting team to take a similar approach on R1. **The SDT has revised the wording in Requirement R1, which now states: "Each Generator Owner that has generator frequency protective relaying activated to trip its new or existing generating unit or generating plant or generating Facility shall set such protective relaying not to trip per PRC-024 Attachment 1 unless the Generator Owner has documented and communicated each equipment limitation in accordance with Requirement R3 for an existing generating unit. Additionally, the generator is allowed to trip within the "no trip zone" if the frequency rate of change is more than 2.5 Hz/sec".**
Response: Thank you for your comments. See specific responses above.		
Luminant Energy	No	Recommended that in the Footnote and in R1 indicate generator protective relaying.
Response: Thank you for your comments. The word "generator" has been added as a modifier to "protective relay" in Requirement R1.		
PPL Electric Utilities	No	Recommend the wording be changed for R1/R2 to " Each GO shall set the generator frequency protective relaying, if installed, not to trip during the following..."

Organization	Yes or No	Question 2 Comment
Response: Thank you for your comments. The SDT has changed the wording to clarify the intent. Requirement R1 now states, in part: "Each Generator Owner that has generator frequency protective relaying activated to trip its new or existing generating unit or generating plant or generating Facility…". Requirement R2 now states, in part: "Each Generator Owner that has generator voltage protective relaying Error! Bookmark not defined. **activated to trip its new or existing unit or generating plant or generating Facility…".**		
Indiana Municipal Power Agency	No	The term "protective relaying" is confusing in a two ways: 1) The footnote needs to clarify how it applies; and 2)the term calls into question whether this is a "generation Protection System" applicable to PRC-004 and PRC-005. **The SDT has revised the standard to use the term generator protection system. This standard does not define the scope of applicable equipment in other NERC standards.** It needs to be made more clear that systems like the GE Mark IV and VI control systems are or are not included. **Footnote 1 has been revised and now states, in part: "…or protective functions within control systems that directly trip or provide tripping signals to the generator based on frequency or voltage inputs) installed or activated on its unit".** R2 is also not clear when using "voltage protective relaying". It is not clear if voltage safeguards on motor contactors are included. **For Requirements R1 and R2, the station service system is not included in the scope. However for new facilities, Requirement R5, states that the facility must ride through the excursions, so the station service system would have to be designed and built to achieve this goal.** The standard also needs to make more clear what "external to the plant" exactly means. **The words "… on the transmission system…" have been added to clarify the intent.**
Response: Thank you for your comments. See specific responses above.		
Alliant Energy Corp. Services, Inc.	Affirmative	While we are voting affirmative on this ballot, we have 2 comments concerning the standard: 1. Standard needs to be clarified such that it is clear whether the no trip zones include or exclude the lines that define the curves. **The SDT has added a note to PRC-024 Attachments 1 and 2 to indicate that the "no trip zones" do not include the lines that define the curves.** 2. R1 - uses the defined term of protective relaying which for other PRC standards does not include excitation controls such as PRC-005, yet there is a footnote attached to the term "protective relaying" that includes excitation controls which trip generators. This can cause confusion on the interpretation of whether controls that trip are considered a protective relay. R1 should be redrafted to state protective relaying and excitation controls instead of attaching a footnote which redefines what in inclusive in the term "protective relaying". **The SDT believes (in consultation with the Protection System Maintenance and Testing SDT) that protection functions in control systems that directly trip a generator are within the scope of PRC-005.**

Organization	Yes or No	Question 2 Comment
Response: Thank you for your comments. See specific responses above.		
SERC Generation Sub-committee (GS)	Yes	The GS recommends that the applicability section be revised from "GO" to "GO's that have frequency and voltage protection functions activated to trip a new/existing generation unit." **The SDT disagrees that this wording should be added to the Applicability section.** Also, while the GS does, in general, agree with the content of footnote #2 on page 2 (under R1), we believe that this is verbiage is better placed in the implementation plan because it puts commercial considerations into the standard. **The SDT disagrees that this wording would be better placed in the Implementation Plan.**
Response: Thank you for your comments. See specific responses above.		
Idaho Power - Power Production	Yes	Yes, R1 and R2 do make it clear that the GO does not have to install or set these functions however we believe that the standard should clarify better that the standard is applicable to all "voltage-based" protection functions such as the backup impedance function (21) and the voltage controller (51C) or voltage restrained (51V) Overcurrent functions. These functions may operate if not coordinated properly. We do not believe that was made very clear. **The SDT agrees and has revised Footnote 1 to read, in part: "… relaying (including but not limited to frequency and voltage protective functions for discrete relays, volts per hertz relays evaluated at nominal frequency, impedance relays, voltage controlled overcurrent relays, multi-function protective devices…"** Particularly for units that fully compliant with this standard, providing an estimate of unit performance during a frequency or voltage excursion is burdensome and unnecessary. If the event is within the parameters of the standard, the planner can rely on the unit staying on, if not, the planner should model the unit as a trip. In particular, we are unaware of any methodology that would be capable of providing an "estimated probability". Protection consistently operates as designed and configured. **The SDT agrees that the "estimated probability" does not provide any reliability value and has removed the wording from the standard. The SDT agrees that determining the operation of protection system functions for a specific set of conditions is relatively straightforward, but the requirement for estimating the length of time a facility will remain connected includes evaluating upsets to the prime mover process that may result in a generator trip.**
Response: Thank you for your comments. See specific responses above.		
Public Service Enterprise Group	Yes	A one-sentence statement should be added stating that the protective relays affected by this standard are only the generator protective relays, not any other relays for the unit and/or facility.

Organization	Yes or No	Question 2 Comment
Response: Thank you for your comments. The word "generator" has been added in Requirement R1 to clarify the intent.		
Southern Company	Yes	1) The footnote is clear, however, the exact meaning of the phrase "non-protective system equipment" limitation in R1 and R2 is not clear. Does this exclude any equipment limitation that is protected by a protective relay? Does this allow tripping using protective relays that are protecting a turbine from underfrequency conditions or a generator or transformer from excessive volts-per-hertz conditions? We feel that a fundamental tenant of reliability includes adequately protecting generating plant equipment from detrimental conditions - a generator owner needs to be allowed to protect its equipment from possible damaging consequences of off-nominal voltage and frequency. **The SDT agrees that protection of generating plant equipment is fundamental. The meaning of the phrase "non-protection system equipment" is that limitations of the protection system itself cannot be used as an exemption from meeting Requirements R1 and R2.** 2) We believe examples of "non-protection system equipment" include, but are not limited to, turbine generators, transformers, feed pump systems/controls, boiler control systems, reactor protection systems, emergency diesel generators, AC motors, pumps, fans, AC motor contactors, auxiliary relays, etc. **The SDT agrees.** 3) Nuclear stations have an approved Setpoint Methodology which governs the process of determining and documenting setpoints for the equipment at that station. This methodology will incorporate some margin between the expected operating condition and setpoint actuation to help ensure proper operation of the unit but provide the necessary protection as well. How was this considered in the development of this standard? **Standard coordination methodologies apply. If "proper operation of the unit" to meet NRC or other nuclear safety needs requires tripping within the No Trip Zone of either PRC-024 Attachment 1 or Attachment 2, this would be considered a legitimate technical limitation.**
Response: Thank you for your comments. See specific responses above.		
American Electric Power	Yes	Although the footnote is worded somewhat awkwardly, it is clear that a Generator Owner is not required to have protective relaying installed or set for these functions. Suggest using "Generator Owners are not required to have... installed or activated on their units". **Thank you for your comments. The SDT has decided to retain the existing wording.**

3. Requirement R4 has been added for owners of existing units or generating plant/facilities to provide an estimate of the performance of the units during frequency and voltage excursions. This information is intended to provide Transmission Planners with information useful in performing planning studies. Do you agree with this approach? If not please explain and provide alternative language.

Summary Consideration: The question, in error, contained a reference to R4 rather than R5. As this question is in error, the drafting team will ask this question on the next posting. Some commented as if the question was really about R4, while most commented as if the question was about R5.

Summary of the R4 comments: Either the specific details of the response required by R4 is needed or R4 is not needed due to no reliability impact.

Summary of the R5 comments:

Many entities (8) feel that there is no additional reliability gain in this requirement - the information is not useful - there is little value technically of this information.

Others (5) expressed that it is very difficult, if not impossible, to predict the consistent response of the balance of (a generating) plant to the system excursions shown in Attachment 1 & 2.

Further, 10 companies expressed that it is unlikely that any steam plants will survive for the entire "no trip zones" of the attachments.

Other, less frequent, opinions included the following:

- **R1-R4 adequately fulfill the purpose of the standard.**
- **Standard requirements should be limited to devices that directly respond to the generator V and F – write standard to exclude all aux system equipment.**
- **The TP needs only to know when the protective relaying V-t and F-t will trip the unit so the models can switch the generators off when the simulated V and F levels are reached.**
- **30 days is too short for a response.**

Organization	Yes or No	Question 3 Comment
PacifiCorp	Negative	(5) PacifiCorp believes that the SDT should rewrite Requirement R4 to add specificity as to what must be included in a written response to a submission concerning an equipment limitation, similar to the specificity

Organization	Yes or No	Question 3 Comment
		and clarity included in MOD-026, Requirement R3.
Response: Thank you for your comments The SDT has removed Requirement R4.		
Occidental Chemical	Negative	3. Requirement R4 has been added for owners of existing units or generating plant/facilities to provide an estimate of the performance of the units during frequency and voltage excursions. This information is intended to provide Transmission Planners with information useful in performing planning studies. Do you agree with this approach? If not please explain and provide alternative language. No: Comments: Ingleside Cogeneration LP assumes this question actually applies to Requirement R5. It is not clear what extra reliability information will be provided to Transmission Planners as long as Generator Owners confirm that their voltage and frequency settings comply with the performance curves in the attachments. It may be valid to require an estimate of performance if the GO identifies a limitation as allowed under R3. Otherwise, the TP should assume generator relays will operate if the magnitude and duration thresholds defined in the attachments are exceeded.
Response: Thank you for your comments. The SDT agrees with stakeholders who have commented that the estimated probability of ride-through does not provide any reliability value and has removed the wording from the standard. The SDT agrees that determining the operation of protection system functions for a specific set of conditions is relatively straightforward, but the requirement for estimating the length of time a facility will remain connected includes evaluating upsets to the prime mover process that may result in a generator trip.		
Balancing Authority of Northern California NCR11118; Sacramento Municipal Utility District	Negative	In Requirement 4, the response content is ambiguous regarding what an acceptable response should contain. Consider requiring the response to be similar to the MOD-026-1 R3 response that identifies a technical basis.
Response: Thank you for your comments. The SDT has removed Requirement R4.		
Luminant Energy	Negative	R5 would still be required but the study would only involve fault conditions that have trip times less than 45 cycles.
Response: Thank you for your comments. The SDT agrees with stakeholders who have commented that the estimated probability of ride-through does not provide any reliability value and has removed the wording from the standard. The SDT agrees that determining the operation of protection system functions for a specific set of conditions is relatively straightforward, but the requirement for estimating the length of time a facility will remain connected includes evaluating upsets to the prime mover process that may result in a generator trip.		
Black Hills Corp	Negative	Suggest rewrite R4 to add specificity as to what must be included in the required written response, similar to

Organization	Yes or No	Question 3 Comment
		the specificity & clarity included in MOD-026, R3.
Response: Thank you for your comments. The SDT has removed Requirement R4.		
Lower Colorado River Authority; Platte River Authority; Snohomish County PUD No. 1	Negative	The response content for R4 is ambiguous regarding what the written response should contain. o Other than the R1.1 frequency range of 59.5 Hz and 60.5 Hz, are the other points of the curve of Attachment 1 allowable points for tripping?
Response: Thank you for your comments. The SDT has removed Requirement R4. The SDT has added a note to PRC-024 Attachment 1 to indicate that the lines that define the curves are allowable tripping points.		
Avista Corp.; BrightSource Energy, Inc.; Chelan County Public Utility District #1; City of Farmington; City of Redding; Colorado Springs Utilities; City of Tacoma, Department of Public Utilities, Light Division, dba Tacoma Power; Cogentrix Energy, Inc.; Idaho Power Company; Los Angeles Department of Water & Power; Pacific Gas and Electric Company; Salt River Project; South California Edison Company; Tacoma Public Utilities; Western Area Power Administration; Western Electricity Coordinating Council; Seattle City Light	Negative	We suggest that Requirement R4 be rewritten to add specificity as to what must be included in the required written response, similar to the specificity and clarity included in MOD-026, Requirement R3.
Response: Thank you for your comments. The SDT has removed Requirement R4.		
Pepco Holdings Incand Affiliates	No	Believe this question is referring to Requirement R5 not R4 as stated in the question. Not sure how useful the R 5.2 probability assessment would be, therefore suggest eliminating that requirement. R 5.1 coupled with the basis requirement in R 5.3 would appear sufficient to quantitatively assess the performance during voltage

Organization	Yes or No	Question 3 Comment
		and frequency excursions. Also, see responses to question #6.
Response: Thank you for your comments. The SDT agrees with stakeholders who have commented that the estimated probability of ride-through does not provide any reliability value and has removed the wording from the standard. The SDT agrees that determining the operation of protection system functions for a specific set of conditions is relatively straightforward, but the requirement for estimating the length of time a facility will remain connected includes evaluating upsets to the prime mover process that may result in a generator trip.		
Northeast Power Coordinating Council	No	The reference to "R4" in this question should be R5.
Response: Thank you for your comments. The SDT agrees.		
ACES Power Members	No	Requirement R4 references inquiries regarding equipment limitations that have been identified in R3. This particular question should apply to R5 instead. If applied to R5, the approach in theory seems reasonable.
Response: Thank you for your comments. The SDT agrees with stakeholders who have commented that the estimated probability of ride-through does not provide any reliability value and has removed the wording from the standard. Requirement R5 retains the obligation of the Generator Owner to evaluate the time that a generating unit or facility will remain connected following an excursion that is defined by the Transmission Planner.		
BC Hydro and Power Authority	No	The requirement R5 (R4 is a typo in the Question) is ambiguous and redundant. What does "estimating" mean? One could infer that the GOs are actually required to do what TPs are normally doing as part of their studies: estimating (assessing, simulating) the performance of units during frequency or voltage excursions.In order to fulfill requirements R1, R2 and R3 of this standard, GOs have to do engineering analysis and studies to develop adequate protection settings and to assess other non-protection systems and equipment. By declaring compliance GOs commit to keeping their units on-line during defined frequency or voltage excursions. In the case that a GO identifies a particular limitation, they would inform the TPs so that this limitation is taken into account in system studies. Hence, the goal of the standard would be fully met without R5. In light of the above, the requirement R5 should be removed. Technically it is of little value, if any, becoming just an unnecessary burden for GOs. In compliance terms it could be a source of perpetual confusion and disputes.
Response: Thank you for your comments. As stated in the Requirement, the estimate is to be based on experience, event histories, or sound engineering judgment. The SDT agrees that determining the operation of protection system functions for a specific set of conditions is relatively straightforward, but the requirement for estimating the length of time a facility will remain connected includes evaluating upsets to the prime mover process that may result in a generator trip.		

Organization	Yes or No	Question 3 Comment
SERC Generation Sub-committee (GS)	No	The ride through criteria should not be anything beyond currently used critical clearing times (2nd zone protection or breaker failure) that switchyard breaker failure protection is based on. It is questionable whether large steam plants can survive anything beyond this. Plants with aux power systems normally fed from the switchyard would be even more questionable as the transient is not shielded by the action of the voltage regulator for the generator.
Response: Thank you for your comments. The SDT agrees that determining the operation of protection system functions for a specific set of conditions is relatively straightforward, but the requirement for estimating the length of time a facility will remain connected includes evaluating upsets to the prime mover process that may result in a generator trip.		
Idaho Power - Power Production	No	
SPP Reliability Standards Develpment Team	No	The question should mention R5 and not R4. We feel like the planners shouldn't have to request this data and should be supplied for each unit once and again if the characteristics change. We also feel like 30 days might not be appropriate time to gather such information and would suggest that 90 days would be a better time frame for supplying this data.
Response: Thank you for your comments. The SDT agrees that more time should be allowed and has changed the time to 60 days.		
Electric Market Policy	No	Requirement R4 seems to be duplicative of the obligation to notify the same entities under Requirement R3. Perhaps the language in R4 could be clarified to indicate the distinction.
Response: Thank you for your comments. The SDT has removed Requirement R4.		
LG&E and KU Energy	No	: LG&E and KU Energy agrees with the approach but recommends 60 days. Moreover, this appears to be R5, not R4.
Response: Thank you for your comments. The SDT agrees and has changed the time to 60 days.		
Santee Cooper	No	It should be ascertained how and if the TP will use this in TPL-001 analysis. It will be unclear how to demonstrate compliance.
Response: Thank you for your comments. The Requirement is written for the Generator Owner to respond to the requesting entity (Reliability Coordinator, Planning Coordinator, Transmission Operator or Transmission Planner). If these entities do not want this information, they are not required to request it.		

Organization	Yes or No	Question 3 Comment
PPL Supply	No	1. Excursion-estimate requirements for existing units are presented in R5, not R4. Our comments below pertain to R5.2. The question above cites “frequency and voltage excursions [emphasis added],” the question 4 below deals with “frequency or voltage excursions,” para. R5.1 states “Frequency Excursion...and a Voltage Excursion” and para. R6 references “Frequency Excursion or Voltage Excursion.” The combinations of simultaneous frequency and voltage variations that units must ride-though should be clarified. **The SDT has revised section 5.1 to indicate that the frequency excursion and/or voltage excursion are to be defined by the Transmission Planner.** 3. Preparing the estimates in question appears to constitute a duplication of the excitation and governor model verifications required by MOD-026 and MOD-027. Para. R5 states that the PRC-024 estimates are to be used in modeling studies; but there should be one, definitive source of modeling data, not two different sources. Para. R5 of PRC-024 should be replaced by a reference to using the tools developed for MOD-026 and MOD-027. **The SDT disagrees. Standards MOD-026 and MOD-027 require verification of the excitation and frequency control responses, but do not discuss the ability of a generating unit or facility to remain connected to the grid.** 4. In the event that R5 remains as-is, a standard-specific definition of the word “plant” is needed, restricting applicability to NERC-registered generators. A plant consisting of two 750 MW fossil units and a standby 10 MW diesel generator, for example, should not have to model the diesel unit’s behavior. **The applicability of this standard is to generating units and facilities that meet the NERC Registry Criteria.** 5. It is necessary in any event to limit the requirement for estimates to that which can reasonably be modeled. Unit auxiliary system buses may drop-out and cause a unit to trip, even if the generator and protective relays can handle any given transient, and dynamic behavior at the 4160V and 460V levels may be impossible to predict for the radical excursions specified in PRC-024. **The SDT expects the Generator Owner to estimate as best as he can the performance of the entire unit or facility based on past experience, event histories, or sound engineering judgment as described in the requirement.**
Response: Thank you for your comments. See specific responses above.		
Florida Municipal Power Agency	No	R4 is missing the VRF and Time Horizon. FMPA recommends “Lower” and “Long-term Planning”.
Response: Thank you for your comments. The SDT has removed Requirement R4.		
Bonneville Power Administration	No	R3-R4 - Generator Owners may be unwilling to share proprietary information in response to requests from Reliability Coordinators, Planning Coordinators, Transmission Operators, or Transmission Planners, because of manufacturer restrictions or for other reasons. Should the standard anticipate this issue?

Organization	Yes or No	Question 3 Comment
Response: Thank you for your comments. The SDT has removed Requirement R4.		
TVA - GO	No	The ride through criteria should not be anything beyond currently used critical clearing times (2nd zone protection or breaker failure) that switchyard breaker failure protection is based on. It is questionable whether large steam plants can survive anything beyond this. Plants with aux power systems normally fed from the switchyard would be even more questionable as the transient is not shielded by the action of the voltage regulator for the generator.
Response: Thank you for your comments. The SDT agrees and feels the comment is a good statement of the rationale for this Requirement. The information provided by the Generator Owner for modeling his facility based on experience, past event histories, or good engineering judgment will allow better modeling of the performance of the facility.		
Arizona Public Service Company	No	AZPS believes this question applies to R5. In any event, this requirement does not add anything to the reliable modeling since most GO(s) will be making a guess, and that does not make the simulation any more accurate.Additionally, the requirement for providing this information within 30 days is unreasonable. It should be at least 90 days. There is no reliability reason for requiring this data within 30 days. These are long range planning studies and modeling data is usually submitted on the annual basis.
Response: Thank you for your comments. The Requirement is written for the Generator Owner to respond to the requesting entity (Reliability Coordinator, Planning Coordinator, Transmission Operator or Transmission Planner). If these entities do not believe the information will be of value, they are not required to request it. The SDT agrees that more time should be allowed and has changed the time to 60 days.		
Westar Energy	No	This question better addresses R5 rather than R4. We propose that the SDT team consider revising the 30 day requirement to provide documentation of the equipment limitation to 90 days in R5. We recommend that 90 days is a more appropriate timeframe for supplying this documentation.
Response: Thank you for your comments. The SDT agrees that more time should be allowed and has changed the time to 60 days.		
Luminant Power	No	Luminant believes this standard should only apply to voltage and frequency relay settings.
Response: Thank you for your comments. The SDT disagrees. Restricting the scope to the protection system settings would not meet the intent of FERC Order 693.		
Progress Energy	No	This appears to actually refer to R5. PE submits the comments below with the assumption that this question is directed toward R5:PE agrees with the requirement of R5 in general, but disagrees with the approach to the extent that R5.1 contains two options for GOs’ providing of information regarding voltage excursions, one of

Organization	Yes or No	Question 3 Comment
		which is problematic. Specifically, the requirements of Attachment 2 are too stringent and cannot be used by the majority of GOs, which leaves the second option as the only feasible method. The second option, provision of a voltage profile "at the Point of Interconnection for the generating unit or generating plant or Facility of the most severe normally-cleared Zone 1 fault described by dynamic simulation provided by the Transmission Planner", puts the responsibility back on the Transmission Planner. Requirement R5 is intended to aid Transmission Planners in providing information on Generator models needed for Transmission Planning analyses, and yet as it exists the only option for provision of the information is a hindrance to Transmission Planners rather than an aid. PE requests that the SDT simplify the language to merely state that GOs have an obligation to provide information that the TPs request.
Response: Thank you for your comments. The SDT agrees with stakeholders who have commented that the estimated probability of ride-through does not provide any reliability value and has removed the wording from the standard. The SDT has revised the wording for Requirement R5 so that, if requested, the Generator Owner must provide an estimate of the time a generating unit or facility will remain connected based on an excursion defined by the Transmission Planner.		
Westinghouse	No	a. This is for requirement 5 not requirement 4 **The SDT agrees.** b. We cannot evaluate the performance of units during frequency and voltage excursions at the transmission interface point, only at the generator and 6.9kV bus level where the auxiliary equipment interface exists. Therefore, the frequency and voltage excursion profiles would be different than those submitted by the RC, PC, TO or TP. **The SDT agrees that the profiles would be different which requires the Generator Owner to determine how they would translate to the specific facility based on its characteristics.** Also, 30 days is too short to perform a detailed analysis on plant performance during the frequency or voltage excursion. **The SDT agrees that more time should be allowed and has changed the time to 60 days.** Further evaluation would be required for the transformers, turbine and auxiliary equipment to determine satisfactory operation in the long time periods encompassed in the "No Trip Zones". **The SDT agrees that this would be part of the evaluation.**
Response: Thank you for your comments. See specific responses above.		
Southern Company	No	1) This Question is for R5, not R4. **The SDT agrees.** 2) We disagree with this approach due to the uncertainty about how to estimate the performance. The detailed dynamic analysis required to make an estimate of a specific units performance is not reasonable to require. The voltage excursion profile needed for an evaluation is that voltage present on the generator bus and plant distribution system auxiliary buses rather than at the point of interconnect. The protective relays and control equipment susceptible to high/low voltage excursions are located on the low voltage side of the

Organization	Yes or No	Question 3 Comment
		generator step up transformer. Does agreeing with the approach mean the philosophical desire to provide the TP with information or mean agreement with the requirement to provide estimations of the voltage excursion ride-through ability? We agree with the philosophical mantra, but we are not sure if a conclusive determination of a unit ride-through capability is possible. Generation Owners need a curve from Transmission that is referenced to the lowside since that is where the relays/equipment are located. **The SDT has revised the wording for Requirement R5 so that, if requested, the Generator Owner must provide an estimate of the time a generating unit or facility will remain connected based on an excursion defined by the Transmission Planner.** 3) Does "estimate of that unit's performance" only include the estimated time duration of 5.1 and probability of remaining connected in 5.2? Or, does it also include things like the estimated generator terminal voltage, MW, MVars, etc. for the duration of the frequency or voltage excursion? This needs to be clear. **The SDT agrees with stakeholders who have commented that the estimated probability of ride-through does not provide any reliability value and has removed the wording from the standard. The Requirement does not mention generator voltage, real power, reactive power, etc.** 4) The 30 days requirement is much too short. There are a large number of systems and components that would first have to be identified as susceptible to responding to these extreme conditions (especially the voltage conditions). Each of these would then require evaluation, including dynamic analysis for systems and components that respond dynamically over these relatively long time periods. This amounts to major study work on a single unit, much less over many units of many different system configurations and designs having equipment of many different manufacturers and vintages. Also, dynamic studies require accurate system and equipment models to produce valid results and the effort to establish accurate models is no simple task. **The SDT agrees that more time should be allowed and has changed the time to 60 days.**
Response: Thank you for your comments. See specific responses above.		
Oncor Electric Delivery Company LLC	No	It is unclear as to what constitutes an estimate of performance.
Response: Thank you for your comments. The SDT agrees with stakeholders who have commented that the estimated probability of ride-through does not provide any reliability value and has removed the wording from the standard. The SDT has revised the wording for Requirement R5 so that, if requested, the Generator Owner must provide an estimate of the time a generating unit or facility will remain connected based on an excursion defined by the Transmission Planner.		
Exelon	No	This question refers to Requirement R5 not Requirement R4. **The SDT agrees.** The "ride through" criteria should not extend beyond currently used critical clearing time (2nd zone of

Organization	Yes or No	Question 3 Comment
		protection or breaker failure) that switchyard breaker failure protection is based on. It is questionable whether nuclear units can survive anything beyond this. **The SDT does not believe it is necessary to extend the 0.0 pu voltage portion of PRC-024 Attachment 2 out to the critical clearing time (where this may be slower than 9-cycles). If normally cleared faults are cleared faster than 9-cycles at a specific location, the Generator Owner may use a voltage profile provided by the Transmission Planner for that site in lieu of PRC-024 Attachement 2.** Plants with auxiliary power systems fed directly from the nuclear switchyard would be even more questionable as the transient is not shielded by the generator bus. **The SDT agrees that it is challenging for many existing generation facilities (not just nuclear facilities). That is the reason for Requirement R5 (so the Transmission Planner, et al, have better information on how an existing facility will respond.**
Response: Thank you for your comments.		
Independent Electricity System Operator	No	We believe the SDT meant R5, not R4, unless R4 is a sub-requirement or a part of R3 (which seems to be the case by the way R4 is worded) and a format error resulted in R4 becoming R5. **The SDT agrees and has removed Requirement R4.** We do not support the provision of such an estimate. First of all, the requirement does not distinguish whether it applies to units that are equipped with frequency/voltage protective relays or otherwise. Secondly, the intent of providing the suggested estimate is to allow Transmission Planners to apply valid or supported assumptions in their planning studies. Given the requirements in Attachments 1 and 2, and Requirement R3 (which, by the way, should be modified as we suggest below), the TPs can apply the following relevant assumptions:a. For units that are equipped with frequency/voltage protective relays, the GO's submitted relay settings will determine when the units will trip;b. For units that are NOT equipped with frequency/voltage protective relays, the units are conservatively assumed to trip when the simulated frequency/voltage goes outside the bounds of Attachments 1 and 2.We do not see what other estimates that can be more relevant and valid than the above. We see that there may be some value in providing these estimates but only in the case of generators not equipped with frequency/voltage protective relays where tripping takes place beyond the no-trip zones of Attachments 1 and 2. For this information to be useful however, the generator's behavior must be predictable. While it may facilitate some "what-if" analysis, it is not clear that using this information would be better than the conservative assumption "b" above. How does the SDT envisage that the Transmission Planner will use this additional information if it cannot be relied upon? **The SDT agrees that determining the operation of protection system functions for a specific set of conditions is relatively straightforward, but the requirement for estimating the length of time a facility will remain connected includes evaluating upsets to the prime mover process that may result in a generator trip.**

Organization	Yes or No	Question 3 Comment
Response: Thank you for your comments. See specific responses above.		
Wisconsin Electric	No	(We believe the relevant requirement for this question is R5).The estimate of generator performance desired by the RC/PC/TO/TP can be obtained via informal means, including meetings, discussion, and simply working together. Not all information that may be "useful" should be codified by a Requirement in a Standard.Also, R5 and associated Measure M4 refer to a "written request". This would seem to limit the request and response to a hardcopy. Using simply "request" instead of "written request" would allow the use of electronic means as well.
Response: Thank you for your comments. The SDT included Requirement R5 in order to ensure that the information is provided expeditiously. The SDT believes the word "written" (as opposed to "verbal") would include electronic communications as well as hard copies.		
We Energies	No	(We believe the relevant requirement for this question is R5). The estimate of generator performance desired by the RC/PC/TO/TP can be obtained via informal means, including meetings, discussion, and simply working together. Not all information that may be "useful" should be codified by a Requirement in a Standard. Also, R5 and associated Measure M4 refer to a "written request". This would seem to limit the request and response to a hardcopy. Using simply "request" instead of "written request" would allow the use of electronic means as well.
Response: Thank you for your comments. The SDT included Requirement R5 in order to ensure that the information is provided expeditiously. The SDT believes the word "written" (as opposed to "verbal") would include electronic communications as well as hard copies.		
We Energies	No	(We believe the relevant requirement for this question is R5). Great River Energy	No	Requirement R4 is unnecessary and completely administrative. It provides no reliability value. It appears to be an attempt to compel a Generation Owner to be responsive to its Reliability Coordinator, Planning Coordinator, Transmission Operator and Transmission Planner. In fact, it does not compel any real responsiveness as the Generation Owner could simply document their disagreement. It is already in the

Organization	Yes or No	Question 3 Comment
		Generator Owner's best interest to be responsive. Thus, this requirement is not necessary.
Response: Thank you for your comments. The SDT has removed Requirement R4.		
Duke Energy	No	Should be R5. We question the value of this requirement, and how the TP use the probabilistic information in any TPL analysis. It's unclear how compliance with planning requirements would be demonstrated. The planner needs to know under what voltage/frequency conditions a unit will trip so that when those conditions are attained in the model the unit will be turned off. Generator owners/operators need to make their best efforts to determine the conditions and provide it to their TP's, updating the information as plant design changes occur or operating history indicates the conditions have changed. Having a time estimate as specified in R5.1 does not provide the voltage/frequency threshold that the planner must know so that the unit can be tripped when those conditions occur in the model, no matter what time those conditions occur.
Response: Thank you for your comments. The SDT agrees with stakeholders who have commented that the estimated probability of ride-through does not provide any reliability value and has removed the wording from the standard. The SDT has revised the wording for Requirement R5 so that, if requested, the Generator Owner must provide an estimate of the time a generating unit or facility will remain connected based on an excursion defined by the Transmission Planner.		
Western Electricity Coordinating Council	No	The question above appears to be referring to R5, not R4. R5 has the requirements for providing estimates of the performance of the units. I have no comments on R5, However, I have the following comment on R4.We agree with the intent of the requirement, but believe that more specificity in what is required in the written response is necessary. As written it could be argued that a simple response from the Generator Owner indicating they received the inquiry was sufficient. Suggest adding detail similar to that included in MOD-026, Requirement 3 that identifies what the response must contain.
Response: Thank you for your comments. The SDT has removed Requirement R4.		
Ingleside Cogeneration LP	No	Ingleside Cogeneration LP assumes this question actually applies to Requirement R5. It is not clear what extra reliability information will be provided to Transmission Planners as long as Generator Owners confirm that their voltage and frequency settings comply with the performance curves in the attachments. It may be valid to require an estimate of performance if the GO identifies a limitation as allowed under R3. Otherwise, the TP should assume generator relays will operate if the magnitude and duration thresholds defined in the attachments are exceeded.
Response: Thank you for your comments. The SDT has removed Requirement R4.		

Organization	Yes or No	Question 3 Comment
Luminant Energy	No	Note: This appears to be dealing with R5 and not R4.R5 Because of the requirement under R5.3 (identification for basis for estimates of probability of staying on-line, etc), the study would take considerable time to compile. I would recommend that the generator owner be provided 90 calendar days rather that the suggested 30 to submit the results. **The SDT agrees that more time should be allowed and has changed the time to 60 days.** R5.1 It appears that a frequency and voltage excursion must occur at the same time with the estimated time duration that the unit will remain connected. Was it intended that the “and” be an “or”? **The SDT has revised the wording for Requirement R5 so that, if requested, the Generator Owner must provide an estimate of the time a generating unit or facility will remain connected based on an excursion defined by the Transmission Planner.** Would LVRT dovetail into relay loadability for stressed conditions for low voltage conditions between 45 and 90%? (Generator relay loadability is evaluated at 85% (PRC-023-2).) . **The SDT does not believe that this would replace an evaluation of relay loadability.** R5.3 Luminant recommends removing this requirement. . **The SDT believes this information will help the Transmission Planner determine a level of confidence in the estimate.**
Response: Thank you for your comments. See specific responses above.		
Ameren	No	Unless written to exclude all auxiliary system equipment which may result in a unit shut down, it will be impossible to determine this probability with any reasonable accuracy. For example, where auxiliary motors would stall and trip off, or contactors drop out would be variable
Response: Thank you for your comments. The SDT agrees that this is an estimate and not deterministic. The performance of contactors is highly dependent on the phase angle of the voltage wave when the excursion occurs – which cannot be predicted. The Generator Owner may want to assume a worst case scenario.		
PPL Electric Utilities	No	1. Excursion-estimate requirements for existing units are presented in R5, not R4. Our comments below pertain to R5.2. The question above cites “frequency and voltage excursions [emphasis added],” the question 4 below deals with “frequency or voltage excursions,” para. R5.1 states “Frequency Excursion...and a Voltage Excursion” and para. R6 references “Frequency Excursion or Voltage Excursion.” The combinations of simultaneous frequency and voltage variations that units must ride-though should be clarified. **The SDT has revised the wording for Requirement R5 so that, if requested, the Generator Owner must provide an estimate of the time a generating unit or facility will remain connected based on an excursion defined by the Transmission Planner.**

Organization	Yes or No	Question 3 Comment
		3. Preparing the estimates in question appears to constitute a duplication of the excitation and governor model verifications required by MOD-026 and MOD-027. Para. R5 states that the PRC-024 estimates are to be used in modeling studies; but there should be one, definitive source of modeling data, not two different sources. Para. R5 of PRC-024 should be replaced by a reference to using the tools developed for MOD-026 and MOD-027. **Requirement R5 in PRC-024 requires the Generator Owner to develop an estimate of the time a facility will ride through an excursion. This is significantly different than the verification of performance called for in MOD-026 or MOD-027.** 4. In the event that R5 remains as-is, a standard-specific definition of the word "plant" is needed, restricting applicability to NERC-registered generators. A plant consisting of two 750 MW fossil units and a standby 10 MW diesel generator, for example, should not have to model the diesel unit's behavior. **The Applicability is to Generator Owners. By default, all generating units and facilities that meet the NERC Registry Criteria fall within the applicability of this standard.** 5. It is necessary in any event to limit the requirement for estimates to that which can reasonably be modeled. Unit auxiliary system buses may drop-out and cause a unit to trip, even if the generator and protective relays can handle any given transient, and dynamic behavior at the 4160V and 460V levels may be impossible to predict for the radical excursions specified in PRC-024. **The SDT agrees that this is an estimate and not deterministic. The performance of contactors, for example, is highly dependent on the phase angle of the voltage wave when the excursion occurs – which cannot be predicted. The Generator Owner may want to assume a worst case scenario.**
Response: Thank you for your comments. See specific responses above.		
Indiana Municipal Power Agency	No	This is actually requirement R5. IMPA does not see any value in assigning a standard requirement to a Generator Owner that is just an estimation of performance when it might be a far off estimation of performance compared against actual performance of an existing unit or generating plant. This standard should concentrate on the setting of relays and not have Generator Owners estimate how their unit or generating plant will perform during a Frequency/Voltage Excursion. This standard should also not force Generator Owners to perform studies or model their unit or generating plant since they are not guaranteed or reliable either.
Response: Thank you for your comments. The SDT is charged with complying with FERC Order 693 and the recommendations in the 2003 Black Out Report to improve system modeling. If the Reliability Coordinator, Planning Coordinator, Transmission Operator, or Transmission Planner do not believe there is a reliability value in requesting the information described in Requirement R5, then they are not required to request it.		

Organization	Yes or No	Question 3 Comment
GenOn Energy	No	The comment is for R5 for the June 15, 2011 draft. The wording is too open-ended and subjective in scope. Similar to R1 & R2, the requirement should be clearly defined and limited to devices that directly respond to generator voltage or frequency. **The SDT is charged with complying with FERC Order 693 and the recommendations in the 2003 Black Out Report to improve system modeling, including the performance of the generating unit or generating facility beyond just the performance of the protection system.** R3 already requires the information of other control or protective devices. **The SDT disagrees. Requirement R3 requires information on equipment limitations (other than limitations of control or protection systems).** Typically, the Generator Owner does not monitor the interconnection voltage for protection purpose; rather generator terminal voltage is used for generator protection. The modeling is performed by others, but the burden of analysis is being placed upon the Generator Owner to determine performance probability for information not in their possession. **The SDT believes that the Generator Owner is the entity that can best develop an estimate of performance of a generating unit or generating facility as described in Requirement R5.** 30 days is a short period of time for this analysis when hit cold with a request like this, especially during outage season. **The SDT agrees that more time should be allowed and has changed the time to 60 days.**
Response: Thank you for your comments. See specific responses above.		
Imperial Irrigation District (IID)	Yes	According to the standard this language is R5
Response: Thank you for your comments. The SDT agrees.		
MRO's NERC Standards Review Forum	Yes	This question seems to be referring to R5 rather than R4.
Response: Thank you for your comments. The SDT agrees.		
Dynamics Review Subcommittee	Yes	We assume this pertains to R5 not R4. 30 days is probably not enough time for a GO to determine a suitable estimate. We recommend 90 days.
Response: Thank you for your comments. The SDT agrees that more time should be allowed and has changed the time to 60 days.		

Organization	Yes or No	Question 3 Comment
FirstEnergy	Yes	Although we agree with the requirement, we noticed that the VRF and Time Horizon is missing for R4. We suggest a LOWER VRF and Long-term Planning Time Horizon.
Response: Thank you for your comments. The SDT has removed Requirement R4.		
ISO New England Inc.	Yes	The RC/PC/TOP/TP functional entities provide for a wide-area view of the transmission system and its operating limitations. These entities need accurate generator characteristics in order to correctly plan the system and to operate it within known limits.
Response: Thank you for your comments. The SDT agrees.		
American Electric Power	Yes	A Generator Owner should only be required to report known limitations that might cause their unit to trip. As written, one could be in violation of the standard for some unknown limitation which might exist and that might only be known after an event has occurred. This question seems unrelated to R4 which states the time provided to respond to a written request for information. Rather, it seems to be related instead to R3 or R5.
Response: Thank you for your comments. The question was written to apply to Requirement R5. If the Generator Owner has activated protective functions that are set inside the "no trip zone" in PRC-024 Attachment 1 or Attachment 2 and does not know of a technical limitation to changing the settings, then they can be changed and the Generator Owner will be in compliance.		
American Electric Power	Yes	A Generator Owner should only be required to report known limitations that might cause their unit to trip. As written, one could be in violation of the standard for some unknown limitation which might exist and that might only be known after an event has occurred. This question seems unrelated to R4 which states the time provided to respond to a written request for information. Rather, it seems to be related instead to R3 or R5.

Consolidated Edison Co. of NY, Inc.	Yes	
GE Energy	Yes	
American Transmission Company	Yes	

4. Requirement R5 requires a Generator Owner's new unit or generating plant/facility to be able to stay on line when exposed to point-of-interconnection frequency or voltage excursions depicted in the curves of Attachment 1 and Attachment 2. Do you believe this requirement is technically achievable for new units or generating plant/facilities? Please provide comments supporting your answer.

Please provide along with your comment, what you believe the timeframe is needed to implement this requirement.

Summary Consideration: The question mistakenly referred to Requirement R5 due to changes to the standard made by NERC Staff after the SDT had submitted the standard. This error was observed by the stakeholders and the SDT believes the responses accurately reflect the feelings of industry to the intended question. The majority of stakeholders agreed with the proposed requirement.

Based on the response to the question, no major changes were made to Requirement R6.

Organization	Yes or No	Question 4 Comment
Occidental Chemical	Negative	4. Requirement R5 requires a Generator Owner's new unit or generating plant/facility to be able to stay on line when exposed to point-of-interconnection frequency or voltage excursions depicted in the curves of Attachment 1 and Attachment 2. Do you believe this requirement is technically achievable for new units or generating plant/facilities? Please provide comments supporting your answer. Please provide along with your comment, what you believe the timeframe is needed to implement this requirement. Yes: Comments: Ingleside Cogeneration LP assumes this question actually applies to Requirement R6. The frequency and voltage ride-through specifications are reasonable for new generating facilities in Ingleside Cogeneration LP's view.
Response: Thank you for your comments.		
Northeast Power Coordinating Council	No	The refererence to "R5" in this question should be R6.
Response: Thank you for your comments. The SDT agrees.		
SERC Generation Sub-committee (GS)	No	This appears to refer to R6.The proposed bands would need to be considered by new plant designers and incorporated into their design basis if feasible. Specific criteria have not been provided in new plant design

Organization	Yes or No	Question 4 Comment
		guidance provided by EPRI Utility Requirements Document (URD) nor in other industry standards used by new plant designers. The frequency band was considered for some new plant designs and no concerns were identified. However, It is not clear if all or even most of the designers for other nuclear/fossil designs have considered this.The proposed voltage band has caused many concerns and probably is not achievable for existing or new steam plants because electrically powered equipment (motors, MCC components, contactors, etc.) have been and are normally designed for proper operation as follows:The normal voltage boundaries have been specified to be for the steady-state operating conditions based on the ANSI C84.1-2006 “American National Standard for Electric Power Systems and Equipment - Voltage Ratings (60Hz)”as follows:a. Normal Conditions: Â±5% Continuous Durationb. Emergency Conditions: Â±10% not specified DurationThese Criteria are currently widely used in practice and can be complied with by all types of new generating plants designed with an in-plant voltage regulation capability. In connection with these criteria, all new equipment, both on the transmission system and in new generation plants must be chosen in order to be able to operate and withstand these voltage excursions.For transients, the above should be applied for conditions lasting more than one second. Transient conditions lasting less than one second, can be more severe and the equipment can still ride through it for about 0.5 seconds. A design solution to address severely degraded voltage lasting more than one second, is to utilize expensive voltage regulation devices, normally not utilized in the past at most power generation plants.It's not clear why a plant should be required to withstand any transient beyond that expected by a switchyard fault with one failed breaker (the basis for critical clearing times for second zone or breaker failure protection). An R&D effort should be considered to investigate reasonable steam plant voltage excursion ride through capabilities if a criteria is needed.
Response: Thank you for your comments. The SDT has extended the implementation of Requirement R6 to six years to allow for the development of designs that meet the Requirement. ANSI C84.1-2006 (now called NEMA C84.1) only defines continuous voltage levels. The designer of a new generating facility would have to determine how best to ensure the equipment be installed to ensure compliance with Requirement R6. The Standard allows the Generator Owner to design for faster clearing and faster voltage recovery if provided by the Transmission Planner. Critical clearing time may be significantly longer than nine cycles and the SDT did not want to subject generators to those conditions.		
MRO's NERC Standards Review Forum	No	If design standards have not been previously developed or implemented for all plant equipment and therefore the plant itself to not trip during the defined excursions it is uncertain when and if equipment design standards and the equipment itself can become available to achieve the requirements.
Response: Thank you for your comments. The SDT has extended the implementation of Requirement R6 to six years to allow for the development of designs that meet the Requirement.		
Electric Market Policy	No	This appears to be a design question that presumably the standard drafting team researched and quantified to provide a basis in framing the curves of Attachment 1 and Attachment 2. If this is true, more documentation

Organization	Yes or No	Question 4 Comment
		should be provided to the ballot body.
Response: Thank you for your comments. The curves of PRC-024 Attachment 1 match the curves for "Expected Generator Tripping" in PRC-006 Attachment 1 that sets expectations for UFLS system performance. There is a margin between the UFLS performance expectation and the generator tripping curves. The curves of PRC-024 Attachment 2 were developed based on the existing wind generator low voltage ride through curve in FERC Order 661-A, studies done in WECC and various European voltage ride through requirements (see the Reference cited in the Standard). All of this information is available to the ballot body.		
FirstEnergy	No	Requirement R5 - It may not be feasible for the GO to provide this information in 30 days. We suggest allowing 90 days. **The SDT agrees that more time should be allowed and has changed the time to 60 days.** Regarding 5.2 and the estimation of the probability, we are not clear as to what is required. The wording is confusing and cannot offer suggestions because we are not sure what the intent is. **The SDT agrees with stakeholders who have commented that the estimated probability of ride-through does not provide any reliability value and has removed the wording from the standard.** R5.1 - Some nuclear plants will not be able to run at 95% voltage indefinitely as required as that voltage is lower than each plant's Licensing Basis for degraded grid voltage. We ask that this standard include an exception for nuclear generators that allow them to report what % of grid voltage will force them into a Limiting Condition of Operation if that % voltage is higher than 95%. **The condition described would be a technical limitation and would allow the Generator Owner of that facility an exemption from that portion of the PRC-024 Attachment 2 "no trip zone" that the limitation describes.**
Response: Thank you for your comments. See specific responses above.		
Santee Cooper	No	This appears to refer to R6.The proposed bands should be considered by new plant designers and incorporated into their design basis if feasible. Specific criteria have not been provided in new plant design guidence provided by EPRI Utility Requirements Document (URD) nor in other industry standards used by new plant designers. The frequency band was considered for some new plant design basis and no concerns were identified. It's not clear if all or even most of the designers for other nuclear/fossil designs have considered this.The proposed voltage band has caused many concerns and probably is not achievable for existing or new steam plants because electrically powered equipment (motors, MCC components, contactors, etc.) has been and is normally designed for proper operation as follows:The normal voltage boundaries have been specified to be for the steady-state operating conditions based on the ANSI C84.1-2006 "American National Standard for Electric Power Systems and Equipment - Voltage Ratings (60Hz)"as follows:a. Transient conditions lasting more than one second, can be more severe and the equipment can still ride through it. A design solution to address severely degraded voltage lasting more than one second, is to utilize expensive voltage regulation devices, normally not utilzed at power generation plants.It's not clear why a plant should be required to withstand any transient beyond that expected by a switchyard fault with one failed breaker (the basis for critical clearing times for second zone or breaker failure protection). An R&D effort should be considered to investigate steam plant ride through capabilities if a criteria is needed.
Response: Thank you for your comments. The SDT has extended the implementation of Requirement R6 to six years to allow for the development of designs that meet the Requirement. ANSI C84.1-2006 (now called NEMA C84.1) only defines continuous voltage levels. The designer of a new generating facility would have to determine how best to ensure the equipment be installed to ensure compliance with Requirement R6. The Standard allows the Generator Owner to design for faster clearing and faster voltage recovery if provided by the Transmission Planner. Critical clearing time may be significantly longer than nine cycles and the SDT did not want to subject generators to those conditions.		
Florida Municipal Power Agency	No	First, FMPA believes the SDT is referring to R6 not R5. Technically, the requirement is inconsistent with the question. The requirement is to design, build and maintain to prevent tripping, it does not say “thou shall not trip”. If a generator is designed, built and maintained to specifications that should not trip, but, a generator trips anyway in a real-life event, is that a violation?
Response: Thank you for your comments. The SDT disagrees that with FMPA’s interpretation. The actual wording is “Each Generator Owner shall design, build, and maintain its new unit or new generating plant or generating Facility so that it <u>will not trip</u>… “. As written, a trip during a frequency or voltage excursion that remains within the boundaries of the “no trip zones” in PRC-024 Attachments 1 and 2 would be a violation.		
TVA - GO	No	The proposed bands would need to be considered by new plant designers and incorporated into their design basis if feasible. Specific criteria have not been provided in new plant design guidance provided by EPRI Utility Requirements Document (URD) nor in other industry standards used by new plant designers. The frequency band was considered for some new plant designs and no concerns were identified. However, it is not clear if all or even most of the designers for other nuclear/fossil designs have considered this. For transients, the above should be applied for conditions lasting more than one second. Transient conditions lasting less than one second, can be more severe and the equipment can still ride through it for about 0.5 seconds. A design solution to address severely degraded voltage lasting more than one second, is to utilize expensive voltage regulation devices, normally not utilized in the past at most power generation plants. It's not clear why a plant should be required to withstand any transient beyond that expected by a switchyard fault with one failed breaker (the basis for critical clearing times for second zone or breaker failure protection). An R&D effort should be considered to investigate reasonable steam plant voltage excursion ride through capabilities if a criteria is needed.
Response: Thank you for your comments. The SDT has extended the implementation of Requirement R6 to six years to allow for the development of designs that meet the Requirement. ANSI C84.1-2006 (now called NEMA C84.1) only defines continuous voltage levels. The designer of a new generating facility would have to determine how best to ensure the equipment be installed to ensure compliance with Requirement R6. The Standard allows the Generator Owner to design for faster clearing and faster voltage recovery if provided by the Transmission Planner. Critical clearing time may be significantly longer than nine cycles and the SDT did not want to subject generators to those conditions.		
Arizona Public Service Company	No	AZPS believes this question applies to R6. There should be an implementation period for the requirement for new units to allow the plants which have been ordered already to not to have to be redesigned.
Response: Thank you for your comments. The SDT has extended the implementation of Requirement R6 to six years to allow for the development of designs that meet the Requirement.		
Luminant Power	No	Luminant believes it may be technically possible to design a new generating unit or facility to ride through a low voltage event even though the cost to do so may be prohibitive and impractical. However, Luminant does not believe it is reasonable or achievable to expect the Generator Owner to be able to maintain those capabilities in perpetuity due to equipment deterioration and aging over time even though proper maintenance practices were implemented.
Response: Thank you for your comments.		
Progress Energy	No	This appears to actually refer to R6. **The SDT agrees.** PE submits the comments below with the assumption that this question is directed toward R6: The ride through voltage profile in attachment 2 is not achievable for either new or existing facilities. The issue is not the relay protection but in the capability of the auxiliary equipment (such as motor contactors, coal feeders,

Organization	Yes or No	Question 4 Comment
		instrument sensors). I do not know of any motor control contactor that will hold in when voltage goes to zero. The energy that is stored in the coil holding the contactor in place is rapid returned into the system during a time of fault. While the short circuit contribution of motors and contactors may last up to .2 seconds the majority of the stored energy is returned in the first 1/5 of the decay curve. The requirements that are specified in this standard are outside the IEEE and ANSI standards associated with manufacturing equipment used in power plants, while manufacturing of equipment to specialized standards MAY be possible the cost would be extremely high and in some cases may not be possible. **Existing plants are not required to comply with Requirement R6. For the example cited regarding contactor performance, a new plant could be designed with the contactors fed from a DC source or a UPS system. European utilities must comply with ride-through standards now. The SDT agrees that this would increase the cost of a facility.**
Response: Thank you for your comments. See specific responses above.		
Westinghouse	No	a. This is for requirement 6 not requirement 5 **The SDT agrees.** b. It is uncertain that the requirements, when translated to the 6.9kV AC distribution system and below, can be achieved with the equipment installed in new generating facilities. Most motor specifications do not require demonstrated operability below 75% motor rated terminal voltage or >5% deviation in rated frequency. Additional vendor testing would be required in order to effectively demonstrate equipment design capabilities. Additionally, plant performance has not been evaluated for the entire range of frequencies in the "No Trip Zone". More analysis would have to be performed in order to verify acceptable plant operation in these frequency bands.
Response: Thank you for your comments. A 5% deviation in frequency is 3 Hz. PRC-024 Attachment 1 allows the generator to trip if the frequency reaches 57.0 Hz or 63.0 Hz. The SDT believes the comment regarding 75% voltage relates to continuous voltage level, not a fast transient.		
Southern Company	No	1) This question is for R6, not R5. **The SDT agrees.** 2) We highly doubt that the requirement is technically feasible based on our experience with vendors and the various technical requirements and modifications that would have to be made to make sure that low or high voltage ride thru is possible. Complicating factors include the many different equipment suppliers, limited control of manufacturing standards by the purchasers, and continuing changes in technology must be considered to be able to determine whether or not all plant sub-systems can ride through. The economic impact and technical feasibility of this requirement has not yet been considered by suppliers. **European utilities must comply with ride-through standards now.** 3) Even if this can be achieved, it will require significant changes in the power plant industry. This will

Organization	Yes or No	Question 4 Comment
		include major changes to plant system and equipment design standards (both U.S. and International). This alone will take years to accomplish. Then, manufacturers will have to design, build, and test plant systems and equipment to meet the new requirements. It is impractical to expect a new plant that can meet both the frequency and voltage requirements to be built in less than 10 years after R6 is imposed. **The SDT has extended the implementation of Requirement R5 to six years to allow for the development of designs that meet the Requirement.**
Response: Thank you for your comments. See specific responses above.		
PacifiCorp	No	There are going to be certain exceptions to new units or facilities being capable of staying on line under the listed circumstances just as there are current exemptions for existing facilities. Exceptions could be related to VFD (variable frequency drive) operation or motor operation at the plants, which would be true of both existing and new generating plants. There is also a possibility of overcurrent trips during these voltage conditions, tripping would not necessarily be limited to voltage or frequency relays. It would be difficult for Generator Owners to answer this question fully without a thorough study of how the frequency and voltage excursions will impact generation loads. Generation protective relays do not typically base their protection on transmission system voltages at the point of interconnection.
Response: Thank you for your comments.		
Manitoba Hydro	No	While the requirement is technically achievable, justification should be provided by the drafting team for the curves in Attachments 1 and 2. It is not clear why the 'no trip zone' limits are set where they are.
Response: Thank you for your comments.		
Great River Energy	No	If design standards have not been previously developed or implemented for all plant equipment and therefore the plant itself to not trip during the defined excursions it is uncertain when and if equipment design standards and the equipment itself can become available to achieve the requirements.
Response: The SDT has extended the implementation of Requirement R5 to six years to allow for the development of designs that meet the Requirement.		
Duke Energy	No	This appears to refer to R6. **The SDT agrees.** The proposed bands should be considered by new plant designers and incorporated into their design basis if feasible. Specific criteria have not been provided in new plant design guidance provided by EPRI Utility Requirements Document (URD) nor in other industry standards used by new plant designers. The frequency

Organization	Yes or No	Question 4 Comment
		band was considered for some new plant design basis and no concerns were identified. It's not clear if all or even most of the designers for other nuclear/fossil designs have considered this.The proposed voltage band has caused many concerns and probably is not achievable for existing or new steam plants because electrically powered equipment (motors, MCC components, contactors, etc.) has been and is normally designed for proper operation as follows:The normal voltage boundaries have been specified to be for the steady-state operating conditions based on the ANSI C84.1-2006 “American National Standard for Electric Power Systems and Equipment - Voltage Ratings (60Hz)”as follows:a. Normal Conditions: Â±5% Continuous Durationb. Emergency Conditions: Â±10% not specified DurationThese Criteria are currently widely used in practice and can be complied with by all types of new generating plants designed with an in-plant voltage regulation capability. In connection with these criteria, all new equipment, both on the transmission system and in new generation plants must be chosen in order to be able to operate and withstand these voltage excursions.For transients, the above should be applied for conditions lasting more than one second. Transient conditions lasting more than one second, can be more severe and the equipment can still ride through it. A design solution to address severely degraded voltage lasting more than one second is to utilize expensive voltage regulation devices, normally not utilized at power generation plants. This standard shouldn’t dictate a solution to the situation where a generator goes offline due to low voltage on the transmission system, because in many cases the generator going offline may not be a problem for the overall transmission system. In situations where it is a problem, a collaborative effort between the Transmission Planner and the Generator Owner would be the best approach (see AREVA white paper that has been provided to the SDT).It's not clear why a plant should be required to withstand any transient beyond that expected by a switchyard fault with one failed breaker (the basis for critical clearing times for second zone or breaker failure protection). An R&D effort should be considered to investigate steam plant ride through capabilities if a criteria is needed.
Response: Thank you for your comments. The SDT has extended the implementation of Requirement R6 to six years to allow for the development of designs that meet the Requirement. ANSI C84.1-2006 (now called NEMA C84.1) only defines continuous voltage levels. The designer of a new generating facility would have to determine how best to ensure the equipment be installed to ensure compliance with Requirement R6. The Standard allows the Generator Owner to design for faster clearing and faster voltage recovery if provided by the Transmission Planner. Critical clearing time may be significantly longer than nine cycles and the SDT did not want to subject generators to those conditions.		
US Army Corps of Engineers	No	R5 applies to existing units. This requirement seems vague and subjective - recommend clarification. Please clarify the term "less stringent" - do you mean 'in the no-trip zone' or 'outside the no-trip zone. How will the information be used and what are the implicatios if the response is not satisfactory? R6 applies to new units - I have no comments on R6.
Response: Thank you for your comments. The SDT intended “less stringent” to mean a smaller “no trip zone” due to faster fault clearing and/or		

Organization	Yes or No	Question 4 Comment
faster voltage recovery time. The information would be used to better model generator response to system disturbances.		
Luminant Energy	No	Generating units placed in service prior to this standard normally have 30+ years lifespan. During the life span, components targeted for LVRT will experience loss of life (time in use, number of operations, environment, etc) which could result in a failure of an LVRT event at the point of interconnection. Because a study may not be able to locate every component, an increase in reliability or the ability of the plant to ride through a low voltage condition could never be guaranteed above its current level. The same issue exist for new units. If the plant was designed to maintain LVRT conditions, there is no guarantee that the plant's ability to ride through low voltage conditions can be maintained during its life span.
Response: Thank you for your comments.		
Ameren	No	Unless written to exclude all auxiliary system equipment which may result in a unit shut down, it will be impossible to determine with any reasonable accuracy where auxiliary motors would stall and trip off, or contactors drop out.
Response: Thank you for your comments. The SDT agrees that this is an estimate and not deterministic. The performance of contactors, for example, is highly dependent on the phase angle of the voltage wave when the excursion occurs – which cannot be predicted. The Generator Owner may want to assume a worst case scenario.		
American Electric Power	No	This question references R5, but we believe the team intended to reference R6. **The SDT agrees.** The requirement for new units and plants to not trip within the envelope of Attachment 1 is reasonable; the design of turbines involves some off-nominal frequency versus accumulated time criteria and Attachment 1 is being proposed in view of existing design criteria of major manufacturers. While the Standards team has proposed this in view of OEM design criteria, it would be beneficial to obtain input from the OEMs to learn what issues if any they have with this proposal and what changes and/or incremental costs could be incurred to meet the Standard for new or existing generators. **The SDT has reviewed OEM information. Modern steam and combustion turbines can all meet PRC-024 Attachment 1. Two OEM's have commented on this standard and have not objected to Attachment 1.** The design and ability of auxiliary systems to meet the requirements outlined in Attachment 1 will require review.To not trip within the envelope of the Attachment 2 Voltage Ride-through Time Duration Curves is another matter. No requirement such as this has ever been imposed on generating units in the past and we question the need for it now. The appearance of such graphs seems to have been in response to the performance of wind farms that tripped off-line by protective relays when disturbances occurred on the transmission system. The Attachment 2 VRT curve may thus be an appropriate requirement for wind turbine generators. The applicability to conventional generation, however, is questionable. Further, the curve and the

Organization	Yes or No	Question 4 Comment
		supplemental tables (curve data points) seem to be at odds with the language of R2, e.g. R2.1.1 which states for three-phase transmission system zone 1 faults with Normal Clearing, interpreted to mean as little as 3 cycles up to and not to exceed 9 cycles depending on the transmission relay practice and transmission voltage application.Specific comments on and objections to R6-Attachment 2 are as follows: (1) It is not at all clear that a conventional generating unit could maintain synchronism during POI voltage events within the envelope of Attachment 2. The standard needs to explicitly state that Attachment 2 is not a requirement to maintain synchronism (which is already covered by TPL standards). This point must be made clear within either the text of the requirement or else in a footnote, not just the comment form. (2) Should the SDT retain this requirement, it would be advisable to limit the scope of Attachment 2 in R6 to generator over- and under-voltage relay settings and any unit auxiliary equipment over- and under-voltage protection whose operation could lead to the loss of the unit. However, it is also not at all clear whether auxiliary systems could be designed to withstand voltage disturbances within the envelope of Attachment **Requirement R6, part 6.7 allows generating units to trip for an actual or impending loss of synchronism.** 2. Further complicating auxiliary systems ride-through, while such a graph may be appropriate for wind farms, it is not appropriate for conventional synchronous generators that have a substantial capability to control the voltage they are subjected to during a system disturbance (unlike most wind farms) and whose critical auxiliary systems are usually (and should be) served from the generator bus (low side of GSU) and are thus insulated to some extent from what may happen on the transmission system. A more appropriate requirement for conventional generation would be to require an automatic over-excitation limiting (OEL) function that is coordinated with over-excitation protection. However, we believe OELs are now standard equipment among excitation equipment suppliers and should not need to be required in a standard. (3) It would be impractical, if not impossible, to test or otherwise verify generator ride-through for POI voltage disturbances within the envelope of Attachment 2. In view of the above considerations, and in the interest of treating all generation types equitably, we believe a more appropriate approach to generator voltage ride-through would be deference to TPL standards for the types of transmission system disturbances where stability needs to be maintained. This has always been an acceptable criterion for conventional generation ride-through in the past. It is not stated in these terms in this proposed standard and independent review of a random sample of units could demonstrate the units may not meet this R6-Attachment 2 performance requirement though they would meet R2.1.1 and TPL standard requirements.It would be beneficial to state somewhere that any fault or other disturbance on the transmission system for which a conventional generator is expected to survive, a wind farm must also survive without tripping. (A statement such as that may be out of place in this standard and perhaps ought rather to have been included in the new TPL-001-1.) The proposed VRT criteria requires more study and analyses before introducing it so broadly in this standard for other than for wind turbine generators for which it has already been applied. Therefore, for the purposes of the R6 performance requirement, we believe that reference to Attachment 2 should be removed. **The SDT agrees that it is not necessary to place a requirement for OEL's in a standard and has not added it to this standard. The SDT also agrees with the impracticality of verifying ride-through capability through testing and has**

Organization	Yes or No	Question 4 Comment
		not included any requirements to this effect. One of guidelines the SDT is working under is FERC's desire for ride through performance to meet the TPL standards as they expressed in Order 693. The SDT has tried to write this standard in a technology-neutral manner. The requirements apply equally to wind (and other variable energy resources) as to conventional synchronous generators.
Response: Thank you for your comments. See specific responses above.		
Indiana Municipal Power Agency	No	This is actually requirement R6. **The SDT agrees.** IMPA does not believe this technology is currently achievable for new units or generating plant/facilities on all generation producing fronts. The technology should be in place and proven on all generation fronts before such writing of standard requirements.
Response: Thank you for your comments.		
GenOn Energy	No	Applied to R6 of the June 15, 2011 draft. It does not appear that the SDT has carefully considered the possible impact of Attachment 2 on plant electrical auxiliary motors and contactors. The SDT should ask an power plant engineering company the impact on the electrical auxiliaries of an 800MW coal unit with a scrubber.
Response: Thank you for your comments. The SDT realizes that there would be a significant impact on the design of plant auxiliary systems.		
Idaho Power - Power Production		This requirement should not exist. Generator Owners are required to comply will all approved NERC and RRO standards. It is the responsibility of the Generator Owner to see that the plant is built according to specifications which should include all approved NERC Reliability standards governing power plants.
Response: Thank you for your comments. The SDT is charged with complying with FERC Order 693 and the recommendations in the 2003 Black Out Report to improve system modeling.		
Bonneville Power Administration		R5 - WECC Reliability Subcommittee discussions indicated that protection generation relay performance at the Point of Interconnection was different than if the measurement point is at the low side or high side of the step-up transformer. The NERC Standard should specify the measurement point at the high side of either the generator step up transformer, or at the high side of the collector transformer where multiple small generators are aggregated at a collector substation.Attachment 2 - BPA suggests modifying the diagram to reflect changes to Requirement R2.1.1 above, e.g. to show that allowable voltage relay trip time is greater than the normal fault clearing time if the normal clearing time is less than 9 cycles.

Organization	Yes or No	Question 4 Comment
Response: Thank you for your comments. The voltage curves presented in PRC-024 Attachment 2 are already described as being at the high side of the GSU or collector transformer. The SDT believes that section 2.1.2 conveys the Generator Owner is allowed to use actual fault clearing times of less than nine cycles to set voltage-affected relays if the Transmission Planner provides the site-specific expected voltage characteristics.		
Austin Energy		The curves in Attachment 1 are more restrictive than the current ERCOT Operating Guide requirements. The equipment impact of this new requirement requires additional internal review, before AE can respond definitively. If the requirement can be implemented without equipment risk, it will take up to 3 years to implement the new settings.
Response: Thank you for your comments.		
Pepco Holdings Incand Affiliates	Yes	Believe this question is referring to Requirement R6 not R5 as stated in the question. **The SDT agrees.** Yes, it is possible to design a new facility to operate within the requirements identified in this standard. However, it may require specification of equipment with higher than normal overvoltage capabilities. Also, significant analyses would have to be conducted on the behavior of plant control systems (exciter controls, boiler controls, etc.), as well as equipment connected to auxiliary busses (including low voltage motor contactors) to ensure that all systems are designed with appropriate ride-through capabilities. However, it is unclear how this standard would apply to the ride through capability of units connected to the BES, but whose source of auxiliary station service power is from a non-BES interconnection. Would the units also have to ride through expected voltage excursions at the point of interconnection with the station service transformer even if the station service transformer was not fed directly from the BES?
Response: Thank you for your comments. The SDT believes that a generating facility that meets the NERC Registry Criteria for size and connection voltage would have to meet this standard regardless of its source of auxiliary station service power.		
Imperial Irrigation District (IID)	Yes	According to the standard this language is R6
Response: Thank you for your comments. The SDT agrees.		
BC Hydro and Power Authority	Yes	Frequency and voltage excursions specified in this standard are reasonable and actually less stringent then certain regional or area requirements. Generating facilities designed in line with industry practices and applicable standards should be able to ride through such disturbances. Lastly, it is in GOs best interest to have a robust design for new generating facilities.
Response: Thank you for your comments.		

Organization	Yes or No	Question 4 Comment
SPP Reliability Standards Develpment Team	Yes	Question should read R6 not R5. **The SDT agrees.** We feel that as long as everyone knows about these requirements ahead of time that there shouldn't be an issue with achieving these requirements.
Response: Thank you for your comments.		
Dynamics Review Subcommittee	Yes	Requirement R6 not R5.
Response: Thank you for your comments. The SDT agrees.		
LG&E and KU Energy	Yes	: This appears to be R6, not R5 and should be achievable for new units.
Response: Thank you for your comments.		
PPL Supply	Yes	1. Excursion-estimate requirements for new units are presented in R6, not R5. Our comments below pertain to R6. 2. Avoiding tripping for 10 minutes of operation at +/- 10% voltage may not be practical, especially if combined with the frequency excursions of Att. 1. **The intent is to ride through a voltage excursion or a frequency excursion, not both simultaneously.** 3. See also the final two comments for question 3 above. Preventing (and demonstrating via dynamic analysis the ability to prevent) aux buses from dropping-out at the specified interconnect voltage transients may be especially difficult. **This standard does not require demonstration by dynamic simulation.**
Response: Thank you for your comments. See specific responses above.		
American Wind Energy Association	Yes	New reliability standards should be accompanied by grandfathering provisions for existing generators and an implementation grace period of sufficient length to ensure that manufacturers have enough time to engineer their generators to comply with the standard and that generators for which purchase orders are already in the pipeline will not need to be re-designed. The grandfathering provisions and implementation grace period schedule that were included in FERC Order 661A should be sufficient to achieve those goals if they are incorporated into this standard.
Response: Thank you for your comments. These grandfathering provisions are already written into the standard. Requirement R6 specifically states that it applies to units that are designed and built after the standard goes into effect.		

Organization	Yes or No	Question 4 Comment
New York Power Authority	Yes	It is achieveable but signficant analyses must be performed. Undervoltage relay settings must be coordinated with the plant components most sensitive to system wide voltage excursions, particularly voltage drops. In some facilities, a POI voltage dip to 0.95pu would translate to a much larger drop within the local facility such that facility auxiliaries would start tripping due to the lower volatges on the facilities internal buses. The result is that even thogh the HV bus undervolatge relay is set to allow 0.95pu on the system the facility internal distribution may not be able to cope with voltage at that low a level. Nuclear power plants are particularly susceptible to low voltage conditions as unplanned tripping of a nuclear unit is to be avoided as much as possible. Nuclear units are also susceptible to overfrequency excursions as overfrequency causes motors within the plant to run at higher speeds. Nuclear reactor coolant pumps have overspeed limits due to core internals vibration limits that must be analyzed and coordiated with system overfrequency relay settings. These analyses typically take six to twelve months to complete and validate so a 12 to 18 month timeframe should be sufficient to implement the requirement.
Response: Thank you for your comments. Existing generating facilities are allowed an exemption from portions of PRC-024 Attachment 1 and Attachment 2 for documented technical limitations such as you describe in your examples. No additional analysis would be necessary. For new units that are designed and built after the standard is implemented, the SDT believes the analysis cited would be part of the plant design process.		
Puget Sound Energy	Yes	This would require detailed information from the manufacturer of a combustion turbine. The requirement appears to be entirely reasonable for hydro installations. We expect it would take two years to complete this work.
Response: Thank you for your comments. The SDT has reviewed information from various steam and combustion turbine manufacturers. Two OEM's have commented on this standard.		
Independent Electricity System Operator	Yes	First of all, we believe the SDT meant R6, not R5. **The SDT agrees.** Also see our editorial comments under Q3, above. We believe this requirement is achievable for most cases. However, provision should be given to the Generator Owners which for specific technical reasons are unable to design a generating units to comply with the requirements. As worded, R6 does not contain this provision. **The SDT does not agree that this would be workable exception.**
Response: Thank you for your comments. See specific responses above.		
Xcel Energy	Yes	It is Requirement R6 that requires new units to ride through excursions. We believe it is technically feasible to design generating units to reach a high probability of riding through these excursions. However we do not consider the additional expense necessary to meet this objective to be of value to our customers given the

Organization	Yes or No	Question 4 Comment
		infrequency of occurrence of excursions of the magnitude described in this standard. Excursions of this type have occurred on our system and some generating units have tripped due to the excursion, but it has never led to a cascading outage. In addition, we believe new plants should not be considered in violation for a trip during an excursion if the GO can identify the reason for the trip and correct the deficiency. If the standard is made mandatory, we believe that an additional five years should be allowed for new units so that the A/E firms can develop proper design criteria for plant auxiliaries and equipment OEM's to develop designs that can handle the requirements
Response: Thank you for your comments. The SDT does not agree that the Generator Owner would not be in violation even if a mitigation plan were developed to address the cause of a trip during a frequency or voltage excursion.		
ISO New England Inc.	Yes	ISO-NE has frequency data from all generators operating within the New England footprint demonstrating, with the exception of certain nuclear plants and some smaller and very old generating units, that all generators can operate to meet the under-frequency curve depicted by PRC-024 - Attachement 1, and, in fact, can and do meet our more stringent underfrequency requirements. Within the NPCC Region existing requirements for generators have been in place for many years that are more stringent than the underfrequency curve shown here. The NPCC more stringent requirements have been shown by studies to be necessary to support a viable automatic unferfrequency load shedding program. It is our position that generators within NPCC will be required to continue meeting these more stringent requirements independent of the approval of PRC-024-2. New generating units should meet all the PRC-024-2 requirements at the time of their interconnection or in-service date. No special implementation plan should be afforded these units beyond the regulatory approval date of the standard.
Response: Thank you for your comments. The SDT believes that designing new facilities to meet the PRC-024 Attachment 2 voltage ride-through requirements will be challenging and has extended implementation of this requirement to six years from the date of approval.		
Ingleside Cogeneration LP	Yes	Ingleside Cogeneration LP assumes this question actually applies to Requirement R6. **The SDT agrees.** The frequency and voltage ride-through specifications are reasonable for new generating facilities in Ingleside Cogeneration LP's view.
Response: Thank you for your comments.		
RFC	Yes	For R5, Part 5.1 and 5.2 - suggest adding the word "PRC-024" in front of "Attachment 2" in the last line of the respected Parts.

Organization	Yes or No	Question 4 Comment
Response: Thank you for your comments. The wording in this requirement has been revised.		
Tacoma Power	Yes	
GE Energy	Yes	**1.** The requirement is achievable in concept, however, there is a serious omission in the definition of the requirement. It is not clear how the magnitude of the three phase voltage is defined, for example: average of the individual phase magnitudes, magnitude of the least phase, positive sequence. Also, it should be clearly defined whether the requirement applies to the rms, 60 Hz component, or peak magnitude of the voltage. **Thank you for your comments. The SDT agrees and has changed the wording accordingly. Clarification #5 has been added to PRC-024 Attachment 2 that states "Additionally, voltages in the curve assume minimum fundamental frequency phase-to-ground or phase-to-phase voltage for the low voltage duration curve and maximum crest phase-to-ground or phase-to-phase voltage for the high voltage duration curve."**
PPL Electric Utilities	Yes	1. Excursion-estimate requirements for new units are presented in R6, not R5. **Requirement R5 contains the requirement for estimating performance during an excursion.** Our comments below pertain to R6. 2. Avoiding tripping for 10 minutes of operation at +/- 10% voltage may not be practical, especially if combined with the frequency excursions of Att. 1. **Events that cause severe frequency excursions frequently are accompanied by voltage excursions (though usually not of the severity described by PRC-024 Attachment 2).** 3. See also the final two comments for question 3 above. Preventing (and demonstrating via dynamic analysis the ability to prevent) aux buses from dropping-out at the specified interconnect voltage transients may be especially difficult. **This standard does not require demonstration by dynamic simulation.**
Response: Thank you for your comments. See specific responses above.		
Public Service Enterprise Group	Yes	
NERC Staff Technical Review Team	Yes	
Westar Energy	Yes	
Tri-State Generation and Transmission, Inc.	Yes	

Organization	Yes or No	Question 4 Comment
Oncor Electric Delivery Company LLC	Yes	
Tacoma Power	Yes	
Consolidated Edison Co. of NY, Inc.	Yes	
American Transmission Company	Yes	

5. The voltage ride-through Tables HVRT and LVRT Duration in Attachment 2, specify time duration of up to 600 seconds that a unit or a generating plant/facility should ride through a voltage excursion. Do you agree with this time duration value? If not, please provide an alternative value and supporting information in the comments.

Summary Consideration: The slight majority of stakeholders indicated that they agree with the 600 second value. A large portion of stakeholders who responded "no" indicated that they felt the 600 seconds was acceptable but had other concerns with the standard. As a result of the responses to this question the SDT did not make any changes to Attachment 2.

Organization	Yes or No	Question 5 Comment
PacifiCorp	Negative	(3) PacifiCorp has concerns that certain references to Attachment 2 in Requirement R2 need to be clarified. Attachment 2 references the generator point of interconnection not the terminal voltage; therefore, clarifications to the proposed language are necessary. As such, the following recommended revisions to Requirement R2 are offered: 2.1 When operating under normal system operating conditons within 95% and 105% of rated generator terminal voltage and during the transmission system conditions define in PRC-024 Attachment 2, with the following clarifications for PRC-024 Attachment 2 are provided: 2.1.1 For three-phase transmission system zone 1 faults with Normal Clearing, set voltage relays transmission system faults should be cleared based on actual fault clearing times, not to exceed 9 cycles. Voltage relays should be set to not trip prior to transmission system fault clearing time. 2.1.2 If a Transmission Planner's study (based on the location specific voltage recovery characteristics) recommends less stringent voltage relay settings system protection settings than those on PRC-024 Attachment 2, set voltage relays either to the less stringent Transmission Planner's settings or the setting applicable to in PRC-024 Attachment 2. 2.1.3 Tripping a generator via If a Special Protection System (SPS) or Remedial Action Scheme (RAS) includes tripping a generator after fault initiation, then setting the SPS or RAS relay to trip the generator even if in the is acceptable in the "no trip zone" in PRC-024 Attachment 2 is acceptable. 2.1.4 If clearing a system fault necessitates disconnecting a generator, this action is acceptable than setting relays to trip the generator even if operating within the "no trip zone" specified in PRC-024 Attachment 2 is acceptable.
Response: Thank you for your comments. The SDT has revised the wording in the subsections of Requirement R2 to make the intent clearer. Section 2.1.1 has been removed. Section 2.1.3 now says "Tripping a generator via a Special Protection System (SPS) or Remedial Action Scheme (RAS) is acceptable in the "no trip zone" of PRC-024 Attachment 2." Section 2.1.4 now says" If clearing a system fault necessitates disconnecting a generator, this action is acceptable within the "no trip zone" specified in PRC-024 Attachment 2."		

Organization	Yes or No	Question 5 Comment
Ameren Energy Marketing Co.; Amerenue; Ameren Services	Negative	(3) This 90% and 110% ride through times should be longer to handle contingency periods of high voltage during light load conditions or periods where large VAr resources are lost during peak loads.
Response: Thank you for your comments. The 600 seconds (10 minutes) was determined based on the anticipated time periods for automatic and manual (operator) system adjustments which should have taken effect and been completed. The SDT has not changed the standard in response to this comment.		
PacifiCorp	Negative	(7) PacifiCorp has a concern that the PRC-024 voltage ride-through requirements identified in Attachment 2 are wholly independent of dynamic reactive power requirements for generators. As an analogy, some European generator interconnection standards and requirements link these two variable. PacifiCorp understands that PRC-024-1 is a generator protection standard; however, the SDT should address the manner in which generator dynamic reactive requirements impact PRC-024-1 Attachment 2. **Interaction of other power system parameters has not been addressed. However, it should be noted that reactive requirements for generating facilities is identified in Standard VAR-001 and VAR-002, and the LGIA.** (8) Many European generator interconnection standards and requirements include different voltage ride-through requirements for synchronous and non-synchronous generation. PacifiCorp is concerned that the SDT has inappropriately developed a “one-size fits all” standard applicable to all generation platforms. PacifiCorp recommends that, based on the significant differences between existing and emerging generation platforms, separate voltage ride-through standards be developed for synchronous and non-synchronous (i.e., wind and solar) generation platforms. Different sets of standards will more effectively address such differences in the various generation technologies. **The SDT is well aware that many European generation interconnection standards and requirements (Grid Codes) that have been developed, which include different voltage ride-through requirements for synchronous and non-synchronous generators (see Reference 1). While this same approach could have been included in this standard, after much discussion the STD has decided to develop one frequency and voltage ride-through standard that is inclusive of all technologies. Such an approach is considered technology neutral.**
Response: Thank you for your comments. See specific responses above. .		
Occidental Chemical	Negative	5. The voltage ride-through Tables HVRT and LVRT Duration in Attachment 2, specify time duration of up to 600 seconds that a unit or a generating plant/facility should ride through a voltage excursion. Do you agree with this time duration value? If not, please provide an alternative value and supporting information in the comments. Yes: Comments: The voltage ride-through specifications are reasonable for new generating facilities in Ingleside Cogeneration LP’s view. Existing facilities that cannot meet this specification must be able to document an equipment limitation as allowed in R3.

Organization	Yes or No	Question 5 Comment
Response: Thank you for your comments.		
Northeast Power Coordinating Council, Inc.	Negative	Generator frequency ride-through capability is too lenient and will may not be feasible within the NPCC footprint. Â· **Regional Entities are allowed to set requirements that are more stringent than those set in continent-wide NERC standards, In the interest of accommodating regional differences, the SDT solicited region-specific off nominal frequency requirements to be incorporated into PRC-024 Attachment 1. Curves specific to the Quebec Interconnection and to WECC have been added** The standard appears to allow a SPS to be used instead of meeting the requirements of the standard. This is not a good practice and could lead to a proliferation of SPS installations. Â· **Special Protection Schemes (SPS) are intended to maintain transmission system reliability/security requirements following system disturbances not to subvert the requirements for voltage or frequency ride through requirements of a generator. (Note: As SPS are added, they are required to meet the requirements of PRC-015-1.) SPS requirements should not be used to avoid PRC-024-1 requirements as not every system disturbance affecting a given generator would result in initiation of the SPS.** The standard provides for a number of exceptions for new generating units. New units should meet the standard in its entirety without exception. Standards should not be written in this manner which is contrary to reliability principals. **PRC-024-1 does not include any exemptions for new generating units, but rather, the standard includes clarifications relative to the application of the standard. These clarifications have been included to assure consistency in the application of the standard. In developing PRC-024-1, the SDT believes that the new standard enhances reliability principles as future generation will be required to meet requirements that many existing generation facilities do not have to meet.**
Response: Thank you for your comments. See specific responses above.		
Commonwealth of Massachusetts Department of Public Utilities	Negative	Generator frequency ride-through capacity is too lenient and will not work within the NPCC footprint. **Regional Entities are allowed to set requirements that are more stringent than those set in continent-wide NERC standards, In the interest of accommodating regional differences, the SDT solicited region-specific off nominal frequency requirements to be incorporated into PRC-024 Attachment 1. Curves specific to the Quebec Interconnection and to WECC have been added** The standard infers that the voltage relay settings should be based on actual fault clearing times. ISO New England maintains that the settings should be 9 cycles since clearing times may vary over time. **The SDT believes that Generator Owners should be allowed to base protection system settings on site-specific fault clearing conditions. This is consistent with the requirements in FERC Order 661-A.** The standard appears to allow a SPS to be used instead of meeting the requirements of the standard. This is

Organization	Yes or No	Question 5 Comment
		not a good practice and could lead to a proliferation of SPS installations. **Special Protection Schemes (SPS) are intended to maintain transmission system reliability/security requirements following system disturbances not to subvert the requirements for voltage or frequency ride through requirements of a generator. (Note: As SPS are added, they are required to meet the requirements of PRC-015-1.) SPS requirements should not be used to avoid PRC-024-1 requirements as not every system disturbance affecting a given generator would result in initiation of the SPS.** The standard provides for a number of exceptions for new generating units. New units should meet the standard in its entirety without exception. Standards should not be written in this manner which is contrary to reliability principals. **PRC-024-1 does not include any exemptions for new generating units, but rather, the standard includes clarifications relative to the application of the standard. These clarifications have been included to assure consistency in the application of the standard. In developing PRC-024-1, the SDT believes that the new standard enhances reliability principles as future generation will be required to meet requirements that many existing generation facilities do not have to meet.**
Response: Thank you for your comments. See specific responses above.		
	Negative	My negative vote is baseed on the following: The generator ride-through capability is not sufficient and is too lenient. **Regional Entities are allowed to set requirements that are more stringent than those set in continent-wide NERC standards,** The standard needs to specify voltage relay setting requirements that include ensuring the settings are based on the actual fault clearing times of the installed circuit breakers recognizing the clearing times of the circuit breakers that are in-service on the BES. **The wording in Requirement R2 allows settings based on actual fault clearing times and voltage recovery profile if these can be provided by the Transmission Planner. In lieu of this the Generator Owner must allow for the full "no trip zone" envelope in PRC-024 Attachment 2.** The wording in the standard appears to approve the use of an SPS rather than meeting the requirements of the standard. An SPS should only be used as a limited/short time reliability resolve. Multiple Special Protetions Systems within an Area/Region risk safe and reliable operation of the Area's/Region's BES. **Special Protection Schemes (SPS) are intended to maintain transmission system reliability/security requirements following system disturbances not to subvert the requirements for voltage or frequency ride through requirements of a generator. (Note: As SPS are added, they are required to meet the requirements of PRC-015-1.) SPS requirements should not be used to avoid PRC-024-1 requirements as not every system disturbance affecting a given generator would result in initiation of the SPS.** New generating units that interconnect with the BES must meet all requirements of the standard. Standards should no longer be written to include a list of acceptable exemptions. If the generating unit is unable to meet

Organization	Yes or No	Question 5 Comment
		each and every standard requirement, it should not be permitted to interconnect to the BES. **PRC-024-1 does not include any exemptions for new generating units, but rather, the standard includes clarifications relative to the application of the standard. These clarifications have been included to assure consistency in the application of the standard.**
Response: Thank you for your comments. See specific responses above.		
Tennessee Valley Authority	Negative	The ride through criteria should not be anything beyond currently used critical clearing times (2nd zone protection or breaker failure) that switchyard breaker failure protection is based on. It is questionable whether large steam plants can survive anything beyond this. Plants with aux power systems normally fed from the switchyard would be even more questionable as the transient is not shielded by the action of the voltage regulator for the generator. **Actual clearing time (generally less than the critical clearing time) for a zone 1 three-phase fault, not to exceed 9 cycles was selected by the SDT, as a fixed 9 cycles could exceed critical clearing times for a given generating plant. The SDT is well aware of issues relative to potential steam plant auxiliary load tripping following a disturbance. Under the requirements of this standard, new generating plants will need to be designed to mitigate auxiliary load tripping.** For frequency, the ride-thru criteria should be sufficient for UFLS to perform its function. Also, the lowest frequency allowed for unit operation must accommodate the turbine blade resonance low frequency requirement for large steam plants (57.5 to 58.5 Hz, depending on the turbine OEM). Similar steam turbine restrictions also apply for the high frequency requirement. **The SDT considered inputs from major turbine manufacturers in developing the off nominal frequency requirements. Existing generating units that cannot meet a portion of the "no trip zone" in PRC-024 Attachment 1 can receive an exemption by documenting the technical limitation per Requirement R3,** For voltage, the ride-thru criteria should be long enough in duration for second zone or breaker failure protection critical clearing time. Voltage recovery to 0.9 PU following critical clearing time is necessary to ensure electrically powered equipment will perform correctly. **Voltage ride-through requirements defined in the standard were determined based on a three-phase zone 1 transmission fault with normal clearing (which implies normal communication and breaker operation). Breaker failure analysis relative to Figure 2 is considered beyond the scope of this standard.** Nuclear power plant interface requirements are addressed in NERC NUC-001-2. PRC-024 should refer to nuclear plant interface requirements managed under NUC-001-2. **NERC Standard NUC-001-2 addresses steady state interface requirements while PRC-024-1 addresses transient conditions. Some of the wording in PRC-024-1 has been modified to address nuclear-specific regulatory issues.**
Response: Thank you for your comments. See specific responses above.		

Organization	Yes or No	Question 5 Comment
SERC Generation Sub-committee (GS)	No	Comments: The GS proposes that the LVRT portion of the curve between 0.4 secs and 3.0 secs be changed to 0.90 PU voltage. Electrical powered devices at the plant can begin to lose their ride-thru capability in the window of 0.2 to 0.65 seconds (as referenced in the AREVA whitepaper on PRC-024 and based on industry experience)
Response: Thank you for your comments. The white paper provided by AREVA provides an excellent review of the impacts of transmission voltage perturbations on synchronous generating plants. As the performance requirement will be applicable to only new generation facilities that will be in-service following approval of the standard, many of the issues raised by AREVA are not applicable to the standard. As AREVA noted in their white paper that *"AREVA designs our new plant power systems with voltage regulators capability to support long-term variations in transmission system voltages,"* the SDT is confident that future generating plants designs should be able to meet the standard.		
SPP Reliability Standards Develpment Team	No	We would like to see the technical background/justification of why the timeframe of 600s was chosen. We understand seeing the reasoning to expand it from 4s, but 600s (10 Minutes) seems extremely too long for voltage recovery. From a planning perspective 15 cycles (.25seconds) is standard for voltage recovery. Holding .9 from 3s to 600s could prove difficult if full load on unit and might not be enough bandwidth before you hit a loss of field relay. If enough current is provided to the field it will cause this relay to trip instantaneously. Not sure that taking a 10% hit during this instance will work.
Response: Thank you for your comments. The 600 seconds (10 minutes) was determined based on the anticipated time periods for automatic and manual (operator) system adjustments which should have taken effect and been completed. When the transmission system voltage is low, generators operating in AVR will be at a lagging power factor (delivering reactive power to the system). They should be a long way from the operating characteristic of a Loss of Field relay.		
LG&E and KU Energy	No	LG&E and KU Energy agrees with the SERC Generation Subcommittee and proposes that the LVRT portion of the curve between 0.4 secs and 3.0 secs should be 0.90 voltage PU. Electrical powered devices at the plant will begin to loose their ride-thru capability in the window of 0.2 to 0.65 seconds (as referenced in the AREVA whitepaper on PRC-024 and based on industry experience).
Response: Thank you for your comments. The white paper provided by AREVA provides an excellent review of the impacts of transmission voltage perturbations on synchronous generating plants. As the performance requirement will be applicable to only new generation facilities that will be in-service following approval of the standard, many of the issues raised by AREVA are not applicable to the standard. As AREVA noted in their white paper that *"AREVA designs our new plant power systems with voltage regulators capability to support long-term variations in transmission system voltages,"* the SDT is confident that future generating plants designs should be able to meet the standard.		
Santee Cooper	No	The LVRT portion of the curve between 0.4 secs and 3.0 secs should be 0.90 voltage PU. Electrical powered devices at the plant will begin to loose their ride-thru capability in the window of 0.2 to 0.65 seconds (as

Organization	Yes or No	Question 5 Comment
		referenced in the AREVA whitepaper on PRC-024 and based on industry experience)
Response: Thank you for your comments. The white paper provided by AREVA provides an excellent review of the impacts of transmission voltage perturbations on synchronous generating plants. As the performance requirement will be applicable to only new generation facilities that will be in-service following approval of the standard, many of the issues raised by AREVA are not applicable to the standard. As AREVA noted in their white paper that *"AREVA designs our new plant power systems with voltage regulators capability to support long-term variations in transmission system voltages,"* the SDT is confident that future generating plants designs should be able to meet the standard.		
Public Service Enterprise Group	No	Typical OEM recommended protective relay settings for generator UV are significantly more stringent than that which is outlined in Attachment 2 of the draft standard. Intuitively, it would seem that a generator and its auxiliary connect loads having the requirements to ride out 0.7 pu voltage for a period of 2 seconds is unrealistic.
Response: Thank you for your comments. The voltage duration curves in PRC-024 Attachment 2 are set at the point of interconnection with the transmission system. The generator will experience a different voltage depending on the specific characteristics of the generator, step-up transformer, and transmission system. IEEE does not recommend activating undervoltage protection for generators. If the Generator Owner chooses to activate this protection, it must be set to allow the transmission system to clear a fault and for the voltage to recover. For new generation facilities (designed and built after PRC-024-1 is implemented) the SDT believes auxiliary systems can be designed so that they will ride through the voltage excursions described in the standard.		
PPL Supply	No	Att. 2 extends to 1000 sec in the present draft of PRC-024, with 600 sec at +/- 10% voltage. See our comments above for question 4.
Response: Thank you for your comments. The SDT agrees that the curves in PRC-024 Attachment 2 extend to 1000 seconds, but the period after 600 seconds is within the normal operating band of 95 – 105%.		
TVA - GO	No	TVA proposes that the LVRT portion of the curve between 0.4 secs and 3.0 secs be changed to 0.90 PU voltage. Electrical powered devices at the plant can begin to lose their ride-thru capability in the window of 0.2 to 0.65 seconds (as referenced in the AREVA whitepaper on PRC-024 and based on industry experience.)
Response: Thank you for your comments. The white paper provided by AREVA provides an excellent review of the impacts of transmission voltage perturbations on synchronous generating plants. As the performance requirement will be applicable to only new generation facilities that will be in-service following approval of the standard, many of the issues raised by AREVA are not applicable to the standard. As AREVA noted in their white paper that *"AREVA designs our new plant power systems with voltage regulators capability to support long-term variations in transmission system voltages,"* the SDT is confident that future generating plants designs should be able to meet the standard.		

Organization	Yes or No	Question 5 Comment
Westar Energy	No	We suggest that the SDT provide the technical justification for this time duration. We do not agree with the time duration of up to 600 seconds. This time duration appears to be significantly long for voltage recovery. From a planning perspective, 15 cycles or 0.25 seconds is standard for voltage recovery. Holding 0.9 from 3 seconds to 600 seconds could be difficult if there is full load on the unit. There may not be enough bandwidth before a loss of field relay occurs. If enough current is provided to the field, it will cause the relay to trip instantaneously. FERC pro-forma Generator Interconnection Agreement requirements should also be considered in the development of the attachment.
Response: Thank you for your comments. The 600 seconds (10 minutes) was determined based on the anticipated time periods for automatic and manual (operator) system adjustments which should have taken effect and been completed. The "No Trip Zone" within the Voltage Ride-Through Time Duration Curve defines the maximum time that a voltage at a given level would be expected. When the transmission system voltage is low, generators operating in AVR will be at a lagging power factor (delivering reactive power to the system). They should be a long way from the operating characteristic of a Loss of Field relay. The SDT does not believe there will be conflicts between the pro-forma Generator Interconnection Agreement requirements and the requirements of this standard.		
Luminant Power	No	Luminant believes the settings are reasonable and achievable for relay settings only.
Response: Thank you for your comments.		
Progress Energy	No	The ride through capabilities should be within the IEEE and ANSI C84.1-2006 "American National Standard for Electric Power Systems and Equipment - Voltage Ratings (60Hz)". Standards associated with manufacturing electrical equipment
Response: Thank you for your comments. ANSI C84.1-2006 addresses the requirements for continuously supplied voltages, while PRC-024-1 addresses transient conditions.		
Westinghouse	No	Due to the excessive duration of the +/- 10% voltage excursion, it is uncertain that many new manufactured turbine generators will be able to meet the V/HZ limits set by the manufacturers. Detailed studies would need to be performed to determine the ability of newer turbine generators to ride through these conditions.
Response: Thank you for your comments. The SDT reviewed the V/Hz limits in place for existing generating equipment and found that they were outside of the "no trip zone" boundaries set by PRC-024 Attachment 2 when evaluated at 60 Hz. The SDT recognizes that under conditions of a low frequency excursion coupled with a voltage transient, the resulting V/Hz condition experienced by the generation facility could exceed equipment limitations. The SDT considers a resulting trip to protect the equipment would not be a violation of the standard.		

Organization	Yes or No	Question 5 Comment
Southern Company	No	1) The 600 seconds for +/- 10% voltage excursion is excessive. GE has published recommended generator permissible V/Hz settings for a stairstep protective solutions of not allowing > 118% V/Hz to exist longer than 2 seconds, and not allowing > 110% V/Hz to exist longer than 45 seconds. The HVRT curve requires allowing 110% V/Hz for 10 minutes, which is much longer. **The voltage duration curves in PRC-024 Attachment 2 are defined at the point of interconnection with the transmission system. The SDT expects that when the transmission system voltage is high, a generator operating under AVR would be at a lower voltage due to operation of the AVR and the impedance of the step-up transformer.** 2) Generators need a generator side excursion curve to even see if this is feasible. **The voltage at the generator terminals is highly dependent on the characteristics of a the particular generator, its step-up transformer and the transmission system at the particular location. All industry ride-through standards define voltage excursions at the transmission level.** 3) We believe a detailed study needs to be conducted by the industry for typical power plant designs to help determine the feasibility of power plants being able to ride through these extreme voltage conditions. We believe this study will demonstrate that this will not be possible without major re-design of power plant systems and components. **As the ride-through performance requirement will be applicable only to new generation facilities designed and built following approval of the standard, many of the issues raised should not be an issues relative to compliance with PRC-024-1. The SDT believes that future generating plants designs should be able to meet the standard.**
Response: Thank you for your comments. See specific responses above.		
PacifiCorp	No	In studying PRC-024 Attachment 2, PacifiCorp believes that the "high voltage duration" curve, which defines the upper edge of the no trip envelope by depicting a 1.10 pu voltage between 1 second and 600 seconds, may potentially conflict with the synchronous generator Inverse-Time V/HZ Relay with Fixed-Time Unit setting recommendations contained in IEEE Std C37-102. For example: At 110% V/Hz, the relay will trip in 291.6 seconds (within the PRC-024-1 No Trip Zone). Additionally, at 109% the setting would be at 1166.4 seconds. PacifiCorp requests that the Standards Drafting Team ("SDT") further evaluate PRC-024 Attachment 2 to determine if an adjustment to the high voltage duration curve could eliminate this potential conflict.
Response: Thank you for your comments. The voltage duration curves in PRC-024 Attachment 2 are defined at the point of interconnection with the transmission system. The SDT expects that when the transmission system voltage is high, a generator operating under AVR would be at a lower voltage due to operation of the AVR and the impedance of the step-up transformer. The SDT does not believe there will be a conflict with equipment V/Hz limits when evaluated at 60 Hz.		

Organization	Yes or No	Question 5 Comment
Duke Energy	No	The LVRT portion of the curve between 0.4 seconds and 3.0 seconds should be 0.90 voltage PU. Electrical powered devices at the plant will begin to lose their ride-thru capability in the window of 0.2 to 0.65 seconds (as referenced in the AREVA whitepaper on PRC-024 and based on industry experience).
Response: Thank you for your comments. The white paper provided by AREVA provides an excellent review of the impacts of transmission voltage perturbations on synchronous generating plants. As the performance requirement will be applicable to only new generation facilities that will be in-service following approval of the standard, many of the issues raised by AREVA are not applicable to the standard. As AREVA noted in their white paper that *"AREVA designs our new plant power systems with voltage regulators capability to support long-term variations in transmission system voltages,"* the SDT is confident that future generating plants designs should be able to meet the standard.		
Luminant Energy	No	The LVRT chart should only be limited by values pertaining to a system fault condition as a result of primary and backup transmission line relaying trip times (usually 0-30 cycles)
Response: Thank you for your comments. Voltage ride-through requirements defined in the standard were determined based on a three-phase zone 1 transmission fault with normal clearing (which implies normal communication and breaker operation). Breaker failure analysis relative to Figure 2 is considered beyond the scope of this standard.		
Ameren	No	This 90% and 110% ride through times should be longer to handle contingency periods of high voltage during light load conditions or periods where large VAr resources are lost during peak loads. Per our Transmission Planning department high voltages of 110% have been experienced for up to 8hrs.
Response: Thank you for your comments. The 600 seconds (10 minutes) was determined based on the anticipated time periods for automatic and manual (operator) system adjustments which should have taken effect and been completed.		
American Electric Power	No	We agree that a new generating unit reasonably could be required to ride-though 90 percent or 110 percent voltage at the point of interconnection for 600 seconds at nominal frequency. However, this does not take away from the concerns expressed in response to Q4.
Response: Thank you for your comments. See the SDT response to your comments on Question 4.		
Tacoma Power	No	The required voltage and frequency settings should be determined by the interconnecting entities regional off nominal voltage and frequency plans.
Response: Thank you for your comments. The SDT agrees that the Generator Owner should set protection systems to meet regional as well as NERC requirements.		

Organization	Yes or No	Question 5 Comment
PPL Electric Utilities	No	Att. 2 extends to 1000 sec in the present draft of PRC-024, with 600 sec at +/- 10% voltage. See our comments above for question 4.
Response: Thank you for your comments. The SDT agrees that the curves in PRC-024 Attachment 2 extend to 1000 seconds, but the period after 600 seconds is within the normal operating band of 95 – 105%.		
CenterPoint Energy	No	(a) CenterPoint Energy agrees with the time duration value of the 0.9 pu voltage level up to 600 seconds and believes this will coordinate with existing undervoltage load shedding systems (UVLS). However, CenterPoint Energy believes there are numerous relays presently set at 2.0 seconds and 3.0 seconds to shed load in a voltage excursion and, therefore, there is not a sufficient margin for coordination at the two second and three second low voltage points in Attachment 2. CenterPoint Energy recommends these two points in Attachment 2 be revised to 2.5 and 3.5 seconds. That is, the data points (Time / Voltage) in the LVRT DURATION table would be as follows: 0.15 / 0.000, 0.30 / 0.450, 2.50 / 0.650, 3.50 / 0.750, and 600 / 0.900.(b) In addition, CenterPoint Energy believes there is insufficient margin at 1.0 seconds for high voltage ride through due to voltage over-shoot following a zone 1 fault. To provide an adequate margin, CenterPoint Energy recommends the 1.0 second high voltage point in Attachment 2 be revised to 1.5 seconds. That is, the data points (Time / Voltage) in the HVRT DURATION table would be as follows: 0.20 / 1.200, 0.50 / 1.175, 1.50 / 1.150, and 600 / 1.100.
Response: Thank you for your comments. The SDT realizes that there may be existing relays that could trip during an excursion as defined by PRC-024 Attachment 2, but could be set differently without compromising the protected equipment. The SDT would need better technical justification to change the curves.		
GenOn Energy	No	10 minutes is a long time for some unavoidable configuration of electrical auxiliaries.
Response: Thank you for your comments. The 600 seconds (10 minutes) was determined based on the anticipated time periods for automatic and manual (operator) system adjustments which should have taken effect and been completed.		
Austin Energy		The equipment impact of this new requirement requires additional internal review before AE can respond definitively. If the requirement can be implemented without equipment risk, it will take up to 3 years to implement the new settings.
Response: Thank you for your comments. The SDT has extended the implementation of Requirement R6 to six years to allow for the development of designs that meet the Requirement.		

Organization	Yes or No	Question 5 Comment
Exelon	Yes	Most nuclear units will not be able to meet the time duration of "up to 600 seconds" unless they have an installed Load Tap Changer (LTC). This is due to the NRC required Degraded Voltage relay protection. The purpose of degraded voltage relaying is to protect emergency buses that feed equipment necessary for safe nuclear plant shutdown during an emergency or transient.
Response: Thank you for your comments. Existing generating units (including nuclear units) that cannot meet a portion of the "no trip zone" in PRC-024 Attachment 2 can receive an exemption by documenting the technical limitation per Requirement R3,		
ISO New England Inc.	Yes	Although the time duration is acceptable ISO-NE does not agree with the band shown. See our comments on Question 1, above.
Response: Thank you for your comments. See the SDT response to your comments on Question 1.		
Ingleside Cogeneration LP	Yes	The voltage ride-through specifications are reasonable for new generating facilities in Ingleside Cogeneration LP's view. Existing facilities that cannot meet this specification must be able to document an equipment limitation as allowed in R3.
Response: Thank you for your comments.		
Dynamics Review Subcommittee	Yes	While we agree, a technical basis for this 600 secs. duration (and each breakpoint) would be helpful.
Response: Thank you for your comments. The 600 seconds (10 minutes) was determined based on the anticipated time periods for automatic and manual (operator) system adjustments which should have taken effect and been completed. The breakpoints were developed after review of FERC Order 661-A, various European grid standards, and voltage profiles from simulations done in the WECC and SERC regions.

6. Do you have any other questions or concerns with the proposed standard that have not been addressed? If yes, please explain.

Summary Consideration: Many of the comments provided are duplications of comments provided in response to the other five questions. There are not any new concerns raised by a large number of stakeholders.

Organization	Yes or No	Question 6 Comment
Ameren Energy Marketing Co.; Amerenue; Ameren Services	Negative	(6)R6.2 why are smaller generators allowed to trip 10% of their units? Is this fair to large generators? **The SDT feels that allowing 10% of small generators to trip is fair because it is similar to a large unit experiencing a run back following an event. Runbacks do not result in a compliance violation.** (7)Do all the requirements of PRC-024-1 apply to all the auxiliary systems, or just the generating unit protection systems? This needs to be made clear for compliance. If applying to all auxiliary systems, guidance will need to be provided on how to meet these standards. **Requirements R1 and R2 apply only to the generator protection system as stated in the Footnote 1. Requirement 6 applies to the performance of the entire facility, not just the generator protection system.** (8)For R2 and R6, if clearing a transmission line outlet end of line fault with zone-2 timing exceeds the requirements of Attachment #2, which should be designed for. Does transmission line relays need to be designed to provide performance of Attachment #2 for newly installed facilities? **This standard does not set requirements for the protection of the transmission system. If the voltage profile at a specific generating site exceeds the requirements of Attachment #2, then the generator(s) at that site would not be out of compliance if they tripped.**
Response: Thank you for your comments. See specific responses above.		
PacifiCorp	Negative	o R3 - This requirement was clear in the initial February 2009 draft of PRC-024-1, but the current draft does not clarify that the Generator Owner must upgrade the equipment that is causing a limitation. For example, if an entity upgrades its (synchronous) turbines to increase capacity by greater than 10%, but the voltage limitations still exist because they are related to the generator, which is not upgraded, the exemption would expire under the current language. The SDT should revisit this issue using the initial draft of PRC-024-1 as a guide. **The SDT has revised Requirement R3 to clarify that the limitation must be eliminated if the equipment causing the limitation is modified or upgraded resulting in an increase in nameplate**

Organization	Yes or No	Question 6 Comment
		capacity greater than 10%. o R6 - The failure to include exemptions for new generating plants may have unintended consequences. Some voltage excursions have caused excessive torque on PacifiCorp-owned generators which has caused the controls to trip the units, rather than the relays themselves. If an entity constructs a new plant and cannot document any exemptions due to equipment limitations, such entity may experience future compliance and operational issues. The SDT should revisit this in light of further consideration of potential unintended consequences. . **Tripping generating units is allowed to protect the equipment from damage. In the example cited, it would be considered an impending loss of synchronism.**
Response: Thank you for your comments. See specific responses above.		
MidAmerican Energy Co.	Negative	Comment: Given the number and depth of comments at the NERC webinar, it is clear the NERC standard is not clear or enforceable. This will generate the need for interpretations and Compliance Application Notices which cause further confusion and enforcement issues. Technical issues are also present. It is clear that NERC standards have not been coordinated with nuclear plant NRC standards and that conflicts will result. It seems likely that many nuclear plants will have trouble meeting the new standard and performance curves. Other power plants may not be able to upgrade the many subsystems required to ensure that a plant never trips for the PRC-024 standard given in the implementation period.
Response: Thank you for your comments. Existing plants, including those in design or construction phase when this standard goes into effect, do not have to meet Requirement R6 (the performance requirement). If there are technical limitations why their protection systems cannot be set so that they operate outside of the No Trip Zones of Attachments #1 and #2, then per Requirement R3 they must document the limitation and inform the Reliability Coordinator, Planning Coordinator, Transmission Operator, and Transmission Planner of the limitation.		
Constellation Energy Commodities Group; Constellation Power Source Generation, Inc.	Negative	Constellation Energy Commodites Group believes that the 7 Requirements in this standard can be condensed into a single requirement simply stating that a generator must have frequency and voltage protection set per the curves in the attachments. However, it should be noted that even if a relay is set to operate according to the curves in the attachments, a minute deviation will exist in the operation of the relay, and as such, a protection system may operate in what the SDT has deemed the “no trip zone.” If a relay operates in that zone, then an entity will technically be out of compliance with this standard even though it set its protection system correctly as per this standard. An allowable tolerance needs to be including in the requirements in order to capture real world conditions.
Response: Thank you for your comments. The Drafting Team believes more than one requirement is needed, both to meet the directives of Order 693 and the Blackout Report and for clarity.		

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 6 Comment</th></tr>
<tr><td>Cowlitz County PUD</td><td>Negative</td><td>Cowlitz defers to WECC comments.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. Please refer to the response to WECC.</td></tr>
<tr><td>Dominion Resources Services</td><td>Negative</td><td>Dominion submits a negative ballot for the following technical reasons: 1. Do not understand R3 bullets. How does increasing your units rating by =10% change this? The SDT has revised Requirement R3 to clarify that the limitation must be eliminated if the equipment causing the limitation is modified or upgraded resulting in an increase in nameplate capacity greater than 10%.

2. Attachment 2 does not match the Â±5% voltage schedule per the definition of Voltage Excursion. This curve is not possible. The definition of Voltage Excursion has been removed. PRC-024 Attachment 2 defines the outer boundaries of a voltage excursion. The SDT realizes that an actual excursion will never follow these boundaries, but as long as the excursion remains inside the boundaries, the generator protection system should not operate.

3. R6 grants new generators exceptions. Where are the exceptions for existing generators? Requirement R6 only applies to new generators. Existing generators are allowed exemption from portions of R1 and R2 if they can document technical limitations to their equipment as defined in Requirement R3.

4. This standard only applies to frequency and voltage excursions within the defined limits. The attachments and requirements go outside of this bound placing much more stringent criteria on the operation of the units. These more stringent criteria may not be possible and should be removed from the standard to align with the definition of applicability. The Attachments define the boundaries of the excursions. The SDT does not understand how the requirements create more stringent criteria.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. See specific responses above.</td></tr>
<tr><td>Liberty Electric Power LLC</td><td>Negative</td><td>Due to the need for changes to the underlying standard.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. Changes have been made to the standard.</td></tr>
<tr><td>Balancing Authority of Northern California NCR11118; Sacramento Municipal Utility District</td><td>Negative</td><td>For Requirement 5.2 what does it mean to provide an estimate of performance in 25% increments? Specifying an estimate lends itself to varying interpretations, confusion and judgments. The “estimate of performance in 25% increments” portion of the requirement has been removed. The SDT agrees that it would not improve reliability.

Please consider the unit size and applicability for Requirement 6 to coincide with the development of the BES proposed definition. The applicability for Requirement R6 is for Generator Owners. This is not affected</td></tr>
</table>

Organization	Yes or No	Question 6 Comment
		by the definition of BES. The facilities that will have to comply with Requirement R6 are only new facilities that begin design, construction, and operation after this standard goes into effect. Requirement 7 dictates that generator trip settings be provided to the RC, PC, TO and TP when any request is made, is the response for the written request necessary for all four entities or just the requesting party? **The SDT agrees that the wording in Requirement R7 was confusing and has revised the wording to clarify the intent.**
Response: Thank you for your comments. See specific responses above.		
PacifiCorp	Negative	In addition to the feedback noted in the comments submitted via the NERC comment process, the NO votes submitted by PacifiCorp are accompanied with the following comments: (1) Industry practice for generation protective relays is to use the terminal voltage of the generators, not the system voltage or point of interconnection. Generator Owners could provide generation responses and data as contemplated by the standard, but they should not be held responsible for the answers provided without the benefit of associated transmission planning groups. Generator Owners, under this framework, will rely completely on feedback from their associated transmission planning groups in order to provide responses. It concerns PacifiCorp that the draft standard does not address the need for transmission planners to provide the required transmission system response data to Generation Owners in order to make these assessments, or allow for the joint responsibility of transmission planner for the accuracy of the data as it concerns planning studies. **It is not practical to define the excursions at the generator terminals due to the differences in generator, step-up transformer, and system characteristics. Other voltage ride through standards (e.g. FERC Order 661A and various European standards) all define the voltage profile at the transmission level (where the event occurs).** (2) PacifiCorp maintains several additional concerns about complying with the standard as drafted: o R1.1.5 - PacifiCorp is not aware of relays used for generator protection that use frequency rate of change to calculate trip points. Generator protection relays use frequency set points and time at certain values, not rate of change of frequency to make tripping decisions. It may not be technically feasible to immediately comply with this sub-requirement of the standard as written. **There are several standard generator protection relays (e.g. GE's G-60, Schweitzer's 700G, and Beckwith's M-3425A) in addition to relays that are designed specifically for Aurora Scenario protection that incorporate a frequency rate of change function. R1.1.5 does not require tripping for a frequency rate of change over the stated value, but does allow that tripping even if the frequency magnitude is still within the No Trip Zone.** o R2.1.1 - PacifiCorp requests clarification concerning what the SDT has considered a zone 1 fault. PacifiCorp acknowledges that transmission and distribution line relays have zone 1 and zone 2, but the Company does not believe that this is something typically used in the generator protection context. A zone 1

Organization	Yes or No	Question 6 Comment
		fault needs to be defined somewhere to the extent that it is not clarified in the standard already. **Part 2.1.1 states "… transmission system zone 1 faults…" The SDT believes this makes it clear that it does not involve the generator or distribution system.** o R3 - This requirement was clear in the initial February 2009 draft of PRC-024-1, but the current draft does not clarify that the Generator Owner must upgrade the equipment that is causing a limitation. For example, if an entity upgrades its (synchronous) turbines to increase capacity by greater than 10%, but the voltage limitations still exist because they are related to the generator, which is not upgraded, the exemption would expire under the current language. The SDT should revisit this issue using the initial draft of PRC-024-1 as a guide. **The SDT has revised Requirement R3 to clarify that the limitation must be eliminated if the equipment causing the limitation is modified or upgraded resulting in an increase in nameplate capacity greater than 10%.** o R6 - The failure to include exemptions for new generating plants may have unintended consequences. Some voltage excursions have caused excessive torque on PacifiCorp-owned generators which has caused the controls to trip the units, rather than the relays themselves. If an entity constructs a new plant and cannot document any exemptions due to equipment limitations, such entity may experience future compliance and operational issues. The SDT should revisit this in light of further consideration of potential unintended consequences. . **Tripping generating units is allowed to protect the equipment from damage. In the example cited, it would be considered an impending loss of synchronism.**
Response: Thank you for your comments. See specific responses above.		
Brazos Electric Power Cooperative, Inc.	Negative	It is not clear that this standard is needed. While attempting to eliminate unit tripping from frequency and voltage excursions is a laudable goal, it may not be practical to eliminate all unit tripping for these reasons. Furthermore, it creates the situation where literally every unit trip could become subject to a compliance violation investigation. Before this standard is finalized, NERC needs to assess how it is going to manage compliance enforcement with it. The posting of the ballot is confusing. The red-line documents are, in fact, clean (i.e. there are no red-lines) documents that do not line up with the "clean" documents. Thus, it is not clear what is being voted on. For example, the "clean" document shows that there are five parts with Requirement R1. The "redline to last posted" document has four subrequirements under the main requirement R1. **The SDT apologizes that a true redline document was not posted. The document being balloted was the second draft of version 1 of the standard.** The basis for the values established in parts 1.1 through 1.5 does not appear to be well documented. We understand from reviewing the documentation that the SDT appears to have reviewed a number of actual events. Documentation of this review would allow us to better understand the drivers for these values. **The events studied are documented in the WECC White Paper listed in Section G, References. This is**

Organization	Yes or No	Question 6 Comment
		available on the WECC web site. The values in parts 1.1 through parts 1.5 do not appear to be well coordinated with UFLS. For instance, UFLS will actuate at 59.3 Hz per the UFLS standard while many generators could trip at 59.4 Hz that could cause a cascade of units tripping from degrading frequency. Hopefully, the UFLS actuation would prevent a downward spiral of frequency but that coordination is not clear at this point **The curves in Attachment 1 were developed in coordination with the PRC-006 SDT which is now approved by the NERC Board of Trustees. You will note that the Generator Protection curves in PRC-006 Attachment 1 match the curves in PRC-024 Attachment 1. A Regional Variance has been added to ensure the standard coordinates with the WECC UFLS program.** It is not clear why the exception for R1 and R2 would expire with a capacity up-rate greater than 10% in R3. That implies that the reason for the exception must be fixed with such a capacity up-rate. Was this the SDT's purpose? Why? **The SDT has revised Requirement R3 to clarify that the limitation must be eliminated if the equipment causing the limitation is modified or upgraded resulting in an increase in nameplate capacity greater than 10%.**
Response: Thank you for your comments. See specific responses above.		
North Carolina Electric Membership Corp.	Negative	It is not clear that this standard is needed. While attempting to eliminate unit tripping from frequency and voltage excursions is a laudable goal, it may not be practical to eliminate all unit tripping for these reasons. Furthermore, it creates the situation where literally every unit trip could become subject to a compliance violation investigation. Before this standard is finalized, NERC needs to assess how it is going to manage compliance enforcement with it. The posting of the ballot is confusing. The red-line documents are, in fact, clean (i.e. there are no red-lines) documents that do not line up with the "clean" documents. Thus, it is not clear what is being voted on. For example, the "clean" document shows that there are five parts with Requirement R1. The "redline to last posted" document has four subrequirements under the main requirement R1. **The SDT apologizes that a true redline document was not posted. The document being balloted was the second draft of version 1 of the standard.** The basis for the values established in parts 1.1 through 1.5 does not appear to be well documented. We understand from reviewing the documentation that the SDT appears to have reviewed a number of actual events. Documentation of this review would allow us to better understand the drivers for these values. **Requirement R1, Parts 1.1 through 1.5 have been removed. The information from Part 1.5 has been incorporated into the body of Requirement R1. The curves in Attachment 1 were developed in coordination with the UFLS SDT. These curves match the Generator Tripping expectation in PRC-006-2 Attachment 1.** The values in parts 1.1 through parts 1.5 do not appear to be well coordinated with UFLS. For instance, UFLS

Organization	Yes or No	Question 6 Comment
		will actuate at 59.3 Hz per the UFLS standard while many generators could trip at 59.4 Hz that could cause a cascade of units tripping from degrading frequency. Hopefully, the UFLS actuation would prevent a downward spiral of frequency but that coordination is not clear at this point. **Requirement R1, Parts 1.1 through 1.5 have been removed. The information from Part 1.5 has been incorporated into the body of Requirement R1. The curves in Attachment 1 were developed in coordination with the UFLS SDT. These curves match the Generator Tripping expectation in PRC-006-2 Attachment 1.** It is not clear why the exception for R1 and R2 would expire with a capacity up-rate greater than 10% in R3. That implies that the reason for the exception must be fixed with such a capacity up-rate. Was this the SDT's purpose? Why? **The SDT has revised Requirement R3 to clarify that the limitation must be eliminated if the equipment causing the limitation is modified or upgraded resulting in an increase in nameplate capacity greater than 10%.** Requirement R4 is unnecessary and completely administrative. It provides no reliability value. It appears to be an attempt to compel a Generation Owner to be responsive to its Reliability Coordinator, Planning Coordinator,Transmission Operator and Transmission Planner. In fact, it does not compel any real responsiveness as the Generation Owner could simply document their disagreement. It is already in the Generator Owner's best interest to be responsive. Thus, this requirement is not necessary. **The SDT agrees and has removed Requirement R4.** Requirement R7 is partially redundant with Requirement R3. R3 already requires documentation and communication of equipment limitations. Thus, R7 creates the potential of double jeopardy. **The SDT agrees that there was potential confusion and has revised the wording in Requirement R7 to address your concern.**
Response: Thank you for your comments. See specific responses above.		
Old Dominion Electric Coop.	Negative	It is not clear that this standard is needed. Response: Thank you for your comments. See specific responses above.		

Organization	Yes or No	Question 6 Comment
Nebraska Public Power District	Negative	NPPD supports the comments submitted by the Midwest Reliability Organization (MRO) NERC Standards Review Forum (NSRF).
Response: Thank you for your comment. See response to the MRO NSRF.		
Liberty Electric Power LLC	Negative	Objection to the use of the word "inclusive" with the trip points for frequency relaying.
Response: Thank you for your comment. The word has been removed and an explanatory note has been added to each of the Attachments indicating that the No Trip Zone is exclusive of the lines, so setting relays to operate on a line is acceptable.		
Omaha Public Power District	Negative	OPPD is concerned with the rate of frequency change setting requested by R1.5 and would ask the SDT for justification behind the 2.5 Hz/Sec rate of frequency change. Further, some units may not be compliant to the frequency capability and voltage ride-through time duration curves requested by this standard. These technical limitations will prevent strict compliance to the standard as written.
Response: Thank you for your comments. R1.5 allows tripping if the rate of change of frequency exceeds 2.5 Hz/sec. It does not require tripping. This allows generators to have Aurora Scenario protection, which uses frequency rate of change as part of the detection scheme. The value 2.5 Hz/sec is commonly used in this type of protection. Existing generating units that cannot meet Requirements R1 or R2 for a technical limitation are allowed an exemption from the portions of Attachments 1 and 2 that the limitation prevents them from meeting. In order to receive this exemption, they must perform the actions described in Requirement R3.		
Northeast Utilities	Negative	Opposed with comments: 1) Generator frequency ride-through capability is too lenient and will not work within the NPCC footprint. **The frequency ride-through capability (Attachment 1) matches the generator tripping expectation from PRC-006 Attachment 1, which includes a margin from the UFLS Underfrequency Performance Characteristic defined in the same attachment. Any Regional Entity can set requirements that are more stringent than a NERC standard.** 2) The standard infers that the voltage relay settings should be based on actual fault clearing times. ISO New England maintains that the settings should be 9 cycles since clearing times may vary over time. **The SDT does not believe there is a significant reliability gain to making all generators set relaying to account for 9-cycle clearing.** 3) The standard appears to allow a SPS to be used instead of meeting the requirements of the standard. This is not a good practice and could lead to a proliferation of SPS installations. **In many cases an SPS will trip a generator for loss of certain transmission elements in order to prevent overloading the remaining elements. Overriding the operation of an SPS by not allowing it to trip generation could lead to grid instability and cascading outages. NERC Standard PRC-015 requires an SPS to meet NERC and RRO**

Organization	Yes or No	Question 6 Comment
		criteria, so GO's do not have carte blanche to install an SPS to avoid compliance with the PRC-024 requirements. 4) The standard provides for a number of exceptions for new generating units. New units should meet the standard in its entirety without exception. Standards should not be written in this manner which is contrary to reliability principals. **Requirement R6 sets expectations for new generating units that are far more challenging than those for existing units. The SDT believes this requirement will increase reliability while recognizing the realities of operating generating facilities.**
Response: Thank you for your comments. See specific responses above.		
Portland General Electric Co.	Negative	Per WECC Position Paper
Response: Thank you for your comments. See response to WECC.		
SERC Reliability Corporation	Negative	Please see comments of the SERC Dynamics Review Subcommittee and the SERC Generator Subcommittee.
Response: Thank you for your comments. See response to the SERC Dynamics Review Subcommittee and the SERC Generator Subcommittee.		
ISO New England, Inc.	Negative	Please see detailed comments submitted. Of specific concern, we are voting negative due to: 1. Generator frequency ride-through capability is too lenient and will not work within the NPCC footprint. **The frequency ride-through capability (Attachment 1) matches the generator tripping expectation from PRC-006 Attachment 1, which includes a margin from the UFLS Underfrequency Performance Characteristic defined in the same attachment. Any Regional Entity can set requirements that are more stringent than a NERC standard.** 2. The standard infers that the voltage relay settings should be based on actual fault clearing times. ISO New England maintains that the settings should be 9 cycles since clearing times may vary over time. **The SDT does not believe there is a significant reliability gain to making all generators set relaying to account for 9-cycle clearing.** 3. The standard appears to allow a SPS to be used instead of meeting the requirements of the standard. This is not a good practice and could lead to a proliferation of SPS installations. **In many cases an SPS will trip a generator for loss of certain transmission elements in order to prevent overloading the remaining elements. Overriding the operation of an SPS by not allowing it to trip generation could lead to grid instability and cascading outages. Organization	Yes or No	Question 6 Comment
		requirements. 4. The standard provides for a number of exceptions for new generating units. New units should meet the standard in its entirety without exception. Standards should not be written in this manner which is contrary to reliability principals. **Requirement R6 sets expectations for new generating units that are far more challenging than those for existing units. The SDT believes this requirement will increase reliability while recognizing the realities of operating generating facilities.**
Response: Thank you for your comments. See specific responses above.		
Wisconsin Energy Corp.	Negative	R1.5 requires generator relaying to not trip for a rate of change of frequency of 2.5 Hz/Second. The requirement to be able to detect the rate of change of frequency is not achievable with existing equipment, and therefore should be removed. Also, the need for the information in R5 is not sufficient to make this a Requirement in this Standard. This information can be provided by informal means.
Response: Thank you for your comments. R1.5 *allows* a generator to trip within the No Trip Zone of Attachment 1 if the rate of change of frequency *exceeds* 2.5 Hz/sec. There are several standard generator protection relays (e.g. GE's G-60, Schweitzer's 700G, and Beckwith's M-3425A) in addition to relays that are designed specifically for Aurora Scenario protection that incorporate a frequency rate of change function.		
Florida Municipal Power Pool	Negative	R6.1.1 is ambiguous, what does "at least 20% of the Facility's rated capacity" imply? Would a single test at full output suffice, or is "book-ending" the output between minimum and maximum output of the generator implied?
Response: Thank you for your comments. The intent is nameplate capacity. The wording has been changed accordingly.		
Public Utility District No. 1 of Chelan County	Negative	Requirement R1 of the proposed PRC-024-1 reliability standard conflicts with the WECC Off-Nominal Frequency Load Shedding Plan (WECC Coordinated Plan), and could potentially result in negative reliability impacts if enforced in the Western Interconnection. A WECC regional Variance needs to be added to this draft.
Response: Thank you for your comments. A Regional Variance has been added for WECC.		
Minnkota Power Coop. Inc.	Negative	See comments of NSRF
Response: Thank you for your comment. See response to the MRO NSRF.		

Organization	Yes or No	Question 6 Comment
National Association of Regulatory Utility Commissioners	Negative	The following issues have been identified by the NPCC and need to be resolved: Â· Generator frequency ride-through capability is too lenient and will not work within the NPCC footprint. **The frequency ride-through capability (Attachment 1) matches the generator tripping expectation from PRC-006 Attachment 1, which includes a margin from the UFLS Underfrequency Performance Characteristic defined in the same attachment. Any Regional Entity can set requirements that are more stringent than a NERC standard.** Â· The standard infers that the voltage relay settings should be based on actual fault clearing times. ISO New England maintains that the settings should be 9 cycles since clearing times may vary over time. **The SDT does not believe there is a significant reliability gain to making all generators set relaying to account for 9-cycle clearing.** Â· The standard appears to allow a SPS to be used instead of meeting the requirements of the standard. This is not a good practice and could lead to a proliferation of SPS installations. **In many cases an SPS will trip a generator for loss of certain transmission elements in order to prevent overloading the remaining elements. Overriding the operation of an SPS by not allowing it to trip. NERC Standard PRC-015 requires an SPS to meet NERC and RRO criteria, so GO's do not have carte blanche to install an SPS to avoid compliance with the PRC-024 requirements.** Â· The standard provides for a number of exceptions for new generating units. New units should meet the standard in its entirety without exception. Standards should not be written in this manner which is contrary to reliability principals. **Requirement R6 sets expectations for new generating units that are far more challenging than those for existing units. The SDT believes this requirement will increase reliability while recognizing the realities of operating generating facilities.**
Response: Thank you for your comments. See specific responses above.		
Northern Indiana Public Service Co.	Negative	The related Standard Drafting subteams held a webinar on July 29 where they fielded numerous questions; issues still need to be addressed
Response: Thank you for your comments. The wording in the standard has been revised to improve clarity and remove ambiguities.		
Luminant Energy	Negative	The standard should not be addressing loadability issues as they are being evaluated in PRC-023-2. This standard should apply to generator protective relaying and its ability to ride through fault conditions.
Response: Thank you for your comments. The voltage curves in PRC-024 Attachment 2 do not require evaluating operation at 0.85 pu voltage for an extended period of time, as does PRC-023-2. Any relays that can meet PRC-023-2 requirements, will also meet the requirement the requirement to		

Organization	Yes or No	Question 6 Comment
operate at 0.90 pu voltage for an extended period.		
Lakeland Electric	Negative	The terms used in R1, R2 and R3 are inconsistent. R1 and R2 refer to "protective relaying", R3 refers to "protection system equipment".
Response: Thank you for your comments. The SDT has revised the wording to make it consistent.		
Public Utility District No. 1 of Lewis County	Negative	This is another standard that should be reserved for generators larger that 100MW. Smaller generators should be exempt from frequency standards. Our plant only has a planel board frequency meter; no relaying or recording of frequency.
Response: Thank you for your comments. Without strong technical justification for changing the applicability, the SDT must use the Registry Criteria sizes (individual units 20 MVA or greater and facilities with aggregate size of 75 MVA or greater). Footnote 1 clearly states that the Generator Owner does not have to install or activate protection. If a generating unit does not have protective functions that trip the generator for frequency excursions, then it meets Requirement R1 by default.		
PSEG Energy Resources & Trade LLC; PSEG Fossil LLC; Public Service Electric and Gas Co.	Negative	This standard has made progress, but there are ambiguities that we addressed in our comments and which the team also addressed on its July 29 Webinar. We recommend that the standard incorporate the suggested comments and the team repost the standard for a round of comments only.
Response: Thank you for your comments. The wording in the standard has been revised to improve clarity and remove ambiguities.		
Independent Electricity System Operator	Negative	We cannot support this standard for following reasons: i. Requirement R5: We do not support the requirement to provide an estimate of the performance of the units during frequency and voltage excursions. First of all, the requirement does not distinguish whether it applies to units that are equipped with frequency/voltage protective relays or otherwise. Secondly, the intent of providing the suggested estimate is to allow Transmission Planners to apply valid or supported assumptions in their planning studies. Given the requirements in Attachments 1 and 2, and Requirement R3 (which, by the way, should be modified as we suggest below), the TPs can apply the following relevant assumptions: a. For units that are equipped with frequency/voltage protective relays, the GO's submitted relay settings will determine when the units will trip; b. For units that are NOT equipped with frequency/voltage protective relays, the units are conservatively assumed to trip when the simulated frequency/voltage goes outside the bounds of Attachments 1 and 2. We do not see what other estimates that can be more relevant and valid than the above. We see that there may be some value in providing these estimates but only in the case of generators not equipped with frequency/voltage protective relays where tripping takes place beyond the no-trip zones of Attachments 1 and

Organization	Yes or No	Question 6 Comment
		2. For this information to be useful however, the generator's behavior must be predictable. While it may facilitate some "what-if" analysis, it is not clear that using this information would be better than the conservative assumption "b" above. How does the SDT envisage that the Transmission Planner will use this additional information if it cannot be relied upon? **The "estimate of performance in 25% increments" portion of the requirement has been removed. The SDT agrees that it would not improve reliability.** ii. R3: Please clarify the meaning of the expression "non-protection system equipment". Does it mean "a limitation imposed by equipment other than the protection system"? **SDT: Yes** Or does it refer to generating units that are NOT equipped with frequency/voltage protective relays? **SDT: No** In the latter case, how would the GO determine that the units that are not so equipped are unable to meet the criteria in Requirement R1 or R2? In our view, units that are unable to meet these criteria are those that are equipped with frequency/voltage protective relays and whose trip settings do not meet the criteria specified in R1 and R2 for specific technical reasons that are communicated to the Transmission Planners. For units that are NOT equipped with such protective relays, the suggestion that any of them may be unable to meet the criteria in R1 and R2 could be those which in the past have tripped before the thresholds. However, unless a unit repeatedly trips under like circumstances, isolated incidences do not provide sufficient evidence to arrive at a conclusive determination. And for those units that are NOT equipped with the protective relays and have never tripped before the thresholds, there is no telling whether or not they can meet the criteria. For the above reasons, we suggest the SDT to revise the R3 to convey the requirement that the GOs shall provide the technical reasons for not meeting the R1 and R2 criteria only for those units that ARE equipped with the protective relays and ARE set at different thresholds. **If a unit does not have voltage or frequency protective relays, then by default it will not be tripped by such relays during an excursion and the GO is in compliance.** iii. We believe R4 is a sub-requirement or part of R3 since R4 mandates the GO to respond to the listed entities within 30 days of receiving a request, and that in the requirement there is no mention of "what" the response should entail. The "what" is stipulated in R3. **The SDT agrees and has removed Requirement R4.** iv. R7: We assess that this requirement duplicates with what we interpret as the intent of a good part of R3, i.e., to provide the listed entities with the settings of the frequency/voltage protective relays. Regardless of whether or not a GO is able to meet R1 and R2, it should be obligated to provide the generator protection trip settings to these other entities for modeling purpose (consistent with our comments under Q3). If a GO sets the protective relays at values that do not meet the R1 and R2 criteria, then it should be obligated to provide the technical limitations that form the basis of the deviation. This requirement thus should come after R1 and R2, and replaces the as written R3 for reasons that we mention in our comments in (1), above. **The SDT agrees that there was potential confusion and has revised the wording in Requirement R7 to address your concern.**

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 6 Comment</th></tr>
<tr><td colspan="3">Response: Thank you for your comments. See specific responses above.</td></tr>
<tr><td>Seattle City Light</td><td>Negative</td><td>We suggest that Requirement 5 be rewritten to require that the Generator Owner to provide the expected design performance of relaying and the performance results from a valid dynamic simulation. Requiring "estimates" of the probability of the generators remaining online after a severe fault seems arbitrary at best. It is unlikely that there is enough empiric evidence to form a valid statistical probability, and it is unclear what useful information a probability of the relaying design actually working would provide.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. The “estimate of performance in 25% increments” portion of the requirement has been removed. The SDT agrees that it would not improve reliability.</td></tr>
<tr><td>Beaches Energy Services; Lakeland Electric; City of Green Cove Springs; City of Vero Beach</td><td>Negative</td><td>What does "external to the plant" mean as used in several of the requirements (e.g., R1, R2, R6)? We assume that this would also mean beyond any radial connection (e.g., generator lead) to the plant and would suggest changing the term to something like: "caused by an event beyond the point at which the plant is radially connected to the transmission system". Your assumption is correct.

Considering R1, many generators have speed protection embedded in control systems (e.g., a GE Mark V or VI), is that included in footnote 1 to the requirement in the phrase: "multi-function protective devices or protective functions within excitation controls that directly trip or provide tripping signals to the generator based on frequency or voltage inputs"? The SDT agrees and has revised the wording in the footnote to clarify the intent.

In R2, does "voltage protective relaying" include station service protection, such as motor-contactors? The terms used in R1, R2 and R3 are inconsistent. R1 and R2 refer to "protective relaying", R3 refers to "protection system equipment". The wording has been changed for consistency.

R6.1.1 is ambiguous, what does "at least 20% of the Facility's rated capacity" imply? Would a single test at full output suffice, or is "book-ending" the output between minimum and maximum output of the generator implied? The intent is nameplate capacity. The wording has been changed accordingly..</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. See specific responses above.</td></tr>
<tr><td>Brazos Electric Power Cooperative, Inc.</td><td>Negative</td><td>Requirements R1, R2 and R6 all should have Medium VRFs. In the long-term planning horizon, a VRF can be high if a violation “under emergency, abnormal or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation or cascading”. Requirements R1, R2 and R5 do not meet the “directly cause” condition as multiple violations of this standard would have to occur along with violations of other standards. The TPL standards already require the BES to be planned for contingencies of individual units as well Category C contingencies which will result in loss of multiple units at</td></tr>
</table>

Organization	Yes or No	Question 6 Comment
		the same plant. Additionally, TPL-004 requires the Transmission Planner and Planning Coordinator to study multiple events such as loss of a substation which could include loss of an entire generating plant. FAC-014-2 R6 requires the Planning Coordinator to identify the subset of multiple contingencies which result in stability limits. FAC-011-2 R3.3 requires the RC to determine which of these multiple contingencies qualify for use in the operating horizon. Then, of course, TOP-004-2 R1 requires the Transmission Operator to operate within the associated SOLs and IROLs and IRO-009-1 R4 requires the Reliability Coordinator to operate with IROLs. Thus, R1, R2, and R6 VRFs should be Medium. Requirement R4 does not have a VRF assigned.
Response: Thank you for your comments. This standard assumes a contingency has already occurred on the Transmission System to cause the voltage or frequency excursion. The loss of generation during a contingency could potentially lead to cascading outages. NERC defines this as a High VRF. Requirement R4 has been removed.		
Pacific Gas and Electric Company	Negative	The language contained in the VSL/VRF matrix must match the language in the Standard. Requirements R1 and R2 of PRC-024-1 require that frequency protective relaying (R1) and voltage protective relaying (R2) be set so that it does not trip within the criteria listed in the respective requirements “unless the Generator Owner has documented and communicated a non-protection system limitation in accordance with Requirement R3.” However, the language of the binary Severe VSL for Requirements R1 and R2 only identifies failure to set protective relaying, without recognizing the exception granted for documenting and communicating a non-protective system limitation. As written the applicable entity could be compliant with the language of Requirements R1 and R2, but based on the language of the VSLs, would be non-compliant.
Response: Thank you for your comments. The VSL’s have been revised to address this issue.		
PacifiCorp	Negative	(6) PacifiCorp offers one comment on the Violation Severity Limits (“VSLs”) proposed for Requirements R1 and R2 of PRC-024-1, which require that frequency protective relaying (R1) and voltage protective relaying (R2) be set so that they do not trip within the criteria listed in the respective requirements “unless the Generator Owner has documented and communicated a non-protection system limitation in accordance with Requirement R3.” However, the language of the binary Severe VSL for Requirements R1 and R2 only identifies the failure to set protective relaying, without recognizing the exception granted for documenting and communicating a non-protective system limitation. As written, the applicable entity could be compliant with the language of Requirements R1 and R2, but based on the language of the VSLs, they would be non-compliant. The SDT should add this critical clarification to the VSLs.
Response: Thank you for your comments. The VSL’s have been revised to address this issue.		
Arizona Public Service Co.	Negative	“Going from Lower VSL to Severe VSL, they are spaced 10 days apart. This is very unreasonable. They

Organization	Yes or No	Question 6 Comment
		should be spaced at least 30 to 90 days apart. The settings are used in studies for long range planning horizon and delay in information on relay setting of an individual unit is not significant to BES reliability. The drafting team should not follow generic guide lines and should use reasonability in setting these VSL levels."
Response: Thank you for your comments. The time increments are based on the NERC VSL Guidelines.		
Indiana Municipal Power Agency	Negative	IMPA does not agree with the VSLs for requirement 5 which is just an estimation of unit or plant performance. IMPA recommends lower the VSLs.
Response: Thank you for your comments. The risk factor for this requirement is "Lower". The VSL's are a measure of how severity of the violation. NERC requires that all VSL's contain a "Severe" level.		
Black Hills Corp	Negative	R1 & R2 require that frequency protective relaying & voltage protective relaying be set so that it does not trip within the criteria listed in the respective requirements "unless the GO has documented & communicated a non-protection system limitation in accordance with R3". However, the language of the binary Severe VSL for R1 & R2 only identifies failure to set protective relaying, without recognizing the exception granted for documenting and communicating a non-protective system limitation. As written the applicable entity coul be compliant with the language of R1 & R2, BUT based on the language of the VSL's, would be non-compliant.
Response: Thank you for your comments. The VSL's have been revised to address this issue.		
Florida Municipal Power Pool	Negative	R4 is missing the VRF and Time Horizon - would recommend Lower and Long-term Planning.
Response: Thank you for your comments. Requirement R4 has been removed.		
Sunflower Electric Power Corporation	Negative	Requirement R4 does not have a VRF assigned. Requirements R1, R2 and R6 all should have Medium VRFs. In the long-term planning horizon, a VRF can be high if a violation "under emergency, abnormal or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation or cascading". Requirements R1, R2 and R5 do not meet the "directly cause" condition as multiple violations of this standard would have to occur along with violations of other standards. The TPL standards already require the BES to be planned for contingencies of individual units as well Category C contingencies which will result in loss of multiple units at the same plant. Additionally, TPL-004 requires the Transmission Planner and Planning Coordinator to study multiple events such as loss of a substation which could include loss of an entire generating plant. FAC-014-2 R6 requires the Planning Coordinator to identify the subset of multiple contingencies which result in stability limits. FAC-011-2 R3.3 requires the RC to determine which of these multiple contingencies qualify for use in the operating horizon. Then, of course,

Organization	Yes or No	Question 6 Comment
		TOP-004-2 R1 requires the Transmission Operator to operate within the associated SOLs and IROLs and IRO-009-1 R4 requires the Reliability Coordinator to operate with IROLs. Thus, R1, R2, and R6 VRFs should be Medium.
Response: Thank you for your comments. Requirement R4 has been removed. This standard assumes a contingency has already occurred on the Transmission System to cause the voltage or frequency excursion. The loss of generation during a contingency could potentially lead to cascading outages. NERC defines this as a High VRF.		
Avista Corp.;BrightSource Energy, Inc.; City of Farmington; City of Redding; Cogentrix Energy, Inc.; Colorado Springs Utilities; Idaho Power Company; Los Angeles Department of Water & Power; Pacific Gas and Electric Company; South California Edison Company; Western Electricity Coordinating Council	Negative	Requirements R1 and R2 of PRC-024-1 require that frequency protective relaying (R1) and voltage protective relaying (R2) be set so that it does not trip within the criteria listed in the respective requirements “unless the Generator Owner has documented and communicated a non-protection system limitation in accordance with Requirement R3.” However, the language of the binary Severe VSL for Requirements R1 and R2 only identifies failure to set protective relaying, without recognizing the exception granted for documenting and communicating a non-protective system limitation. As written the applicable entity could be compliant with the language of Requirements R1 and R2, but based on the language of the VSLs, would be non-compliant.
Response: Thank you for your comments. The VSL’s have been revised to address this issue.		
MidAmerican Energy Co.	Negative	The standard nor VSL are ready
Response: Thank you for your comments. The standard has been revised to clarify intent and remove ambiguities.		
Independent Electricity System Operator	Negative	We do not agree with the standard as posted, for which we have casted a NO vote. We are unable to support the VRFs and VSLs for the standard/requirements that we reject, and we expect the standard to be materially revised which may result in corresponding changes to the VRFs and VSLs.
Response: Thank you for your comments. The standard has been revised to clarify intent and remove ambiguities.		
Beaches Energy Services; Lakeland Electric; City of Green Cove Springs; City of Vero Beach	Negative	R4 is missing the VRF and Time Horizon - would recommend Lower and Long-term Planning

Organization	Yes or No	Question 6 Comment

Organization	Yes or No	Question 6 Comment
Manitoba Hydro	Affirmative	Manitoba Hydro is voting affirmative but justification should be provided by the drafting team for the curves in Attachments 1 and 2. It is not clear why the 'no trip zone' limits are set as they are.
Response: Thank you for your comments. The frequency curves in Attachment 1 match the generator tripping curves from PRC-006 and provide a margin for UFLS programs to operate before generator tripping occurs. The voltage profile in Attachment 2 was developed using information from FERC Order 661A and studies done in the WECC and SERC regions. The WECC White Paper on their studies is cited in the Reference Section.		
Southern Company Generation	Affirmative	R4 does not have a VRF assigned to it.
Response: Thank you for your comments. Requirement R4 has been removed.		
Texas Reliability Entity	Affirmative	The VSL for R6 refers to "Requirement 6" in connection with frequency parameters and to "Attachment 2" in connection with voltage parameters. It would be more direct and consistent to refer to "Attachment 1" in connection with frequency parameters.
Response: Thank you for your comments. The SDT agrees and has revised the VSL accordingly.		
Southwest Transmission Cooperative, Inc.	Affirmative	While we are voting affirmative for the VSLs and VRFs, conforming changes will be necessary if requirements our modified per our ballot comments.
Response: Thank you for your comments. If the Standard had passed the initial ballot, then there would not have been changes to the requirements.		
Pepco Holdings Incand Affiliates	Yes	1) The applicability section from the previous draft of this standard should be re-inserted. Although the SDT chose to remove that section since the standard is intended to apply to all generation facilities that meet Compliance Registry Criteria, adding the specific generation criteria for which this standard applies within the body of the standard provides much more clarity than having to refer to a second document to define applicability. In addition, inserting the full applicability criteria would be consistent with the way Applicable Facilities are identified in Section 4.2 of PRC-019-1. **Unless there are deviations from the Registry Criteria, NERC Staff has told the SDT to write the Applicability as currently drafted. PRC-019-1 deviates with the inclusion of synchronous condensers.** 2) Requirement R 2.1.1 should be re-worded as follows: "For three-phase faults with Normal Clearing on transmission system facilities (lines, busses, transformers, etc.) adjacent to the point of interconnection, set voltage relays to ride through expected fault clearing times, not to exceed 9 cycles." The use of the term "zone 1 faults" implies that zone 1 relaying schemes are always employed on the transmission system, which may not be the case. Pilot schemes, overcurrent schemes, differential schemes, etc. may be used instead.

Organization	Yes or No	Question 6 Comment
		Also, the unit should stay connected if a fault were to occur on an adjacent bus or transformer rather than just on lines. Also, use of the term "Zone 1 fault" in Requirement R5 needs to be similarly addressed. **Requirement R2, section 2.1.1 has been removed. Clarification #2 to PRC-024 Attachment 2 has been revised to state "The curves depicted were derived from to a three-phase transmission system zone 1 faults with Normal Clearing…"** 3) Requirement R 2.1.1 should also address ride through capability for TPL Category C contingencies (i.e. single line to ground faults with a stuck breaker, or other cause for delayed clearing) since generation units are expected to remain on line during these contingencies as well. Granted, a three phase fault would be the most severe, however a single line to ground fault with delayed clearing times could also cause unwanted unit tripping, leading to a violation of Reliability Criteria. **Although PRC-024 Attachment 2 curves were derived based on the voltage profile of normally cleared Zone 1 faults, the SDT believes they cover many other contingencies, including some, but not all, from TPL Category C. The SDT believes it is unrealistic to expect generators to be designed to accommodate all Category C contingencies at all possible generating sites.** 4) The SDT in their response to comments on Draft #1 of this standard stated that "Attachment 2 was developed based on a positive sequence model. As such, only balanced voltages should be considered when addressing relay settings." This is fine for evaluating the response to three phase faults, or other balanced system disturbances. However, if it is critical to the reliability of the BES to not have generators trip off line for voltage excursions associated with three phase faults, then it is equally as important to have them remain on-line for single line to ground faults, which are much more common. During a phase to ground fault at the point of interconnection the faulted phase voltage collapses to zero but the unfaulted phase to ground voltages could rise as high as 80% of the line to line voltage for an effectively grounded system (with a coefficient of grounding = 80%). This is well in excess of the 1.2 p.u. requirement shown in Attachment 2. Generator voltage protection relays respond to actual phase voltages not just positive sequence voltages. As such, for the unit to ride through phase to ground faults at the point of interconnection then the short time 1.2 p.u. overvoltage threshold needs to be raised above 0.8 x 1.73 = 1.38 p.u. **The SDT agrees and has added Clarification #5 to PRC-024 Attachment 2 that states: "Additionally, voltages in the curve assume minimum fundamental frequency phase-to-ground or phase-to-phase voltage for the low voltage duration curve and maximum crest phase-to-ground or phase-to-phase voltage for the high voltage duration curve".** 5) The revised language in R3 referring to "the equipment limitation expires coincident with ...." is unclear and confusing. How can the "limitation" expire merely by the generating unit continuous capacity rating being increased > 10%. The Draft #1 version of this standard uses the phrase "the Generator Owner is granted an exception for that unit meeting the portion of R1 or R2 for that limitation once it provides documentation of the equipment limitation(s)..." "This exception for the equipment limitation shall expire coincident with..." The use of the term "exception, or exemption", makes more sense and is more in line with the intent of this

Organization	Yes or No	Question 6 Comment
		section. As such, the original language from Requirement R5 from Draft #1 should be re-instated. **The SDT agrees and has restored the Draft #1 wording.** 6) Typically unit connected generator protection packages, which include frequency and voltage protective elements, are supplied by voltage transformers connected on the terminals of the generator rather than on the high side of the generator step-up (GSU) transformer. For frequency elements, the frequency at the terminals of the generator is the same as on the high side of the GSU transformer. So comparison of frequency protective element set points can be made directly with Attachment 1. However, this is not true for voltage. The generator terminal voltage could be higher, or lower, than the system voltage on the high side of the GSU transformer depending on the voltage drop across the transformer, which varies depending on the generator real power output and whether the generator is supplying or absorbing reactive power. Since this standard requires the generation to remain connected for specific voltage criteria as measured at the point of interconnection, but the voltage sensing protection is connected to the generator terminals, some technical guidance (with specific examples) must be provided to allow the Generator Owner to translate these voltage criteria to the voltages seen by the protective relays on the terminals of the generator. Otherwise an incorrect evaluation may result. It is recommended that a Technical Reference Document similar to the "Power Plant and Transmission System Protection Coordination" document developed by the NERC System Protection and Control Subcommittee be produced, or the above mentioned document revised, to provide illustrative examples of how to apply the Attachment 2 POI voltage criteria to voltage sensing protective elements connected to the terminals of the generator. **The SDT agrees that the voltage seen at the generator terminals will not be the same as at the point of interconnection where the excursion occurs. Normally, the voltage at the generator terminals will be higher during the fault due to the impedance of the Generator Step-Up transformer (typically in the neighborhood of 0.4 pu during a close-in three phase fault). The GO may conservatively evaluate protective functions with voltage inputs using the POI voltage profile with the assumption that if they ride through that profile they will ride through the voltage seen at the generator terminals. Alternatively, the GO may choose to do a dynamic simulation and evaluate based on the results of that study. There are a number of good texts available on system stability. The SDT does not feel the need to write another one.** 7) Comments on "Voltage Ride-Through Curve Clarifications" which appears on the last page of the standard:Item#1 - Suggest replacing the term "scheduled operating voltage" with "nominal operating voltage". Voltage schedules may change over time, whereas "nominal" or "rated" voltages do not. Also, the protective systems are usually set based on voltage excursions above, or below, "rated" or "nominal" voltage. **The SDT agrees that "nominal" is better than "scheduled" and has changed the wording accordingly.** Item #2 - Suggest eliminating item 2. The ride-through curve is to ensure the unit remains on line for voltage excursions up to the limits defined by Attachment 2, regardless of the cause of the voltage excursion. **The SDT agrees and has changed Clarification #2 to PRC-024 Attachment 2 to read as follows: "The curves depicted were derived from to a three-phase transmission system zone 1 faults with Normal**

Organization	Yes or No	Question 6 Comment
		Clearing not to exceed 9 cycles." Item #3 - The use of the term "cumulative voltage duration" is confusing since Attachment 2 is made up of a series of discrete allowable voltage magnitudes and durations. **The SDT intentionally used the word "cumulative" so that OEM's will know how much time their equipment has to withstand any particular voltage level. It also gives relay setting engineers the ability to evaluate settings for different voltage levels at the specified duration times.** Also, the language only mentions voltage protective relaying and not other non-protective equipment, which could cause the unit to trip. Suggest re-wording as follows: "The generator shall remain connected (i.e., "ride-through") voltage excursions caused by disturbances on the transmission system, when the voltage at the point of interconnection with the BES remains within the boundaries of these curves. **The SDT agrees and has added the words "…control systems that directly trip or provide tripping signals to the generator based on frequency or voltage inputs…" to Footnote 1.** "Item #5 d - suggest removing the term "scheduled", making it read "d. Voltage is measured at the point of interconnection" **The SDT agrees and has removed part "d.".**
Response: Thank you for your comments. See specific responses above.		
Northeast Power Coordinating Council	Yes	In R3, the SDT should review that generators are not required to provide a remedial plan for an equipment limitation. For the SDT's consideration is the work done by and for the NPCC UFLS RSDT. It was recommended to retain the more conservative NPCC Frequency Capability Curve for setting generator protection as opposed to the proposed Frequency Capability Curve in PRC-024-1 for the following reasons:1. Some portions of the NPCC Region have additional stages of UFLS set at lower frequency thresholds below 58 Hz. Adopting the curve in Attachment 1 may impact the effectiveness of the UFLS program from arresting frequency decline in these depressed frequency ranges. **The frequency ride-through capability (Attachment 1) matches the generator tripping expectation from PRC-006 Attachment 1, which includes a margin from the UFLS Underfrequency Performance Characteristic defined in the same attachment. Any Regional Entity can set requirements that are more stringent than a NERC standard.** 2. As the numbers of distributed generators connected to the system increase, it is expected that overall generator frequency response is expected to be reduced. The distributed generation may also not need to comply with the generation trip thresholds as they may not meet the existing thresholds applicable to Generator Owners in NERC's Statement of Compliance Registry Criteria. Adopting the proposed PRC-024-1 curve would jeopardize the survival of islands that may contain increasingly larger portions of distributed generation should the frequency decline below 58 Hz. **This Standard cannot extend applicability to distributed generation that is not within the Registry Criteria. There is a separate NERC project that is**

Organization	Yes or No	Question 6 Comment
		addressing frequency response. 3. Adopting the proposed PRC-024-1 curve reduces the probability that the UFLS program will successfully arrest declining frequency for system conditions that are not addressed in NPCC's 2006 UFLS Assessment. **The Attachment 1 curves matches the generator tripping curves in the recently-approved PRC-006 standard. These curves provide some margin beyond the UFLS performance required in PRC-006.** 4. Adopting the proposed PRC-024-1 curve would decrease the ability of an island to survive more severe conditions than those considered in the UFLS design (for example, islands with a generation deficiency greater than 25 percent). **The SDT agrees that this is possible, but feels there must be a balance between system security under extreme contingencies and destroying generating equipment by requiring operation for long periods of time at very low frequencies.**
Response: Thank you for your comments. See specific responses above.		
ACES Power Members	Yes	R3 is an unnecessary requirement. Enforcement of R1 and R2 already create a de facto requirement to document limitations. Thus, R3 creates an opportunity for double jeopardy.
Response: Thank you for your comments. The SDT disagrees that Requirements R1 and R2 create a de facto requirement to document limitations. Requirement R3 is included so that the Reliability Coordinator, Planning Coordinator, Transmission Operator, and Transmission Planner are aware of the documented limitation and can model the performance of the generator correctly when evaluating its performance during excursions.		
BC Hydro and Power Authority	Yes	1. R2 introduces Remedial Action Schemes (RAS) as an alternative description. We recommend keeping to Special Protection System and leaving RAS in the NERC glossary. **In one region the term "Remedial Action Scheme" is used instead of "Special Protection System". The SDT does not believe the use of the term "RAS" in this standard causes confusion.** 2. We recommend a consistent use of the terms Planning Coordinator and Planning Authority. In the Purpose of this standard, Planning Coordinators are referred to. In the NERC glossary, under Planning Coordinator it says "refer to Planning Authority". The compliance registry list includes a column for Planning Authorities. The NERC Reliability Functional Model version 5 discusses Planning Coordinators only. Is the term Planning Coordinator going to replace Planning Authority? **The NERC Functional Model does not contain a "Planning Authority". The Functional Model and this standard use "Planning Coordinator".**
Response: Thank you for your comments. See specific responses above.		
SERC Generation Sub-	Yes	During the drafting process, quite a bit of feed back was provided to the SDT about concerns if this became a performance standard and the response was that this is only a relay setting criteria. However, plant

Organization	Yes or No	Question 6 Comment
committee (GS)		performance aspects have been incorporated using the allowed operating bands developed as for use in relay setting coordination. The concerns with this include: o Important Existing nuclear plant settings are inside the published no-trip bands o How quickly plant secondary system motors will decelerate with voltage below ANSI MG-1 criteria. o Why is a voltage ride through criteria beyond existing second zone or breaker failure/critical clearing time design approaches needed? For frequency, the ride-thru criteria should be sufficient for UFLS to perform it's function. Also, the lowest frequency allowed for unit operation must accommodate the turbine blade resonance low frequency requirement for large steam plants (57.5 to 58.5 Hz, depending on the turbine OEM). Similar steam turbine restrictions also apply for the high frequency requirement.For voltage, the ride-thru criteria should be long enough in duration for second zone or breaker failure protection critical clearing time. Voltage recovery to 0.9 PU following critical clearing time is necessary to ensure electrically powered equipment will perform correctly. Nuclear power plant interface requirements are addressed in NERC NUC-001-2. PRC-024 should refer to nuclear plant interface requirements managed under NUC-001-2."The comments expressed herein represent a consensus of the views of the above named members of the SERC Generation Subcommittee only and should not be construed as the position of SERC Reliability Corporation, its board or its officers."
Response: Thank you for your comments. There is a performance requirement only for facilities that are designed and built after this standard is approved and becomes effective. Existing plants, nuclear or otherwise, that can document technical limitations to operating in portions of the No Trip Zones defined in Attachments 1 and 2 are allowed by Requirement R3 to trip to protect the equipment as long as the Reliability Coordinator, Planning Coordinator, Transmission Operator, and Transmission Planner are notified so they can correctly model the generator's performance during an excursion. Nuclear plants must comply with many NERC Standards beyond NUC-001-2.		
Idaho Power - Power Production	Yes	In section 2.1.1, we believe that the "three phase transmission system zone 1 fault" should be clarified. Is the zone 1 referring to the generator relay backup zone 1 element? The zone 1 element of the interconnection station line protection relays? Shortest line? Longest line? Another zone 1? Also, the language was a little confusing, is this an if-then statement? Since the voltage ride through curve apparently applies to all conditions (both operating and various fault configuration), reference to the "three phase transmission system zone 1 fault" implies a limitation to applicability that is not intended, and the reference should be deleted. For R3, because the time horizon for this standard is long-term planning, we believe the 30 day communication requirement is not necessary. We believe 180 days is more in line with other reporting time frames with modeling related standards. We also believe that the equipment limitation expiration section is not needed. A simple statement stating that the when the limitation is no longer valid, the RC, PA, etc should be notified. For R6, we believe it is unnecessary to have different requirements for existing and new units. We do not see the need for performance requirements for new units. We believe this standard should be a relay settings

Organization	Yes or No	Question 6 Comment
		standard, with generator performance being considered in modeling standards. R7 is burdensome to both the Generator Owner and to the receiving entities, and also prone to causing confusion. The entities proposed to receive the protection settings (RC, PC, TO, TP) would face a difficult task to be able to properly interpret the relay settings sent. The Generator Owner is the proper entity to determine the relay settings to remain in compliance with the standard. In addition, the requirement to transmit the settings within 30 days of changes is burdensome and unnecessary. Draft PRC-019-1 properly address the issue of coordinating settings with machine capabilities, and PRC-001 properly addresses the issue coordinating settings with the TO.
Response: Thank you for your comments. See specific responses above.		
SPP Reliability Standards Develpment Team	Yes	Would like to see a more consistent approach to the comment forms and the standard. It seems there is room for clean up in the posted standard/comment form.
Response: Thank you for your comments. The SDT apologizes for the inconsistency between the comment form and the standard.		
MRO's NERC Standards Review Forum	Yes	It is not clear what the basis for the requirement of R3 with regard to a 10% or more increase in capacity would lead to an expiration of an equipment limitation as the change that results in the capacity increase may not be related in any way to the origin of the equipment limitation.
Response: Thank you for your comments. The SDT has revised Requirement R3 to clarify that the limitation must be eliminated if the equipment causing the limitation is modified or upgraded resulting in an increase in nameplate capacity greater than 10%.		
Electric Market Policy	Yes	Dominion suggests the following:Section 3 should capitalize “frequency and voltage excursions”, as they are defined terms. **The definitions have been removed from the standard.** Do not understand R3 bullets. How does increasing your units rating by â‰¥10% change this? **The SDT has revised Requirement R3 to clarify that the limitation must be eliminated if the equipment causing the limitation is modified or upgraded resulting in an increase in nameplate capacity greater than 10%.** Attachment 2 does not match Â±5 voltage schedule per the definition of Voltage Excursion. This curve is not possible. R6 grants new generators exceptions. Where are the exceptions for existing generators?This standard only applies to frequency and voltage excursions within the defined limits. The attachments and requirements go outside of this bound placing much more stringent criteria on the operation of the units. These more stringent criteria may not be possible and should be removed from the standard to align with the definition of

Organization	Yes or No	Question 6 Comment
		applicability. The last sentence of the associated Implementation Plan is confusing. Suggest revising to read: "Upon the effective date of PRC-024-1, R4 of PRC-006-1 will also go into effect."
Response: Thank you for your comments. See specific responses above.		
Dynamics Review Subcommittee	Yes	Under R5, Severe VSL Requirement 55 should be Requirement 5.R7 refers to generator protection trip settings as "specified" in R1 & R2. Settings are not specified in R1 & R2. We recommend using "referred to" instead of "as specified.""The comments expressed herein represent a consensus of the views of the above named members of the [insert the full name of the group] only and should not be construed as the position of SERC Reliability Corporation, its board or its officers."
Response: Thank you for your comments. The SDT agrees and has revised the VSL's accordingly.		
LG&E and KU Energy	Yes	LG&E and KU Energy would prefer to have 60 calendar days on
Response: Thank you for your comments. The SDT does not understand which requirement you are referring to.		
FirstEnergy	Yes	FirstEnergy offers the following additional comments and suggestions:Requirement R3 - It is not clear how this requirement relates to the identified generator equipment limitations. Furthermore we are not clear what "continuous capacity rating" is referring to. We suggest the removal of the second bullet which states "the generator unit continuous capacity rating increases >= 10%". **The SDT has revised Requirement R3 to clarify that the limitation must be eliminated if the equipment causing the limitation is modified or upgraded resulting in an increase in nameplate capacity greater than 10%.. The wording has been changed from "continuous capacity" to "nameplate" to clarify intent.** Requirement R3 - This standard does not account for the fact that nuclear plants have equipment other than the generator that potentially will trip the unit at frequencies/ voltages outside of the limits shown in Attachments 1 and 2. Nuclear plant voltage and frequency trip points are set to ensure safety equipment will operated as specified in the plant's License. The standard needs to allow nuclear generators the ability to specify if something other than the generator protective relays dictates where a unit will trip. **The SDT believes that Requirement R3, as written, allows nuclear plants (or any others) to trip during a frequency or voltage excursion if the Generator Owner has documented these conditions. The intention of the SDT is that nuclear safety requirements do qualify as technical equipment limitations described in the requirement.** Under 6.7 (exception) - A unit or generating plant or generating Facility may trip if the protective functions

Organization	Yes or No	Question 6 Comment
		(such as out of step or loss of field functions) operate due to an impending or actual loss of synchronism or due to instability in power conversion control equipment. Maybe this section should include an exception for Volts/Hertz protection. **The SDT agrees and has made the wording more general to allow tripping to protect the equipment from damage.** General - The standard should state whether disturbances that include both frequency and voltage excursions are covered under the standard. For example, our Volts/Hertz protection trips in 45 seconds at 110%. The standard calls for a HVRT of 600 seconds at 110%. This current Volts/Hertz setting would not meet the standard. **The Clarifications to Attachment 2 state that the voltage excursions are to be evaluated at 60 Hz. In your example, the 600 seconds at 110% voltage is on the transmission system. Generators running in AVR voltage control mode behind a step-up transformer would be at a lower voltage due to the impedance of the transformer and operation of the AVR.**
Response: Thank you for your comments. See specific responses above.		
Public Service Enterprise Group	Yes	a. Per the July 29 webinar discussion, R2.1.1 needs to be rewritten for clarity. **The SDT agrees. This section has been revised to clarify intent.** b. The "exception" process in R3 and R4 is too vague as to "who" decides whether this standard applies to a generator. If a GO describes the limitations per R3 and one of the four entities listed in R4 inquires about a specific limitation, and the GO subsequently replies to that entity, is the exception confirmed? Under what circumstances a description of limitations by a GO in R3 would be challenged? Unless the exemption to this standard is made clear, the result will be confusion when the standard is approved. **The GO has the sole discretion in determining what equipment qualifies for a limitation under Requirement R3. There is no provision for a challenge. Requirement R4 has been removed.**
Response: Thank you for your comments. See specific responses above.		
PPL Supply	Yes	1. The term “continuous capacity rating” in the second bull-dot item of R3 should be replaced with “Normal Rating or Emergency Rating,” to eliminate ambiguity via use of NERC Glossary-defined terms. **The SDT has determined that “nameplate” rating is more appropriate.** 2. The term “non-protection system” in R3 should be replaced with “non-Protection System,” to make it clear that achieving the criteria of R1 and R2 might be prevented by in some cases by OEM controls trip settings, thereby constituting a protection system function (acceptable) that does not involve the Protection System (would be unacceptable) **The SDT agrees and has revised the wording to clarify intent.** 3. Paras. R5.1 and R5.2 suffer in terms of clarity. Suggest rewording these paragraphs to make them easier

Organization	Yes or No	Question 6 Comment
		to understand. **The SDT agrees and has revised the wording.** 4. An exception should be added for nuclear facilities that may not be able to ride through the frequency and voltage excursion outline in PRC-024 with out impact to nuclear safety systems. **Any existing facility (including nuclear) is allowed an exception to portions of the curves in Attachments 1 and 2 if they document the limitation and communicate the information described in Requirement R3.**
Response: Thank you for your comments. See specific responses above.		
Florida Municipal Power Agency	Yes	The bullets in R3 are onerous. The bullets would essentially eliminate the ability to replace like-with-like which would have an impact on spare equipment strategy and stores since existing spares in the warehouse could not be used. If spares were not available that could meet the new criteria, the GO would be forced to either keep a unit off-line or be non-compliant. FMPA suggests eliminating the bullet, or at most, institute something like a Cyber Security Technical Feasibility Exception (TFE) process. **The SDT disagrees since a like-for-like replacement would not result in a nameplate capacity increase, so the GO would be allowed to maintain its exception.** In addition, in the bullets at the end of R3, is the 10% incremental or cumulative over time? E.g., if a GO does a capacity augmentation of 5% one year and then another 5% increase 3 years later, does that trigger the 10%? **The intent is a cumulative increase. The wording has been revised to reflect the intent.** R6.1.1 is ambiguous, what does "at least 20% of the Facility's rated capacity" imply? Would a single test at full output suffice, or is "book-ending" between minimum and maximum output of the generator implied? **The intent is 20% of nameplate capacity. No testing or operational data would be needed to determine the value. The wording has been revised to reflect the intent.**
Response: Thank you for your comments. See specific responses above.		
NERC Staff Technical Review Team	Yes	The applicability section should be expanded to address both applicable entities and applicable facilities similar to MOD-025-2 and should apply to individual generating units >20 MVA (gross nameplate rating) and generating plants/Facilities >75 MVA (gross aggregate nameplate rating), regardless of interconnection voltage. **Unless there are deviations from the Registry Criteria, NERC Staff has told the SDT to write the Applicability as currently drafted.** The percentage of units that must be compliant in Effective Date sections 5.1.1, 5.2.1, and 5.3.1 should be based on an MVA basis similar to other standards in Project 2007-09, such that the phrase “% of its applicable units” is replaced with “% of its applicable units on an MVA basis. **The SDT does not see an advantage to using MVA basis as opposed to number of generating units. The intent of the three-year implementation plan is to allow any protective relay settings changes to be accomplished within**

Organization	Yes or No	Question 6 Comment
		normally scheduled maintenance outages. Using number of generating units allows Generator Owners a better chance to avoid having to schedule an outage specifically to implement changes required by this standard. ”The SDT should consider the implications of Requirement R1, part 1.5, which appears to preclude unit tripping when frequency rate-of-change is less than 2.5 Hz/s, even if the frequency is above 62.2 Hz or below 57.8 Hz. **The intent is to *allow* tripping within the No Trip Zone if the rate of change of frequency *exceeds* 2.5 Hz/sec. The wording has been changed to reflect the intent.** The voltage curves in Attachment 2 should be applicable for any operating condition that falls within the voltage-time curves regardless of the initiating event that causes the voltage excursion. As such, Requirement R2, part 2.1.1 should be removed from the standard. **The SDT agrees and has removed Requirement R2, part 2.1.1. In addition, it has revised PRC-024 Attachment 2, Clarification #2 to say “The curves depicted were derived from to a three-phase transmission system zone 1 faults with Normal Clearing not to exceed 9 cycles.”** Also, we understand from the webinar that the voltage curves in Attachment 2 represent positive sequence voltage. If voltage relays that sense phase-to-ground or phase-to-phase voltage are set according to this curve, generator tripping could occur for normally cleared unbalanced faults (e.g., the unfaulted phase voltage during a single-line-to-ground may exceed 1.2 per unit on an effectively grounded system). The drafting team must develop curves that can be used directly for setting protective relays to assure that generators remain connected for both balanced and unbalanced faults.System conditions may change more quickly than a Transmission Planner can identify and convey applicable voltage relay setting requirements to a Generator Owner. **The SDT has determined that “least phase voltage” for the low voltage portion of Attachment 2, and “greatest phase voltage” for the high voltage portion of Attachment 2 are more correct than “positive sequence voltage” and the wording has been changed accordingly.** We are not aware of any reason a Transmission Planner would require less stringent criteria than Attachment 2. For these reasons, the following items should be deleted:(1) Requirement R2, part 2.1.2;(2) The phrase referring to “the voltage profile at the Point of Interconnection for the generating unit or generating plant or Facility of the most severe normally-cleared Zone 1 fault . . .” in Requirement R5, parts 5.1 and 5.2;(3) Requirement R6, part 6.3; and (4) Note 2 to the Voltage Ride-Through Curve Clarifications.Equipment limitations will not change based on modifications to changes in generating unit capacity. **The SDT allows the Transmission Planner to provide a voltage profile to a Generator Owner based on the actual clearing times at that site. This may be less stringent than the curves in PRC-024 Attachment 2, but may not be more stringent.** The second sentence in Requirement R3 should be changed from “the equipment limitation expires . . .” to “The waiver for compliance with Requirements R1 and R2 associated with the equipment limitations expires .

Organization	Yes or No	Question 6 Comment
		The SDT agrees and has changed the wording accordingly. ”The conditions in Requirement R6, parts 6.1 and 6.2 could be interpreted to indicate that this requirement only applies to generating plants/Facilities greater than 75 MVA. The standard should be revised to be clear that it also applies to generating units greater than 20 MVA. **The SDT intent is that these 6.2 only apply to facilities with generating units <20 MVA that aggregate to >75 MVA. 6.1 is written without size designations, although 6.1.1 is written similarly to 6.2 with the same intent.**
Response: Thank you for your comments. See specific responses above.		
Bonneville Power Administration	Yes	The proposed standard uses both "zone 1" and "Zone 1", which we assume mean the same thing. What is the source of the Zone 1 determination?
Response: Thank you for your comments. The SDT used studies of normally cleared three-phase Zone 1 transmission system faults as the basis for developing the curves in PRC-024 Attachment 2 since this provided the most severe voltage profile. The curves in Attachment 2 are similar to those developed in FERC’s Order 661-A and various international grid codes.		
TVA - GO	Yes	During the drafting process, quite a bit of feed back was provided to the SDT about concerns if this became a performance standard and the response was that this is only a relay setting criteria. However, plant performance aspects have been incorporated using the allowed operating bands developed as for use in relay setting coordination. The concerns with this include: o Important Existing nuclear plant settings are inside the published no-trip bands o How quickly plant secondary system motors will decelerate with voltage below ANSI MG-1 criteria. o Why is a voltage ride through criteria beyond existing second zone or breaker failure/critical clearing time design approaches needed? For frequency, the ride-thru criteria should be sufficient for UFLS to perform its function. Also, the lowest frequency allowed for unit operation must accommodate the turbine blade resonance low frequency requirement for large steam plants (57.5 to 58.5 Hz, depending on the turbine OEM). Similar steam turbine restrictions also apply for the high frequency requirement. For voltage, the ride-thru criteria should be long enough in duration for second zone or breaker failure protection critical clearing time. Voltage recovery to 0.9 PU following critical clearing time is necessary to ensure electrically powered equipment will perform correctly. Nuclear power plant interface requirements are addressed in NERC NUC-001-2. PRC-024 should refer to nuclear plant interface requirements managed under NUC-001-2.
Response: Thank you for your comments. There is a performance requirement only for facilities that are designed and built after this standard is approved and becomes effective. Existing plants, nuclear or otherwise, that can document technical limitations to operating in portions of the No Trip Zones defined in Attachments 1 and 2 are allowed by Requirement R3 to trip to protect the equipment as long as the Reliability Coordinator, Planning Coordinator, Transmission Operator, and Transmission Planner are notified so they can correctly model the generator’s performance during an		

Organization	Yes or No	Question 6 Comment
excursion. Nuclear plants must comply with many NERC Standards beyond NUC-001-2.		
Progress Energy	Yes	Forcing the utility to delay fault clearing (a three phase bolted fault at the point of interconnection causing a zero voltage) will increase the damage to the generation facility caused by the fault. Protective relay schemes have two primary objectives, to clear a fault rapidly to minimize the impact on the Bulk Electric System and to prevent (minimize) the damage to the faulted component and the components close to the faulted component. By forcing utilities to keep a generator feeding a fault of the magnitude implied by attachment 2 of PRC-024 the regulation may increase the costs of maintaining the generator. Additional inspections after a fault may be required to assure no internal damage occurred during the event that would not be required if the generator could be isolated from the fault more rapidly.
Response: Thank you for your comments. This standard does not set any requirements for the speed of fault clearing, but does allow a generator to trip if a close-in transmission fault is not cleared within nine cycles. Good utility practice has always assumed generators will feed fault current to allow protective relaying to sense faults and operate correctly. Even if the generator trips, it will have already seen fault current so any maintenance activities the owner chooses to perform as a result of the event would occur whether it trips or rides through.		
Southern Company	Yes	1) It is recommended to rephrase R4 so that the requirement (shall statement) is first and the conditions (within x of receiving a request) is second as follows: "The Generator Owner shall provide a written response within 90 calendar days of receipt of a written inquiry from the RC, PC, TOP, or TP regarding an equipment limitation identified in accordance with Requirement R3." More response time than 90 days is needed for cases were a written inquiry is given to a GO (with a very large number of units) for all units in one request. **The SDT has removed Requirement R4.** 2) We believe that the condition specified in R6.2 should be limited to PV plants and wind farms? **The SDT has been charged to write the standard in a technology-neutral manner. If R6.2 is allowed for wind farms and PV plants and not for an hydro facility with a number of small generators it would be discriminatory.** 3) Since Requirement R6 provides exceptions to the requirement (6.3 thru 6.7) these exceptions need to be mentioned in Measure M6. (add "unless one of the exceptions 6.3-6.7 apply" to the end of the sentence.) **The Measure refers to the Requirement, which includes all sub parts.** 4) Employing new grid frequency and voltage ride-through requirements may impact the licensing and design basis of nuclear facilities. NUC-001-1 requires coordination between Nuclear Plant Generator Operators and Transmission Entities for the purpose of ensuring nuclear plant safe operation and shutdown. This is achieved through development of Nuclear Plant Interface Requirements (NPLRs) for each nuclear unit that are based on plant-specific Nuclear Plant Licensing Requirements and Bulk Electric System requirements that have been mutually agreed to by the Nuclear Plant Generator Operator and the applicable

Organization	Yes or No	Question 6 Comment
		Transmission Entities. The NPLRs are requirements included in the design basis of the nuclear plant and statutorily mandated for the operation of the plant, including nuclear power plant licensing requirements for 1) Off-site power supply to enable safe shutdown of the plant during an electric system or plant event; and 2) Avoiding preventable challenges to nuclear safety as a result of an electric system disturbance or transient condition is important. It is essential that this process be followed closely in attempting to apply new grid frequency and voltage requirements that are more extreme than those currently addressed in each plant's licensing and design basis. It is fundamental that the safety of nuclear power plants take precedence. **While the Transmission Owner can address preventable challenges, equipment failures and weather-induced transients can still occur. Grid stability would be compromised if one type of generating facility is allowed to trip for any excursion in voltage or frequency.** 5) R3 states "each" non-protection system equipment limitation where R1 and R2 say "a". Is there a reason for this difference? The feasibility of fully analyzing an existing plant to determine this is extremely questionable. There is no doubt that the cost would be horrendous. **The SDT has revised Requirements R1 and R2 to use the word "each". The SDT disagrees that the analysis is onerous. Requirements R1 and R2 apply only to the generator protection system. If the settings for this system are such that the generator would be tripped for conditions inside the No Trip Zone of Attachments 1 and 2, then the Generator Owner can either modify the settings or document the limitation that prevents modifying the settings (e.g. LP blade resonance during low frequency operation).** 6) We suggest modifying Footnote 2 - add "being built to a completed certified standard design" to this list. If the industry is going to move forward in utilizing standard plant designs to reduce cost and expedite getting plants built, the certified design must be acknowledged. If the equipment to meet this standard can be obtained, which is doubtful, the only way to reasonably attempt to have a design that meets it is to start with these requirements as design criteria at the very beginning. To place requirements such as this on completed standard designs would destroy the use of that concept. **Footnote 2 already includes generators "under construction". This would include those "being built to a completed certified standard design". The SDT has extended the Effective Date of Requirement R5 (the performance requirement for new facilities) from three years to six years past the date of approval in order to accommodate the need to develop new designs.** 7) The approval of this standard as written will have extreme effects on the construction and operation of generating units which could also affect safety and availability. It would greatly increase the cost and schedule for building generation units and impose a huge cost on existing ones. We believe those developing this reliability standard should be sensitive to such concerns and give them consideration. Has this been done? Is it fully documented and available for review by the industry impacted by the proposal? **Wind facilities are already required to perform to similar criteria through FERC Order 661A. European utilities also have ride through requirements in place. The SDT realizes that this will impact the design of future generating facilities and increase their cost. The SDT is also charged with complying**

Organization	Yes or No	Question 6 Comment
		with FERC Order 693 and the recommendations in the 2003 Black Out Report.
Response: Thank you for your comments. See specific responses above.		
PacifiCorp	Yes	In addition to the feedback noted above, the NO votes submitted by PacifiCorp are accompanied with the following comments: (1) Industry practice for generation protective relays is to use the terminal voltage of the generators, not the system voltage or point of interconnection. Generator Owners could provide generation responses and data as contemplated by the standard, but they should not be held responsible for the answers provided without the benefit of associated transmission planning groups. Generator Owners, under this framework, will rely completely on feedback from their associated transmission planning groups in order to provide responses. It concerns PacifiCorp that the draft standard does not address the need for transmission planners to provide the required transmission system response data to Generation Owners in order to make these assessments, or allow for the joint responsibility of transmission planner for the accuracy of the data as it concerns planning studies. (2) PacifiCorp maintains several additional concerns about complying with the standard as drafted: o R1.1.5 - PacifiCorp is not aware of relays used for generator protection that use frequency rate of change to calculate trip points. Generator protection relays use frequency set points and time at certain values, not rate of change of frequency to make tripping decisions. It may not be technically feasible to immediately comply with this sub-requirement of the standard as written. **R1.5 *allows* a generator to trip within the No Trip Zone of Attachment 1 if the rate of change of frequency *exceeds* 2.5 Hz/sec. There are several standard generator protection relays (e.g. GE's G-60, Schweitzer's 700G, and Beckwith's M-3425A) in addition to relays that are designed specifically for Aurora Scenario protection that incorporate a frequency rate of change function.** o R2.1.1 - PacifiCorp requests clarification concerning what the SDT has considered a zone 1 fault. PacifiCorp acknowledges that transmission and distribution line relays have zone 1 and zone 2, but the Company does not believe that this is something typically used in the generator protection context. A zone 1 fault needs to be defined somewhere to the extent that it is not clarified in the standard already. **The standard refers to transmission system Zone 1 faults.** o R3 - This requirement was clear in the initial February 2009 draft of PRC-024-1, but the current draft does not clarify that the Generator Owner must upgrade the equipment that is causing a limitation. For example, if an entity upgrades its (synchronous) turbines to increase capacity by greater than 10%, but the voltage limitations still exist because they are related to the generator, which is not upgraded, the exemption would expire under the current language. The SDT should revisit this issue using the initial draft of PRC-024-1 as a guide. **The SDT has revised Requirement R3 to clarify that the limitation must be eliminated if the equipment causing the limitation is modified or upgraded resulting in an increase in nameplate**

Organization	Yes or No	Question 6 Comment
		capacity greater than 10%. o R6 - The failure to include exemptions for new generating plants may have unintended consequences. Some voltage excursions have caused excessive torque on PacifiCorp-owned generators which has caused the controls to trip the units, rather than the relays themselves. If an entity constructs a new plant and cannot document any exemptions due to equipment limitations, such entity may experience future compliance and operational issues. The SDT should revisit this in light of further consideration of potential unintended consequences. **Requirement R6 contained an exception for impending or actual loss of synchronism. The SDT has revised the wording to include any condition that will damage the equipment, such as the torque swings cited.** (3) PacifiCorp has concerns that certain references to Attachment 2 in Requirement R2 need to be clarified. Attachment 2 references the generator point of interconnection not the terminal voltage; therefore, clarifications to the proposed language are necessary. As such, the following recommended revisions to Requirement R2 are offered:2.1 When operating under normal system operating conditons within 95% and 105% of rated generator terminal voltage and during the transmission system conditions define in PRC-024 Attachment 2, with the following clarifications for PRC-024 Attachment 2 are provided:2.1.1 For three-phase transmission system zone 1 faults with Normal Clearing, set voltage relays transmission system faults should be cleared based on actual fault clearing times, not to exceed 9 cycles. Voltage relays should be set to not trip prior to transmission system fault clearing time.2.1.2 If a Transmission Planner's study (based on the location specific voltage recovery characteristics) recommends less stringent voltage relay settings system protection settings than those on PRC-024 Attachment 2, set voltage relays either to the less stringent Transmission Planner's settings or the setting applicable to in PRC-024 Attachment 2.2.1.3 Tripping a generator via If a Special Protection System (SPS) or Remedial Action Scheme (RAS) includes tripping a generator after fault initiation, then setting the SPS or RAS relay to trip the generator even if in the is acceptable in the "no trip zone" in PRC-024 Attachment 2 is acceptable.2.1.4 If clearing a system fault necessitates disconnecting a generator, this action is acceptable than setting relays to trip the generator even if operating within the "no trip zone" specified in PRC-024 Attachment 2 is acceptable. **The wording in Requirement R2 has been revised to clarify intent.** (4) As drafted, Requirement R1 of proposed PRC-024-1 conflicts with WECC's Off-Nominal Frequency Load Shedding Plan ("WECC Coordinated Plan"), and could potentially result in negative reliability impacts if enforced in the Western Interconnection. A WECC Regional Variance that includes the WECC Generator underfrequency and overfrequency operation requirements, as identified in the WECC Off-Nominal Load Shedding Plan, must be added to the proposed standard. WECC has developed, implemented, and verified the effectiveness of the WECC Coordinated Plan and any deviations from the requirements of the plan may negatively impact its effectiveness. **The SDT has added a WECC-specific curve to Attachment 1 to address WECC's UFLS program.**

Organization	Yes or No	Question 6 Comment
		(5) PacifiCorp believes that the SDT should rewrite Requirement R4 to add specificity as to what must be included in a written response to a submission concerning an equipment limitation, similar to the specificity and clarity included in MOD-026, Requirement R3. **Requirement R4 has been removed.** (6) PacifiCorp offers one comment on the Violation Severity Limits ("VSLs") proposed for Requirements R1 and R2 of PRC-024-1, which require that frequency protective relaying (R1) and voltage protective relaying (R2) be set so that they do not trip within the criteria listed in the respective requirements "unless the Generator Owner has documented and communicated a non-protection system limitation in accordance with Requirement R3." However, the language of the binary Severe VSL for Requirements R1 and R2 only identifies the failure to set protective relaying, without recognizing the exception granted for documenting and communicating a non-protective system limitation. As written, the applicable entity could be compliant with the language of Requirements R1 and R2, but based on the language of the VSLs, they would be non-compliant. The SDT should add this critical clarification to the VSLs. **The SDT agrees and has revised the VSL's for Requirements R1 and R2 accordingly.** (7) PacifiCorp has a concern that the PRC-024 voltage ride-through requirements identified in Attachment 2 are wholly independent of dynamic reactive power requirements for generators. As an analogy, some European generator interconnection standards and requirements link these two variable. PacifiCorp understands that PRC-024-1 is a generator protection standard; however, the SDT should address the manner in which generator dynamic reactive requirements impact PRC-024-1 Attachment 2. **The SDT believes specifying dynamic reactive power requirements is beyond the scope of the SAR for this project.** (8) Many European generator interconnection standards and requirements include different voltage ride-through requirements for synchronous and non-synchronous generation. PacifiCorp is concerned that the SDT has inappropriately developed a "one-size fits all" standard applicable to all generation platforms. PacifiCorp recommends that, based on the significant differences between existing and emerging generation platforms, separate voltage ride-through standards be developed for synchronous and non-synchronous (i.e., wind and solar) generation platforms. Different sets of standards will more effectively address such differences in the various generation technologies. **The SDT has been charged to make this standard technology neutral. If PacifiCorp feels there are significant differences in how different technologies can perform, please provide detailed information to the SDT.**
Response: Thank you for your comments. See specific responses above.		
Tri-State Generation and Transmission, Inc.	Yes	The proposed WECC-0065 does not comply with the generator overfrequency curve.

Organization	Yes or No	Question 6 Comment
Response: Thank you for your comments. The SDT has added a WECC-specific curve to Attachment 1 to address WECC's UFLS program.		
Manitoba Hydro	Yes	Please provide justification for the curves provided in Attachments 1 and 2.
Response: Thank you for your comments.		
Exelon	Yes	Applicability section and Requirements R.1 and R.2Most nuclear power plants will not meet the requirements for frequency due to NRC required protection for Reactor Coolant Pumps and Reactor Protection System Motor Generator sets. In addition, most nuclear power plants will not meet the voltage requirements due to NRC required degraded voltage protection. Although a provision for exemption is permitted in R.3, Exelon requests that the SDT communicate with the NRC and with the FERC to ensure a conflict of dual regulation is not imposed on a nuclear generating unit without the necessary evaluation. **The SDT believes that the existence of Requirement R3 removes any conflicting dual regulation with regard to nuclear plants.** Requirement R.3 second bulletThe equipment limitation expiration should not be dependent on a capacity increase of the generating unit. An equipment limitation may be the result of NRC regulations and not the generating unit capacity. **The SDT agrees that NRC nuclear safety requirements form a valid technical limitation. Requirement R3 has been revised so that the allowance for an equipment limitation expires only if the equipment causing the limitation is being replaced or upgraded such that there is a 10% increase in generator nameplate capacity.**
Response: Thank you for your comments. See specific responses above.		
Independent Electricity System Operator	Yes	1. R3: Please clarify the meaning of the expression "non-protection system equipment". Does it mean "a limitation imposed by equipment other than the protection system"? **SDT: Yes.** Or does it refer to generating units that are NOT equipped with frequency/voltage protective relays? **SDT: No.** In the latter case, how would the GO determine that the units that are not so equipped are unable to meet the criteria in Requirement R1 or R2? In our view, units that are unable to meet these criteria are those that are equipped with frequency/voltage protective relays and whose trip settings do not meet the criteria specified in R1 and R2 for specific technical reasons that are communicated to the Transmission Planners. For units that are NOT equipped with such protective relays, the suggestion that any of them may be unable to meet the criteria in R1 and R2 could be those which in the past have tripped before the thresholds. However, unless a unit repeatedly trips under like circumstances, isolated incidences do not provide sufficient evidence to arrive at a conclusive determination. And for those units that are NOT equipped with the protective relays and have never tripped before the thresholds, there is no telling whether or not they can meet the criteria. For the above reasons, we suggest the SDT to revise the R3 to convey the requirement that the GOs shall provide the technical reasons for not meeting the R1 and R2 criteria only for those units that ARE equipped with the

Organization	Yes or No	Question 6 Comment
		protective relays and ARE set at different thresholds. **If a unit does not have voltage or frequency protective relays, then by default it will not be tripped by such relays during an excursion and the GO is in compliance.** 2. As indicated in our comments under Q3, we think R4 is a sub-requirement or part of R3 since R4 mandates the GO to respond to the listed entities within 30 days of receiving a request, and that in the requirement there is no mention of "what" the response should entail. The "what is stipulated in R3. **The SDT agrees and has removed Requirement R4.** 3. R7: We assess that this requirement duplicates with what we interpret as the intent of a good part of R3, i.e., to provide the listed entities with the settings of the frequency/voltage protective relays. Regardless of whether or not a GO is able to meet R1 and R2, it should be obligated to provide the generator protection trip settings to these other entities for modeling purpose (consistent with our comments under Q3). If a GO sets the protective relays at values that do not meet the R1 and R2 criteria, then it should be obligated to provide the technical limitations that form the basis of the deviation. This requirement thus should come after R1 and R2, and replaces the as written R3 for reasons that we mention in our comments in (1), above. **The SDT agrees that there was potential confusion and has revised the wording in Requirement R7 to address your concern.**
Response: Thank you for your comments. See specific responses above.		
Wisconsin Electric	Yes	1. The Applicability of this standard should be specifically stated to be limited to generators connected at 100kv or above, as in the Registry Criteria. **The Applicability is to Generator Owners. By default, the applicable equipment defers to the Registry Criteria which includes only equipment connected at 100 kV or above plus black start facilities regardless of connection voltage.** 2. The Effective Dates should be increased by one year. 5.1 should be two years, 5.2 should be three years, and 5.3 should be four years. This change would more appropriate for the significant analysis needed to meet these requirements. **The SDT has increased the Effective Date for Requirement 5 (the performance requirement) from three years to six years past the date of approval. The SDT feels the effective date for the remaining Requirements can remain the same.** 3. Requirement R1.5 should be deleted. The rate of change of frequency is not a parameter that is widely available in generator protection schemes on existing units. Requirements 1.1 through 1.4 are sufficient to prevent undesirable operation. **R1.5 allows tripping if the frequency rate of change exceeds 2.5 Hz/sec. It does not require installation of equipment that has this capability. Allowing tripping for this rate of change within the No Trip Zone is not allowed in Requirement 1, parts 1.1 through 1.4.** 4. Requirement R2.1.1 needs more clarity. Generator voltage relaying is not generally set to trip for system

Organization	Yes or No	Question 6 Comment
		faults. Also, R2.1.2 is unclear as to what "less stringent" means; the reference to the Transmission Planner "settings" should perhaps be changed to "requirements". **Requirement R2 has be revised to clarify intent.** 5. In R3 and in R7, the allowable times should be 90 days rather than 30 days. This is due to the effort required to perform an adequate investigation. The "Lower" Violation Risk Factors for these two requirements would seem to be consistent with this. In R7, change "written request" to "request". **The SDT does not feel that 30 days is unreasonable to provide documentation of a limitation (R3) or to provide trip settings information (R7). The SDT is leaving the word "written" to differentiate between a verbal request that is not normally recorded.** 6. In R2 (second sentence), replace "shall set its protective relaying not to trip ... " with, "shall set its protective relaying to avoid tripping ..." **The SDT believes there is not a substantial difference between the existing and proposed wording and has not made a change.**
Response: Thank you for your comments. See specific responses above.

		and proposed wording and has not made a change.
Response: Thank you for your comments. See specific responses above.		
Great River Energy	Yes	It is not clear that this standard is needed. While attempting to eliminate unit tripping from frequency and voltage excursions is a laudable goal, it may not be practical to eliminate all unit tripping for these reasons. Furthermore, it creates the situation where literally every unit trip could become subject to a compliance violation investigation. Before this standard is finalized, NERC needs to assess how it is going to manage compliance enforcement with it.The posting of the ballot is confusing. The red-line documents are, in fact, clean (i.e. there are no red-lines) documents that do not line up with the “clean” documents. Thus, it is not clear what is being voted on. For example, the “clean” document shows that there are five parts with Requirement R1. The “redline to last posted” document has four subrequirements under the main requirement R1. **The SDT apologizes that a true redline document was not posted. The document being balloted was the second draft of version 1 of the standard.** The basis for the values established in parts 1.1 through 1.5 does not appear to be well documented. We understand from reviewing the documentation that the SDT appears to have reviewed a number of actual events. Documentation of this review would allow us to better understand the drivers for these values. **Requirement R1, Parts 1.1 through 1.5 have been removed. The information from Part 1.5 has been incorporated into the body of Requirement R1. The curves in Attachment 1 were developed in coordination with the UFLS SDT. These curves match the Generator Tripping expectation in PRC-006-2 Attachment 1.** The values in parts 1.1 through parts 1.5 do not appear to be well coordinated with UFLS. For instance, UFLS will actuate at 59.3 Hz per the UFLS standard while many generators could trip at 59.4 Hz that could cause a cascade of units tripping from degrading frequency. Hopefully, the UFLS actuation would prevent a downward spiral of frequency but that coordination is not clear at this point. **Requirement R1, Parts 1.1 through 1.5 have been removed. The information from Part 1.5 has been incorporated into the body of Requirement R1. The curves in Attachment 1 were developed in coordination with the UFLS SDT. These curves match the Generator Tripping expectation in PRC-006-2 Attachment 1.** Requirement R7 is partially redundant with Requirement R3. R3 already requires documentation and communication of equipment limitations. Thus, R7 creates the potential of double jeopardy. **The SDT agrees that there was potential confusion and has revised the wording in Requirement R7 to address your concern.**
Response: Thank you for your comments. See specific responses above.		

Organization	Yes or No	Question 6 Comment
Duke Energy	Yes	During the drafting process, quite a bit of feedback was provided to the SDT about concerns if this became a performance standard and the response was that this is only a relay setting criteria. However, plant performance aspects have been incorporated, using the allowed operating bands developed as a setting coordination. The concerns include: o Existing nuclear plant settings are inside the published no-trip bands o How quickly plant secondary system motors will decelerate with voltage below ANSI MG-1 criteria. o Why is a voltage ride-thru criteria beyond existing second zone or breaker failure/critical clearing time design approaches needed?For frequency, the ride-thru criteria should be long enough in duration for UFLS to perform its function. Also, the lowest frequency allowed for unit operation must accommodate the turbine blade resonance low frequency requirement for large steam plants (57.5 to 58.5 Hz, depending on the turbine OEM). Similar restrictions may also apply for the high frequency requirement.For voltage, the ride-thru criteria should be long enough in duration for second zone or breaker failure protection critical clearing time. Voltage recovery to 0.9 PU following critical clearing time is necessary to ensure electrically powered equipment will perform correctly.Nuclear power plant interface requirements are addressed in NERC Reliability Standard NUC-001-2. PRC-024-1 should allow nuclear power plant interface requirements to be managed under NUC-001-2.(See PowerPoint and AREVA white paper provided to the SDT).
Response: Thank you for your comments. There is a performance requirement only for facilities that are designed and built after this standard is approved and becomes effective. Existing plants, nuclear or otherwise, that can document technical limitations to operating in portions of the No Trip Zones defined in Attachments 1 and 2 are allowed by Requirement R3 to trip to protect the equipment as long as the Reliability Coordinator, Planning Coordinator, Transmission Operator, and Transmission Planner are notified so they can correctly model the generator's performance during an excursion. Nuclear plants must comply with many NERC Standards beyond NUC-001-2.		
US Army Corps of Engineers	Yes	-R2.1.1 - 'not to exceed 9 cycles' this wording is confusing and needs to be clarified.-Suggest that Requirement R4 be rewritten to add specificity as to what must be included in the required written response, similar to the specificity and clarity includ
Response: Thank you for your comments. This part has been revised to clarify intent.		
ISO New England Inc.	Yes	Comments are provided by ISO-NE on the following requirements: R2.1. This requirement specifies when operating (within the band specified) of rated terminal voltage (VT) and during the transmission system operating conditions defined in PRC-024 Attachment 2 .... ISO-NE maintains that the band applies to the voltage as shown in Attachment 2 on the Y axis as the "Point of Interconnection-Voltage (PU). R2.1 should refer to the voltage at the point of interconnection and not the generator terminal voltage. The band shown as .95 p.u to 1.05 p.u. should be widened to at least .90 p.u. to 1.05 p.u. as suggested in our comments on Question 1 above R2.1.1 infers that the standard is to base the voltage relay settings on actual fault clearing times. The

Organization	Yes or No	Question 6 Comment
		standard should be 9 cycles. As the system changes, clearing times may change and then problems with an existing generator who has set its relays to the actual clearing times may be an issue. Changing this requirement would also require a change in the curve shown in Attachment 2. If this comment is ignored, as an alternative ISO-NE suggests that R2.1.1 be modified to state, "For three-phase transmission system zone 1 faults with Normal Clearing, set voltage relays based on actual fault clearing times, plus margin, not to exceed 9 cycles." This is suggested to direct the setting of relays in a manner that will prevent a relay race that could trip the generator sooner than the actual fault clearing time. **The SDT does not believe there is a significant reliability gain to making all generators set relaying to account for 9-cycle clearing. If the voltage profile remains within the No Trip Zone, then the Generator Owner would be out of compliance if a generator trips due to operation of a voltage relay. The SDT expects that the GO will recognize this and provide some margin in the settings.** R2.1.3 appears to provide a way to get around the intent of the standard. If a generator cannot meet the requirements of the standard, they could put in an SPS to trip the generator and avoid meeting the intent of the standard. This has the potential to lead to a proliferation of SPSs. **In many cases an SPS will trip a generator for loss of certain transmission elements in order to prevent overloading the remaining elements. Overriding the operation of an SPS by not allowing it to trip generation could lead to grid instability and cascading outages. NERC Standard PRC-015 requires an SPS to meet NERC and RRO criteria, so GO's do not have carte blanche to install an SPS to avoid compliance with the PRC-024 requirements.** Notwithstanding the concern over R 2.1.3, R2.1.3 and R2.1.4 should be rewritten as follows: 2.1.3. If a Special Protection System (SPS) or Remedial Action Scheme (RAS) includes tripping a generator after fault initiation, then setting the SPS or RAS relays to trip the generator even if [voltage is] in the "no trip zone" in PRC-024 Attachment 2 is acceptable [provided that the voltages will not enter the trip zone for criteria faults that do not initiate the SPS or RAS].2.1.4. If clearing a system fault necessitates disconnecting a generator, then setting relays to trip the generator even if operating [voltage is]within the "no trip zone" specified in PRC-024 Attachment 2 is acceptable. **The SDT believes the suggested additional wording is not necessary.** R3 is a significant concern. In the event that a generator has a piece of equipment which prevents it from meeting the requirements of R1 and R2, such as a motor contactor which drops out on voltages in the "No Trip Zone", there is no requirement to correct the issue. Instead, the generator must only document the limitation. This completely undermines the intent of this standard. There is no point to setting undervoltage relays to meet the curve if other equipment is still going to trip the plant. **The SDT recognizes that contactor performance can be a factor in the ability of a generating facility to ride through a voltage excursion. We believe that requiring existing facilities to rebuild their entire auxiliary system to ride through events as severe as described by Attachment 2 (which are not common occurrences) would**

Organization	Yes or No	Question 6 Comment
		divert resources that could be better used elsewhere in improving grid reliability. Over time, as existing facilities are retired, the new facilities that are built will have to be designed to meet the performance requirement of this standard. R5 appears similar to R3 in that the generator is only required to document if it trips in the "No Trip Zone", rather than correct the issue. **This Requirement is intended to improve the modeling of generator performance by giving the Reliability Coordinator, Planning Coordinator, Transmission Operator, and Transmission Planner an estimate of how long a facility will remain connected following a voltage or frequency excursion defined by one of those four entities.** Exceptions in 6.1.1 and 6.2 should not be allowed. Each generating unit that is registered based on the NERC Registry Criteria as a single unit, or as part of a generating facility, should comply with PRC-024-2 without exception. In general, R6 and sub-requirements R6.1 through R6.7 introduce a number of conditions and exceptions for new units that are unnecessary and cumbersome to monitor. Some of them represent common sense conditions, such that if they were to occur, an auditor would be able to deem the entity to be in compliance since it is not posiible to comply with the letter of the requirement. However, there are many more cases that could be listed and you will never capture all possibilities here. Overall R6.1 through R6.7 should be deleted. As the system changes, the requirements will change. The machine should be properly designed upon installation to allow the necessary flexibility in the development of the transmission system over time. **The SDT realizes that these conditions and exceptions may not be all inclusive, but believes they cover the majority of real-world cases that would justify tripping. If the conditions and exceptions were eliminated, auditors would not have guidance to realize the intent that there are some justifiable reasons for tripping.**
Response: Thank you for your comments. See specific responses above.		
Luminant Energy	Yes	Luminant still believes that the standard should be directed to generator protective relaying only.
Response: Thank you for your comments. In order to comply with FERC Directives, a performance requirement was added to Draft 2.		
Ameren	Yes	1)Comments: Requirement R1.5 is unclear. Are the relays not allowed to trip regardless of frequency if the rate of change is less than 2.5 Hz/sec. If so, the existing generator relays don't have the capability to block for this condition. It would seem undesirable to block for this condition and risk damage to generation. **R1.5 *allows* a generator to trip within the No Trip Zone of Attachment 1 if the rate of change of frequency *exceeds* 2.5 Hz/sec.** 2)R2.1.3 needs to be more specific. With multiple outlet lines, generators may only be tripped for certain lines or breaker failure conditions. Generators would only be allowed to trip in the "no trip zone" for the specific

Organization	Yes or No	Question 6 Comment
		conditions of the SPS or RAS schemes? **The SDT believes the wording is clear as written. If an SPS or RAS detects a condition that requires tripping a generator, then that tripping is allowed.** 3)R6.2 why are smaller generators allowed to trip 10% of their units? Is this fair to large generators? **The SDT feels that allowing 10% of small generators to trip is fair because it is similar to a large unit experiencing a run back following an event. Runbacks do not result in a compliance violation.** 4)Do all the requirements of PRC-024-1 apply to all the auxiliary systems, or just the generating unit protection systems? This needs to be made clear for compliance. If applying to all auxiliary systems, guidance will need to be provided on how to meet these standards. **Requirements R1 and R2 apply only to the generator protection system as stated in the Footnote 1. Requirement 6 applies to the performance of the entire facility, not just the generator protection system.** 5)For R2 and R6, if clearing a transmission line outlet end of line fault with zone-2 timing exceeds the requirements of Attachment #2, which should be designed for. Does transmission line relays need to be designed to provide performance of Attachment #2 for newly installed facilities? **This standard does not set requirements for the protection of the transmission system. If the voltage profile at a specific generating site exceeds the requirements of Attachment #2, then the generator(s) at that site would not be out of compliance if they tripped.**
Response: Thank you for your comments. See specific responses above.		
American Electric Power	Yes	The second point under R3 causes the limitation to expire with rating increases. Is a 10 percent or more rating increase a realistic scenario and common enough to justify attention? 10 percent seems arbitrary and this provision could pose a hindrance to rating increases that may supply other reliability benefits. It may be advisable to remove this point. **The SDT has revised Requirement R3 to clarify that the limitation must be eliminated if the equipment causing the limitation is modified or upgraded resulting in an increase in nameplate capacity greater than 10%.** We believe that R2.1.4 must not allow relay settings to trip a generator within the no-trip zone for other system events that would not disconnect the generator. **The SDT agrees and has added wording to clarify that this tripping is only acceptable if the generator must be tripped in order to clear the fault.** The phrase "generating plant or Facility" is used in R2, R3, R5 and R6, but not R1. **The SDT agrees and has changed the wording in Requirement R1 accordingly.**
Response: Thank you for your comments. See specific responses above.		
Texas Reliability Entity	Yes	In the ERCOT Interconnection (ERCOT) there are well-established generator under-frequency relay settings

Organization	Yes or No	Question 6 Comment
		(ERCOT Nodal Operating Guides 2.6.2) that are more stringent than those proposed in this standard. ERCOT also has existing low/high-voltage ride-through requirements (ERCOT Nodal Operating Guides 2.9(2)) that are less stringent than those proposed in the standard. We would prefer to include the existing ERCOT parameters in this standard to apply within the ERCOT Region, rather than having different ERCOT and NERC requirements. We suggest that the drafting team consider adding ERCOT-specific parameters in Attachments 1 and 2, matching the existing ERCOT Nodal Operating Guide requirements, in addition to the stated parameters for the other interconnections.
Response: Thank you for your comments. The SDT has added ERCOT-specific curves to Attachment 1.		
RFC	Yes	For R3, add the word “generating” in front of the word “Facility” to be consistent with other requirements. **The SDT agrees and has changed the wording accordingly.** The followoing are reccomendations related to the Violation Severity Levels:1. VSL for R1 - a. The VSL should start off with the following language to be consistent with the language within the requirement: “The Generator Owner that has frequency protective relaying activated to trip its new or existing generating unit failed to...” **The SDT agrees and has changed the wording accordingly.** b. Since there are a number of Parts associated with R1, the SDT may want to consider gradating the VSL rather than making it Binary. **The sub parts of R1 have been removed. The VSL will remain binary.** 2. VSLs for R2 - a. The VSL should start off with the following language to be consistent with the language within the requirement: “Generator Owner that has voltage protective relaying activated to trip its new or existing unit or generating plant or Facility failed to...”b. There is no reference to any of the Part numbers for R2. Suggest adding references to the Parts to the VSL or since there are a number of Parts associated with R2, the SDT may want to consider gradating the VSL rather than making it Binary. **The sub parts of Requirement R2 are conditions that allow tripping within the No Trip Zone. They do not create violation conditions. The VSL will remain binary.** 3. VSLs for R3a. Suggest not using the language “...prevents compliance with Requirement R1 or R2...” since it is not consistent with the language of the requirement. Suggest stating: “... prevents the Generator Owner from meeting the criteria in Requirement R1 or R2...” **The SDT agrees and has changed the wording accordingly.** 4. VSLs for R5a. Fix the typo in the “Severe” VSL. Change “R55” to “R5”5. **The SDT agrees and has changed the wording accordingly.** VSLs for R6a. The first VSL under the “Severe” suggest referencing “Attachment 1” rather than “Requirement 6.” This will make it consistent with the other “Severe” VSL. **The SDT agrees and has changed the**

Organization	Yes or No	Question 6 Comment
		wording accordingly. b. Suggest adding another VSL which references the GO not following the conditions and exceptions in Parts 6.1 through 6.7. As written, there is currently no reference to the Parts. **The sub parts of Requirement R6 are conditions that allow tripping within the No Trip Zone. They do not create violation conditions. The VSL will remain binary.**
Response: Thank you for your comments. See specific responses above.		
Consolidated Edison Co. of NY, Inc.	Yes	Requirement R3. - Delete the word “expires” and replace it with the words “documentation should be renewed” **The SDT has changed the wording to clarify intent.** The underlying technical justification for this standard should be supported by a white paper similar to the document available at this link (AREVA PRC-24 White Paper Clean.doc): http://xa.yimg.com/kq/groups/28536519/188315025/name/AREVA%20PRC-24%20White%20Paper%20Clean.doc **The SAR that justified drafting of this revision to PRC-024 was approved by industry in 2007.** Requirement R3, bullet 1 allows for an exemption for existing plants subject to equipment failures until “the limitation [limiting equipment] is repaired or replaced.” Similar temporary exemption language should be incorporated in R6 for new units that experience equipment failure-related limitations. **The exemption in Requirement R3 is intended for permanent conditions due to the design of existing equipment (e.g. steam turbine LP blade fatigue life at reduced operating frequencies). If a new plant experiences an equipment failure that would prevent it from riding through an excursion, the GO can request a waiver from the Reliability Coordinator, since the RC may need the generation for reliability reasons and elect to allow a unit to operate with its greater risk of tripping during an excursion** The drafting team may also wish to address a requirement for repair or replacement timeliness in both R3 and R6. **. The SDT believes that changes made for Requirement R3 will be part of a planned uprate project and the RC’s ability to deny or rescind a waiver for Requirement R6 is incentive for the GO to make repairs expeditiously.**
Response: Thank you for your comments. See specific responses above.		
GE Energy	Yes	Clause 6.1.1 allows an exception from meeting the ride through requirements for voltage support equipment that is not in service. Often such equipment is installed solely for the purpose of acheiving ride through. It is not clear that there are any NERC standards requiring that this equipment be maintained to have a minimum

Organization	Yes or No	Question 6 Comment
		level of availability. As worded, this clause could create a means by which a GO could indefinitely avoid requirements, and subsequent penalties for non-compliance.
Response: Thank you for your comments. The SDT agrees and has removed the wording regarding voltage support equipment.		
PPL Electric Utilities	Yes	1. The term "continuous capacity rating" in the second bull-dot item of R3 should be replaced with "Normal Rating or Emergency Rating," to eliminate ambiguity via use of NERC Glossary-defined terms. **The SDT has changed the wording to "nameplate rating".** 2. The term "non-protection system" in R3 should be replaced with "non-Protection System," to make it clear that achieving the criteria of R1 and R2 might be prevented by in some cases by OEM controls trip settings, thereby constituting a protection system function (acceptable) that does not involve the Protection System (would be unacceptable). **The SDT agrees the wording was less than optimal and has revised Requirement R3 to state, in part, "Each Generator Owner of an existing generating unit or generating plant or Facility shall document each equipment limitation (excluding generator frequency and voltage protective relay limitations)…"** 3. Paras. R5.1 and R5.2 suffer in terms of clarity from consisting of a single sentence that is over 80 words long, with not a single comma or semicolon to guide the reader. NERC standards should make use of normal technical-writing style and punctuation **The SDT agrees. Requirement R5, section 5.2 has been removed. Section 5.1 now states "An estimate of the time duration the existing unit or generating plant or generating Facility will remain connected (considering performance of the auxiliary systems as well as the generator) as a result of a frequency excursion and/or a voltage excursion defined by the voltage and/or frequency profile at the point of interconnection described by dynamic simulation provided by the Transmission Planner. If the Generator Owner expects the existing unit, generating plant or generating Facility will remain connected for longer than 10 minutes, then the estimate should indicate that the existing unit, generating plant or generating Facility is not expected to trip."**
Response: Thank you for your comments. See specific responses above.		
American Transmission Company	Yes	Please give consideration to the following suggestions:1. In Requirements, R1, R2, & R3 - include a footnote for the references to "non-protection system equipment" that defines or gives a few examples of this equipment to add clarity. **The SDT believes the primary limitation will be steam turbine LP blade fatigue loss of life when operating at reduced frequencies. Generator Owners are well aware of this limitation.** 2. In Requirements, R3 - add the requirement that the GO provides the expected duration of the limitation, if it is known. **The SDT believes these would normally be permanent limitations. If the Reliability**

Organization	Yes or No	Question 6 Comment
		Coordinator, Planning Coordinator, Transmission Operator or Transmission Planner had reason to believe a limitation was not permanent, it could make an inquiry of the Generator Owner. 3. In Requirements, R5.2 - include a footnote or example of "25% estimated probability increments" to add clarity. **The SDT has removed the Requirement R5, section 5.2 (the requirement to provide 25% probability estimates).** 4. In References - include references that provide more technical justification and background for the voltage and frequency limits given in Attachment 1 and Attachment 2 **The WECC white paper cited in References provides justification for the curves in Attachment 2. The curves in Attachment 1 are identical to PRC-006 Attachment 1 Generator Tripping expectation curves and are set to provide a margin beyond the UFLS performance expectations.** .5. In Attachment 1 - add a "Return to between 59.5 Hz and 60.5 Hz frequency" text box to be consistent with the labeling in Attachment 2. **The SDT disagrees that this is necessary because with the addition of WECC-specific and Quebec-specific curves, adding another text box would add to information overload.** 6. In Attachment 1 - add the title "Curve Data Points" to the Frequency/Time table to be consistent with Attachment 2. **The SDT agrees and has changed the wording accordingly.** 7. In Attachment 2 - modify HVRT and LVRT tables (perhaps combine them into one more compact table) to be consistent with the table in Attachment 1 and fit on the same page. **The SDT agrees and has reformatted the tables for both Attachment 1 and Attachment 2.** 8. In Attachment 2, 5a - expand to "Power factor is 0.95 lagging (i.e. supplying reactive power to the system as measured at the generator terminal)" to be more definitive. **The SDT agrees and has changed the clarification to state: "Power factor is 0.95 lagging (i.e. supplying reactive power to the system) as measured at the generator terminals)".**
Response: Thank you for your comments. See specific responses above.		
Hydro-Quebec TransEnergie	Yes	The graph of voltage from the interconnexion of Quebec was reflected from the FERC order 661-A which is different from the graph from this standard. Please justify the source of the present standard.
Response: Thank you for your comments. The voltage profile in Attachment 2 was developed using the voltage profile from FERC Order 661A, the profile developed in WECC (see the WECC White Paper listed as a Reference in the Standard), and studies done in the SERC region.		
CenterPoint Energy	Yes	(a) CenterPoint Energy does not agree with limiting the applicability of Requirement 2 to just "voltage protective relaying". In effect, this would allow possible tripping of generation during off nominal voltage

Organization	Yes or No	Question 6 Comment
		excursions from several other types of relays, such as generator backup over-current and impedance. CenterPoint Energy recommends that this standard be applicable to any generator Protection System relays that operate on voltage and / or current. **The SDT agrees and has revised Footnote 1 to state, in part, "…frequency or voltage protective relaying (including but not limited to frequency and voltage protective functions for discrete relays, volts per hertz relays evaluated at nominal frequency, impedance relays, voltage controlled overcurrent relays, multi-function protective devices or protective functions within control systems that directly trip or provide tripping signals to the generator based on frequency or voltage inputs)…"** (b) In Requirement 2.1.1, the fault clearing time should be established at a fixed 9 cycles, instead of site-specific, actual clearing times. R2.1.1 should be written as: "For three-phase transmission zone 1 faults, set generator Protection System relays based on a fault clearing time of 9 cycles". **The SDT disagrees that Generator Owners should be prevented from using site-specific clearing times and voltage profiles when they can be provided by the Transmission Planner.** (c) Requirement 2.1.2 provides for location-specific criteria that are unnecessary and could have unintended consequences, as such criteria can change over time with additions and modifications of the bulk electric system. CenterPoint Energy believes NERC reliability standards should not include fill-in-the-blank, location-specific criteria and recommends R2.1.2 be deleted. **The SDT disagrees that Generator Owners should be prevented from using site-specific clearing times and voltage profiles when they can be provided by the Transmission Planner.**
Response: Thank you for your comments. See specific responses above.		
GenOn Energy	Yes	A strong disapproval of the R3 equipment limitation expiration with a generating unit rating increase of 10%. The expiration is unnecessary and is based upon an arbitrary criterion that may be totally unrelated to basis for the limitation. **The SDT has revised Requirement R3 to clarify that the limitation must be eliminated if the equipment causing the limitation is modified or upgraded resulting in an increase in nameplate capacity greater than 10%.** A backwards approach has been taken with the application of Attachment 2, which represents very poor performance of the transmission system for voltage recovery after a fault. This standard will have the affect of permanently defining this as acceptable transmission performance, which should not be the case. This is inequitable since it imposes the lowest common denominator of one segment of the industry and unilaterally transfers the responsibility for that performance upon another seqment (every generating unit on the continent). **The voltage profile in Attachment 2 was developed using the voltage profile from FERC Order 661A, the profile developed in WECC (see the WECC White Paper listed as a Reference in the Standard), and studies done in the SERC region. It does not represent the lowest common**

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 6 Comment</th></tr>
<tr><td></td><td></td><td>denominator.

The Generator Verification team has developed extensive requirement for Generator Owners to provide accurate model data for system studies, but Generator Owners get no benefits in return for their effort and expense. The SDT believes the Generator Owners get the benefit of a more reliable transmission system.

Rather than imposing Attachment 2 on Generator Owners, the more correct way is to require Planning Coordinators, Transmission Operators or Transmission Planners to provide planning study results and voltage recovery profile at the generator terminals (this is where the protection and controls are applied). This will enable Generator Owners correctly apply protection settings as appropriate. Another option is to drive performance improvements on the Transmission system. Attachment 2 should be set a much higher standard of performance of the transmission system (median or higher), and require the Planning Coordinators, Transmission Operators or Transmission Planners to identify the locations where the higher standard is not attainable and provide the voltage recovery profile. Setting performance requirements for Planning Coordinators, Transmission Operators, and Transmission Planners is beyond the scope of the SAR for this project. The SDT suggests the commenter submit a SAR if he feels this would improve grid reliability.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. See specific responses above.</td></tr>
<tr><td>Arizona Public Service Company</td><td></td><td>The measurement M6 for the new plant is not clear. One does not know how long a time it would take to get a significant event. M6 should be written such that if a unit did not trip for a system event, it will be considered compliant.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. The Measure requires evidence that any trips that a generating unit experienced did not occur during a frequency or voltage excursion that remained within the No Trip Zone boundaries of Attachments 1 and 2. If the generating plant did not trip during the audit period, the final sentence in the Measure allows an attestation that the generating unit did not trip to serve as evidence of compliance.</td></tr>
<tr><td>Western Electricity Coordinating Council</td><td></td><td>For the WECC variance we would need a revised Attachment 1 that also shows the WECC No Trip Zone or an additional Attachment to illustrate the WECC variance No Trip Zone. WECC also requires modified language to R1 and the parts 1.1-1.5 to reflect the WECC variance. Requirements R5 and R6 will need to be modified to identify the appropriate Attachment for the WECC variance.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. A WECC-specific pair of curves has been added to Attachment 1.</td></tr>
</table>

Additional Comments submitted by PacifiCorp – Sandra Shaffer:

In addition to the feedback submitted via the NERC comment website, the NO votes submitted by PacifiCorp are accompanied with the following comments:

(1) Industry practice for generation protective relays is to use the terminal voltage of the generators, not the system voltage or point of interconnection. Generator Owners could provide generation responses and data as contemplated by the standard, but they should not be held responsible for the answers provided without the benefit of associated transmission planning groups. Generator Owners, under this framework, will rely completely on feedback from their associated transmission planning groups in order to provide responses. It concerns PacifiCorp that the draft standard does not address the need for transmission planners to provide the required transmission system response data to Generation Owners in order to make these assessments, or allow for the joint responsibility of transmission planner for the accuracy of the data as it concerns planning studies. **It is not practical to define the excursions at the generator terminals due to the differences in generator, step-up transformer, and system characteristics. Other voltage ride through standards (e.g. FERC Order 661A and various European standards) all define the voltage profile at the transmission level (where the event occurs).**

(2) PacifiCorp maintains several additional concerns about complying with the standard as drafted:

- R1.1.5 – PacifiCorp is not aware of relays used for generator protection that use frequency rate of change to calculate trip points. Generator protection relays use frequency set points and time at certain values, not rate of change of frequency to make tripping decisions. It may not be technically feasible to immediately comply with this sub-requirement of the standard as written. **There are several standard generator protection relays (e.g. GE's G-60, Schweitzer's 700G, and Beckwith's M-3425A) in addition to relays that are designed specifically for Aurora Scenario protection that incorporate a frequency rate of change function. R1.1.5 does not require tripping for a frequency rate of change over the stated value, but does allow that tripping even if the frequency magnitude is still within the No Trip Zone.**
- R2.1.1 - PacifiCorp requests clarification concerning what the SDT has considered a zone 1 fault. PacifiCorp acknowledges that transmission and distribution line relays have zone 1 and zone 2, but the Company does not believe that this is something typically used in the generator protection context. A zone 1 fault needs to be defined somewhere to the extent that it is not clarified in the standard already. **Part 2.1.1 states "… transmission system zone 1 faults…" The SDT believes this makes it clear that it does not involve the generator or distribution system.**
- R3 – This requirement was clear in the initial February 2009 draft of PRC-024-1, but the current draft does not clarify that the Generator Owner must upgrade the equipment that is causing a limitation. For example, if an entity upgrades its (synchronous) turbines to increase capacity by greater than 10%, but the voltage limitations still exist because they are related to the generator, which is not upgraded, the exemption would expire under the current language. The SDT should revisit this issue using the initial draft of PRC-024-1 as a guide. **The SDT has revised**

Requirement R3 to clarify that the limitation must be eliminated if the equipment causing the limitation is modified or upgraded resulting in an increase in nameplate capacity greater than 10%.

- R6 – The failure to include exemptions for new generating plants may have unintended consequences. Some voltage excursions have caused excessive torque on PacifiCorp-owned generators which has caused the controls to trip the units, rather than the relays themselves. If an entity constructs a new plant and cannot document any exemptions due to equipment limitations, such entity may experience future compliance and operational issues. The SDT should revisit this in light of further consideration of potential unintended consequences. **Tripping generating units is allowed to protect the equipment from damage. In the example cited, it would be considered an impending loss of synchronism.**

(3) PacifiCorp has concerns that certain references to Attachment 2 in Requirement R2 need to be clarified. Attachment 2 references the generator point of interconnection not the terminal voltage; therefore, clarifications to the proposed language are necessary. As such, the following recommended revisions to Requirement R2 are offered:

2.1 When operating under normal system operating conditions within 95% and 105% of rated generator terminal voltage ~~and during the transmission system conditions define in PRC-024 Attachment 2, with~~ the following clarifications for PRC-024 Attachment 2 are provided:

2.1.1 For three-phase transmission system zone 1 faults with Normal Clearing, ~~set voltage relays~~ transmission system faults should be cleared based on actual fault clearing times, not to exceed 9 cycles. Voltage relays should be set to not trip prior to transmission system fault clearing time.

2.1.2 If a Transmission Planner's study (based on the location specific voltage recovery characteristics) recommends less stringent ~~voltage relay settings~~ system protection settings than those on PRC-024 Attachment 2, set voltage relays either to the less stringent Transmission Planner's settings or the setting applicable to ~~in~~ PRC-024 Attachment 2.

2.1.3 Tripping a generator via ~~If~~ a Special Protection System (SPS) or Remedial Action Scheme (RAS) ~~includes tripping a generator after fault initiation, then setting the SPS or RAS relay to trip the generator even if in the~~ is acceptable in the "no trip zone" in PRC-024 Attachment 2 ~~is acceptable~~.

2.1.4 If clearing a system fault necessitates disconnecting a generator, this action is acceptable ~~than setting relays to trip the generator even if operating~~ within the "no trip zone" specified in PRC-024 Attachment 2 ~~is acceptable~~.

The wording in Requirement R2 has been revised to clarify intent. It now states: "Each Generator Owner that has generator voltage protective relaying Error! Bookmark not defined. **activated to trip its new or existing unit or generating plant or generating Facility shall set its protective relaying not to trip as a result of a voltage excursion**

(at the point of interconnection3) caused by an event on the transmission system external to the plant per the following operating conditions and relay settings unless the Generator Owner has documented and communicated each non-protection system equipment limitation in accordance with Requirement R3 for an existing unit or generating plant or generating Facility.

2.1 When operating within 95% to 105% of rated generator terminal voltage and during the transmission system operating conditions defined in PRC-024 Attachment 2, with the following clarifications:

2.1.1 **If a Transmission Planner's study (based on the location specific voltage recovery characteristics) recommends less stringent voltage relay settings than those in PRC-024 Attachment 2, set voltage relays either to the Transmission Planner's settings or the settings in PRC-024 Attachment 2.**

2.1.2 Tripping a generator via a Special Protection System (SPS) or Remedial Action Scheme (RAS) is acceptable in the "no trip zone" of PRC-024 Attachment 2.

2.1.3 **If clearing a system fault necessitates disconnecting a generator, this action is acceptable within the "no trip zone" specified in PRC-024 Attachment 2."**

(4) As drafted, Requirement R1 of proposed PRC-024-1 conflicts with WECC's Off-Nominal Frequency Load Shedding Plan ("WECC Coordinated Plan"), and could potentially result in negative reliability impacts if enforced in the Western Interconnection. A WECC Regional Variance that includes the WECC Generator underfrequency and overfrequency operation requirements, as identified in the WECC Off-Nominal Load Shedding Plan, must be added to the proposed standard. WECC has developed, implemented, and verified the effectiveness of the WECC Coordinated Plan and any deviations from the requirements of the plan may negatively impact its effectiveness. **The SDT has added a WECC-specific curve to Attachment 1 to address WECC's UFLS program.**

(5) PacifiCorp believes that the SDT should rewrite Requirement R4 to add specificity as to what must be included in a written response to a submission concerning an equipment limitation, similar to the specificity and clarity included in MOD-026, Requirement R3. **The SDT agrees and has removed Requirement R4.**

(6) PacifiCorp offers one comment on the Violation Severity Limits ("VSLs") proposed for Requirements R1 and R2 of PRC-024-1, which require that frequency protective relaying (R1) and voltage protective relaying (R2) be set so that they do not trip within the criteria listed in the respective requirements "unless the Generator Owner has documented and communicated a non-protection system limitation in accordance with Requirement R3." However, the language of the binary Severe VSL for Requirements R1 and R2 only identifies the failure to set protective relaying, without recognizing the exception granted for documenting and communicating a non-protective system limitation. As written, the applicable entity could be compliant with the language of Requirements R1 and R2, but based on the language of the VSLs, they

[3] For the purposes of this standard, point of interconnection means the transmission (high voltage) side of the generator step-up or collector transformer.

would be non-compliant. The SDT should add this critical clarification to the VSLs. **The VSL's have been revised to address this issue.**

(7) PacifiCorp has a concern that the PRC-024 voltage ride-through requirements identified in Attachment 2 are wholly independent of dynamic reactive power requirements for generators. As an analogy, some European generator interconnection standards and requirements link these two variable. PacifiCorp understands that PRC-024-1 is a generator protection standard; however, the SDT should address the manner in which generator dynamic reactive requirements impact PRC-024-1 Attachment 2. **The SDT believes that creating dynamic reactive power requirements is beyond the scope of the SAR that was created for this project.**

(8) Many European generator interconnection standards and requirements include different voltage ride-through requirements for synchronous and non-synchronous generation. PacifiCorp is concerned that the SDT has inappropriately developed a "one-size fits all" standard applicable to all generation platforms. PacifiCorp recommends that, based on the significant differences between existing and emerging generation platforms, separate voltage ride-through standards be developed for synchronous and non-synchronous (i.e., wind and solar) generation platforms. Different sets of standards will more effectively address such differences in the various generation technologies. **The SDT has been charged to make this standard technology neutral. If PacifiCorp feels there are significant differences in how different technologies can perform, please provide detailed information to the SDT.**

Response: Thank you for your comments. See specific responses above.

END OF REPORT

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. SAR posted for comment (April 20–May 21, 2007).
2. Revised SAR and response to comments posted.
3. Revised SAR and response to comments approved by SC (June 14, 2007).
4. SDT appointed on (August 18, 2007).
5. First Draft of MOD-024-2 was posted for comment January 18 – February 18, 2010. MOD-024-2 was later combined with MOD-025-1 to form MOD-025-2.

Proposed Action Plan and Description of Current Draft:

This is the first draft of the proposed revision to this standard including Time Horizons, Data Retention, Violation Risk Factors, and Violation Severity Levels. This first posting is for a 30-day comment period.

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Post first draft revision of standard.	April-May 2011
2. Post response to comments and second version draft revision of standard.	July – August 2011
3. Post response to comments and request authorization to ballot the revised standard.	September - October 2011
4. Conduct initial ballot.	November 2011
5. Post response to comments.	December 2011
6. Conduct recirculation ballot.	January 2012
7. BOT adoption.	February 2012
8. File with regulatory authorities.	March 2012

A. Introduction

1. **Title:** Verification and Data Reporting of Generator Real and Reactive Power Capability

2. **Number:** MOD-025-2

3. **Purpose:** To ensure that planning entities have accurate generator Real and Reactive Power capability data when assessing Bulk Electric System (BES) reliability.

4. **Applicability:**

   4.1. Functional entities

   4.1.1 Generator Owner

   4.1.2 Transmission Owner

   4.2. Facilities:

   4.2.1 Individual generating unit or synchronous condenser > 20 MVA (gross nameplate rating) in a generating Facility connected at the point of interconnection at 100 kV or above.

   4.2.2 Generating plant/Facility > 75 MVA (gross aggregate nameplate rating) and connected at the point of interconnection at 100 kV or above.

   4.2.3 Blackstart units, regardless of size that are included in a Transmission Operator's restoration plan.

5. **Effective Date:**

   5.1. In those jurisdictions where regulatory approval is required:

   5.1.1 By the first day of the first calendar quarter, one calendar year following applicable regulatory approval each Generator Owner and Transmission Owner shall have verified at least 20% of its applicable units.

   5.1.2 By the first day of the first calendar quarter, two calendar years following applicable regulatory approval each Generator Owner and Transmission Owner shall have verified at least 40% of its applicable units.

   5.1.3 By the first day of the first calendar quarter, three calendar years following applicable regulatory approval each Generator Owner and Transmission Owner shall have verified at least 60% of its applicable units.

   5.1.4 By the first day of the first calendar quarter, four calendar years following applicable regulatory approval each Generator Owner and Transmission Owner shall have verified at least 80% of its applicable units.

   5.1.5 By the first day of the first calendar quarter, five calendar years following applicable regulatory approval each Generator Owner and Transmission Owner shall have verified 100% of its applicable units.

   5.2. In those jurisdictions where regulatory approval is not required:

5.2.1 By the first day of the first calendar quarter, one calendar year following Board of Trustees approval each Generator Owner and Transmission Owner shall have verified at least 20% of its applicable units.

5.2.2 By the first day of the first calendar quarter, two calendar years following Board of Trustees approval each Generator Owner and Transmission Owner shall have verified at least 40% of its applicable units.

5.2.3 By the first day of the first calendar quarter, three calendar years following Board of Trustees approval each Generator Owner and Transmission Owner shall have verified at least 60% of its applicable units.

5.2.4 By the first day of the first calendar quarter, four calendar years following Board of Trustees approval each Generator Owner and Transmission Owner shall have verified at least 80% of its applicable units.

5.2.5 By the first day of the first calendar quarter, five calendar years following Board of Trustees approval each Generator Owner and Transmission Owner shall have verified 100% of its applicable units.

B. Requirements

R1. Each Generator Owner shall: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

1.1. Verify the Real and Reactive Power capability of its generating units and shall verify the Reactive Power capability of its synchronous condenser units in accordance with Attachment 1 –.

1.2. Record the information on Attachment 2 (or on the Generator Owner's form that contains the same information as Attachment 2);

1.3. Submit within 90 calendar days of the date the data is recorded to its Transmission Planner.

R2. Each Transmission Owner shall: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

2.1. Verify the Reactive Power capability of its synchronous condenser units in accordance with Attachment 1 ;

2.2. Record the information on Attachment 2 (or on the Transmission Owner's form that contains the same information as Attachment 2)

2.3. Submit within 90 calendar days of the verification to its Transmission Planner.

C. Measures

M1. Each Generator Owner has evidence that it performed the verification, such as a completed MOD-025 Attachment 2 or Generator Owner form with equivalent information, and has evidence that it submitted the information, such as dated electronic mail messages or mail receipts, in accordance with Requirement R1.

M2. Each Transmission Owner has evidence that it performed the verification, such as a completed MOD-025 Attachment 2 or Transmission Owner form with equivalent information, and has evidence that it submitted the information, such as dated electronic mail messages or mail receipts, in accordance with Requirement R2.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

Regional Entity

1.2. Data Retention

The Generator Owner and Transmission Owner shall each keep the latest data or evidence to show compliance as identified below, and the previous set of evidence if updated since the last compliance audit unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

- The Generator Owner shall retain the latest MOD-025 Attachment 2 or Generator Owner form with equivalent information and submittal evidence for Requirement 1, Measure 1.
- The Transmission Owner shall retain the latest MOD-025 Attachment 2 or Transmission Owner form with equivalent information and submittal evidence for Requirement 2, Measure 2.

If a Generator Owner or Transmission Owner is found non-compliant, it shall keep information related to the non-compliance until found compliant or for the time specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes

Compliance Audits

Self-Certifications

Spot Checking

Compliance Violation Investigations

Self-Reporting

Complaints

1.4. Additional Compliance Information

None

2. Violation Severity Levels

R #	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The Generator Owner verified and recorded the Real and Reactive Power capability of its applicable generating unit or applicable synchronous condenser, but submitted the data to its Transmission Planner more than 90 calendar days but within 100 calendar days from the date the data was recorded.	The Generator Owner verified and recorded the Real and Reactive Power capability of its applicable generating unit or applicable synchronous condenser, but submitted the data to its Transmission Planner more than 100 calendar days but within 110 calendar days from the date the data was recorded.	The Generator Owner verified and recorded the Real and Reactive Power capability of its applicable generating unit or applicable synchronous condenser but submitted the data to its Transmission Planner more than 110 calendar days but within 120 calendar days of the date the data was recorded.	The Generator Owner verified and recorded the Real and Reactive Power capability of its applicable generating unit or applicable synchronous condenser, but submitted the data to its Transmission Planner more than 120 calendar days from the date the data was recorded. OR The Generator Owner failed to verify the Real and Reactive Power capability of an applicable generating unit. OR The Generator Owner failed to verify the Reactive Power capability of an applicable synchronous condenser unit.

				OR The Generator Owner failed to submit its verified Real or Reactive Power capability for an applicable generating unit or an applicable synchronous condenser unit to its Transmission Planner.
R2	The Transmission Owner verified and recorded the Reactive Power capability of its applicable applicable synchronous condenser, but submitted the data to its Transmission Planner more than 90 calendar days but within 100 calendar days from the date the data was recorded.	The Transmission Owner verified and recorded the Reactive Power capability of its applicable applicable synchronous condenser, but submitted the data to its Transmission Planner more than 100 calendar days but within 110 calendar days from the date the data was recorded.	The Transmission Owner verified and recorded the Reactive Power capability of an applicable synchronous condenser unit but submitted the data to its Transmission Planner more than 110 calendar days but within 120 calendar days of the date the data was recorded.	The Transmission Owner failed to verify the Reactive Power capability of an applicable synchronous condenser unit. OR The Transmission Owner failed to submit its verified Reactive Power capability for an applicable synchronous condenser unit to its Transmission Planner.

Version History

Version	Date	Action	Change Tracking
Version 1	12/1/2005	1. Changed tabs in footer. 2. Removed comma after 2004 in “Development Steps Completed,” #1. 3. Changed incorrect use of certain hyphens (-) to “en dash” (–) and “em dash (—).” 4. Added “periods” to items where appropriate. 5. Changed apostrophes to “smart” symbols. 6. Changed “Timeframe” to “Time Frame” in item D, 1.2. 7. Lower cased all instances of “regional” in section D.3. 8. Removed the word “less” after 94% in section 3.4. Level 4.	01/20/06

MOD-025 Attachment 1 – Verification of Generator Real and Reactive Power Capability

1. For units of less than 20 MVA that are part of a plant greater than 75 MVA in aggregate, record data either on an individual unit basis or as a group. Perform verification individually for every generating unit greater than 20 MVA (gross nameplate rating).

2. Perform verification with all auxiliary equipment needed for expected normal operation in service for both the Real Power and Reactive Power capability verification, and the automatic voltage regulator in service for the Reactive Power capability verification. Operational data from within the year prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is within 20% of the expected value:

2.1. Perform verification of Real and Reactive Power capability of all generating units at maximum over-excited (lagging) and under-excited (leading) reactive capability at rated gross Real Power capability[1]. Verify variable generating units, such as wind, solar, and run of river hydro, at the maximum Real Power output the variable resource can provide at the time of the verification. Perform verification of reactive capability of wind turbines and photovoltaic inverters with ninety percent of the wind turbines or photovoltaic inverters at a site on line. Maintain as steady as possible Real and Reactive Power output during verification.

2.2. Verify Reactive Power of all generating units other than wind and photovoltaic for maximum overexcited (lagging) and under-excited (leading) reactive capability at the minimum Real Power output at which they could normally be expected to operate. Nuclear Units are not required to perform Reactive Power verification at minimum Real Power output.

2.3. Conduct the rated Real Power and overexcited Reactive Power verifications required in 2.1 for a minimum of one continuous hour.

2.4. Record the under-excited reactive capability verification data required in 2.1 and 2.2 and the over-excited reactive capability verification data required in 2.2 as soon as a limit is reached.

2.5. For hydrogen-cooled generators, perform the verification at normal operating hydrogen pressure.

3. Record the following data for the verification specified above:

3.1. The value of the gross Real and Reactive Power generating capabilities at the end of the verification period.

3.2. The voltage schedule provided by the Transmission Operator.

[1] The generating unit's normal expected maximum Real Power at the time of the verification.

3.3. The voltage at the high and low side of the generator step-up and/or system interconnection transformer(s) at the end of the verification period.

3.4. The ambient air temperature at the end of the verification period and a correction factor, if any, to allow the Transmission Owner to correct the Real Power rating to a different ambient temperature if needed.

3.5. The date and time of the verification period, including start and end time in hours and minutes.

3.6. The existing generator step-up and/or system interconnection transformer(s) tap setting.

4. Develop a simplified key one-line diagram (refer to MOD-025 Attachment 2) showing sources of auxiliary Real and Reactive Power and associated system connections for each unit verified. Include generator step-up and/or system interconnection and auxiliary transformers. Show Reactive Power flows, with directional arrows.

4.1. If metering does not exist to measure specific reactive auxiliary load(s), provide an engineering estimate and associated calculations.

5. The periodicity for performing Real and Reactive Power generating capability verification is as follows:

5.1. For staged verification; verify each generator and/or synchronous condenser or plant/facility at least every five years, (with no more than 66 calendar months between verifications), or within one year of the discovery of a change that is expected to affect its Real Power or Reactive Power capability by more than 10% of the last reported verified capability and is expected to last more than six months.

5.2. For verification using operational data; verify each generator and/or synchronous condenser or plant/facility at least every five years, within 66 calendar months between verifications, or within one year following the discovery of a change that is expected to affect its Real Power or Reactive Power capability by more than 10% of the last reported verified capability and is expected to last more than six months. If data for different points is recorded on different days, the Generator Owner shall designate one of the dates as the verification date, and report that date as the verification date on MOD-025- Attachment 2 for periodicity purposes.

5.3. For either verification method, new units shall be verified within one year of their commercial operation date.

Note 1: The data points obtained by the MVAR verification required by the standard may not duplicate the manufacturer supplied thermal capability curve (D-curve) due to transmission system conditions. However, the verification required by the standard may be able to uncover unit limitations such as rotor thermal instability, improper tap settings, inaccurate AVR operation, etc. which could be further analyzed for resolution. For any verification limited by transmission system conditions, the verified MVAR value obtained most likely will not be the value entered into the

Transmission Planner's database; nor is it likely this value will agree with data required to be submitted by the MOD-010 standard.

Note 2: While not required by the standard, it is desirable to perform engineering analysis to determine expected unit capabilities under less restrictive system conditions. Even though this analysis will not verify the complete MVAR capability curve, it provides a reasonable estimate of unit capability that the Transmission Planner can use for modeling.

MOD-025 Attachment 2

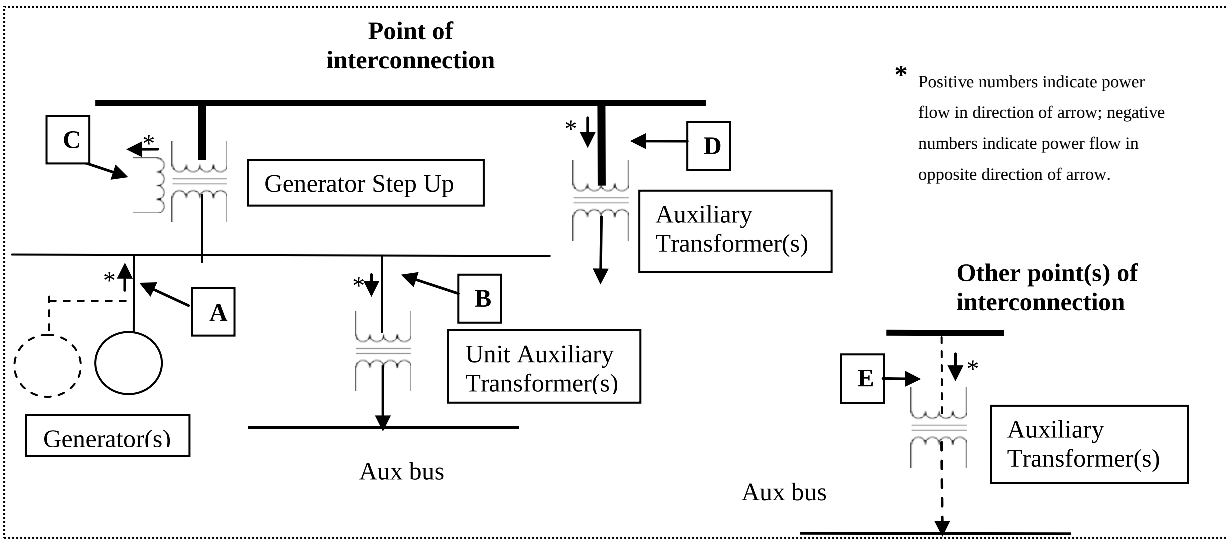
One-line Diagram, Table and Summary for Verification Information Reporting

Note: If the configuration of the generation facility does not lend itself to the use of the diagram, tables or summaries for reporting the required information, changes may be made to this form provided that all required information (identified in MOD-025 Attachement 1) is reported.

Company: **Reported By (name):**

Plant: **Unit No.:** **Date of Report:**

Simplified one-line diagram showing plant auxiliary load connections and verification data:



Point	Voltage	Real Power	Reactive Power	Comment
A	**kV**	**MW**	**MVAR**	Sum multiple Generators that are verified together or are part of the same unit.
Identify values that are calculated if any:				
B	**kV**	**MW**	**MVAR**	Sum multiple Unit Auxiliary Transformers.
Identify values that are calculated if any:				
C	**kV**	**MW**	**MVAR**	Sum multiple tertiary load, if any.
Identify values that are calculated if any:				
D	**kV**	**MW**	**MVAR**	Sum multiple Auxiliary Transformers.
Identify values that are calculated if any:				
E	**kV**	**MW**	**MVAR**	If multiple points of interconnection describe these for accurate modeling; report points individually (Sum multiple Auxiliary Transformers).
Identify values that are calculated if any:				

MOD-025 -Attachment 2 (continued)

Verification Data

Provide data by unit or Facility as appropriate

Data Type	Data Recorded	Last Verification (Previous Data)
Gross Reactive Power Generating Capability (*MVAR)		
Aux Reactive Power (*MVAR)		
Net Reactive Capability (*MVAR) equals Gross Reactive Power Capability (*MVAR) minus Aux Reactive Power (*MVAR)		
Gross Real Power Generating Capability (*MW)		
Aux Real Power (*MW)		
Net Capability (*MW) equals Gross Real Power Capability (*MW) minus Aux Power (*MW)		

* Note: Enter values at the end of the verification period.

Summary of Verification

- Date of Verification __________,Verification Start Time _____, Verification End Time ______
- Scheduled Voltage _______________
- Transformer Tap Settings: GSU ______, Unit Aux _____, Station Aux _____, Other Aux _____
- Ambient air temperature at the end of the verification period:

  Air temperature: _________°F Include in remarks below, any correction factor for different temperatures.
- The recorded MVAR values were adjusted to rated generator voltage, where applicable.
- Most recent verification Date used in table above ______________

Check all that apply:

☐ Overexcited Full Load Verification

☐ Underexcited Full Load Verification

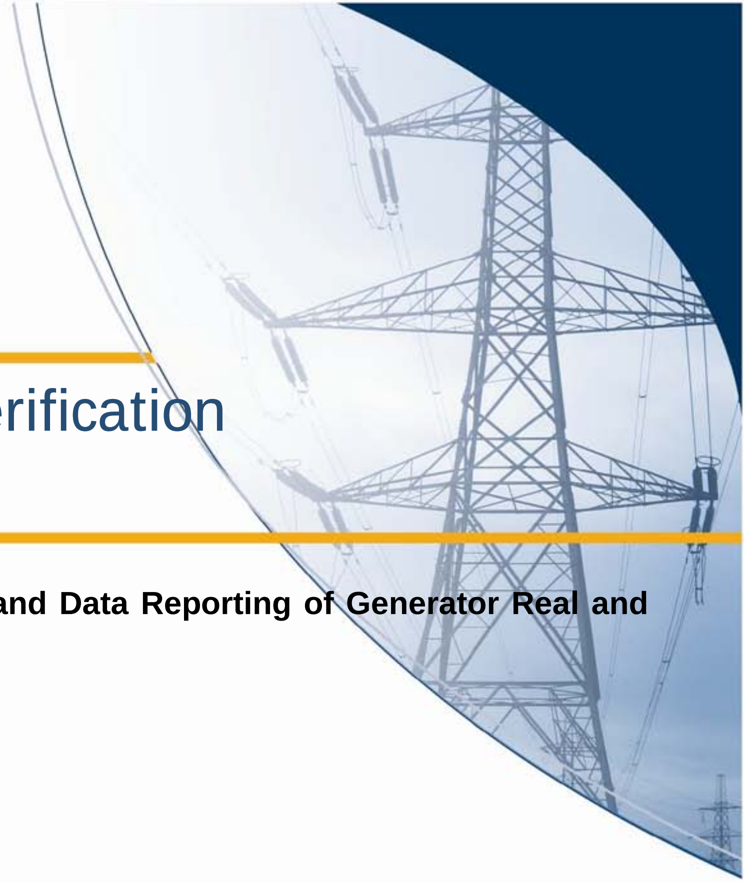
☐ Overexcited Minimum Load Verification

☐ Underexcited Minimum Load Verification

☐ Real Power Verification

Remarks :

Note: If the verification value did not reach the Thermal Capability Curve (D-Curve), describe the reason.



Project 2007-09 Generator Verification Implementation Plan

Implementation Plan for MOD-025-2, Verification and Data Reporting of Generator Real and Reactive Power Capability

Prerequisite Approvals

None

Revisions to Approved Standards and Definitions

Replace all requirements of MOD-025-1 and retire all requirements of MOD-024-1.

Compliance with the Standard

The following entities are responsible for being compliant with all requirements of MOD-025-2:

- Transmission Owner
- Generator Owner

- Facilities

    - Individual generating unit > 20 MVA (gross nameplate rating) in a generating facility connected at the point of interconnection at 100 kV or above.
    - Generating plant/facility > 75 MVA (gross aggregate nameplate rating) and connected at the point of interconnection at 100 kV or above.
    - Blackstart units, regardless of size that are included in a Blackstart Capability Plan.
    - Synchronous condensers greater than or equal to 50 MVA.

Effective Date

In those jurisdictions where regulatory approval is required:

- By the first day of the next calendar quarter, one calendar year following applicable regulatory approval each Generator Owner and Transmission Owner shall have verified at least 20% of its applicable units.

116-390 Village Blvd.
Princeton, NJ 08540
609.452.8060 | www.nerc.com

- By the first day of the next calendar quarter, two calendar years following applicable regulatory approval each Generator Owner and Transmission Owner shall have verified at least 40% of its applicable units.
- By the first day of the next calendar quarter, three calendar years following applicable regulatory approval each Generator Owner and Transmission Owner shall have verified at least 60% of its applicable units.
- By the first day of the next calendar quarter, four calendar years following applicable regulatory approval each Generator Owner and Transmission Owner shall have verified at least 80% of its applicable units.
- By the first day of the next calendar quarter, five calendar years following applicable regulatory approval each Generator Owner and Transmission Owner shall have verified 100% of its applicable units.

In those jurisdictions where regulatory approval is not required:

- By the first day of the next calendar quarter, one calendar year following Board of Trustees approval each Generator Owner and Transmission Owner shall have verified at least 20% of its applicable units.
- By the first day of the next calendar quarter, two calendar years following Board of Trustees approval each Generator Owner and Transmission Owner shall have verified at least 40% of its applicable units.
- By the first day of the next calendar quarter, three calendar years following Board of Trustees approval each Generator Owner and Transmission Owner shall have verified at least 60% of its applicable units.
- By the first day of the next calendar quarter, four calendar years following Board of Trustees approval each Generator Owner and Transmission Owner shall have verified at least 80% of its applicable units.
- By the first day of the next calendar quarter, five calendar years following Board of Trustees approval each Generator Owner and Transmission Owner shall have verified 100% of its applicable units.

The Implementation Plan phasing proposed is designed to allow large entities with dozens of units requiring verification an adequate amount of time to obtain resources and conduct testing to become fully compliant with standard requirements. The phase in period is set at five years with expectation at least 20% of an entities' applicable units will be verified annually with full compliance achieved by the end of the five year period. The 20% annual increment threshold was also selected to ensure that small entities with few units have incentive to become fully compliant in a timely manner and not delay verification of its applicable units until the fifth year of the phasing period.

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. SAR posted for comment (April 20–May 21, 2007).
2. Revised SAR and response to comments posted.
3. Revised SAR and response to comments approved by SC (June 14, 2007).
4. SDT appointed on (August 18, 2007).

Proposed Action Plan and Description of Current Draft:

This is the first draft of the this standard including Time Horizons, Data Retention, Violation Risk Factors, and Violation Severity Levels. This first posting is for a 30-day comment period.

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Post first draft revision of standard.	April-May 2011
2. Post response to comments and second version draft revision of standard.	July – August 2011
3. Post response to comments and request authorization to ballot the revised standard.	September - October 2011
4. Conduct initial ballot.	November 2011
5. Post response to comments.	December 2011
6. Conduct recirculation ballot.	January 2012
7. BOT adoption.	February 2012
8. File with regulatory authorities.	March 2012

A. Introduction

1. **Title:** Verification of Models and Data for Turbine/Governor and Load Control or Active Power/Frequency Control Functions

2. **Number:** MOD-027-1

3. **Purpose:** To verify that the turbine/governor and Load control or active power/frequency control[1] model and the model parameters used in dynamic simulation that assess Bulk Electric System (BES) reliability accurately represent generator unit real power response to system frequency variations.

4. **Applicability:**

   4.1. Functional entities

   4.1.1 Generator Owner

   4.1.2 Transmission Planner

   4.2. Facilities

   For the purpose of this standard, the following Facilities are considered, "applicable units." Units or plants with an average capacity[2] factor greater than 5% over the last three calendar years that meet the following:

   4.2.1 Generating units connected to the Eastern or Quebec Interconnections with the following characteristics:

   - Each generating unit with a gross nameplate rating greater than 100 MVA, connected at the point of interconnection[3] at greater than 100 kV.
   - For each plant with a gross aggregate nameplate rating greater than 100 MVA, connected at the same point of interconnection at greater than 100 kV:
     - Each unit with a gross nameplate rating greater than 20 MVA; and
     - The remainder of the plant as an aggregate.

---

[1] Turbine/governor and Load control or active power/frequency control:

a. Turbine/governor and Load control applies to conventional synchronous generation.

b. Active power/frequency control applies to variable energy plants.

[2] Once a capacity factor exemption is declared by notifying the Transmission Planner, verification is not required for 10 calendar years from the date eligibility occurs. At the end of this 10 calendar year timeframe, the current average 3 year capacity factor (for years 8, 9, and 10) is examined to determine if the capacity factor exemption can be declared for the next 10 calendar year period. If not eligible for the capacity factor exemption, then model verification must be completed within one year of the date the capacity factor exemption expired with the 10 calendar year periodicity requirement reset based on the verification date.

[3] The common transmission bus voltage level at which the generator step up transformer is connected.

4.2.2 Generating units connected to the Western Interconnection with the following characteristics:

- Each generating unit with a gross nameplate rating greater than 75 MVA, connected at the point of interconnection[3] at greater than 100 kV.
- For each plant with a gross aggregate nameplate rating greater than 75 MVA, connected at the same point of interconnection t greater than 100 kV:
  - Each unit with a gross nameplate greater than 20 MVA; and
  - The remainder of the plant as an aggregate.

4.2.3 Generating units connected to the ERCOT Interconnection with the following characteristics:

- Each generating unit with a gross nameplate rating of greater than 50 MVA, connected at the point of interconnection[3] with rating greater than 100 kV.
- For each plant with a gross aggregate nameplate rating of greater than 75 MVA, connected at the same point of interconnection at greater than 100 kV:
  - Each unit with a gross nameplate greater than 20 MVA; and
  - The remainder of the plant as an aggregate.

5. Effective Date:

5.1. In those jurisdictions where regulatory approval is required:

5.1.1 By the first day of the first calendar quarter, three years following applicable regulatory approval:

- At least 25% of each Generator Owner’s applicable units per Interconnection on an MVA basis compliant with Requirement R2.
- 100% compliant with Requirements R1, and R3 through R5.

5.1.2 By the first day of the first calendar quarter, five years following applicable regulatory approval:

- At least 50% of each Generator Owner’s applicable units per Interconnection on an MVA basis compliant with Requirement R2.

5.1.3 By the first day of the first calendar quarter, seven years following applicable regulatory approval:

- At least 75% of each Generator Owner’s applicable units per Interconnection on an MVA basis compliant with Requirement R2.

5.1.4 By the first day of the first calendar quarter, nine years following applicable regulatory approval:

- 100% of each Generator Owner's applicable units compliant with Requirement R2.

5.2. In those jurisdictions where no regulatory approval is required:

5.2.1 By the first day of the first calendar quarter, three years following Board of Trustees adoption:

- At least 25% of each Generator Owner's applicable units per Interconnection on an MVA basis compliant with Requirement R2.
- 100% compliant with Requirements R1, and R3 through R5.

5.2.2 By the first day of the first calendar quarter, five years following Board of Trustees adoption:

- At least 50% of each Generator Owner's applicable units per Interconnection on an MVA basis compliant with Requirement R2.

5.2.3 By the first day of the first calendar quarter, seven years following Board of Trustees adoption:

- At least 75% of each Generator Owner's applicable units per Interconnection on an MVA basis compliant with Requirement R2.

5.2.4 By the first day of the first calendar quarter, nine years following Board of Trustees adoption:

- 100% of each Generator Owner's applicable units compliant with Requirement R2.

B. Requirements

R1. Each Transmission Planner shall provide its Generator Owner with the following instructions and data within 30 calendar days of receiving a request from its Generator Owner for those instructions and data: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

- Instructions on how to obtain the list of acceptable turbine/governor and Load control or active power/frequency control system models for use in dynamic simulation.
- Instructions on how to obtain the Transmission Planner's software manufacturer's dynamic turbine/governor and Load control or active power/frequency control system model library block diagrams and/or data sheets.
- Any of the Generator Owner's existing unit or plant specific turbine/governor and Load control or active power/frequency control system data contained in the Transmission Planner's dynamic database from the current in-use model(s).

R2. Each Generator Owner shall provide a verified turbine/governor and Load control or active power/frequency control model (for each of its applicable Facilities) to its Transmission Planner in accordance with the periodicity specified in MOD-027 Attachment 1 to ensure modeling data is accurate for use in simulation software subject to the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

2.1. Each Generator Owner shall perform its verifications with one or more models acceptable to its Transmission Planner that collectively include the following information:

2.1.1. Documentation from the turbine/governor and Load control or active power/frequency control model verification activities including the on-line response compared to the recorded response for either a frequency excursion from a system disturbance, or a frequency reference change.

2.1.2. Type of governor and Load control or active power control/frequency control equipment.

2.1.3. A description of the turbine (e.g. for Hydro turbine - Kaplan, Francis, or Pelton; for steam turbine - boiler type, normal fuel type, and turbine type; for gas turbine - the type and manufacturer; for variable energy plant - type and manufacturer).

2.1.4. Turbine/governor and Load control or active power/frequency control model structure and data.

2.1.5. Representation of the real power response effects of outer loop controls (such as operator set point controls, Load control, etc. but excluding AGC control) which would override the governor response (including blocked or nonfunctioning governors or modes of operation that limit Frequency Response), if applicable.

R3. Each Generator Owner shall provide a written response that contains either the technical basis for maintaining the current model, a list of future model changes, or a plan to perform model verification[4] to its Transmission Planner within 90 calendar days of receiving written notice of one of the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

- Written notification, including a technical description from its Transmission Planner of why the turbine/governor and Load control or active power/frequency control model is not "usable" as identified in Requirement R5, Parts 5.1 through 5.3 criteria, or
- Written comments from its Transmission Planner identifying technical concerns with the verification documentation, or
- Written comments and supporting evidence from its Transmission Planner indicating that the predicted turbine/governor and Load control or active power/frequency control response did not match the recorded response for three or more transmission system events.

R4. Each Generator Owner shall provide revised model data or plans to perform model verification to its Transmission Planner within 180 calendar days of making changes to the turbine/governor and Load control or active power/frequency control system that

[4] If verification is performed, the 10 year period as outlined in Attachment 1 is reset.

alter equipment response [5] characteristic. *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

R5. Each Transmission Planner shall determine if the model meets the criteria identified in Requirement R5, Parts 5.1 through 5.3 and provide a written response to the Generator Owner indicating whether the model is useable or not useable; including a technical description if the model is not useable. This written response shall be submitted within 90 calendar days of receiving the turbine/governor and Load control or active power/frequency control system verified model information. *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

5.1. The turbine/governor and Load control or active power/frequency control function model can initialize to compute modeling data without error.

5.2. A no-disturbance simulation results in negligible transients.

5.3. For an otherwise stable simulation, a disturbance simulation results in the turbine/governor and Load control or active power/frequency control model exhibiting positive damping.

C. Measures

M1. The Transmission Planner shall have evidence to show that it provided requested instructions and data (such as dated electronic mail messages or mail receipts) within 30 calendar days of receiving a request as specified in Requirement R1.

M2. Each Generator Owner shall have evidence (such as dated electronic mail messages or mail receipts) including the verification report to show that it provided the verified turbine/governor and Load control or active power/frequency control model as specified in Requirement R2.

M3. Each Generator Owner shall have evidence to show that it provided a written response (such as a dated copy of the response, dated electronic mail messages or mail receipts) containing identified information and submitted within 90 calendar days of receiving any written notification as specified in Requirement R3.

M4. Each Generator Owner shall have evidence to show that it provided a written response (such as dated electronic mail messages or mail receipts) submitted within 180 calendar days of making system changes specified in Requirement R4.

M5. Each Transmission Planner shall have evidence to show that it provided a written response (such as dated electronic mail messages or mail receipts) within 90 calendar days of receiving the model as specified in Requirement R5.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

[5] Control replacement or alteration including software alterations or plant digital control system addition or replacement, plant digital control system software alterations that alter droop, and/or dead band, and/or frequency response and/or a change in the frequency control mode (such as going from droop control to constant MW control, etc).

Regional Entity

1.2. Data Retention

The Generator Owner and Transmission Planner shall each keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

- The Transmission Planner shall retain the information/data request and provided response evidence of Requirements R1 and R5, Measures M1 and M5 for 3 calendar years from the date the document was provided.
- The Generator Owner shall retain the latest and previous turbine/governor and Load control or active power/frequency control system model verification evidence of Requirement R2, Measure M2.
- The Generator Owner shall retain the information/data request and provided response evidence of Requirements R3, and R4 Measures M3 and M4 for 3 calendar years from the date the document was provided.

If a Generator Owner or Transmission Planner is found non-compliant, it shall keep information related to the non-compliance until found compliant or for the time specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes

2. Violation Severity Levels

R #	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The Transmission Planner provided the instructions and data to the Generator Owner more than 90 calendar days but less than or equal to 120 calendar days of receiving a request.	The Transmission Planner provided the instructions and data to the Generator Owner more than 120 calendar days but less than or equal to 150 calendar days of receiving a request.	The Transmission Planner provided the instructions and data to the Generator Owner more than 150 calendar days but less than or equal to 180 calendar days of receiving a request.	The Transmission Planner failed to provide the instructions and data to the Generator Owner within 181 calendar days of receiving a request.
R2	The Generator Owner provided its verified model(s) to its Transmission Planner after the periodicity timeframe specified in MOD-027 Attachment 1 but less than or equal to 30 calendar days late; OR The Generator Owner provided the Transmission Planner a verified model that omitted one of the five Parts identified in Requirement R2, Parts 2.1.1, through 2.1.5.	The Generator Owner provided its verified model(s) to its Transmission Planner more than 30 calendar days but less than or equal to 60 calendar days late as specified by the periodicity timeframe in MOD-027 Attachment 1. OR The Generator Owner provided the Transmission Planner a verified model that omitted two of the five Parts identified in Requirement R2, Parts 2.1.1, through 2.1.5.	The Generator Owner provided its verified model(s) to its Transmission Planner more than 60 calendar days but less than or equal to 90 calendar days late as specified by the periodicity timeframe in MOD-027 Attachment 1. OR The Generator Owner provided the Transmission Planner verified models that omitted three of the five Parts identified in Requirement R2, Parts 2.1.1, through 2.1.5.	The Generator Owner failed to provide its verified turbine/governor and Load control or active power/frequency control[1] model(s) or failed to provide the verified model(s) no more than 90 calendar days late to its Transmission Planner in accordance with the periodicity specified in MOD-027 Attachment 1. OR The Generator Owner failed to use model(s) acceptable to the Transmission Planner as specified in Requirement R2, Part 2.1. OR The Generator Owner provided the Transmission Planner verified model(s) that omitted four or more of the five Parts identified in Requirement R2, Parts 2.1.1, through 2.1.5.

R3	The Generator Owner provided a written response more than 90 calendar days but less than or equal to 120 calendar days of receiving written notice. (R3)	The Generator Owner provided a written response more than 120 calendar days but less than or equal to 150 calendar days of receiving written notice. (R3)	The Generator Owner provided a written response more than 150 calendar days but less than or equal to 180 calendar days of receiving written notice. (R3)	The Generator Owner failed to provide a written response within 181 calendar days of receiving notice as specified in Requirement R3. OR The Generator Owner's written response was provided within 181 calendar days of receiving written notice however failed to contain either the technical basis for maintaining the current model, or a list of future model changes, or a plan to perform model verification.
R4	The Generator Owner provided revised model data or plans to perform model verification more than 180 calendar days but less than or equal to 210 calendar days of making changes to the turbine/governor and Load control or active power/frequency control[1] system that alter the equipment response characteristic. (R4)	The Generator Owner provided revised model data or plans to perform model verification more than 210 calendar days but less than or equal to 240 calendar days of making changes to the turbine/governor and Load control or active power/frequency control[1] system that alter the equipment response characteristic. (R4)	The Generator Owner provided revised model data or plans to perform model verification more than 240 calendar days but less than or equal to 270 calendar days of making changes to the turbine/governor and Load control or active power/frequency control[1] system that alter the equipment response characteristic. (R4)	The Generator Owner failed to provide revised model data or failed to provide plans to perform model verification within 271 calendar days of making changes to the turbine/governor and Load control or active power/frequency control[1] system that alter the equipment response characteristic as specified in Requirement R3.
R5	The Transmission Planner provided a written response to the Generator Owner indicating whether the model is useable or not useable; including a technical description if the model is not useable, more than 90 calendar days but less than 120 calendar days of receiving verified model information. (R5)	The Transmission Planner provided a written response to the Generator Owner indicating whether the model is useable or not useable; including a technical description if the model is not useable, more than 120 calendar days but less than 150 calendar days of receiving the verified model information. (R5) OR	The Transmission Planner provided a written response to the Generator Owner indicating whether the model is useable or not useable; including a technical description if the model is not useable, more than 150 calendar days but less than 180 calendar days of receiving the verified model information. (R5) OR	The Transmission Planner failed to provide a written response to the Generator Owner within 181 calendar days of receiving the verified model information as specified in Requirement R5. OR The Transmission Planner provided a

		The Transmission Planner provided a written response within 181 calendar days to the Generator Owner however the written response omitted confirmation for one of the specified model criteria listed in Requirement R5, Parts 5.1 through 5.3.	The Transmission Planner provided a written response within 181 calendar days to the Generator Owner however the written response omitted confirmation for two of the specified model criteria listed in Requirement R5, Parts 5.1 through 5.3.	written response within 181 calendar days to the Generator Owner however the written response omitted confirmation for all specified model criteria listed in Requirement R5, Parts 5.1 through 5.3.

Project 2007-09 Generator Verification Implementation Plan

Implementation Plan for MOD-027-1, Verification of Models and Data for Turbine/Governor and Load Control or Active Power/Frequency Control Functions

Approvals Requested

MOD-027-1 – Verification of Models and Data for Turbine/Governor and Load Control or Active Power/Frequency Control Functions

Prerequisite Approvals

None

Revisions to Approved Standards and Definitions

None

Compliance with the Standard

The following entities are responsible for being compliant with all requirements of MOD-027-1:

- Transmission Planner
- Generator Owner

- Facilities

For the purpose of this standard, the following Facilities are considered, "applicable units." Units or plants with an average capacity[1] factor greater than 5% over the last three calendar years that meet the following:

Generating units connected to the Eastern or Quebec Interconnections with the following characteristics:

[1] Once a capacity factor exemption is declared by notifying the Transmission Planner, verification is not required for 10 calendar years from the date eligibility occurs. At the end of this 10 calendar year timeframe, the current average 3 year capacity factor (for years 8, 9, and 10) is examined to determine if the capacity factor exemption can be declared for the next 10 calendar year period. If not eligible for the capacity factor exemption, then model verification must be completed within one year of the date the capacity factor exemption expired with the 10 calendar year periodicity requirement reset based on the verification date.

- Each generating unit with a gross nameplate rating greater than or equal to 100 MVA, connected at the point of interconnection [2] at greater than or equal to 100 kV.
- For each plant with a gross aggregate nameplate rating greater than or equal to 100 MVA, connected at the same point of interconnection at greater than or equal to 100 kV:
    - Each unit with a gross nameplate rating greater than or equal to 20 MVA; and
    - The remainder of the plant as an aggregate.

Generating units connected to the Western Interconnection with the following characteristics:

- Each generating unit with a gross nameplate rating greater than or equal to 75 MVA, connected at the point of interconnection[2] at greater than or equal to 100 kV.
- For each plant with a gross aggregate nameplate rating greater than or equal to 75 MVA, connected at the same point of interconnection with at greater than or equal to 100 kV:
    - Each unit with a gross nameplate greater than or equal to 20 MVA; and
    - The remainder of the plant as an aggregate.

Generating units connected to the ERCOT Interconnection with the following characteristics:

- Each generating unit with a gross nameplate rating of greater than or equal to 50 MVA, connected at the point of interconnection[2] with rating greater than or equal to 100 kV.
- For each plant with a gross aggregate nameplate rating of greater than or equal to 75 MVA, connected at the same point of interconnection at greater than or equal to 100 kV:
    - Each unit with a gross nameplate greater than or equal to 20 MVA; and
    - The remainder of the plant as an aggregate.

Effective Date

In those jurisdictions where regulatory approval is required:

[2] The common transmission bus voltage level at which the generator step up transformer is connected.

By the first day of the first calendar quarter, three years following applicable regulatory approval:

- At least 25% of each Generator Owner's applicable units per Interconnection on an MVA basis compliant with Requirement R2.
- 100% compliant with Requirements R1, and R3 through R5.

By the first day of the first calendar quarter, five years following applicable regulatory approval:

- At least 50% of each Generator Owner's applicable units per Interconnection on an MVA basis compliant with Requirement R2.

By the first day of the first calendar quarter, seven years following applicable regulatory approval:

- At least 75% of each Generator Owner's applicable units per Interconnection on an MVA basis compliant with Requirement R2.

By the first day of the first calendar quarter, nine years following applicable regulatory approval:

- 100% of each Generator Owner's applicable units compliant with Requirement R2.

In those jurisdictions where no regulatory approval is required:

By the first day of the first calendar quarter, three years following Board of Trustees adoption:

- At least 25% of each Generator Owner's applicable units per Interconnection on an MVA basis compliant with Requirement R2.
- 100% compliant with Requirements R1, and R3 through R5.

By the first day of the first calendar quarter, five years following Board of Trustees adoption:

- At least 50% of each Generator Owner's applicable units per Interconnection on an MVA basis compliant with Requirement R2.

By the first day of the first calendar quarter, seven years following Board of Trustees adoption:

- At least 75% of each Generator Owner's applicable units per Interconnection on an MVA basis compliant with Requirement R2.

By the first day of the first calendar quarter, nine years following Board of Trustees adoption:

- 100% of each Generator Owner's applicable units compliant with Requirement R2.

Justification

This phased implementation supports the ten year cycle for the collection of generator response data necessary for required verifications and typical generating unit outage schedules, and it also provides ample time for Generator Owners to either purchase new recording equipment as required or to make necessary modifications to existing recording equipment (frequency triggers, length of recordings for frequency excursions, additional event storage capacity, etc).

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. SAR posted for comment (April 20–May 21, 2007).
2. Revised SAR and response to comments posted.
3. Revised SAR and response to comments approved by SC (June 14, 2007).
4. SDT appointed on (August 18, 2007).

Proposed Action Plan and Description of Current Draft:

This is the first draft of the proposed standard including Time Horizons, Data Retention, Violation Risk Factors, and Violation Severity Levels; and is being submitted for a 30-day formal comment period.

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Post first draft revision of standard.	April-May 2011
2. Post response to comments and second version draft revision of standard.	July – August 2011
3. Post response to comments and request authorization to ballot the revised standard.	September - October 2011
4. Conduct initial ballot.	November 2011
5. Post response to comments.	December 2011
6. Conduct recirculation ballot.	January 2012
7. BOT adoption.	February 2012
8. File with regulatory authorities.	March 2012

A. Introduction

1. Title: Coordination of Generating Unit or Plant Voltage Regulating Controls with Generating Unit or Plant Capabilities and Protection

2. Number: PRC-019-1

3. Purpose: To improve the reliability of the Bulk Electric System by preventing tripping of generating units and generating Facilities due to mis-coordination of generating unit and generating Facility voltage regulating controls and limit functions with generator capabilities and protection system settings.

4. Applicability:

4.1. Functional Entities

4.1.1 Generator Owner

4.1.2 Transmission Owner

4.2. Facilities

4.2.1 Individual generating unit or synchronous condenser > 20 MVA (gross nameplate rating) connected at the point of interconnection at 100 kV or above.

4.2.2 Generating plant and generating Facility > 75 MVA (gross aggregate nameplate rating) connected at the point of interconnection at 100 kV or above.

4.2.3 Blackstart Resources, regardless of size included in a Transmission Operator's restoration plan.

5. Effective Date:

5.1. In those jurisdictions where regulatory approval is required:

5.1.1 By the first day of the first calendar quarter, one calendar year following applicable regulatory approval each Generator Owner and Transmission Owner shall have verified at least 20% of its applicable units.

5.1.2 By the first day of the first calendar quarter, two calendar years following applicable regulatory approval each Generator Owner and Transmission Owner shall have verified at least 40% of its applicable units.

5.1.3 By the first day of the first calendar quarter, three calendar years following applicable regulatory approval each Generator Owner and Transmission Owner shall have verified at least 60% of its applicable units.

5.1.4 By the first day of the first calendar quarter, four calendar years following applicable regulatory approval each Generator Owner and Transmission Owner shall have verified at least 80% of its applicable units.

5.1.5 By the first day of the first calendar quarter, five calendar years following applicable regulatory approval each Generator Owner and Transmission Owner shall have verified 100% of its applicable units.

5.2. In those jurisdictions where regulatory approval is not required:

5.2.1 By the first day of the first calendar quarter, one calendar year following Board of Trustees approval each Generator Owner and Transmission Owner shall have verified at least 20% of its applicable units.

5.2.2 By the first day of the first calendar quarter, two calendar years following Board of Trustees approval each Generator Owner and Transmission Owner shall have verified at least 40% of its applicable units.

5.2.3 By the first day of the first calendar quarter, three calendar years following Board of Trustees approval each Generator Owner and Transmission Owner shall have verified at least 60% of its applicable units.

5.2.4 By the first day of the first calendar quarter, four calendar years following Board of Trustees approval each Generator Owner and Transmission Owner shall have verified at least 80% of its applicable units.

B. Requirements

R1. Each Generator Owner and Transmission Owner with applicable Facilities shall coordinate its generating unit and generating Facility voltage regulating system controls, including limiters and protection functions with the generating unit and Facility or synchronous condenser capabilities and protective system settings; to include as applicable: *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*

- In-service [1] excitation system and voltage regulating system control, limiters and protection functions
- In-service generator or synchronous condenser protection system settings
- Generating equipment or synchronous condenser capabilities
- Steady state stability limit

1.1. This coordination requires the following steps:

1.1.1. Verify that the limiters are set to operate before the protection and the protection is set to operate before conditions exceed equipment capabilities (including the steady state stability limit) assuming normal AVR control loop and system steady state operating conditions.

1.1.2. Check that the settings determined in Step 1.1.1 are applied to the in-service equipment.

1.2. Each Generator Owner and Transmission Owner shall verify the existence of the coordination identified in Requirement R1 at least once every five years or within

[1] Limiters or protective functions that are installed and activated on the generator or synchronous condenser.

90 calendar days following the identification or implementation of systems, equipment or setting changes that are expected to affect this coordination, including but not limited to the following

- Voltage regulating equipment changes
- Protection system settings or component changes
- Generating or synchronous condenser equipment capability changes
- Generator or synchronous condenser step-up transformer changes

C. Measures

M1. Each Generator Owner and Transmission Owner will have evidence, such as example plots provided in PRC-019 Section G, to show that its generating unit and generating Facility or synchronous condenser excitation system and voltage regulating system controls and protection functions are coordinated with the generating unit and generating Facility capabilities and protective system settings applied to in-service equipment as specified in Requirement R1, Section 1.1, and one previous dated set of evidence that demonstrates the latest coordination review has been done within the intervals specified in Requirement R1, Section 1.2. If the latest coordination review is performed due to a change in the equipment or settings that changes the coordination, the Generator Owner and Transmission Owner will have evidence (such as a work order) that demonstrates when the change was implemented.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

Regional Entity

1.2. Data Retention

Each Generator Owner and Transmission Owner shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

- The Generator Owner and Transmission Owner shall retain the latest and the prior evidence of compliance with Requirement R1, Measure M1.

If a Generator Owner or Transmission Owner is found non-compliant, it shall keep information related to the non-compliance until found compliant or for the time period specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes

Compliance Audit

Self-Certification

Spot Checking

Compliance Violation Investigation

Self-Reporting

Complaint

1.4. Additional Compliance Information

None

2. Violation Severity Levels

R #	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The Generator Owner or Transmission Owner verified the coordination specified in Requirement R1 more than 90 calendar days but less than or equal to 100 calendar days following the identification or implementation of a change that affected the coordination.	The Generator Owner or Transmission Owner verified the coordination specified in Requirement R1 more than 100 calendar days but less than or equal to 110 calendar days following the identification or implementation of a change that affected the coordination.	The Generator Owner or Transmission Owner verified the coordination specified in Requirement R1 more than 110 calendar days but less than or equal to 120 calendar days following the identification or implementation of a change that affected the coordination.	The Generator Owner or Transmission Owner failed to verify the existence of the coordination specified in Requirement R1 at least once every five years. OR The Generator Owner or Transmission Owner failed to verify the existence of the coordination specified in Requirement R1 within 121 calendar days following the identification or implementation of a change that affected the coordination.

Examples of Coordination

The evidence of coordination associated with Requirement R1 may be in the form of one or more plots including (but not limited to):

- P-Q Diagram (Attachment 1), or
- R-X Diagram (Attachment 2), or
- Inverse Time Diagram (Attachment 3)

These plots contain the equipment capabilities, the operating region for the limiters and protection function such as; under-excitation limiters, steady state stability limits, or loss of field protection curves. Additional limiters and protection function that are installed and in-service can be incorporated as an Inverse Time Limit/Protection Characteristic Plot (Attachment 3) or into the Generator Reactive Capability Curve Plot or an R-X diagram plot, identified above.

Equipment limits, types of limiters and protection functions which could be coordinated include:

- Field over-excitation limiter and associated protection functions.
- Inverter over current limit and associated protection functions.
- Volts per hertz limiter and associated protection functions.
- Stator over-voltage protection system settings.
- Generator and transformer volts per hertz capability.
- Time vs. field current or time vs. stator current.
- Converter over-temperature limiter and associated protection function.

NOTE: This listing is for reference only. This standard does not require the installation or activation of any of the above limiter or protection functions.

For the coordination required by this standard, the Steady State Stability Limit (SSSL) is the limit to synchronous stability in the under-excited region with fixed field current.

On a P-Q diagram using X_d as the direct axis saturated synchronous reactance of the generator, X_s as the equivalent reactance between the generator terminals and the "infinite bus" including the reactance of the generator step-up transformer and V_g as the generator terminal voltage (all values in per-unit), the SSSL can be calculated as an arc with the center on the Q axis with the magnitude of the center and radius described by the following equations

$$C = V^2_g/2*(1/X_s-1/X_d)$$
$$R = V^2_g*(1/X_s+1/X_d)$$

On an R-X diagram using X_d as the direct axis saturated synchronous reactance of the generator, and X_s as the equivalent reactance between the generator terminals and the "infinite bus" including the reactance of the generator step-up transformer the SSSL is an arc with the center on the X axis with the center and radius described by the following equations:

$$C = (X_d-X_s)/2$$
$$R = (X_d+X_s)/2$$

Project 2007-09 Generator Verification Implementation Plan

Implementation Plan for PRC-019-1, Coordination of Generating Unit or Plant Voltage Regulating Controls with Generating Unit or Plant Capabilities and Protection

Approvals Requested:
PRC-019-1 - Coordination of Generating Unit or Plant Voltage Regulating Controls with Generating Unit or Plant Capabilities and Protection

Prerequisite Approvals

None

Revisions to Approved Standards and Definitions

None

Compliance with the Standard

The following entities are responsible for being compliant with all requirements of PRC-019-1:

- Transmission Owner
- Generator Owner

- Facilities:
  - Individual generating unit and synchronous condenser > 20 MVA (gross nameplate rating) in a generating Facility connected at the point of interconnection at 100 kV or above.
  - Generating plant/Facility > 75 MVA (gross aggregate nameplate rating) and connected at the point of interconnection at 100 kV or above.
  - Blackstart units, regardless of size included in a Blackstart Capability Plan.

Effective Date

The first day of the first calendar quarter two years following applicable regulatory approval; or in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter two years following Board of Trustees adoption:

- Each Generator Owner and Transmission Owner shall have at least 20% of applicable units and facilities fully compliant with this standard.

The first day of the first calendar quarter two years following applicable regulatory approval; or in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter three years following Board of Trustees adoption:

- Each Generator Owner and Transmission Owner shall have at least 40% of applicable units and facilities fully compliant with this standard.

The first day of the first calendar quarter three years following applicable regulatory approval; or in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter three years following Board of Trustees adoption:

- Each Generator Owner and Transmission Owner shall have at least 60% of applicable units and facilities fully compliant with this standard.

The first day of the first calendar quarter four years following applicable regulatory approval; or in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter four years following Board of Trustees adoption:

- Each Generator Owner and Transmission Owner shall have at least 80% of applicable units and facilities fully compliant with this standard.

The first day of the first calendar quarter five years following applicable regulatory approval; or in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter five years following Board of Trustees adoption:

- Each Generator Owner and Transmission Owner shall have 100% of applicable units and facilities fully compliant with this standard.

Justification for Phasing:

The coordination activities in this standard (PRC-019) are most effectively performed just prior to the performance of a reactive capability test as required by MOD-025. Hence, the SDT has followed the same implementation schedule in PRC-019 as defined in MOD-025.

Unofficial Comment Form for Generator Verification (Project 2007-09)

Please **DO NOT** use this form to submit comments. Please use the electronic comment form located at the link below to submit comments on the First Posting of MOD-025-2, Verification and Data Reporting of Generator Real and Reactive Power Capability (Project 2007-09). The electronic comment form must be completed by **July 15, 2011.**

Project 2007-09 Generator Verification

If you have questions please contact Stephen Crutchfield at Stephen.Crutchfield@nerc.net or by telephone at 609-651-9455.

Background Information

The purpose of Project 2007-09 Generator Verification is:

- To ensure that generators will not trip off-line during specified voltage and frequency excursions or as a result of improper coordination between generator protective relays and generator voltage regulator controls and limit functions (such coordination will include the generating unit's capabilities).
- To ensure that generator models accurately reflect the generator's capabilities and operating characteristics.

The standard drafting team (SDT) for Project 2007-09 Generator Verification based its work on two existing NERC Board approved standards:

- MOD-024 — Verification of Generator Gross and Net Real Power Capability.
- MOD-025 — Verification of Generator Gross and Net Reactive Power Capability.

And four draft standards developed by the Phase III & IV SDT that were fielded tested by four Regions from mid 2006 through mid 2007.

- PRC-019 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection
- PRC-024 — Generator Performance During Frequency and Voltage Excursions
- MOD-026 —Verification of Models and Data for Generator Excitation System Functions
- MOD-027 — Verification of Generator Unit Frequency Response

Before beginning the detailed work of developing the standards, the SDT was presented the recently completed field test results by the participants from the four field test Regions. The SDT also reviewed how and to what extent the two NERC Board approved standards were used across all the Regions.

Based on comments received from the first posting of MOD-024-2 the SDT is proposing that the Requirements for MOD-024-1 be combined with the Requirements of MOD-025-1 into a single standard, MOD-025-2. The SDT concluded that combining MOD-024-1 and MOD-025-1 would enhance the accuracy of the model for the high demand system conditions because MOD-025-2 would prove the unit's Real Power capability when the unit was producing maximum Reactive Power.

MOD-025-2 Verification and Data Reporting of Generator Real and Reactive Power Capability was developed with consideration to key issues stated in the SAR:

- Provide more details to the applicability section
- Replace the "fill in the blanks" requirements assigned to the Regional Reliability Organization with a set of "continent-wide" requirements
- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the Regional Reliability Organization
- Consider and address issues identified in FERC orders, including the modifications to MOD-024-1 and MOD-025-1 as proposed in FERC Order 693
- Consider and address issues identified during Phase III & IV field testing

The SDT realizes that the data points produced by the MVAR verification required in MOD-025-2 may not duplicate the manufacturer supplied thermal capability curve (D-curve) due primarily to transmission system conditions. However, the MOD-025-2 verification may be able to uncover some unit limitations such as rotor thermal instability, improper tap settings, inaccurate AVR operation, etc. which could then be studied further for resolution. For verifications that are limited primarily by transmission system conditions the resulting verified MVAR value is probably not the value that should be entered into the Transmission Planner's database. It is also likely not the same value that is submitted per MOD-010. While not required by the draft standard it is permissible to perform engineering analysis to determine the expected capabilities of the unit under less restricting system conditions. Although the engineering analysis will not physically verify the complete MVAR capability it is a reasonable estimate of unit capability that the transmission planner can use in his model. The SDT has also allowed the use of either operational data or staged testing for the verification. This allows the Generator more flexibility to obtain the best possible conditions for uncontrollable parameters such as wind speed, solar irradiance, and transmission system voltage conditions during the verification. When operational data is used, the SDT has required that the verification fall within 20% of the expected value. The limit is a compromise, based on engineering judgment, and input is solicited from industry on what this limit should be.

The SDT considered the extent of the facilities to be verified and how to reflect this in the "applicability". Approximately 4% of the overall system capacity is connected at a voltage less than 100kV. The SDT concluded that 4% was not an impact on reliability, and did not require verification of units connected below 100kV. The SDT has proposed that this standard be consistent with the more general Compliance Registry Guidelines. If regions have generating units that are connected at under 100 kV that are important to the reliability of the system due to some local consideration, then the region has the authority to require that those units be verified if they so choose.

In line with minimizing potentially unnecessary work by the Generator Owner and providing maximum benefit to the Transmission Planner, the SDT has developed a "diagram" guideline in the form of Attachment 2 to the standard. The Attachment can be used directly or modified as necessary to reflect the dozens of actual installation configurations. The Attachment sets the basic structure and data needed. The visual diagram provides for easier entry by the Generator Owner and application of information for Transmission Planner simulation models.

The SDT discussed if standard MOD-025-2 should also include verification of synchronous condensers. Synchronous condensers are not currently addressed in the NERC Registry Criteria. Synchronous condensers are not mentioned in the Generation Verification SAR. On an MVA capacity basis, the penetration of Synchronous condensers in North America is extremely low. It is common for Transmission Owners to be the owners of synchronous condensers, although some are owned by Generators. The SDT proposes that synchronous condensers be verified under MOD-025-2 also since they are also rotating synchronous machines, subject to the same issues that synchronous generators are subject to, and their output should be verified periodically to insure they can deliver their rating if required.

The following questions will assist the SDT in finalizing the development of MOD-025-2 Verification and Data Reporting of Generator Real and Reactive Power capability. For questions where you agree with the SDT, please state that you agree and if available, please provide supporting documentation. If you disagree with the SDT, please explain why you disagree and provide data to support your position. To improve this first draft of MOD-025-2 Verification and Data Reporting of Generator Real and Reactive Power capability, the SDT would appreciate responses to as many of these questions as you can answer.

The SDT has provided a mapping of the current NERC Board approved MOD-025-1 requirements to the proposed MOD-025-2 requirements as part of the Implementation Plan. Since the SDT is proposing to put the requirements of the existing MOD-024-1 into MOD-025-2, a second mapping document of the MOD-024-1 requirements to MOD-025-2 is also provided.

You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. The SDT has proposed that the requirements of MOD-024-1 and MOD-025-1 be combined into a single standard MOD-025-2. Do you agree with this approach? If not, please explain.

   ☐ Yes

   ☐ No

   Comments:

2. The SDT has proposed that the data from MOD-025-2 be submitted to the Transmission Owner. Do you believe the Transmission Owner is the appropriate entity to receive this data? If not, please explain.

   ☐ Yes

   ☐ No

   Comments:

3. The SDT has proposed that the ambient temperature during the verification be provided to the Transmission Owner as well as a correction factor to allow the Transmission Owner to adjust the Real Power data to a different ambient temperature if needed. Do you feel the standard should require that the Real Power data submitted be temperature adjusted to some other than ambient temperature? If yes, please explain and include which entity you think should perform the correction and which entity should determine the temperature value that should be used for the correction.

   ☐ Yes

   ☐ No

   Comments:

4. The SDT believes that verification should be performed on units that are connected down to 100 kV. The SDT has also provided how verification should be handled in plants/facilities that are greater than 75 MVA in aggregate gross nameplate rating. The Standard requires a separate verification for every unit greater than 20 MVA gross nameplate rating. This is consistent with the current Compliance Registry. Units 20 MVA and smaller, in a plant/facility greater than 75 MVA, can be verified separately or in aggregate as the Generator Owner chooses. Do you agree with the SDT's decision to have the Standard be applicable to the compliance registry? If not, please explain.

   ☐ Yes

   ☐ No

   Comments:

5. The draft standard requires that the Reactive Power capability be verified at four points: over-excited (lagging) and under-excited (leading) reactive capability at (1) the rated Real Power capability and (2) expected minimum Real Power output. The SDT believes

that this is consistent with the FERC directive in Order 693 at P1321, “Therefore, we adjust the proposal in the NOPR and direct the ERO to modify MOD-025-1 to require verification of reactive power capability at multiple points over a unit’s operating range.” Do you agree that the four points proposed by the SDT is adequate to provide a straight line approximation to a unit’s Reactive Power capability over its actual operating range? If not, please explain.

☐ Yes

☐ No

Comments:

6. Verification of over-excited reactive capability at rated Real Power Capability is required to be conducted over a minimum of one hour. Do you agree with the verification time? If not, please explain.

☐ Yes

☐ No

Comments:

7. Verification of (1) under-excited reactive capability at rated Real Power of the most recent gross verified Real Power capability reported, (2) under-excited reactive capability at expected minimum Real Power output and (3) over-excited reactive capability at expected minimum Real Power output, are all to be recorded as soon as a limit is encountered. Do you agree that such data recorded as soon as a limit is encountered is appropriate for such verification? If not, please explain.

☐ Yes

☐ No

Comments:

8. Synchronous condensers are also reactive resources that may be important to reliability, but they are not generators. The SDT proposes that synchronous condensers be verified under MOD-025-2. Do you feel that this is appropriate?

☐ Yes

☐ No

Comments:

9. The SDT proposes that the size of synchronous condensers to be verified be limited to those greater than 50 MVA. Do you feel that this size criterion for synchronous condenser verification is appropriate?

☐ Yes

☐ No

Comments:

10. Either operational data or staged testing is allowed by the standard for verification. Do you agree that these two methods of verification are acceptable? If not, please explain.

☐ Yes

☐ No

Comments:

11. If operational data is utilized, the standard requires the verification be within 20% of the expected value. Do you agree with the 20% requirement? If not, please explain.

☐ Yes

☐ No

Comments:

12. Are you aware of any regional variances that would be required for this standard?

☐ Yes

☐ No

Comments:

13. Are you aware of any conflicts between the proposed standard and any regulatory function, rule, order, tariff, rate schedule, legislative requirement, or agreement?

☐ Yes

☐ No

Comments:

14. Do you have any other questions or concerns with the proposed standard that have not been addressed? If yes, please provide a reference to the section, requirement or subrequirement that you believe should be changed, added or deleted and the rationale for your proposal.

☐ Yes

☐ No

Project 2007-09 Generator Verification

If you have questions please contact Stephen Crutchfield at Stephen.Crutchfield@nerc.net or by telephone at 609-651-9455.

Background Information

The purpose of Project 2007-09 - Generator Verification is:

- To ensure that generators will not trip off-line during specified voltage and frequency excursions or as a result of improper coordination between generator protective relays and generator voltage regulator controls and limit functions (such coordination will include the generating unit's capabilities).

- To ensure that generator models accurately reflect the generator's capabilities and operating characteristics.

The standard drafting team (SDT) for Project 2007-09 Generator Verification based its work on two existing NERC Board approved standards:

- MOD-024-1 — Verification of Generator Gross and Net Real Power Capability.

- MOD-025-1 — Verification of Generator Gross and Net Reactive Power Capability.

And four draft standards developed by the Phase III & IV SDT that were field tested by four Regions from mid 2006 through mid 2007.

- PRC-019-1 — Coordination of Generator Voltage Regulator Controls with Unit
- Capabilities and Protection

- PRC-024-1 — Generator Performance During Frequency and Voltage Excursions

- MOD-026-1 —Verification of Models and Data for Generator Excitation Control System Functions

- MOD-027-1 — Verification of Generator Unit Frequency Response

This is the second posting of standard MOD-026-1 Verification of Models and Data for Generator Excitation Control System Functions for industry review. It should be noted that the title of the standard has been changed from "Verification of Models and Data for Generator Excitation Control System Functions" to "Verification of Models and Data for Generator Excitation Control System or Plant Volt/Var Control Functions" in order to reflect the SDTs inclusion of plants with several small units, in large part to include Variable Energy Resource plants (discussed in more detail below). The second posting of standard MOD-026-1 Verification of Models and Data for Generator Excitation Control System Functions was developed with consideration of industry response to questions that were posed as part of the Comment Form accompanying the first posting. This posting also includes the initial posting of standard MOD-027-1. Note for the same reason discussed for standard MOD-026-1, standard MOD-027-1 has been re-titled from “Verification of Generator Unit Frequency Response” to “Verification of Models and Data for Turbine/Governor and Load Control or Active Power/Frequency Control Functions”. While there are a few differences between standards MOD-026-1 and MOD-027-1 as detailed below, there are also many similarities. The two standards are similar in both substance and style.

Standard MOD-027-1:

There are many similarities between standards MOD-026-1 and MOD-027-1 since both address verification of dynamic models of critical generation control functionality. These similarities are:

1) Based on industry feedback and consultation with the NERC Functional Model Working Group (FMWG), the Generator Owner was identified as the appropriate entity to assign dynamic model verification responsibility. It is up to the Generator Owner and Generator Operator to define contractual arrangements needed to comply with requirements of these standards.
2) As a baseline, the SDT recognized that the excitation system models and model data are already collected through the processes identified in standards MOD-012 and MOD-013. This information, with few exceptions, already establishes a quality dynamics database. However, as confirmed through field testing, performing verification activities specified in the draft standard will improve the accuracy of exciter models used in dynamic simulation which are used to determine transmission security limits. Therefore, both standard drafts propose an identical base Applicability requiring verification of the dynamic models associated with 80% or greater of the connected MVA per Interconnection.
3) The majority of industry agreed with the standard MOD-026-1 5% capacity factor threshold for dynamic model verification. This same threshold is proposed in this current draft of standard MOD-027-1.
4) Both draft standards contain the philosophy of allowing excitation control system verification for a single unit to satisfy compliance for other units if certain conditions are met (such as having the same MVA rating, having identical applicable components and settings, and being sited at the same physical location).
5) Based on an industry comments from the first posting of MOD-026-1 and technical justification regarding the nameplate MVA of steam units for existing Combined Cycle plant technology, the proposed threshold MVA nameplate rating is ≤350 MVA in both standards.
6) Both draft standards contain a standalone Periodicity Table. The Periodicity Table provides the base ten year applicability timeframe for collecting data needed to perform verification (note: standard MOD-027 exceptions may apply as discussed below). The Periodicity Table also addresses scenarios which could require additional testing and subsequent model re-verification. The Periodicity Table will enable Generator Owners to quickly determine required retest dates for model verification.
7) Both draft standards have similar phase in periods that includes allowances for verification performed using Regional procedures that are applicable for the first 10 year period.

Differences also exist between MOD-026-1 and MOD-027-1:

1) The implementation plan for standard MOD-027-1 is structured to recognize that Generator Owners will either need to install equipment to record the real power output of units during an appropriate frequency excursion or modify the existing recording equipment (such as frequency triggers, recording time, etc.). The proposed implementation plan specifies compliance with R2 at intervals of 25% of applicable units per Interconnection on a MVA basis three years after the effective date, 50% at five years, 75% at seven years, and 100% at nine years. Compliance with R2 as per the Periodicity Table (Table 1), means that beginning on the implementation date, the Generator Owner has 10 years to obtain an appropriate recorded response, and 2 years after obtaining the appropriate recorded response to verify the model (see Item 4 below that discusses exceptions to the aforementioned timeframe).

2) Like the draft standard for verification of excitation control system models, this draft standard allows for both staged tests and for ambient monitoring. However, the SDT expects that the majority of turbine/governor and load control functions will be verified through ambient monitoring. To ensure the impact of outer loop controls is captured and replicated in the model, the standard allows staged tests where a frequency reference change is applied if the unit is on-line. This type of test is not common. Many units do not have a frequency reference change input where such a signal can be applied. Therefore, the SDT recognized that the Generator Owner's opportunity to verify that the predicted model response matches the recorded response for an appropriate system frequency excursion will often be dependent on its unit being on-line and in an operating state to respond to the system frequency excursion when it occurs. The basis for this strategy is:

    a. Large economical units have a higher probability of being on-line in a proper operating state to experience a frequency excursion requiring model verification.
    b. Units which are not on-line or not in a proper operating state will not help arrest the frequency excursion. Even if this is not the case, it is better to experience an event for model verification as opposed to relying on a survey that may be inaccurate.

3) In the current draft of MOD-026, the Generator Owner has one year from the capture of a voltage excursion to verify the excitation control system model. This timeframe is based on the SDT's belief that the majority of exciters will be verified using a staged test; and if ambient monitoring is utilized, there will be frequent naturally occurring transmission system voltage excursions. Since the SDT anticipates that the majority of the units' turbine/governor and load control models will be verified utilizing ambient monitoring, it is recognized that it is appropriate to give the Generator Owner time to retrieve captured data. Unlike ambient voltage excursion data needed for excitation control system model verification, the unit must be in an operating state that would allow the unit to respond to the frequency excursion. Also, it is likely that the number of acceptable frequency excursions (from a compliance perspective) will be significantly fewer than the number of acceptable voltage excursions that would occur for model verification. Therefore, the SDT decided to allow the Generator Owner two years for verifying the model. This timeframe allows adequate time

to a) realize the event has occurred while the unit was in the proper operating state, and b) to verify the model. This timeframe will also assist the Generator Owner with planning contractor, budget and schedule support if activities are outsourced.

4) A unit has to be on-line and in the proper operating state during a frequency excursion in order to capture an effective real power response for model verification. Therefore, the standard provides time for the Generator Owner to capture and record a response requiring verification, even if it takes longer than ten years to do so. This language, which is contained in the Periodicity Table, is specifically crafted so that extension of the ten year periodicity cycle will only happen if a frequency excursion does not occur with the unit on-line and in the proper operating state. Therefore, the lack of installed and operating recording equipment during a frequency excursion is not a valid excuse for obtaining a ten year timeframe extension.

5) Industry experience has shown that a unit's real power response to a system frequency excursion could be different from one event to the next. Reasons include different unit load levels, prime mover control conditions, operator control mode, and magnitude of the frequency deviation. By contrast, excitation control system responses to system voltage excursions are much more consistent. Therefore, the main model verification requirement (R2 Part 2.1.1) calls for the turbine/governor and load control model to be "compared to" the recorded response of actual equipment whereas in standard MOD-026-1, the wording is "matches".

6) In standard MOD-026-1 R3, there is a process where a Transmission Planner can make a written request, including evidence that the excitation control system (or plant volt/var) model response did not match an actual recorded response, to the Generator Owner which essentially requires the Generator Owner to review the model. While there is similar language in standard MOD-027-1 R3, there is the additional stipulation that the Transmission Planner must include supporting evidence of instances where model response did not match an actual recorded response. The reason for this is that the governor response is not consistent enough from one frequency excursion event to the next for several reasons, such as the operating condition of the plant, ambient temperature, the number of coal pulverizes on line, the pre-contingency MW output of the unit, etc. In fact, while the fundamental requirement for verifying the model once every ten years can be satisfied by taking into account only a single frequency excursion, it is strongly recommended that model verification be performed taking into account multiple frequency excursions (if available and assuming the unit was in a proper operating state as required for model verification).

7) The activity specified in Requirement R4 is similar to draft standard MOD-026-1 Requirement, R4 which lists the evidence of compliance that the Generator Owner must maintain whenever certain activities occur that alter the equipment response; resulting in providing either revised model data or re-verifying the model. Unlike excitation control systems, there are many control parameters associated with the turbine/governor and load control system which will not impact equipment performance that is required to be replicated in the dynamic model. Thus, standard MOD-027-1 Requirement R4 is specifically crafted to only include setting changes for droop, and/or dead band, and/or load control mode.

Since it is likely that many Generator Owners will rely on the expertise of consultants to make the determination of how modifications to droop, dead band, and/or load control mode translate into modified model parameter values, a time period of 180 days is proposed.

8) In MOD-026-1, the SDT is proposing a process where the Planning Coordinator can request a review of an excitation control system model for a unit not specified in the standard Applicability section. The new MOD-026-1 Requirement (R5) was added in response to industry comments. It requires the Planning Coordinator to supply technical justification that demonstrates either a) the unit affects a stability limit, or b) the simulated unit response does not match a measured unit response (most likely captured during a system disturbance event). However, this process is not being proposed for MOD-027-1. It is extremely unlikely that the turbine/governor and load control or active power/frequency control system will contribute to a stability limit. Also, as already discussed (Item 6), governor response is not consistent from one frequency excursion event to the next. Therefore, the SDT did not feel that such a Requirement in MOD-027-1 was necessary.

9) There is no need for the Transmission Planner to provide the generator MVA base when providing models for turbine/governor and load control or active power/frequency control systems. The MVA base associated with the generator model is already required to be provided per Requirement R1 of standard MOD-026. The MW base information is reflective of turbine capability and is provided as one of the turbine/governor and load control model data parameters specified. The MW base information, depending on the dynamic simulation software provider model requirements, will either be in the form of an actual MW value or a per unit MW value; with the base being the MVA value that is used in the generator steady state model.

10) The Generation Verification SDT is closely following and coordinating with the Frequency Response SDT. It is hoped that the Frequency Response SDT will create a process where frequency excursions meeting certain criteria for each Interconnection are captured. However, though the Frequency Response SDT has discussed this concept and is investigating the use of a tool to help facilitate the identification of appropriate frequency excursions, the process is still evolving. As an interim step, the Generation Verification SDT has included minimum frequency excursion thresholds in the Periodicity Table for each Interconnection that a) are large enough to be expected to exercise turbine/governor and load control functions for the purpose of model verification and b) would be expected to occur 15 times a year or more. If by chance a process identifying frequency excursions that can be utilized in support of standard MOD-027-1 requirements is not developed by the Frequency Response SDT, then such a process will have to be proposed for future revision to standard MOD-027-1 by the Generation Verification SDT.

Compliance Elements for MOD-027-1:

The SDT added Compliance Elements to the second posting of the standard. The VRF for Requirement, R1-R5 are all designated as low risk. All of these Requirements provide for an update of dynamic modeling data for an existing unit. Violation of these requirements would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system, which is consistent with the low risk level guidelines.

The VSL for R2 was selected using the metric of “Requirements with Parts that Contribute Equally to the Requirement”. All of the items listed in Requirement R2 are required for successful model verification. The remaining VSLs were selected using the metric of “Increments for Tardiness”. The Requirements cover activities that are not typical such as peer reviews and instances where there is concern that the model does not reliably reflect actual equipment performance. As such, timeliness of communications is paramount.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. The Applicability section of MOD-027 standard is expanded to include plants/facilities comprised of multiple small units such as variable energy resource plants/facilities. Are you aware of other generation configurations/types that should be covered in the Applicability?

   ☐ Yes

   ☐ No

   Comments:

2. Because it is not likely that the turbine/governor and load control or active power/frequency control system will contribute to a stability limit, and because governor response is not consistent from one frequency excursion event to the next, the SDT is not proposing a Requirement in MOD-027-1 where the Planning Coordinator can request a review of a turbine/governor and load control or active power/frequency control system model for a unit not specified in the standard Applicability section.

   Do you agree with the proposal to not include a Requirement in MOD-027-1 where the Planning Coordinator can request a review of a turbine/governor and load control or active power/frequency control system model for a unit not specified in the standard Applicability section?

   ☐ Yes

   ☐ No

   Comments:

3. The SDT discussed if MOD-027-1 should also include verification of excitation control systems of synchronous condensers. Synchronous condensers are not currently addressed in the NERC Registry Criteria. Synchronous condensers are not mentioned in the Generation Verification SAR. On an MVA capacity basis, the penetration of synchronous condensers in North America is extremely low. It is common for Transmission Owners to be the owners of synchronous condensers. As such, the peer review draft requirements would not make sense. Therefore, the team decided that a more appropriate strategy would be to include synchronous condensers with other transmission system dynamic reactive devices (such as SVCs, STATCOMs, etc.) in a separate SAR.

   Do you agree with the proposal to not include the verification of synchronous condensers in MOD-027-1?

   ☐ Yes

   ☐ No

   Comments:

4. Are you aware of any regional variances that would be required as a result of MOD-027-1? If yes, please identify the regional variance.

☐ Yes

☐ No

Comments:

5. Are you aware of any conflicts between the proposed MOD-027-1 and any regulatory function, rule, order, tariff, rate schedule, legislative requirement, or agreement?

   ☐ Yes

   ☐ No

   Comments:

6. Do you have any other questions or concerns with the proposed standards that have not been addressed? If yes, please explain.

   ☐ Yes

   ☐ No

Unofficial Comment Form for Generator Verification (Project 2007-09)

Please **DO NOT** use this form to submit comments. Please use the electronic comment form located at the link below to submit comments on the First Posting of PRC-019-1, Coordination of Generating Unit/Facility Voltage Regulating Controls with Generating Unit/Facility Capabilities and Protection (Project 2007-09). The electronic comment form must be completed by **July 15, 2011.**

Project 2007-09 Generator Verification

If you have questions please contact Stephen Crutchfield at Stephen.Crutchfield@nerc.net or by telephone at 609-651-9455.

Background Information

The purpose of Project 2007-09 Generator Verification is:

- To ensure that generators will not trip off-line during specified voltage and frequency excursions or as a result of improper coordination between generator protective relays and generator voltage regulator controls and limit functions (such coordination will include the generating unit's capabilities).

- To ensure that generator models accurately reflect the generator's capabilities and operating characteristics.

The standard drafting team (SDT) for Project 2007-09 Generator Verification based its work on two existing NERC Board approved standards:

- MOD-024-1 — Verification of Generator Gross and Net Real Power Capability.

- MOD-025-1 — Verification of Generator Gross and Net Reactive Power Capability.

And four draft standards developed by the Phase III & IV SDT that were fielded tested by four Regions from mid 2006 through mid 2007.

- PRC-019-1 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection

- PRC-024-1 — Generator Performance During Frequency and Voltage Excursions

- MOD-026-1 —Verification of Models and Data for Generator Excitation Control System Functions

- MOD-027-1 — Verification of Generator Unit Frequency Response

This is the first posting of standard PRC-019-1, Coordination of Generating Unit or Plant Voltage Regulating Controls with Generating Unit or Plant Capabilities and Protection. The SAR instructs that the draft standard PRC-019-1:

☐ Revise the purpose statement to include the reliability-related benefit of the standard.

- ☐ Provide more details to the applicability section of the standard to identify any generators that should be exempt from compliance with the requirements in the standard.
- ☐ Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of ‘continent-wide’ criteria for verification that generator voltage regulator controls and limit functions are coordinated with the generator’s capabilities and protective relays.
- ☐ Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the Regional Reliability Organization.
- ☐ Add a ‘violation risk factor’ and a ‘time horizon’ for each requirement (later).
- ☐ Update all the compliance sections of the standard, including:
  - Update the compliance monitoring section to clarify that the Regional Entity will be the compliance monitor for the Generator Owner.
  - Replace the ‘levels of non-compliance’ with ‘violation severity levels’ (later).

This draft standard was developed after reviewing the applicable FERC order, the results of field testing, and in accordance with the Generator Verification SAR. A standard PRC-019 sub-team developed an initial draft framework and then completed the details of the standard and reviewed the requirements and proposals with the full Generator Verification SDT.

The purpose of this standard is to improve the reliability of the Bulk Electric System by preventing tripping of generating units/facilities due to mis-coordination of generating unit/facility voltage regulating controls and limit functions with generator capabilities and protection system settings. The activities required by this standard are also important and complementary for a generating unit or facility to meet the reactive power capability testing requirements of the proposed standard MOD-025. The SDT considered combining the two standards, but ultimately decided that the coordination of controls, limits and protective functions, while linked to reactive testing, has a distinct reliability purpose that is different than MOD-025. The coordination to prevent tripping is clearly a different reliability purpose than the testing of reactive power capability for modeling verification.

Applicability:

The Generator Owner is the functional entity that has responsibility for performing the evaluations required in this Standard for its registered generating equipment (including synchronous generators and non-synchronous generating equipment that incorporates voltage control at the unit or facility level). Transmission Owners who own synchronous condensers ≥ 50 MVA are responsible for performing the evaluations required in this Standard for such equipment. The intent of the Applicability section is to capture all equipment that is required to meet the reactive power capability verification requirements.

Implementation:

The SDT believes this standard will be used by the Generator Owner/Transmission Owner in conjunction with (or as a preliminary task to) reactive power capability testing (standard MOD-025-2), and has aligned the (Proposed) Effective Dates of this standard to those of standard MOD-025-2. The proposed effective dates provide a “phased-in” approach to establishing compliance with this standard to provide adequate time for entities to include all applicable units/facilities.

Requirements and Measures:

Requirement R1 defines the obligation to perform an evaluation of the coordination of generating unit or facility voltage control limiters with associated protective functions and equipment capabilities. The evaluation is to consider operation under steady state and normal AVR control loop conditions.

The requirement describes this coordination to entail the following aspects:

A) Determine settings are correctly sequenced to ensure that the limiters are set to operate before the protection and the protection is set to operate before conditions exceed equipment capabilities, including the steady state stability limit when operating within the normal AVR control loop and under steady state operating conditions.
B) Check that the settings as determined in Step A are applied to the in-service equipment.

Examples of diagrams and the equipment capabilities, voltage control limiters, and protective function characteristics that demonstrate coordination are included in Section G, “Reference – Examples of Coordination.”

The standard does not require the installation or activation of any of the aforementioned limiters or protective functions.

Requirement R2 defines the obligation to review the evaluation performed in R1 at least once every five years, or within 90 days of making a change to the generating equipment, voltage control limiter settings, or protective function settings that would affect the coordination. The periodicity was set to correlate with the periodicity of verification of reactive power capability defined in Standard MOD-025.

You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that the standard, as written, is "technology neutral" such that it can be used for all forms of generation connected to the BES? If you do not agree, please state your reasons and suggest alternatives to make the standard technology neutral in the Comment area.

   ☐ Yes

   ☐ No

   Comments:

2. The SDT applied the requirements of this standard to the functional entities Generator Owner, and Transmission Owners that own synchronous condensers rated ≥ 50 MVA. The standard applies to generating units/facilities that meet the compliance registry criteria and to synchronous condensers rated 50MVA and greater. Do you agree with this Applicability? If not, please provide an alternative and supporting information in the Comment section.

   ☐ Yes

   ☐ No

   Comments:

3. As currently drafted this standard applies to synchronous generators, synchronous condensers, and variable static reactive resources located at asynchronous generating facilities (e.g. wind and solar sites). Do you see a reliability need for including variable static reactive resources (e.g. static VAr compensators) that are not located at generating sites in this standard? Please explain your answer in the Comments block.

   ☐ Yes

   ☐ No

   Comments:

4. The SDT revised the Purpose of the standard in accordance with the SAR. "To improve the reliability of the Bulk Electric System by preventing tripping of generating units/facilities due to mis-coordination of generating unit/facility voltage regulating controls and limit functions with generator capabilities and protection system settings."

   Do you agree with the revised Purpose of the standard? If not, please provide suggested language changes in the Comment section.

   ☐ Yes

   ☐ No

   Comments:

5. The proposed effective dates provide a "phased-in" approach to establishing compliance with this standard to provide adequate time for entities to include all applicable units/facilities. Do you agree with the proposed implementation schedule? If not,

please provide an alternative implementation schedule, approach and supporting information in the comments.

☐ Yes

☐ No

Comments:

6. Do you agree that the evidence documents and functions listed in Section G are sufficient for giving the Generator Owner/Transmission Owner examples of how the coordination can be demonstrated? If not, please provide suggested language changes to the Measure and supporting information in the Comment section.

☐ Yes

☐ No

Comments:

7. Do you agree with the Data Retention language listed in the Compliance section of the draft standard? If not please comment and provide alternative Data Retention language.

☐ Yes

☐ No

Comments:

8. Are you aware of the need for any regional variances to this standard? If yes, please explain in the comment section.

☐ Yes

☐ No

Comments:

9. Do you have any other questions or concerns with the proposed standard that have not been addressed? If yes, please explain in the comment section.

☐ Yes

☐ No

Comments:

A. Introduction

1. **Title:** **Verification of Generator Gross and Net Real Power Capability**

2. **Number:** MOD-024-1

3. **Purpose:** To ensure accurate information on generator gross and net Real Power capability is available for steady-state models used to assess Bulk Electric System reliability.

4. **Applicability**

   4.1. Regional Reliability Organization.

   4.2. Generator Owner.

5. **Effective Dates:**

   Requirement 1 and Requirement 2 **—** April 1, 2006.

   Requirement 3 — January 1, 2007.

B. Requirements

R1. The Regional Reliability Organization shall establish and maintain procedures to address verification of generator gross and net Real Power capability. These procedures shall include the following:

- **R1.1.** Generating unit exemption criteria including documentation of those units that are exempt from a portion or all of these procedures.
- **R1.2.** Criteria for reporting generating unit auxiliary loads.
- **R1.3.** Acceptable methods for model and data verification, including any applicable conditions under which the data should be verified. Such methods can include use of manufacturer data, commissioning data, performance tracking, and testing, etc.
- **R1.4.** Periodicity and schedule of model and data verification and reporting.
- **R1.5.** Information to be verified and reported:
  - **R1.5.1.** Seasonal gross and net Real Power generating capabilities.
  - **R1.5.2.** Real power requirements of auxiliary loads.
  - **R1.5.3.** Method of verification, including date and conditions.

R2. The Regional Reliability Organization shall provide its generator gross and net Real Power capability verification and reporting procedures, and any changes to those procedures, to the Generator Owners, Generator Operators, Transmission Operators, Planning Authorities, and Transmission Planners affected by the procedure within 30 calendar days of the approval.

R3. The Generator Owner shall follow its Regional Reliability Organization's procedures for verifying and reporting its gross and net Real Power generating capability per R1.

C. Measures

M1. The Regional Reliability Organization shall have available for inspection the procedures for the verification and reporting of generator gross and net Real Power capability in accordance with R1.

M2. The Regional Reliability Organization shall have evidence that its procedures, and any revisions to those procedures, for verification and reporting of generator gross and net Real Power capability were provided to affected Generator Owners, Generator Operators,

Transmission Operators, Planning Authorities, and Transmission Planners within 30 calendar days of approval.

M3. The Generator Owner shall have evidence it provided verified information of its generator gross and net Real Power capability, consistent with that Regional Reliability Organization's procedures.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

For Regional Reliability Organization: NERC

For Generator Owner: Regional Reliability Organization.

1.2. Compliance Monitoring Period and Reset Time Frame

One calendar year.

1.3. Data Retention

The Regional Reliability Organization shall retain both the current and previous versions of the procedures.

The Generator Owner shall retain information from the most current and prior verification.

The Compliance Monitor shall retain any audit data for three years.

1.4. Additional Compliance Information

The Regional Reliability Organization and Generator Owner shall each demonstrate compliance through self-certification or audit (periodic, as part of targeted monitoring or initiated by complaint or event), as determined by the Compliance Monitor.

2. Levels of Non-Compliance for Regional Reliability Organization:

2.1. Level 1: There shall be a level one non-compliance if either of the following conditions is present:

2.1.1 Procedures did not meet one of the following requirements: R1.1, R1.2, R1.4

2.1.2 No evidence that procedures were distributed as required in R2.

2.2. Level 2: There shall be a level two non-compliance if **both** of the following conditions are present:

2.2.1 Procedures did not meet two of the following requirements: R1.1, R1.2, R1.4

2.2.2 No evidence that procedures were distributed as required in R2.

2.3. Level 3: Procedures did not meet R1.3.

2.4. Level 4: Procedures did not meet either R1.5.1, R1.5.2 or R1.5.3

3. Levels of Non-Compliance for Generator Owner:

3.1. Level 1: Complete, verified generator data were provided for 98% or more but less than 100% of a generator owner's units as required by the regional procedures.

3.2. Level 2: Complete, verified generator data were provided for than 96% or more, but less than 98% of a generator owner’s units as required by the regional procedures.

3.3. Level 3: Complete, verified generator data were provided for 94% or more, but less than 96% of a generator owner’s units as required by the regional procedures.

3.4. Level 4: Complete, verified generator data were provided for less than 94% of a generator owner’s units as required by the regional procedures.

E. Regional Differences

None identified.

Lower cased all instances of “regional” in section D.3. 8. Removed the word “less” after 94% in section 3.4. Level 4.	01/20/06

A. Introduction

1. **Title:** **Verification of Generator Gross and Net Reactive Power Capability**

2. **Number:** MOD-025-1

3. **Purpose:** To ensure accurate information on generator gross and net Reactive Power capability is available for steady-state models used to assess Bulk Electric System reliability.

4. **Applicability**

   4.1. Regional Reliability Organization.

   4.2. Generator Owner.

5. **Effective Dates:**

   Requirement 1 and Requirement 2 — January 1, 2007

   Requirement 3:

   January 1, 2008 — 1st 20% compliant

   January 1, 2009 — 2nd 20% compliant

   January 1, 2010 — 3rd 20% compliant

   January 1, 2011 — 4th 20% compliant

   January 1, 2012 — 5th 20% compliant

B. Requirements

R1. The Regional Reliability Organization shall establish and maintain procedures to address verification of generator gross and net Reactive Power capability. These procedures shall include the following:

R1.1. Generating unit exemption criteria including documentation of those units that are exempt from a portion or all of these procedures.

R1.2. Criteria for reporting generating unit auxiliary loads.

R1.3. Acceptable methods for model and data verification, including any applicable conditions under which the data should be verified. Such methods can include use of commissioning data, performance tracking, engineering analysis, testing, etc.

R1.4. Periodicity and schedule of model and data verification and reporting.

R1.5. Information to be reported:

R1.5.1. Verified maximum gross and net Reactive Power capability (both lagging and leading) at Seasonal Real Power generating capabilities as reported in accordance with Reliability Standard MOD-024 Requirement 1.5.1.

R1.5.2. Verified Reactive Power limitations, such as generator terminal voltage limitations, shorted rotor turns, etc.

R1.5.3. Verified Reactive Power of auxiliary loads.

R1.5.4. Method of verification, including date and conditions.

R2. The Regional Reliability Organization shall provide its generator gross and net Reactive Power capability verification and reporting procedures, and any changes to those procedures, to the

Generator Owners, Generator Operators, Transmission Operators, Planning Authorities, and Transmission Planners affected by the procedure within 30 calendar days of the approval.

R3. The Generator Owner shall follow its Regional Reliability Organization's procedures for verifying and reporting its gross and net Reactive Power generating capability per R1.

C. Measures

M1. The Regional Reliability Organization shall have available for inspection the procedures for the verification and reporting of generator gross and net Reactive Power capability in accordance with R1.

M2. The Regional Reliability Organization shall have evidence that its procedures, and any revisions to these procedures, for verification and reporting of generator gross and net Reactive Power capability were provided to affected Generator Owners, Generator Operators, Transmission Operators, Planning Authorities, and Transmission Planners within 30 calendar days of approval.

M3. The Generator Owner shall have evidence it provided verified information of its generator gross and net Reactive Power capability, consistent with that Regional Reliability Organization's procedures.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

For Regional Reliability Organization: NERC.

For Generator Owner: Regional Reliability Organization.

1.2. Compliance Monitoring Period and Reset Timeframe

One calendar year.

1.3. Data Retention

The Regional Reliability Organization shall retain both the current and previous version of the procedures.

The Generator Owner shall retain information from the most current and prior verification.

The Compliance Monitor shall retain any audit data for three years.

1.4. Additional Compliance Information

The Regional Reliability Organization and Generator Owner shall each demonstrate compliance through self-certification or audit (periodic, as part of targeted monitoring or initiated by complaint or event), as determined by the Compliance Monitor.

2. Levels of Non-Compliance for Regional Reliability Organization:

2.1. Level 1: There shall be a level one non-compliance if either of the following conditions is present:

2.1.1 Procedures did not meet one of the following requirements: R1.1, R1.2 or R1.4.

2.1.2 No evidence that procedures were distributed as required in R2.

2.2. Level 2: Procedures did not meet two or three of the following requirements: R1.1, R1.2 or R1.4.

2.3. Level 3: Procedures did not meet R1.3.

2.4. Level 4: Procedures did not meet R1.5.1, R1.5.2, R1.5.3, or R1.5.4.

3. Levels of Non-Compliance for Generator Owner:

3.1. Level 1: Complete, verified generator data were provided for 98% or more but less than 100% of a Generator Owner's units as required by the regional procedures.

3.2. Level 2: Complete, verified generator data were provided for than 96% or more, but less than 98% of a Generator Owner's units as required by the regional procedures.

3.3. Level 3: Complete, verified generator data were provided for 94% or more, but less than 96% of a Generator Owner's units as required by the regional procedures.

3.4. Level 4: Complete, verified generator data were provided for less than 94% less of a Generator Owner's units as required by the regional procedures.

E. Regional Differences

None identified.

These requirements are detailed in the following mapping.
R1.1. Generating unit exemption criteria including documentation of those units that are exempt from a portion or all of these procedures.	Exemption criteria are addressed by Section 4.2, **Applicability,** which follows the Registry Criteria.	**4. Applicability:** **4.1 Functional entities** 4.1.1 Generator Owner 4.1.2 Transmission Owner **4.2 Facilities:** 4.2.1 Individual generating unit or synchronous condenser greater than 20 MVA (gross nameplate rating) in a generating Facility connected at the point of interconnection at 100 kV or above. 4.2.2 Generating plant/Facility greater than 75 MVA (gross aggregate nameplate rating) and connected at the point of interconnection at 100 kV or above. 4.2.3 Blackstart units, regardless of size that are included in a Transmission Operator’s restoration plan.
R1.2. Criteria for reporting generating	**R1** references **Attachment**	**R1.** Each Generator Owner shall: [Violation Risk Factor: Lower] [Time

Standard MOD-025-1 NERC Board Approved	Comment	Proposed Standard MOD-025-2
unit auxiliary loads.	**1.** **Attachment 1**, Section 4 refers to Attachment 2, which is a reporting form or the basis for developing a more specialized form that provides all the auxiliary information required by the Standard. **Attachment 1,** section 4.1 allows engineering estimates in those situations where metering to measure a reactive load is not installed.	Horizon: Long-term Planning] **R1.1.** Verify the Real and Reactive Power capability of its generating units and shall verify the Reactive Power capability of its synchronous condenser units in accordance with Attachment 1. **R1.2.** Record the information on Attachment 2 (or on the Generator Owner's form that contains the same information as Attachment 2); **R1.3.** Submit within 90 calendar days of the date the data is recorded to its Planning Coordinator.
R1.3. Acceptable methods for model and data verification, including any applicable conditions under which the data should be verified. Such methods can include use of manufacturer data, commissioning data, performance tracking, and testing, etc.	**Requirements R1, and R2,** reference **Attachment 1.** Section 2 of **Attachment 1** prescribes the details of how the verification should be performed.	**R1.** Each Generator Owner shall: [Violation Risk Factor: Lower] [Time Horizon: Long-term Planning] **R1.1.** Verify the Real and Reactive Power capability of its generating units and shall verify the Reactive Power capability of its synchronous condenser units in accordance with Attachment 1. **R1.2.** Record the information on Attachment 2 (or on the Generator Owner's form that contains the same information as Attachment 2); **R1.3.** Submit within 90 calendar days of the date the data is recorded to its Planning Coordinator. **R2.** Each Transmission Owner shall: [Violation Risk Factor: Lower] [Time Horizon: Long-term Planning] **R2.1.** Verify the Reactive Power capability of its synchronous

Standards Announcement

Project 2007-09 Generator Verification
Two Initial Ballots and
Two Non-Binding Polls of VRFs and VSLs
Ballot Windows Open July 22 through August 1, 2011

Now available at: https://standards.nerc.net/CurrentBallots.aspx

Initial ballots of two standards, MOD-026-1 – Verification of Models and Data for Generator Excitation System Functions, and PRC-024-1– Generator Performance During Frequency & Voltage Excursions, and concurrent, non-binding polls of the associated VRFs and VSLs are open Friday, July 22, 2011 through **8 p.m. Eastern on Monday, August 1, 2011**.

Clean versions of the standards and associated implementation plans, along with redlines showing changes made since the last posting, have been posted at the project webpage at: http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html.

Instructions for Casting Ballots and Opinions in Non-binding Polls

Members of the ballot pool associated with this project may log in and submit their votes for each standard and each non-binding poll of VRFs and VSLs (a total of four separate votes) from the following page: https://standards.nerc.net/CurrentBallots.aspx.

Special Instructions for Submitting Comments with a Ballot

Comments submitted with ballots are extremely valuable to help the drafting team revise its work. In an effort to reduce the burden on stakeholders providing comments, the drafting requests that all comments (both those submitted with a ballot and those submitted by stakeholders not balloting) be submitted through the electronic comment form. This will ensure that stakeholders only provide a single set of comments, but have an opportunity to notify the drafting team if they have provided comments.

When submitting a ballot with comments, submit the comments through the electronic form and then simply record a "comments submitted" in the comments field of the ballot to indicate that comments were submitted.

Please note that comments submitted during the formal comment period, the ballot for the standard, and the non-binding poll for the VRFs and VSLs all use the same electronic form, and it is NOT necessary for ballot pool members to submit more than one set of comments (one during the comment period; a second with a ballot; a third with a non-binding poll).

Next Steps
The drafting team will consider all comments received, and decide whether to make additional revisions to the standards.

Background
The purpose of Project 2007-09 - Generator Verification is to ensure that: 1) generators will not trip off-line during specified voltage and frequency excursions or as a result of improper coordination between generator protective relays and generator voltage regulator controls and limit functions (such coordination will include the generating unit's capabilities); and 2) that generator models accurately reflect the generator's capabilities and operating characteristics.

The standard drafting team (SDT) for Project 2007-09 Generator Verification based its work on two existing NERC Board approved standards, MOD-024-1 — Verification of Generator Gross and Net Real Power Capability and MOD-025-1 — Verification of Generator Gross and Net Reactive Power Capability. The drafting team has recently moved the Requirements of MOD-024-1 into MOD-025-2 and recommends retiring MOD-024-1.

The drafting team has also based its work on four draft standards developed by the Phase III & IV SDT that were field tested by four Regions from mid 2006 through mid 2007:

- PRC-019-1 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection
- PRC-024-1 — Generator Performance During Frequency and Voltage Excursions
- MOD-026-1 —Verification of Models and Data for Generator Excitation Control System Functions
- MOD-027-1 — Verification of Generator Unit Frequency Response

Additional details are available on the project web page at: http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html.

For more information or assistance, please contact Monica Benson,
Standards Process Administrator, at monica.benson@nerc.net or at 404-446-2560.

Standards Announcement

Project 2007-09 Generator Verification
Ballot Pool Windows Open: June 15 – July 15, 2011
Formal Comment Period Open (Two Standards): June 15 – August 1, 2011
Formal Comment Period Open (Three Standards): June 15 – July 15, 2011

Now available at: http://www.nerc.com/filez/standards/http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html

The Generator Verification standard drafting team has posted five standards and their associated implementation plans for a formal comment period. Please read the following announcement carefully, because although the five standards are being posted together they are at different stages in the standards process and in order to facilitate moving forward those standards that reach consensus, the standards are being processed independently.

1. MOD-026-1 and PRC-024-1 Formal Comment Period and Ballot Pool Formation

Two of the standards, MOD-026-1 – Verification of Models and Data for Generator Excitation System Functions, and PRC-024-1– Generator Frequency and Voltage Protective Relay Settings, are posted for a 45-day formal comment period through August 1, 2011. A ballot and non-binding poll of the associated VRFs and VSLs will be conducted for MOD-026-1 and PRC-024-1 beginning on July 22, 2011. Please note that **separate ballot pools are being formed for each standard and non-binding poll**, and the window to join the ballot pool for each standard and each non-binding poll is open through July 15, 2011.

Ballot Pools Open through 8 a.m. EST on July 15, 2011 for MOD-026-1 and PRC-024-1 Ballots and Non-binding Polls

The Standards Committee has authorized posting these standards and their associated implementation plans for a 45-day formal comment period with an initial ballot and concurrent non-binding poll conducted during the last 10 days of that comment period. A separate ballot pool is being formed for each standard and for each non-binding poll in order to allow Registered Ballot Body members to selectively join those ballot pools in which they have an interest. To register an opinion in the non-binding poll for either standard, you must join the ballot poll for that non-binding poll. Each of the four ballot pools will be open through 8 a.m. EST on July 15, 2011.

Instructions for Joining Ballot Pools for MOD-026-1 and PRC-024-1 Ballots and Non-binding Polls

Registered Ballot Body members may join each of the ballot pools to be eligible to vote in the upcoming ballots and non-binding polls at the following page: https://standards.nerc.net/BallotPool.aspx

During the pre-ballot window, members of the ballot pool may communicate with one another by using their "ballot pool list server." (Once the balloting begins, ballot pool members are prohibited from using the ballot pool list servers.) The list servers for this project are:

- MOD-026-1 ballot bp-2007-09_MOD-026-1_in@nerc.com
- MOD-026-1 non-binding poll bp-2007-09_MOD-026-1_NB_in@nerc.com

- PRC-024-1 ballot bp-2007-09_PRC-024-1_in@nerc.com
- PRC-024-1 non-binding poll bp-2007-09_PRC-024-1_NB_in@nerc.com

Instructions for Commenting

Please use this electronic form to submit comments on MOD-026-1 and PRC-024-1. If you experience any difficulties in using the electronic form, please contact Monica Benson at monica.benson@nerc.net. An off-line, unofficial copy of the comment form is posted on the project page: http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html.

2. MOD-025-2, MOD-027-1, and PRC-019-1 Formal Comment Period

Three additional standards have been posted for a 30-day formal comment period:

- MOD-025-2 – Verification of Generator Gross and Net Reactive Power Capability
- MOD-027-1 – Verification of Models and Data for Turbine/Governor and Load Control or Active Power/Frequency Control Functions
- PRC-019-1 – Coordination of Generating Unit or Plant Voltage Regulating Controls with Generating Unit or Plant Capabilities and Protection

Instructions for Commenting

Please use this electronic form to submit comments on MOD-025-2, MOD-027-1, and PRC-019-1. If you experience any difficulties in using the electronic form, please contact Monica Benson at monica.benson@nerc.net. An off-line, unofficial copy of the comment form is posted on the project page: http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html.

Next Steps

Initial ballots of MOD-026-1 and PRC-024-1, and concurrent non-binding polls of the associated VRFs and VSLs, will begin on July 22, 2011 and end at 8 p.m. Eastern on Monday, August 1, 2011. Following the formal comment period for MOD-025-2, MOD-027-1, and PRC-019-1, the drafting team will consider all comments and determine whether to make changes to the standards, implementation plans, or associated VRFs and VSLs.

Background

The purpose of Project 2007-09 - Generator Verification is to ensure that: 1) generators will not trip off-line during specified voltage and frequency excursions or as a result of improper coordination between generator protective relays and generator voltage regulator controls and limit functions (such coordination will include the generating unit's capabilities); and 2) that generator models accurately reflect the generator's capabilities and operating characteristics.

The standard drafting team (SDT) for Project 2007-09 Generator Verification based its work on two existing NERC Board approved standards, MOD-024-1 — Verification of Generator Gross and Net Real Power Capability and MOD-025-1 — Verification of Generator Gross and Net Reactive Power Capability. The drafting team has recently moved the Requirements of MOD-024-1 into MOD-025-2 and recommends retiring MOD-024-1.

The drafting team has also based its work on four draft standards developed by the Phase III & IV SDT that were field tested by four Regions from mid 2006 through mid 2007:

- PRC-019-1 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection
- PRC-024-1 — Generator Performance During Frequency and Voltage Excursions

- MOD-026-1 —Verification of Models and Data for Generator Excitation Control System Functions
- MOD-027-1 — Verification of Generator Unit Frequency Response

Additional details are available on the project web page at http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html.

Standards Process

The Standard Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

No
Either the Planning Authority of the Transmission Planner are the more likely entity to submit data rather than the Transmission Owner as indicted in R2.3
GO’s typically correct to back pressure. Any other adjustments should be performed by Transmission Operator
No
Blackstart unit testing is covered in he EOP standards, and should not be included in the MOD standards. Most of these are smaller units that don’t have much impact on the BES but are important because they are blackstart—not for the VARs.
The addition of the lagging and leading at (2); the expected minimum Real Power output are new points to test from the existing version of MOD-025. This will eventually double the testing window (at a minimum)
Group
Northeast Power Coordinating Council
Guy Zito
Yes

No
The Transmission Operator (TOP) and Transmission Planner (TP) are far more likely to need and use the data and models identified and dispatch the units in their market area. In New York, the NYISO as the TOP is responsible for real-time modeling and dispatch (specifying both real and reactive schedules), and as TP the longer term modeling. The Transmission Owners (TO's) do not have this type of relationship with the Generation Owners (GO's) and Generation Operators (GOP's). R1: A standard should be developed that makes reactive power testing mandatory for all units above 75 MVA. This standard will provide the TOP with critical information on the total dynamic reactive capability of dispatched generation.
Yes
Real and reactive power output is affected by the thermal conditions in effect a t the time of testing and dispatch. The output of a generator, and therefore the model of its output, can be more or less temperature dependent, e.g., a combustion turbine with versus the same combustion turbine without inlet chillers. Attachment 1 specifies that the temperature only be recorded at the end of the verification period. Temperatures can vary significantly over the course of the verification period, and at a minimum the ambient temperatures at the beginning and end of a verification period should be recorded. It would also be meaningful and helpful to record ambient temperatures at intermediate points during a verification period. The Real Power data submitted should not be adjusted to a temperature other than ambient. When collecting real time data, it should be "what you see is what you get"; adjustments should not be accepted.
No
Generally, only units larger 75 MVA are impactful. It is recommended making 75 MVA the reporting floor [regardless of connected voltage]. This is consistent with current draft BES definition being prepared by the BES SDT.
Yes
Yes
No
Regarding Part 2.1, in the NYISO reactive power is tested at a real power level above 90% of maximum. The tariff was designed in this manner for a few reasons: (1) not to be simultaneous test with 100% real power test and (2) provide a reliable maximum reactive test when the unit is stressed, but is still capable of providing reserve power. Recommend providing some flexibility in this requirement by stating that reactive power can be tested above 90% of maximum real power.
Yes
Yes
Yes
Yes
No
No
No
No
No

A Planning Coordinator should be able to request a review of turbine/governor and load control or active power/frequency control system model even though response is not consistent from one frequency excursion event to the next from any unit connected to the power system. If not being listed in the Applicability section is an issue, then the wording should be changed in the Applicability section so as not to preclude the Planning Coordinator from collecting necessary data.
No
Can't generators be operated as synchronous condensers if needed?
No
No
Yes
In the Applicability Section, why the differences between the Eastern Interconnection/Quebec and WECC in generating unit and plant sizes specified?
No
This draft standard appears to have been written from a traditional steam or combustion turbine generator perspective. It may not work for a photovoltaic or wind generator installation.
No
Generally only units larger 75 MVA are impactful. Recommend making 75 MVA the reporting floor [regardless of connected voltage]. This is consistent with the current draft BES definition being prepared by BES SDT.
Yes
Only units larger 75 MVA are generally impactful. We recommend making 75 MVA the reporting floor [regardless of connected voltage]. Coordination will be needed. Static VAR Compensators are typically self protected by the vendor. As long as the interface point (transformer) is properly and redundantly protected and the Static VAR Compensator safely shuts down for internal faults or out of spec operation, there should be minimal need for coordination with transmission system protection. However, this issue would have to be researched with the vendor of the equipment. Coordination with the Transmission Operator will have to be reviewed for pre and post protection system operation conditions.
No
Modify the wording to reflect all 'real and reactive power sources,' not limiting it exclusively to traditional rotating machinery.
Yes
Yes
No
The data retention section of the standard is vague with respect to responsibilities of the various parties. It would appear that the data retention responsibility falls to either the Generator Owner or the Transmission Owner with a synchronous condenser on its system. If, however, the Transmission Owner is also required to retain compliance data of generator and transmission system coordination, a substantial amount of time may be required to gather this information as it does not exist today. At the very least, once this standard becomes effective an effort with generators will be needed to assemble the appropriate information demonstrating the proper coordination of transmission system and generator relaying. This could take a considerable amount of time to complete. Responsibility for data retention should be placed on the owner of the equipment.
No
Yes
Related to the "Examples of Coordination", the P-Q diagram, the R-X diagram, and the Inverse Time Diagram are not all interchangeable. For this Standard only the P-Q Diagram can be used for compliance because it provides both under and over excitation capabilities of the machine. This curve

is commonly used in industry and is readily understood by Engineers, System Operators and Generator Operators. The R-X Diagram example should be considered optional if impedance relays are used that reach beyond the generator-transformer protection zones. However, the R-X Diagram should not be mandatory. Concerning the Inverse Time Diagram, this example should be deleted since it only provides information on machine overexcitation capabilities and does not address underexcitation settings.

Yes
Yes
Yes
THE REAL POWER DATA OBTAINED FROM GENERATORS IS BASED ON AMBIENT TEMPERATURE AND ADDITIONAL ENVIRONMENTAL AND SYSTEMATIC CONDITIONS. BECAUSE OF THIS REASON, OBTAINING A CORRECTION FACTOR CORRESPONDING SOLELY TO THE AMBIENT TEMPERATURE FOR CALCULATION OF THE REAL POWER WILL NOT BE AN EFFECTIVE APPROACH. IN ADDITION, DUE TO SEVERAL PARAMETERS AS A FUNCTION OF THE REAL POWER AND THE TEMPERATURE, CALCULATION OF AN ACCURATE CORRECTON FACTOR WOULD BE SOMEWHAT DIFFICULT AND COSTLY AS IT MAY REQUIRE SEVERAL GENERATOR TESTING.
Yes
Yes
WE BELIEVE THAT FOUR POINTS IS SUBSTANTIAL INFORMATION FOR STRAIGHT LINE APPROXIMATION AS OVER-EXCITED (LAGGING) AND UNDER-EXCITED (LEADING) REACTIVE CAPABILITY AT RATED REAL POWER WOULD SOLELY BE A SUFFICIENT DATA FOR THIS PURPOSE.

How are sister units to be handled? Do they all need to be tested individually. Also, are all the units counted individually when calculating the percent of units in the implementation schedule?
Yes
Yes
Yes
No
There seems to be a mistake on the Implementation Plan versus the Standard. The implementation plan states two years for the first 20% of applicable units and the standard states one year. Please clarify this inconsistency.
Yes
No
No
Yes
In regards to Measure 1 it should be clarified that only the latest coordination review will be needed for the first 5 years after the standard is implemented and only after 10 years will the entity be required to show both latest and prior evidence of compliance for 100 % of the applicable units. As stated, it looks like the standard would require the entity to verify the existence of coordination twice on 20% of the applicable units in the first year to show evidence of a latest and prior coordination for those units. If an entity were to be audited 3 years after the effective date of the standard, they would have to show coordination of 60% of the applicable units and should not be required to show a prior documented coordination since a 5 year interval would place the prior coordination possibly before the effective date of the standard. This would also apply in the situation of a newly built

applicable unit in which there would be no prior evidence available; only the latest.

In the standard the applicability for synchronous condensers is > 20 MVA for an individual unit. Additional language should be added to the standard to address the applicability for generating units/facilities.
Yes
Currently the requirements do not address variable static reactive resources located at asynchronous generating facilities as the question states. If the intent is for the standard to apply to variable static reactive resources located at asynchronous generating facilities, we propose language be added to the standard to address these resources. Yes, we do see a reliability need for including variable static reactive resources (e.g. static VAr compensators) that are not located at generating sites. We propose that language be included to address the limit on the size of these types of facilities.
Yes
No
We would recommend the following implementation schedule: 20% - 2 years after regulatory approval 40% - 3 years after regulatory approval 60% - 4 years after regulatory approval 80% - 5 years after regulatory approval 100% - 6 years after regulatory approval
Yes
Examples for older units, where the information in the current examples are not readily available, could be included.

It is not a matter of whether the requirements for real power verification is in one numbered standard and reactive verification is in another numbered standard, the important point is that the requirements be clear and separate. The posted standard fails that test by combining two requirements into one. It may look cleaner writing the two together; the problem is with the fact that such a format has the potential to needlessly risk getting some data when the other data is NOT available. If an asset owner could provide real data but not reactive data, the standard as written would incent the owner from providing either data (why waste a test when the owner knows it will be non-compliant anyway? By separating the two actions, the owner would be compliant with one and non-compliant with the other requirement – but the planner would have at least half the information.
No
MOD-025 is a requirement on owners to verify data, nowhere does the requirement state who the data goes to. Of course the owner is NOT the appropriate entity to send the data to since they are the ones that are responsible for generating the information. This standard has many issues related to who gets what data and why. There is no requirement to have the data in the first place. The standard would be better to require a planning entity to request the data that that entity needs to do its mandated functions. Once the planner asks for the data, then the owner can provide / verify the information being asked for. The SDT has rejected the comments that other standards already provide this information. The SDT has parsed the terms “capability” and “rating”. However, the NERC Glossary defines Rating as strictly a transmission line term, and the word capability is not defined. Capability does show up within other definitions related to Transfers and other transmission terms.

The SDT is asked to review their findings in light of the above, and in light of the FAC and TOP standards purposes. The TOP standard has developed the flexible approach of having an entity ask for the data it needs, and for the receiver of the request to provide the needed information. This approach eliminates the idea of a common requirement for all planners (whether or not they want the data elements in the posted Attachment 2). Our proposal is to have a requirement (if it does not already exist) mandating entities asks for what they want, and a separate requirement for the receivers to provide just that data. If the revised standard is written in that fashion than the new MOD-025 COULD replace the old MOD-024 because there would be no need to specify reactive data from real data, because the entities who are asking for the data will do that for you. Editorial: (1) The receiving entity cited in this question (Transmission Owner) seems different than the entity indicated in the standard (Transmission Planner). If it is not a typo, then we may be missing something. Regardless, we commented previously (on MOD-024-2) on a related subject in which we indicated that given the purpose of the standard, which now reads: “To ensure that planning entities have accurate generator Real and Reactive Power capability data when assessing Bulk Electric System (BES) reliability”, we believe that the data is used for planning assessments that could entail both resource adequacy and transmission reliability, and may even include short or near-term transmission reliability assessments. In view of the facility ownership and potential users, submitting the data to the Transmission Owner does not seem to be logical from the following standpoints: a. The TO does not own the generators and may not actually use the data at all if it does not perform transmission planning assessments; b. The Transmission Planner is the entity that conducts transmission planning assessments; c. Other planning entities that use this data are the Planning Coordinators and Resource Planners. For the above reasons, a more logical entity to receive this data and be the one that requests for data is made by other entities that have a need for the data such as Transmission Planners, Resource Planners, Reliability Coordinator and Transmission Operator, would be the Planning Coordinator. We suggest to change Transmission Owner to Planning Coordinator. (2) And also in view of the potential use of this data, we suggest the purpose of the standard be reverted back to its previous version: “To ensure accurate information on generator gross and net Real Power capability is available for steady-state models used to assess Bulk Electric System reliability.”, or be revised to: “To ensure that [the word planning removed] entities have accurate generator Real and Reactive Power capability data when assessing Bulk Electric System (BES) reliability”.
No
See comment to Q2. The planner should ask for the data that it needs to comply with NERC standards (nothing more and nothing less). There is no need for the requirement to get into the details. The Planning standards will force the Planner to ask for the data that it needs for its models. This approach limits the Planners from asking for data that they do not use in their Planning Models or that is not needed to comply with a NERC standard. This approach also allows the Planner to tailor its requests to the Models and technologies that it has and needs. (1) We do not support the notion that a Transmission Owner has the technical expertise to adjust a generator’s real power capability to reflect a difference in ambient temperature. If anyone, it should be the Generator Owner. (2) Reporting the ambient temperature is unnecessary since it is only one of the many factors that could affect the real power output of a generator. Adjusting the real power capability for a different ambient temperature does not really provide a more accurate value, and can be misleading. (3) Notwithstanding the concerns expressed above, to make such an adjustment with some degree of accuracy, the responsible entity needs to have the information on that capability which corresponds to the ambient temperature for which the adjustment is to be made. It thus suggests that a capability-temperature curve be first established to provide credible references, implying that the Generator Owners must conduct a series of verification tests under different ambient temperature conditions. This is overly cumbersome, and creates unnecessary burden to the GOs. We suggest that this requirement be removed from Attachment 1.

There is no technical justification provided to support the 50 MVA criterion. Absent this, we propose to use the 20 MVA for generators as a general criterion for synchronous condensers as well.
Yes
No
We have difficulty interpreting the 20% in Item 2 of Attachment 1, which says: “Operational data from within the year prior to the verification date is acceptable for the verification as long as IT (emphasis added) meets the criteria in 2.1 through 2.5 below and is within 20% of the expected value:” We interpret that the “IT” refers to the operational data. As such, we do not understand the “within 20% of the expected value”. Does it mean the generator’s real power output during the period from which operational data was collected must be within 20% of the generator’s declared or name plate capability, or what? We need clarification, and suggest a revision to this Item 2 to provide the clarity. As written, we are unable to comment on the acceptability of the 20%.

Yes
The proposed MOD-025-2 standard appears to violate many conventions, such as: o The use of Attachments for mandating requirements o The combinations of different actions in the same requirement o The mandating of specific formats

Does this SDT really believe a standard will "prevent" trippings due to mis-coordination?

The standard in Sec B-R1.3 and R2.3 state to submit the data to the TP not the TO. The TP is the appropriate entity. However, the TOP and the TOP also have need of the data. Should dissemination to these entities be covered in the requirements also?
Yes

The ambient temp and correction factor should be provided to the TP with all the data as stated in Question 2.
Yes
Yes
However, based on the requirements and measures identified in the standard it is unclear why the standard was made applicable to Transmission Owners; unless the standard is intended to only apply to Transmission Owners that own synchronous condensers. If that is the case, Section A- 4.1.2 should be re-written as follows: “Transmission Owner that owns a synchronous condenser.” This qualification is consistent with other PRC standards (PRC-010, PRC-015, PRC-023, etc.) where applicability to a specific sub-set of Transmission Owners is clearly defined.
Yes
Question 9 mentions that a threshold was proposed by the SDT for synchronous generators greater than, or equal to, 50MVA. However, the existing language in Section A- 4.2.1 of the standard makes it applicable to both individual generating units and synchronous condensers greater than 20MVA. The 50MVA threshold for synchronous condensers seems reasonable, so if this was the intent then the language in the standard should be revised.
Yes
“Staged” vs “operational” verification should be defined. In Attachment 1, are sections 2 and 5.2 consistent? That is should the % value be the same?
No
20% “appears” to be a large variance. The DT should explain the justification for 20%. 5% or 10% would seem more reasonable, especially for large units.
Yes
Should Attachment 1 Sec 5 be added to the standard list of requirements instead of part of the attachment? It appears that this section is more than just additional details on verification and reporting. In the project background information it is stated “..If regions have generating units that are connected at under 100 kV that are important to the reliability of the system due to some local consideration, then the region has the authority to require that those units be verified if they so choose.” This capability should be noted directly in the standard.
Yes
Yes
Question #2 mentions that a threshold was chosen by the SDT for synchronous generators greater than, or equal to, 50MVA. However, the existing language in Section A- 4.2.1 of the standard makes it applicable to both individual generating units and synchronous condensers greater than 20MVA. The 50MVA threshold for synchronous condensers seems reasonable, so if this was the intent then the language in the standard should be revised.
No
Question #3 indicated that as currently drafted the standard applies to variable static reactive resources located at asynchronous generating facilities (e.g. wind and solar sites). This is either

specifically mentioned, or inferred, within the language of the June 15, 2011 Draft 2 standard. Regarding the question of a reliability need for including variable static reactive resources (e.g. static Var compensators) that are not located at generating sites in this standard, the answer is no. We see no need to make the standard applicable to Static Var Compensators (SVC's), whether they are located at generating sites, or remote from generating sites. An SVC is merely a thyristor switched / controlled capacitor or reactor. Maximum and minimum output is controlled by the firing controls to the thyristor, and is limited by the size of the installed shunt capacitor / reactor banks. When the thyristor is switched off there is no output. As the firing angle is increased toward the full on position the reactive output is increased until the full value of the shunt capacitor bank, or reactor bank, is reached. Protective devices and settings on the shunt capacitor bank and reactor bank within the SVC are typical of those employed on fixed banks. The control system merely provides a means to adjust the output between zero and full bank rating. As in the case of fixed banks, SVC protective devices are set assuming the full bank is in service. Therefore, if fixed shunt reactive banks are not subject to the standard, which they should not be, then SVC's should not be either. Synchronous machines, however, are a different story entirely. The quantity of reactive power produced by, or drawn into, the machine is a function of the machine field current. In an under-excited condition the unit may loose synchronism, or trip via loss of field protection, unless the voltage regulator (min. excitation limiter) is properly set and coordinated with the machine's capability and protective devices. Similarly, excessive Var output and / or terminal overvoltage caused by over-excitation of the field can result in equipment damage, or unit tripping, unless the voltage regulator is properly set and coordinated with the machine's capability and protective devices.

Based on the Requirements and Measures identified in the standard it is unclear why the standard was made applicable to Transmission Owners; unless the standard is intended to only apply to Transmission Owners that own synchronous condensers. If that is the case, Section A- 4.1.2 should be re-written as follows: "Transmission Owner that owns a synchronous condenser." This qualification is consistent with other PRC standards (PRC-010, PRC-015, PRC-023, etc.) where applicability to a specific sub-set of Transmission Owners is clearly defined. Do the requirements in this new standard overlap or duplicative with PRC-001 R3 and R5?
Individual
Brad Haralson
Associated Electric Cooperative, Inc.
No
Real power verification is typically done using historical operating data because units commonly operate at full real power capability. Reactive power verification will most likely not be done using historical operating data. This standard implies that these verifications will be done at the same time. Applicable standards should allow for real and reactive verifications at different times.
No
The TP or PA seems more appropriate.
No
There is no simple correction factor that can be provided that will allow correction to other ambient temperatures. If necessary, a special request could be made to the GO/GOP for correction to another ambient temperature.
No

The use of "sister" (essentially identical) units should be allowed by the standard (as is allowed in SERCs current MOD-025 regional criteria). Independent verification of essentially identical units should not be required.
No
We don't agree that four points are needed for baseload units, since they are rarely expected to operate at or near Pmin. In addition to nuclear units, baseload units should be exempt from reactive capability verification at Pmin.
Yes
Provided that the verification is accomplished through staged testing or through operational data review. This requirement would not apply if the verification is accomplished using an engineering analysis method.
Yes
We believe that there is little value to a minimum load, vars-out requirement. Also, it will be difficult to achieve since the system usually has minimum VAR requirements when operating at low system load. Experience has shown that a large unit cannot reach the full available lagging (many times) or leading (most times) reactive capability values due to voltage limitations. That does not mean that that capability is not available.
Yes
No
It is noted that this criteria is not consistent with the criteria for generators or with 4.2.1 of the draft standard.
No
As the draft is currently written, these two methods are understood to be allowed. However, we believe a third alternative, engineering analysis, is needed in order for GOs to be able to verify more appropriate generating unit reactive capabilities that are needed to ensure that planning entities have accurate generator data when assessing BES reliability. MOD-025-2 should not focus solely upon operational testing to determine capabilities used for planning models, because experience has shown that testing does not provide appropriate reactive power capabilities. It is noted that TOP-002-2a R13 now requires the GOP to perform real and reactive capability testing at the request of the BA or TOP. The test can be specified if determined to be necessary by the BA or TOP.
No
Since the "expected value" is not clearly identified, it is not possible to determine if 20% is an appropriate value. Furthermore, if the "expected value" is the "D curve" for lagging Vars, we believe this is not a realistic expectation since operational data for most generating units does not approach 80% of the "D curve" value in normal operating conditions (or even in staged testing based on our experience). A recent survey of the SERC region has shown that only 34% of 85 generators surveyed performing staged Q production tests could reach 80% of their D curve lagging Q capability. The same survey showed that only 19% of 32 generators surveyed performing staged Q absorption tests could reach 80% of their underexcitation limit (UEL) characteristic setting. Therefore, the "within 20% of the expected value" requirement should be deleted. If an engineering analysis (which uses operational data for analytical model confirmation) is allowed as an alternative verification method, the 20% tolerance given above is not needed.
No
No
Yes
1) We agree with the stated purpose of this standard however we don't believe that this standard, as written, meets the intent related to reactive capabilities. We have already spent significant time, effort and money to perform reactive capability testing, and the test results provide little value toward establishing appropriate capabilities for planning purposes. Additionally, this testing puts our equipment and the BES at risk. It appears that this standard will make us repeat this effort with additional requirements for reactive capability testing at Pmin. 2) This requirement will require units

that normally do not run or have a very low capacity factor to be verified. Please add a provision for excluding these requirements for units that do not regularly run, similar to other NERC standard exemption requirements. 3) The standard needs to allow the inclusion of engineering analysis to supplement or replace testing when appropriate (see comments to question #10). 4) Instead of the periodic requirements, there needs to be a change based validation requirement. If a plant is materially changed (such as significant equipment changes or performance degredation), there needs to be a new validation done. 5) In R1.2 and R2.2, the phrase "same information" is used, while in M1 and M2 the phrase "equivalent information" is used - we suggest changing R1.2 and R2.2. to match the M1 and M2. 6) Specifying Normal Operating H2 pressure in Attachment 1, section 2.5 may not produce the desired maximum Q cap results - consider changing "normal operating " to "maximum sustainable (within design limits)" 7) In Attachment 1, section 2.2, we suggest changing "they could normally be expected to operate" to "they are normally expected to operate". 8) We suggest revising Requirements R1.3 and R2.3 to read: "Submit the capability information to its TP within 90 calendar days of completion of the verification." to clarify these requirements and to make them consistent. We also believe 90 days will create an undue hardship for GOs who own a large number of generators and believe this requirement should allow for additional time when authorized by the TP or PC. 9) The first paragraph of the Compliance Data Retention Section D 1.2 is difficult to understand. Please simplify using multiple sentences, if possible. 10) In the VSL table for R1 and R2, we suggest changing the phrasing "from the date the data was recorded" to "from the verification date" each time it is used (7 times). 11) In the VSL table for R1, both the first and fourth items are not needed in the list of the four items which make up the OR statement. It is sufficient to measure if the data is more than 30 days late to be categorized as Severe. 12) In the VSL table for R2, we suggest replacing the second item in the list of the two items which make up the OR statement to match the corresponding item in R1 relative to the tardiness of the submission to the TP greater than 30 days late (> 120 days total). 13) Revise attachement 1 section 5.1 and 5.2 to change “last more than 6 months” to “last more than 1 year,” to align with the typical long-term planning horizon. 14) Note that the standard is only applicable to the GO/GOP, but needs involvement from the TO/TP/TOP to adequately complete a validation. Thus the standard needs to address the responsibilites of those entities for it to adequately address the issue of model validation. It is noted that MOD-11which is supposed to clarify modeling data requirements has not yet been completed and approved. Yet MOD-25 is requiring verification of this data. It is also recognized that generator verification methods are producing results that are not being directly used in the models (due to various operating or system limitations). As a result, it is not clear that MOD-025 is achiving the reliablity purpose intended. 15) This standard establishes a periodic generator testing regime which, when implemented on a large number if generators, creats a continuous state of testing across the BES. We question if this approach really improves the reliability of the BES. The use of normal operational data, supplemented by analysis, represents a better approach for most generators.

1) Item 2.1.1 should be reworded: ".......model verification activities including the on-line RECORDED response compared to the MODEL'S SIMULATED response....." 2) It is anticipated that many GO/GOP's may not have industry experience with modeling concepts and model verification techniques. It may be beneficial to provide an appendix for reference that basically describes the anticipated mechanics of how the verification is performed. This may help provide consistency for the verification process.

1) In R2.1.1 it is not clear if the “recorded” response refers to the model response. Consider rewording this requirement to make clear the meaning of “recorded”. 2.) Attachment 1 seems to give two options for periodicity of verifying the model frequency control functions for existing generators. One option is to record data for a BES frequency excursion during a ten year calendar period. A second option is to record such data after the ten year period if a suitable BES frequency excursion does not occur. Does this mean existing generators can wait indefinitely for a suitable frequency excursion to verify the model response?
Yes
Yes

The SPCS notes that the posted standard references synchronous condensers rated 20 MVA in Applicability section 4.2.1. The SPCS agrees with the 20 MVA threshold in the posted standard.
Yes
Devices such as Static Var Compensators and STATCOMs have equipment limitations, control systems, and protections that must be coordinated to assure system reliability. The reliability impact of unnecessarily tripping reactive support from a variable static resource is similar to tripping reactive support from a generator or synchronous condenser.
Yes
Yes
No
The diagrams need to incorporate the permissible voltage and frequency ranges. For example, the P-Q diagram probably is based on 1 pu voltage and frequency.
Yes
No
Yes
Requirement R1: The standard lacks clarity on which types of protection functions must be coordinated. The standard should specify which types of protection functions must be coordinated if they are present on the generating unit, such as the list in Section G. Additionally, Attachment 2 could be interpreted to require coordination for protection systems that cannot be coordinated (e.g., the generator backup distance and backup overcurrent functions are required to detect faults that may result in an apparent impedance inside the SSSL) or do not require coordination (e.g., the generator out-of-step function will operate only for an unstable power swing and will not operate for stable operation within its operating characteristic). These protection functions should be removed from the figure or clarification should be added that the standard does not require coordination of these protection functions. Requirement R1, part 1.1.2: The word "check" is subject to interpretation and step 1.1.1 in some cases will verify existing settings rather than determine settings. Part 1.1.2 should be revised to address these issues, such as "Demonstrate that the settings used to verify coordination in part 1.1.1 are applied to the in-service equipment." Requirement R1, part 1.2: When the generating unit equipment or settings are modified as part of a planned project the Generator Owner should be required to verify coordination prior to placing the revised equipment or settings in-service. The SSSL derivation should consider the impact of system strength (e.g., strongest transmission line source out-of-service), generation saturation, and AVR status to assure an appropriately conservative limit. Implementing a UEL based on the steady-state stability limit may prevent under-excited operation, which would otherwise be stable and useful in managing system conditions (such as during system restoration activities or in lightly-loaded areas that need to sink reactive power to control voltage or synchronizing a generator to a long line). Where the Generator Owner and Transmission Owner are separate entities, there is difficulty for the Generator Owner to obtain system impedance information and keep it up to date as the transmission system may be re-configured during on-going operations; this information is necessary to represent the SSSL. The foremost reason for protective relaying is to protect power system equipment. There is a concern that the real purpose of relaying may be lost in the overwhelming emphasis of its coordination with

controlling equipment throughout the document. The generator protective relays are there to protect the generator and its associated equipment and the standard should acknowledge that this primary objective cannot be violated to obtain the desired coordination.

In section B, R1.3, results are required to be submitted to the Transmission Planner. The NYISO agrees with R1.3.
No
Temperature correction shall be performed as required by the Transmission Operator. The NYISO requires ambient temperature data only for Real Power Tests for combined cycle, combustion, and turbine units.
Yes
No
There is no value to performing the lagging testing at minimum real power loading and leading test at maximum power. The testing requirement should be changed to two test points. One test for an hour to verify over-excited (lagging) capability at the real power level specified by the Transmission Operator or the Transmission Planner; a second test to verify under-excited capability (leading) at the real power level specified by the Transmission Operator or the Transmission Planner.
Yes
No
Testing requirements for reactive capability at minimum real power output should be removed. These tests are of no value and lead to system limit concerns. The testing requirement should be changed to two test points. One test for an hour to verify over-excited (lagging) capability at the real power level specified by the Transmission Operator or the Transmission Planner. A second test to verify under-excited capability (leading) at the real power level specified by the Transmission Operator or the Transmission Planner.
Yes
No
100 MVA is a more appropriate limit.
Yes
No
What determines the expected value to be within 20% of?
No
In the NPCC region Directory 9 and 10 were written to meet the original obligations of MOD-024 and MOD-025. These directories are more specific or more stringent than MOD-025-2.
No
Yes
Effective Dates: How is this to be implemented? GOs may have units in multiple control areas. TOs may be in multiple areas. This seems impossible to track and may leave some areas without any verification for 5 years after the standard has been approved. The Planning Coordinator should be given the discretion to require and approve a test schedule within its area. Additional NYISO Comments not addressed above for MOD-25-2 Under A. Introduction • Section 4 – Transmission Planner should be added under Functional Entities • Section 5.1.1 through 5.1.5 and 5.2.1 through

5.2.5 – These requirements should clarify that the Transmission owner requirement is for units that the Transmission owner owns and not for the generators in the Transmission Owners area. Under B. Requirements • Section 1.3 – The requirement should either be up to 225 days after the test or 60 days after the end of the test period. Attachment 1 – Verification of Generator Real and Reactive Power Capability • Section 1 – There should be some provision for allowing the verification results from small, electrically identical units at the same location to apply to other units in the group. • Section 2.1 – It is not practical to determine reactive power at rated gross Real Power capability. The requirement that ninety percent of wind turbines or photovoltaic inverters be online during verification of reactive power should be removed. • Section 2.2 – This verification is not needed. • Section 2.4 - Please clarify the definition of “limit”. • Section 3.2 - Please clarify the definition of “voltage schedule”. • Section 3.3 – This data is not needed. • Section 3.4 - Ambient air temperature is not needed for reactive power test results. It is only necessary for certain generators in Real Power tests (combined cycle, combustion and turbine). • Section 4 – The diagram is not needed. • Section 4.1 – For the NYISO, Real Power verifications are conservatively measured as Net output, so no auxiliary loads are required to be reported. Attachment 2 • Attachment 2 requires an unnecessary level of detail for “Data Type” to be recorded and collected; only gross MVAR, auxiliary reactive power and Net MW readings are required. • What is meant by “MVAR values were adjusted to rate generator voltage”?

The TP or the PC is the entity who needs the data, not the TO. R1.3 and R2.3 specifies that the TP be given this data.
No
The verification data is required by R1.3 and R2.3 to be given to the TP, not the TO. If the Q capacity is determined using a staged test, the ambient temperature during the test should be provided. The planning entity can adjust to other temperatures if they desire.
No
We believe that Section 4 Applicability for this standard should be revised to match the Section 4 Applicability for MOD-026-1 and MOD-027-1 with respect to inidividual unit size of 100 MVA for the Eastern Interconnection. However, for plants with a gross aggregate nameplate rating ≥ 100, we question the need to perform verification for individual units as small as 20 MVA. A 20MVA machine today can not impact the system like it could have 20 years ago. A technical basis for verification of units as small as 20MVA needs to be provided. NERC is focusing on standard requirements that have significant impacts on system reliability, and including smaller units without demonstrating their

criticality to the system seems to be inconsistent with this philosophy. Verification for smaller units should only be required if technically justified by the Planning Coordinator as specified in 4.2.4 of MOD-026-1.
No
We agree that four points are sufficient to provide a straight line approximation over a unit's operating range. However, we strongly agree with the Commission's statement that "such a requirement for all generators may not be necessary." Paragraph 1321 of the FERC Order states, "...other than baseload units, most generating units rarely operate at full MW loading. It is unclear what reactive capability is available throughout a unit’s real power (MW) operating range. Therefore, we believe a clearer standard would require a verification of MVAR capability throughout a unit’s real power (MW) operating range. However, we share concern with several commenters that such a requirement for all generators may not be necessary." These statements indicate the Commission is seeking further guidance from the industry. Based on this, we have the following recommendations. First, we believe 2.2 of Attachment 1 to the standard should exempt all base load units, not just nuclear units, from verification of reactive capability throughout the full MW range. There are other units the industry should be able to justify exempting based on their normal operating modes. Examples are peaker CTs and units that have restrictions (environmental, run of the river, etc.) that prevent operation at minimum load. Second, we suggest that an evaluation be made on a small subset of units that could then be used to respond to the question raised by FERC. Our experience indicates that a unit will typically be capable of delivering or absorbing a comparable amount of reactive power to/from the grid at minimum load when compared to full load. The industry as a whole does not need to perform the verification at multiple points on 100% of the units to respond to an open question from FERC. Third, for units where verification of multiple points are needed, the analytical approach to verification we discuss in our responses to Questions 10, 11, and 14 serves this purpose very well.
Yes
Provided that the verification is accomplished through staged testing or through operational data review. This requirement would not apply if the verification is accomplished using an engineering analysis method (see this proposal in comments to Question 14).
Yes
We believe that the minimum load, it will be difficult for a unit to produce Vars because the system usually has minimum VAR output requirements from generators when the generators are operating at minimum load. Therfore, we believe verification of Vars out at minimum load will not provide the data that transmission planning is seeking and, therfore, this requirement is not necessary. See our response to Question 5 for additional discussion on verification at minimum load.
No
No
This MVA size does not agree with that found in the Applicability section 4.2.1 (20 MVA). As previously stated, we feel that the size of an individual unit that is significant in the Eastern Interconnection is 100 MVA.
No
As the draft is currently written, these two methods are understood to be allowed. However, we believe a third alternative, engineering analysis, is needed in order for GOs to be able to verify generating unit reactive capabilities that are suitable for transmission system planning studies (See our Comment 2 under Question 14 for additional discussion on the verification methods.). Reliance on data from testing or operations alone will result in understated reactive capabilities for planning purposes. To provide these alternative methods of establishing P&Q capabilities for each applicable facility, it is proposed that Requirement R1.1 be re-written as follows: "Verify the Real and Reactive Power capability of its generating units and shall verify the Reactive Power capability of its synchronous condenser units in accordance with either Attachment 1 (staged testing or operational data) or Attachment 3 (by engineering analysis)." Requirement R1.2 could then be qualified to be limited to reporting the results from staged testing or the use of operational data, and a new R1.3 could be inserted to require suitable reporting of the results from an engineering analysis. The time horizon of the two requirements in this standard are Long-Term Planning. MOD-025-2 does not have to focus solely upon operational testing to determine capabilities used for planning entity models. It is

noted that TOP-002-2a R13 now requires the GOP to perform real and reactive capability testing at the request of the BA or TOP. The test can be specified if determined to be necessary by the BA or TOP.
No
The "expected value" is not clearly identified, so it is not possible to determine if 20% of this value is appropriate. Furthermore, if the "expected value" is the D curve for lagging Vars, we believe this is not a realistic expectation because operational data for most generating units does not approach 80% of the D curve value in normal operating conditions or even in staged testing based on our experience. A recent survey of the SERC region has shown that only 34% of 85 generators surveyed performing staged Q production tests could reach 80% of their D curve lagging Q capability. The same survey showed that only 19% of 32 generators surveyed performing staged Q absorption tests could reach 80% of their underexcitation limit (UEL) characteristic setting. Therefore, the "within 20% of the expected value" requirement should be deleted. If an engineering analysis (which uses operational data for analytical model confirmation) is allowed to be an alternative method for verifying the unit capability, the 20% tolerance given above is not needed. See our Comment 2 under Question 14 for additional discussion on the verification methods.
No
No
Yes
1) This requirement will require units that normally do not run or have a very low capacity factor to be run for testing. Please consider a provision for excluding these requirements for units that do not regularly run unless verification using engineering analysis is allowed. 2) Each of the methods of verification proposed have merits and deficiencies. For staged testing, there exists the risk of tripping a unit during testing. System conditions which allow for the maximum reactive power output production/absorption are extreme system voltage conditions - precisely where it is undesirable to perform such testing or trip a unit. Staged testing or verification using operational data during normal system voltage conditions will result in reactive limits constrainted by system conditions (not representative of the actual unit capabilities for extreme voltage conditions when the reserve Var capabilities are needed most). Staged testing may, however, reveal unknown thermal or mechanical problems which, while are good to know, are maintenance related and are not the primary objective of the standard which is verification of reactive capability for use in planning models (Long Term Planning Horizon). But, if system constraints during staged testing do not permit a unit to reach the reactive limits the unit could reach during extreme system votlage conditions, one could argue the results of the test are inconclusive in terms of meeting the reliability objective of the standard. Our experience has shown that unit reactive limits for extreme voltage conditions (when the reserve Var capabilities are needed most) can best be determined using engineering analysis. It is noteworthy that the original NERC Board Approved version of this standard states in requirement R1.3 that acceptable methods for reactive capability verification "include use of commissioning data, performance tracking, engineering analysis, testing, etc." This represents the "allowance to use of all the tools in the toolbox" approach which is appropriate when no single tool is sufficient to accomplish the stated reliability objectives, consistent with the FERC Acceptance Criteria of a Reliability Standard (reference Paragraphs 321, 324, 328, 332). This approach is reflected in the SERC Regional Criteria for MOD-025-1 which was developed by a joint transmission-generation task force. 3) The test interval and new unit test requirement described in Attachment 1, part 5 should be included in the main standard requirement section rather than in the staged test details. However, we believe re-verification every 5 years is too frequent. We agree that re-verification is appropriate for significant changes that impact the real or reactive capabilty by more than 10%, but we question the six month criteria. For the Long Term Planning Horizon, one year would be more appropriate. 4) In R1.2 and R2.2 the phrase "same information" is used, while in M1 and M2 the phrase "equivalent information" is used - we suggest changin R1.2 anf R2.2. to match the M1 and M2. 5) Specifying Normal Operating H2 pressure in Attachment 1, section 2.5 may not produce the desired maximum Q cap results - consider changing "normal operating " to "maximum sustainable (within design limits)" 6) In Attachment 1, section 2.2, we suggest changing "they could normally be expected to operate" to "they are normally expected to operate". 7) We suggest revising Requirements R1.3 and R2.3 to

read: "Submit the capability information to its TP within 90 calendar days of completion of the verification." to clarify these requirements and to make them consistent. We also believe 90 days will create an undue hardship for GOs who own a large number of generators and believe this requirement should allow for additional time when authorized by the TP or PC. 8) The first paragraph of the Compliance Data Retention Section D 1.2 is difficult to understand. Please simplify using multiple sentences, if possible. 9) In the VSL table for R1 and R2, we suggest changing the phrasing "from the date the data was recorded" to "from the verification date" each time it is used (7 times). 10) In the VSL table for R1, both the first and fourth items are not needed in the list of the four items which make up the OR statement. It is sufficient to measure if the data is more than 30 days late to be categorized as Severe. 11) In the VSL table for R2, we suggest replacing the second item in the list of the two items which make up the OR statement to match the corresponding item in R1 relative to the tardiness of the submission to the TP (> 30 days late).
No
1) We are not convinced that wind plants need to be included at all due to a) the uncertainty of the wind availability during a frequency excursion and b) the transient nature of any contribution that the a wind turbine may be able to provide to correct or affect the frequency excursion. It is believed that the time frame of the frequency excursion will far exceed the wind turbine's ability to sustain a correcting action. 2) It is our opinion that a 20MVA machine is too small to be able to significantly impact a frequency perturbation. A technical basis for including units as small as 20MVA in all regions needs to be provided. NERC is focusing on standard requirements that have significant impacts on system reliability, and including units this small seems to be inconsistent with this philosophy.
Yes
Yes
No
No
Yes
1) Requirement 2.1.1 requires a comparison of the on-line response to the recorded response. The comparison needs to be between the on-line recorded response and the model simulated response. 2) The VSL table for R1 has time frames that don’t match the Requirement R1 30 calendar day time frame. 3) The first paragraph of the Severe VSL for R2 needs to be split into two parts to form an additional OR statement which reads: "The GO failed to provide its verified model(s)" OR "The GO provided the verified model(s) more than 90 calendar days late to its TP in accordance with the periodicity timeframe specificed in MOD-027 Attachment 1." 4) The second paragraph of the Severe VSL for R3 is not grammatically correct and does not match the Requirement R3. Please consider changing it to read: "The GO's written response failed to contain one of the following: the technical basis for maintaining the current model, a list of future model changes, or a plan to perform another model verification." 5) For the Lower, Moderate, and Higher VSLs for R5, please consider placing "including a technical description if the model is not useable" within parenthesis to aide in understanding the measure. 6) For the second paragraph of the Severe VSL for R5, please consider rephrasing to read: "The TP provided a written response without including confirmation of all specified model criteria listed in R5, parts 5.1 through 5.3." 7) In Requirement R4, it is unclear how an entity could revise model data without performing a model verification - (the requirement is written to either revise model data or plan to perform model verification) 8) Attachment 1 contains multiple copy/paste errors (from MOD-026) and was difficult to constructively comment on due to these. Those items that need correcting include: 8a) The "Facility" column entries need to better describe the conditions that are being detailed in the "Condition" column. Can some additional words better describe the each row? [for example, the row 2 could have the title 1-existing unit, no sister unit exceptions; row 3 could have the title 2-existing unit, sister unit exception applies, etc.] 8b) The use of "exceptions" in the Draft 1, row 2 is not defined and it is unclear what exceptions may apply. 8c) Can the third AND element of the Condition described in row 2 be written more simply by beginning "While the unit is operating in a frequency responsive mode and is subjected to at least one BES frequency excursion as specified in Criteria 1 above." This change could be used in multiple entries of

this table to simply the reading and understanding. 8d) For row 3 (with exceptions row), we suggest eliminating the requirement for the same physical location being true for allow "sisterhood" - an entity is likely to own multiple units at different physical locations which are identical. 8e) Row 5 contains "new excitation control system equipment" - shouldn't this be "new governor/load control equipment"? 8f) Row 7 contains "Excitation control system model" rather than "Gov/Load control model"
Yes
No
We feel that this standard is not applicable for solar facilities. For other facilities, we recommend that only units > 75MVA be included. If the significant aggregated plant MVA size is > 75 MVA, then an individual unit included as significant should also be 75 MVA. Consider the case where a 21 MVA machine would be included in the scope, yet a 'five unit, 15 MVA each' plant (totaling 75 MVA) would be excluded. A 20MVA machine today can not impact the system like it could have 20 years ago. A technical basis for including units as small as 20MVA in all regions needs to be provided. NERC is focusing on standard requirements that have significant impacts on system reliability, and including units less than 75MVA seems to be inconsistent with this philosophy. We do acknowledge that in some areas of the BES, some units ≤ 75MVA may be identified by a transmission entity as critical for BES reliability. Thus, the standard could include requirements applicable to such units where identified by a tranmission entity as critical for BES reliability.

Only the last two documentation sets are needed to prove the intervals are being met. ALL previous sets are not necessary. The bullet listed under 1.2 Data Retention implies that all records need to be kept indefinitely.
No
Yes
1) The last sentence of Measure M1 is not needed. There is no need to require evidence of the change implemetation, only coordination verification is needed. The requirement for documentation of change identification or implementation is not part of Requirement R1. 2) In several places in the posting documents there is a descrepancy in the size of the synchronous condensor that is in the scope of the standard, some places list the size criteria at 20 MVA, and others state 50MVA. 3) The Implementation plan document effective date is incorrect for the 20% completion step - it states two years rather than the appropriate one year. 4) Section 5.2.5 is missing from effective date in the draft standard.

Combination of closely related standards simplifies compliance program development, and is welcome.
No
Not all Transmission Owners have a complete system view of the BES, let alone modeling software. The standard as written specifies the Transmission Planner, and so the question appears to be in error. Following the purpose statement of the standard, the Planning Coordinator (formerly Planning Authority) might also need the data along with the Transmission Planner. To further complicate the matter, in WECC CUG meetings it has been brought up that entities are experiencing difficulty in identifying their Planning Coordinator and Transmission Planner. Such entities have been rebuffed when approaching the obvious candidates. Therefore, Cowlitz suggests that a mechanism must be devised such that Generator Owners will not left in a compliance quandary in their endeavors to identify the appropriate planner(s).
Yes
As long as correction factors may be documented from normal run history, this would not be burdensome to produce. As currently written, MOD-0025-2 appears to allow the Generator Owner to make a judgment call on whether ambient air temperature plays a significant role in generation capacity. If this is the case, then the report form should have a specific question: Is ambient air temperature correction factor applicable? ______ If yes, include in remarks below correction factors for different temperatures. Also, water coolant temperature may play a greater role. A quick passing hot or cool day during testing may not have any effect on the water coolant temperature. Where water temperature has a greater impact on capability, seasonal trends may be of greater significance. Finally, there is no criterion stipulated to define when ambient temperature correction factors are significant and should be provided. Cowlitz suggests that ambient temperature should only be considered significant if it affects Real or Reactive Power capability more than 10% between the lowest and highest expected ambient temperature extremes.
No
The Compliance Registry Criteria was hastily put together without proper reliability justification. The end result has created a registration process that assumes reliability impact where there is none, and allows exemptions where reliability impact does exist. Cowlitz believes in a protective backbone approach to reliability, the bulk power system (BPS) as a whole need not be completely protected in order to assure its reliability. There exists a core “backbone” subset from the BPS which must be protected; this is known as the Bulk Electric System (BES) and is currently undergoing revision in Project 2010-17. Once this project is complete, it may be necessary to revise the Compliance Registry Criteria to clearly identify entities as users of the BES who must participate in BES protective standard compliance activities. In other words, the Compliance Registry objective should be to identify all entities who must participate in the protection of the BES to assure reliability of the BPS, not identify elements of the BES. Cowlitz is not convinced that the Standard be applicable to the compliance registry of Generator Owners. For example, an entity owning a single small 500 KVA generation plant currently is exempt from registration; however it may own a transmission protection system protecting a BES element from a fault originating on the high side of the step up transformer. Therefore it should register as it is material to the reliability of the bulk power system. From the extensive reference of 20 MVA and 75 MVA in the Standard from the Compliance Registry Criteria, it appears that the SDT would not see a need for the 500 KVA generation plant to verify its capability. Further, pointing to the Compliance Registry Criteria’s generator MVA name plate ratings is also questionable. Cowlitz can find no reliability justification; it appears to be completely arbitrary. After reviewing the Field Test Results, Cowlitz finds that WECC set the line at 10 MVA and SERC recommended 75 MVA with no substantiating arguments. Also noted in the Field Test Results was a

problem in getting the dynamic models to return data results that agreed with actual events. With the Field Test Results dated in 2007, Cowlitz is unsure on the current accuracy of dynamic model predictions. However, if models are currently accurate it should be a simple process to verify the size of generation that can be ignored. Looking over the data requirements of MOD-25, Cowlitz can see that there will be considerable consultant cost – $25,000 – to comply. Using the Compliance Registry Criteria for applicability is not acceptable. Unwarranted compliance efforts will reduce overall reliability results. Cowlitz recommends the SDT consult with Planning Coordinators (Planning Authorities) and Transmission Planners on the current status of modeling accuracy and request documentation for generation that can be ignored. Also, it may be permissible for smaller generation to simply report seasonal historical Real and Reactive Power output.
No
Cowlitz answers “no” in that the question does not address if the data is truly going to be used. The SDT should confer with Transmission Planners requesting specifically how they will implement such data and if it will result in better modeling results. Data collection that will not be used is wasted compliance effort. FERC also seems to be confused as to the purpose of the Standard when it states “[t]he capability of generators to produce reactive power is essential for real-time analysis” rather than system modeling and planning. Based on this, should the reactive capability data also be sent to the Balancing Authority? If the SDT has technical foundation to refute FERC’s directive then it should be communicated. The Standard can be written as FERC demands, but with a recommendation that the requirement be removed.
No
Cowlitz suggests that “rated” be replaced with “normal expected maximum” in requirement 2.1 and “maximum” in requirement 2.3; although the footnote makes the intent clear, there is no need to complicate the reading of the Attachment and effectively redefine the normal understanding of the word rating. As far as running the test at least one hour, this commenter is not sure how quickly a unit achieves thermal stability. Again, Cowlitz questions if the data will be used and its actual contribution to improved modeling and future planning.
No
Cowlitz at this time has insufficient information to formulate an opinion, but at the same time is skeptical of the reliability benefit being great enough to justify the cost of obtaining this data.
Cowlitz does not own such equipment and therefore must defer to those that do. Cowlitz will consider the comments of others in the future.
Cowlitz does not own such equipment and therefore must defer to those that do. Cowlitz will consider the comments of others in the future.
Yes
Operational data will always be the preferred method of obtaining verification; however Cowlitz can’t see how this would be possible for obtaining the reactive capabilities as prescribed. This will require costly and burdensome staged testing.
Yes
No
No
Yes
As already stated, Cowlitz questions the reliability benefit of the extensive reactive capability requirements and is currently consulting with Transmission Planners if such extensive data will actually be beneficial in their modeling efforts. It may be better to require data that must be verified though staged testing only after request by the Transmission Planner with a reasonable time frame to obtain the data.
No
Yes

Yes
No
No
No
Cowlitz has no opinion.
No
The Compliance Registry Criteria was hastily put together without proper reliability justification. The end result has created a registration process that assumes reliability impact where there is none, and allows exemptions where reliability impact does exist. Cowlitz believes in a protective backbone approach to reliability, the bulk power system (BPS) as a whole need not be completely protected in order to assure its reliability. There exists a core “backbone” subset from the BPS which must be protected; this is known as the Bulk Electric System (BES) and is currently undergoing revision in Project 2010-17. Once this project is complete, it may be necessary to revise the Compliance Registry Criteria to clearly identify entities as users of the BES who must participate in BES protective standard compliance activities. In other words, the Compliance Registry objective should be to identify all entities who must participate in the protection of the BES to assure reliability of the BPS, not identify elements of the BES. Using the Compliance Registry Criteria’s generator MVA name plate ratings to assign applicability of the Standard is questionable. Cowlitz can find no reliability justification; it appears to be completely arbitrary. If models are currently accurate it should be a simple process to verify the size of generation that can be ignored. Further, the unit versus plant MVA criteria is illogical. If the BES can withstand the loss of a 75 MVA plant, then logically it will withstand the loss of a 20 MVA unit. Cowlitz believes that after the appropriate study is completed, the applicability line should be somewhere in the range of a verified nominal plant or unit output of 100 to 200 MVA. Last of all, applicability should be assigned to BES generation when it has been defined.
Yes
But not at the 20/75 MVA name plate criteria. First the applicability should be tied to expected maximum MVA output. Second, the MVA basis should be established from a modeling study. Ultimately, the applicability should only include plants that are members of the BES once this has been defined.
Yes
Yes
For Cowlitz, this would be acceptable. However, Cowlitz only owns a few generation plants. We must defer to those who own many plants.
Yes
Cowlitz needs to confer with its consultant to form a more informed opinion. However, it appears to be reasonable.
Yes
No
Yes
Cowlitz understands the difficulty the SDT is under. Although the base line of applicability is in question, this Standard is justifiable and will not present too great a burden to comply with.

The standard states that the data be submitted to the Transmission Planner and we agree with that approach.
No
We recommend that in Item 3.4 of Attachment 1 the wording be changed from “to allow the Transmission Owner” to “to allow the Transmission Planner”. We support the position that the ambient temperature at the end of the verification period and the correction factor should be provided to the Transmission Planner so that the Transmission Planner can adjust the verification results to the ambient temperature that is appropriate for its system planning assessments.
No
There may be generating units or facilities that are included or excluded as BES elements either by the latest BES definition or the latest BES exception procedure that differ from 4.2.1 and 4.2.2. So we recommend adding anItem 4.2.4 to the Applicability section that states, “Generating facility, generating unit or synchronous condenser that are designated as a BES Element according to the BES definition or BES exception procedure.”

Please consider the following comments: Attachment 1, Item 2 – Add the adjective “gross” to the Real Power and Reactive Power reference for added clarity and to assure awareness that the verification is for “gross”, rather than “net” values. Attachment 1, Item 2 – Modify the wording of “with all auxiliary equipment needed for expected normal operation” to “with all auxiliary and voltage regulation equipment, such as reactive power compensation, needed for expected normal operation and voltage regulation” to assure that any reactive power compensation equipment (e.g. capacitor banks, SVCs, STATCOMs) are not overlooked and omitted from the verification data. This added text is particularly needed for wind generation situations. Attachment 1, Item 2 – We would prefer the acceptable verification with operational data to be 10%, rather than 20%. Attachment 1, Item 2 – Expand the text of “expected value” to “expected maximum gross Real and Reactive Power Generator capability values” to add more clarity. Attachment 1, Item 2.1 – Add the adjective “gross” to the Real Power and Reactive Power reference for added clarity and to assure awareness that the verification is for “gross”, rather than “net” values. Attachment 1, Item 2.1 – Replace the wording “at rated gross Real Power capability” with “at the generating unit’s normal expected maximum Real Power capability” and drop the footnote reference. Attachment 1, Item 2.2 – Add the adjective “gross” to the Real Power and Reactive Power references for added clarity and to assure awareness that the verification is for “gross”, rather than “net” values. Attachment 1, Item 2.4 – We think that both “2.1 and 2.2” should be referenced for the over-excited data. If this is incorrect, then please explain why 2.1 should be omitted. Attachment 1, Item 2.6 – Add an Item 2.6 of “Record the generator step up (GSU) transformer losses if the verification measurements are taken from the high side of the GSU transformer”. This addition will help avoid the omission of the GSU transformer reactive power losses when calculating the gross generation power capabilities when high side measurements were taken. We are aware that this oversight has already occurred several times. [Add Point “F” (pointing to the generator step up transformer) to the Verification Information Reporting Form in Attachment 2 to accommodate and remind the Generator Owner or Transmission Owner to record these losses, when it is needed.] Attachment 1, Item 3.4 – Correct the functional entity reference from “Transmission Owner” to “Transmission Planner”. Revise the wording to allow the Generator Owner or Transmission Owner to report, “The ambient air temperature and/or ambient water temperature at the end of the verification period”. [Require that the ‘basis’ ambient air temperature and/or ambient water temperature associated with the reported gross generator Real Power capabilities be stated on the Verification Information Reporting Form along with a correction factor if any, to allow the Transmission Planner to correct the Real Power capability to different ambient temperatures, if needed.] Attachment 1, Item 3.7 – Add an Item 3.7 of “The GSU transformer losses if the verification measurements were taken from the high side of the GSU transformer.” This addition will help avoid the omission of the GSU transformer reactive power losses when calculating the gross generation power capabilities when high side measurements are taken”. Attachment 1, Item 5.3 – Add revise the wording, “within one year of their commercial operation” to “within one year of their commercial operation or as scheduled by the applicable Transmission Planner” to allow the exception of an earlier or later due date when it may be appropriate and agreed to be the affected Transmission Planner. Attachment 2, Item A – Add a note that the individual unit values should be reported separately whenever the verification measurements were taken at the individual unit. In most cases, the individual units are modeled separately (including compound units) in the power flow cases and the loss of individual units are simulated in system planning assessments. So, if the verification data was collected in a manner that would allow individual unit power capability verification, then the reporting form should not direct the Generator Owner or Transmission Owner to mask this information. Attachment 2, Item F – As noted above, add a Point “F” (pointing to the generator step up transformer) to the Verification Information Reporting Form to refer to the GSU transformer losses. Also add a Point “F” row to the data table with entries that indicate to provide the GSU transformer MW and MVAR losses when the verification data was based on measurements that were taken from the high side of the GSU transformer. Otherwise, GOs and TOs that base verification values on measurements from the high side of the GSU transformer may forget to make the proper correction when they calculate the gross values for Point “A”, as others have historically done. The scope of this

standard does not include the verification of high voltage power flow controllers that are connected to the transmission system at 100 kV or above. We propose that a Standard Authorization Request (SAR) be created to address the power capability verification gap that is not being filled with this standard. The test form has remarks space for reactive limit constraints but not for real power constraints. Attachment 1 , #2, the use of the word “all” auxiliary equipment is unnecessary and is over reaching, the Requirement is for expected normal operation. Recommend deleting “all” from this sentence. Attachment 1, # 2.1, should the SDT give an alternate threshold if “90%” could not be achieved during the testing window?
No
Yes
We agree with this proposal as being in line with our overall concern that model verification requirements should be based on cost efficiency and practicality. Facilities outside of the Applicability Section are already judged to be of minimal significance in dynamic impact, and are also typically of vintages and origins whose modeling data and parameters are difficult or impossible to obtain. For facilities of minor dynamic impact in a locality, typical or surrogate model data would serve the simulation purposes the vast majority of times.
No
It is our opinion that synchronous condensers, when in operation, are intended to regulate local voltages but not for regional frequency control.
No
No
Yes
Please consider the following comments: Footnote 2 - Include the explanation that “average capacity factor is the average of all the unit or plant output values compared to the gross nameplate rating value”, since historically some have asked how this factor is defined and calculated”. Requirement R3, bullet 2 – Append wording like, “such as a model is unusable by the Transmission Planner, dubious model type, abnormal model parameter values, and unusual simulation results” to the text, “technical concerns with the verification documentation”. Attachment 1, Row 6 (New or Existing Generator Unit) –Replace “Excitation control system model” with “Turbine/governor and load control or active/frequency control system model”. Comments: We have a number of questions and concerns as follows: • While the Standard uses the word “verified” and “verification” loosely, it is not precisely clear what a GO would have to do to satisfy the verification requirements in R2. Would each of the Time Constants, Forward and/or Feedback Gains, Dead-band Excitation Limits, Saturation Characteristics, etc. to be determined separately each on its own? Or are these parameters taken as a whole so long as their combined effect produces a response characteristic in a simulation that matches the recorded test response during an off-line step-input test? • The response of a unit is dependent on the instantaneous conditions of the external system to which it is connected at the time of the disturbance, in addition to the inherent response characteristics as built. This may result in the modeling parameters derived based on on-line frequency/Load excursion test not being unique. • If a simulation study results in response characteristics that does not match an on-line step input test response, can the GO arbitrarily adjust one or more of the model parametric values to produce a matching response, and send the Transmission Planner these adjusted values as the model data? We have concern about whether this Standard is cost efficient to the industry. The transient stability dynamic modeling for turbine/governor was developed under the assumption of limited bandwidth validity and approximations. The other equipment models in the simulation, e.g. generators, excitation controls, SVCs, HVDC Converters, boiler/burner controls, etc. are all approximations without any correlated degree of accuracies in comparison to each other. On the other hand, the verification efforts are expected to cost quite a bit to GOs, especially for older units whose vendors/manufacturers may not even be in existence any more.

Under the section B. requirements R1, 1.1; it refers us to "attachment - 1" . Under attachment – 1, item 2 – 2.1 it states the following: • Perform verification of real and reactive power capability of all generating units at maximum over excited (lagging) and under-excited (leading) reactive capability at gross real power capability. We would like to propose adding "or to the documented limiting factor of the equipment (generator, voltage regulator, transformer, transmission etc.)". We want to avoid having to test to the min and max of the capability curve if there is some other limiting factor we can document.

No
Is there a typo in the question? Should Transmission Owner be Transmission Planner? If not then adding the Transmission Owner as an intermediate step before submitting data to the Transmission Planner isn't needed.
Yes
We feel that the entity should be the Transmission Planner, but there is a need for the Generator Owner to provide an adjustment factor. The standard should address the temperature to bring the data to and then the Generator Owner could provide the factor to adjust the data. The standard also needs to address the fact that the temperature will not be a single set number and will vary depending on the season and geographic location.
Yes
If the intent is that the team wants to follow the Compliance Registry then we would ask that there be direct language reference to the Registry. If this isn't done and the Registry changes as worded now the standard would be static to the numbers given. This team needs to get plugged into the BES DEF standard drafting team as there are discussions being held currently that could change the Registry criteria.
No
This is a non linear curve. Is the reason for using the 4 point method all that would fit into the model? We also have the concern that isn't addressed here and it is if the unit can't be tested at the time due to system conditions then you must wait until the system is able. We feel that the points should reflect what is usable.
No
Currently SPP has criteria that the testing period should be 15 minutes rather than the listed 1 hour. We have found that this time period is adequate.
No
We would request that the time be a few minutes to make sure after a settling period that it was a limit that was encountered.
Yes
Yes
We agree with the 50 MVA limit but would request that it be included in the actual standard.
Yes
No
We feel that 20% is too great a buffer for this data and would suggest that the number reflect a

buffer of 10% or less. We feel like having a buffer that is too high would cause entities to not use testing verification and would use the operational data verification. We also feel that this verification should be as accurate as possible to reflect the system in planning.
Yes
If the testing time is 1 hour as written then we have a variance of the SPP criteria of 15 minutes, but if the team decides to change that time limit then we wouldn't and our answer would change to no.
No
Yes
VSLS for R2 there is an extra applicable in the chart. Would suggest removing.
No
By setting the MVA rating at 100MVA in section 4.2.1 for single units aren't you excluding units? It is then mentioned in the bullet below that units below 20MVA are included but as an aggregate if the site is over 100MVA. We aren't clear how this is expanding the standard. The other standards in this group refer to the limits used in the Compliance Registry. Should this be consistent with those?
Yes
We agree as long as the SDT creates the new SAR to address such devices including Synchronous condensers.
No
No
Yes
In the VSLS for R2 there is a "no" that needs to be deleted. In VSLS for R2 and R4 there is a footnote referenced on page 2 of the draft standard so it shouldn't be included here as well.
Yes
Yes
This question refers to the applicability of the standard yet doesn't reflect the wording in this question. In the standard the applicability for synchronous condensers is 20 MVA due to it being lumped with single units. This needs to be broken out in the applicability section of the standard.
Yes
We weren't able to locate the variable static reactive resources located at asynchronous generating facilities (e.g. wind and solar sites) within the standard as the question suggests. We feel like variable static reactive resources (e.g. static VAr compensators) that are not located at generating sites should have been included but would request that the team provide a limit on the size of these types of facilities. Our team isn't sure what a cutoff number would be, but would ask that the drafting team investigate this issue to come up with an appropriate number.
Yes
No
The team would like to move out the initial 20% to 2 years and add a year to the following phases as well i.e 40% 3 years 60% 4 years etc. 5.2.5 seems to be missing from the standard which doesn't include a bullet for 100% for those who need Board approval.
Yes
While the team agrees with this evidence, some of the older units in the system may not have this information readily available.
Yes
For new units or units that haven't changed you would not have prior data to provide. The drafting team may need to think about rewording to address this issue.

No
Yes
It seems there is room for clean up in the posted standard.
Individual
John Bee
Exelon
No
The requirements of MOD-024-1 and MOD-025-1 should remain separate. The testing periodicities and the reporting requirements for both of the existing Standards are different. In addition, the SDT needs to closely coordinate with existing testing and reporting requirements 1) Regional requirements and reporting criteria (e.g., MOD-024-RFC-01.1) and 2) Transmission Planner requirements (e.g., PJM has separate reporting criteria). If the SDT continues to push for a combined Standard, then consideration must be given to splitting out the requirements (i.e., separate Attachments) for Real and Reactive Testing.
No
The Transmission Planner should be the appropriate entity to receive this data.
No
The Standard needs to address correction factors for "ambient conditions" instead of "air temperature." Specifically, large generating units are typically water cooled and therefore the correction factor should be revised as such. In addition, as stated in the response to question 2 above, the Transmission Planner should be the appropriate entity instead of the Transmission Owner.
Yes
No
Currently Attachment 1 states that nuclear units are excluded from performing Reactive Power verification at minimum Real Power output. This exclusion must be extended to include a statement that nuclear units are not required to perform under-excited (leading) reactive capability verification testing. Nuclear units do not perform under-excited (leading) reactive capability testing due to concerns with unit stability and potential under voltage conditions on internal nuclear plant safety buses that may challenge safe plant operations and could lead to a plant transient or shutdown in accordance with NRC operating license. Suggest the following revision to Attachment 1 as follows: 2.2 Verify Reactive Power of all generating units other than wind and photovoltaic for maximum overexcited (lagging) and under-excited (leading) reactive capability at the minimum Real Power output at which they could normally be expected to operate. Nuclear Units are not required to perform under-excited (leading) reactive capability verification testing or Reactive Power verification at minimum Real Power output.
Yes
The time of one hour as a minimum is reasonable; however, the reactive capability may not able to be tested at the rated Real Power Capability. It may not be feasible to perform both Real and Reactive tests at the same time. Considerations must be given for the generator reactive capability curve (RCC).
Yes
Recording the test data as soon as a limit is encountered is reasonable; however, the reactive capability may not able to be tested at the rated Real Power Capability. It may not be feasible to perform both Real and Reactive tests at the same time. Considerations must be given for the reactive limits given by the plant specific generator reactive capability curve (RCC) at the attainable real power output. Currently Attachment 1 states that nuclear units are excluded from performing Reactive Power verification at minimum Real Power output. This exclusion must be extended to include a statement that nuclear units are not required to perform under-excited (leading) reactive capability verification testing. Nuclear units do not perform under-excited (leading) reactive capability testing due to concerns with unit stability and potential under voltage conditions on internal nuclear plant safety buses that may challenge safe plant operations and could lead to a plant transient or shutdown in accordance with NRC operating license. Suggest the following revision to Attachment 1

as follows: 2.2 Verify Reactive Power of all generating units other than wind and photovoltaic for maximum overexcited (lagging) and under-excited (leading) reactive capability at the minimum Real Power output at which they could normally be expected to operate. Nuclear Units are not required to perform under-excited (leading) reactive capability verification testing or Reactive Power verification at minimum Real Power output.
Yes
Yes
Yes
Yes
Yes
It is strongly suggested that the SDT review each existing Generator Real and Reactive Power Capability Regional Standard (or other guidance) currently in place for best practices and potential conflicts. As stated in responses to questions 5, 7, 13, and 14 nuclear units do not perform under-excited (leading) reactive capability testing due to concerns with unit stability and potential under voltage conditions on internal nuclear plant safety buses that may challenge safe plant operations and could lead to a plant transient or shutdown in accordance with NRC operating license. Exelon Nuclear is a member of and has 17 nuclear units in two Regions (ReliabilityFirst and SERC). RFC Regional Standard MOD-025-RFC-01, "Verification and Data Reporting of Generator Gross and Net Reactive Power Capability," currently has a specific exclusion that "Under-excited (leading) Reactive Power capability verification is not required of nuclear units." SERC Regional Criteria, "Verification of Generator Real and Reactive Power Capability," has the following statement regarding nuclear units, "(t)he capabilities of nuclear units will be determined taking into consideration the fuel management program of the unit and any restrictions imposed by regulatory agencies.
Yes
Nuclear units do not perform under-excited (leading) reactive capability testing due to concerns with unit stability and potential under voltage conditions on internal nuclear plant safety buses that may challenge safe plant operations and could lead to a plant transient or shutdown in accordance with NRC operating license. Performance of reactive capability tests cannot challenge nuclear plant NRC licensee Technical Specification voltage limit requirements.
Yes
Nuclear units do not perform under-excited (leading) reactive capability testing due to concerns with unit stability and potential under voltage conditions on internal nuclear plant safety buses that may challenge safe plant operations and could lead to a plant transient or shutdown in accordance with NRC operating license. Performance of reactive capability tests cannot challenge nuclear plant NRC licensee Technical Specification voltage limit requirements. Exelon strongly suggests that the SDT coordinate this revised Standard with the Nuclear Regulatory Commission (NRC) to preclude any challenges to the licensing basis of any of the nuclear generating facilities. Suggest that all exceptions to test performance criteria be pulled forward into body of the Standard. Additional comments for MOD-025-2 Attachment 1 • Step 2.3 – remove reference to "rated real power" - the reactive power test is conducted as a stand alone test using the attainable real power (which is generally governed by ambient conditions at the time of the test). • Step 2.4 – remove reference to "over-excited reactive capability" – the over-excited test is conducted for a minimum of 1 hour • Step 3.4 – remove reference to "correction factor: - this applies to correcting MW as part of the MOD-024 test. Reactive power is tested at the attainable MWe.
Yes
No

Yes
The proposed NERC Standard MOD-027-1 should have a specific exclusion for nuclear generating units which have governors that operate to control steam pressure and which do not respond to grid frequency deviations. This is consistent with the Eastern Interconnection Reliability Assessment Group (ERAG) Multi-Regional Modeling Working Group Procedure Manual version 5, May 6, 2010 which states in Appendix II, Section B Dynamic Modeling Requirements, Paragraph 2b) that “Turbine-governor representation shall be omitted for units that do not regulate frequency such as base load nuclear units, pumped storage units…”.
Yes
Exelon strongly suggests that the SDT coordinate this revised Standard with the Nuclear Regulatory Commission (NRC) to preclude any challenges to the licensing basis of any of the nuclear generating facilities. The proposed NERC Standard MOD-027-1 should have a specific exclusion for nuclear generating units which have governors that operate to control steam pressure and which do not respond to grid frequency deviations. As detailed in a memorandum from Jesus (Nano) Sierrra (FERC) to John Odom (ERAG Management Committee Chair), "Follow-up on the Provision of Primary Frequency Response by Nuclear Units in the ERAG-MMWG Dynamic Models," dated April 27, 2011, most all generating units do not respond to frequency deviations; however, there are some nuclear unit designs that do have limited response to under frequency conditions. It is important to note that even if a nuclear unit' s governor design does have limited response to grid frequency deviations, the nuclear unit is administratively restricted by their respective NRC operating license requirements to 100% thermal power. It is not clear from the proposed Standard MOD-027-1 or the Implementation Plan the SDT intended implementation timeline for the first verification period. That is, when must Requirement R2 be completed for the first 25% of the Generator Owner's applicable units? The second 25%? Etc. It is confusing when considering the wording in Section A.5, "Effective Date:" combined with the wording in Attachment 1, Criteria 2 of the Standard. In addition, the Implementation Plan does not provide any further guidance. Is the intent that the staggered percentage implementation provides the start time for the generating units to complete R2 within a following ten year period? This would allow the applicable units to modify/install recording equipment and then set T=0 to then start the ten year staggered verification period. OR Is the intent to short cycle the initial verification period during implementation based on the percentage of units and then set up a ten year staggered verification period thereafter?
No
The SDT needs to evaluate the requirements related to the Steady State Stability Limit (SSSL). Specifically, Section G (top of page 7) states "(F)or the coordination required by this standard, the Steady State Stability Limit (SSSL) is the limit to synchronous stability in the under-excited region with fixed field current." This conflicts with Requirement R1.1.1 that states "… assuming normal AVR control loop and system steady state operating conditions. Currently the two statements are in conflict with one another in that one requires a "fixed" field current (i.e., AVR in "manual") and the other requires "normal operation" (i.e., AVR in "automatic"). The SDT needs to allow for automatic mode for AVR to accommodate those Generators that have redundant automatic channels as is the case for newer digital AVRs. This will allow the owner to use AVRs automatic mode when plotting SSSL.
No
Exelon does not see a reliability need to include static reactive resources in PRC-019. The standard as written is applicable to voltage regulating controls and limit functions with generator capabilities and protection system settings which is generator specific. Adding static reactive resources would require unnecessary additional guidance to be included in the standard. The maintenance and coordination of relays related to static reactive resources is currently covered in PRC-005 and modeling and studies are included in the MOD standard.
Yes
No
There is a conflict with the implementation periods stated within the body of Standard PRC-019-1 and the associated Implementation Plan. PRC-019-1 Section 5 Effective Date Step 5.1.1 states "(b)y the first day of the first calendar quarter, one year following applicable regulatory approval … " [emphasis

added]; however, the Implementation Plan states the Effective Date is "(t)he first day of the first calendar quarter two years following applicable regulatory approval … " [emphasis added]. Exelon requests that the implementation period be 2 years following regulatory approval. Nuclear generating stations have refueling outage schedule windows of approximately 18 months or 24 months (based on reactor type). An implementation period of 2 years will allow for any modifications to existing equipment be completed during a refueling outage.
No
In addition to the methodology listed, a provision should be allowed to use an alternative acceptable methodology that meets the intent of the Standard such as a methodology that uses impedance locus for loss of field for settings for the loss of field relays. Attachment G second formula is incorrect and should be corrected as follows: R = V2 g/2*(1/Xs+1/Xd) (Divide by 2)

David Thompson
Yes
No
The TP or the PC (PA) is the entity who will use the data. R1.3 and R2.3 specifies that the TP be given this data.
No
Providing the ambient temperatures at the time data is collected is acceptable. However, there is no simple correction factor that can be provided. Reactive capabilities under different conditions cannot be assumed to be the same.
No
We believe that Section 4 Applicability (4.2.1 and 4.2.2) for this standard should be revised to match the Section 4 Applicability for MOD-026-1 and MOD-027-1. NERC is focusing on standard requirements that have significant impacts on system reliability. Including smaller units without demonstrating their criticality to the system appears inconsistent with this philosophy. Verification for smaller units should only be required if technically justified by the Planning Coordinator as specified in 4.2.4 of MOD-026-1. The use of "sister" (essentially identical) units should be allowed by the standard (as is allowed in SERC's current MOD-025 procedure). Independent verification of essentialy identical units should not be required.
No
Although we agree that four points are sufficient to provide a straight line approximation over a unit's operating range, we don't agree that four points are needed for baseload units. We strongly agree with the Commission's statement that "such a requirement for all generators may not be necessary." First, we believe 2.2, of Attachment 1 to the standard, should exempt all base load units (not just nuclear units) from verification of reactive capability at minimum real power output. There are other units that the industry should be able to exempt based on their normal operating modes. Examples are peaker CTs and units that have restrictions (environmental, run of the river, etc.) preventing operation at minimum load. Finally, for units where verification of multiple points are needed, the analytical approach to verification, discussed in our responses to Questions 10, 11, and 14, serves this purpose very well. This concern is addressed in Paragraph 1321 of the FERC Order which states: "…other than baseload units, most generating units rarely operate at full MW loading. It is unclear what reactive capability is available throughout a unit's real power (MW) operating range. Therefore, we believe a clearer standard would require a verification of MVAR capability throughout a unit's real power (MW) operating range. However, we share concern with several commenters that such a requirement for all generators may not be necessary." Also, We do not believe that verification for

leading capability should be required where operational practices preclude operation in a leading mode.
Yes
Yes
But, we believe that there is little value to a minimum load, vars-out requirement. Also, it will be difficult to achieve since the system usually has minimum VAR output requirements when operating at minimum load. Experience has shown that a large unit cannot reach the full available lagging (many times) or leading (most times) reactive capability values due to voltage limitations. That does not mean that that capability is not available.
No
It is noted that this criteria is not consistent with the criteria for generators or with 4.2.1 of the draft standard.
No
As the draft is currently written, these two methods are understood to be allowed. However, we believe a third alternative, engineering analysis, is needed in order for GOs to be able to verify generating unit reactive capabilities that are suitable for transmission system planning studies. It is proposed that Requirement R1.1 be re-written as follows: "Verify the Real and Reactive Power capability of its generating units and shall verify the Reactive Power capability of its synchronous condenser units in accordance with either Attachment 1 (staged testing or operational data) or by a new Attachment 3 (addressing engineering analysis)." Requirement R1.2 could then be qualified to be limited to reporting the results from staged testing or the use of operational data, and a new R1.3 could be inserted to require suitable reporting of the results from an engineering analysis. The time horizon of the two requirements in this standard are Long-Term Planning. MOD-025-2 does not have to focus solely upon operational testing to determine capabilities used for planning entity models. It is noted that TOP-002-2a R13 now requires the GOP to perform real and reactive capability testing at the request of the BA or TOP. The test can be specified if determined to be necessary by the BA or TOP.
No
Since the "expected value" is not clearly identified, it is not possible to determine if 20% is an appropriate value. Furthermore, if the "expected value" is the "D curve" for lagging Vars, we believe this is not a realistic expectation since operational data for most generating units does not approach 80% of the "D curve" value in normal operating conditions (or even in staged testing based on our experience). A recent survey of the SERC region has shown that only 34% of 85 generators surveyed performing staged Q production tests could reach 80% of their D curve lagging Q capability. The same survey showed that only 19% of 32 generators surveyed performing staged Q absorption tests could reach 80% of their underexcitation limit (UEL) characteristic setting. Therefore, the "within 20% of the expected value" requirement should be deleted. If an engineering analysis (which uses operational data for analytical model confirmation) is allowed as an alternative verification method, the 20% tolerance given above is not needed. Any operational data should be allowed if accompanied by engineering analysis that calculates appropriate expected limits. This will be more useful to the Transmission Planner than a value from operational data within 20% which does not give the appropriate expected limit.
No
No
Yes
1) This requirement will require units that normally do not run or have a very low capacity factor to be verified. Please add a provision for excluding these requirements for units that do not regularly run, similar to other NERC standard exemption requirements. 2) The standard needs to allow the inclusion of engineering analysis (with operational data) to supplement or replace testing when appropriate. It is noteworthy that the original NERC Board Approved version of this standard states in

requirement R1.3 that acceptable methods for reactive capability verification "include use of commissioning data, performance tracking, engineering analysis, testing, etc." This represents the "allowance to use of all the tools in the toolbox" approach which is appropriate when no single tool is sufficient to accomplish the stated reliability objectives, consistent with the FERC Acceptance Criteria of a Reliability Standard (reference Paragraphs 321, 324, 328, 332). This approach is reflected in the SERC regional procedure for MOD-025-1 which was developed by a joint transmission-generation task force. 3) The 5-year test interval should be changed to a 10 year interval since there is a provision for re-verification with an associated 10% system change. 4) In R1.2 and R2.2, the phrase "same information" is used, while in M1 and M2 the phrase "equivalent information" is used. We suggest changing R1.2 and R2.2. to match the M1 and M2. 5) Specifying Normal Operating H2 pressure in Attachment 1, section 2.5 may not produce the desired maximum Q cap results. Consider changing "normal operating " to "maximum sustainable (within design limits)" 6) In Attachment 1, section 2.2, we suggest changing "they could normally be expected to operate" to "they are normally expected to operate". 7) We suggest revising Requirements R1.3 and R2.3 to read: "Submit the capability information to its TP within 90 calendar days of completion of the verification." to clarify these requirements and to make them consistent. We also believe 90 days will create an undue hardship for GOs who own a large number of generators and believe this requirement should allow for additional time when authorized by the TP or PC. 8) The first paragraph of the Compliance Data Retention Section D 1.2 is difficult to understand. Please simplify using multiple sentences, if possible. 9) In the VSL table for R1 and R2, we suggest changing the phrasing "from the date the data was recorded" to "from the verification date" each time it is used (7 times). 10) Revise attachement 1 section 5.1 and 5.2 to change “last more than 6 months” to “last more than 1 year,” to align with the typical long-term planning horizon. 11) It is noted that MOD-11, which is supposed to clarify modeling data requirements, has not yet been completed and approved. Yet MOD-25 is requiring verification of this data. It is also recognized that generator verification methods are producing results that are not being directly used in the models (due to various operating or system limitations). As a result, it is not clear that MOD-025 is achiving the reliablity purpose intended. 12) This standard establishes a periodic generator testing regime which, when implemented on a large number if generators, creates a continuous state of testing across the BES. We question if this approach really improves the reliability of the BES. The use of normal operational data, supplemented by analysis, represents a better approach for most generators. Targeted testing can have application on a limited basis.
No
Yes
Yes
Yes
We think it is possible that the unit rating which is critical to the BES may vary from region to region.
No
Yes
It is our opinion that a 20MVA machine is too small to be able to significantly impact a frequency excursion. A technical basis for including units as small as 20MVA in all regions needs to be provided. NERC is focusing on standard requirements that have significant impacts on system reliability, and including units this small seems to be inconsistent with this philosophy. 2)
Yes
Yes
No

No
Group
SERC Planning Standards Subcommittee
Charles W. Long
Yes
No
TThe PSS believes that the Transmission Planner (TP) should receive this information initially (which is what the standard currently requires).
Yes
The Transmission Planner should be allowed to require that the Generator Owner provide an adjusted real power value (instead of an adjustment factor) based on different ambient temperature(s).
No
The use of sisters units should be allowed by the standard. Also, verification should apply on the 75 MVA units, and above. Units smaller than this have very little impact on grid reliability. However, the standard should apply to designated blackstart units included in a system restoration plan, regardless of size.
Yes

Yes
No
We recommend a limit of 20 MVA since these may be in remote areas where reactive capability is critical.
Yes
No
The 20 % requirement is too restrictive. Any operational data should be allowed to be used if it is accompanied by engineering analysis which calculates appropriate expected limits. This will be more useful to the Transmission Planner than a value from operational data within 20% which does not give the appropriate expected limit.
No
No
Yes
If the demonstrated value is less than the expected value, then the GO's should be required to provide calculated values for reactive capability in addition to the demonstrated values (this should be included in R1). Without this, the data is useless to the Transmission Planners. The comments expressed herein represent a consensus of the views of the above-named members of the SERC EC Planning Standards Subcommittee only and should not be construed as the position of SERC Reliability Corporation, its board, or its officers”

Tacoma Power is not aware of any industry accepted standard air ambient real power correction factor for hydro units.
No
1) Gross unit nameplate is not an industry defined term. The size of unit required for verification for hydro units should be the FERC defined licensed hydro unit nameplate rating. 2) Aggregate gross nameplate plant/facility capacity for hydro units is not a defined term and may not be the combined unit capacities. It is common for hydro facilities with multiple units have increased head losses or other restrictions that restrict or limit plant capacity below the aggregate gross nameplate capacity. For determining gross aggregate hydro plants and units for verification it should be the FERC defined plant licensed capacity.
Yes
No
Depending on the size of the unit and location in the transmission system operating the unit at full rated reactive capability with normal steady state transmission voltages may subject the plant and transmission system to a sustained overvoltage. The over-excitation limit should be verified in the same way the under-excitation limit is verified.

Even if the variable devices or their impact is well defined, such as "Devices within 2 buses and that can affect the transmission system voltage plus or minus 5% or greater", including this requirement for variable static reactive sources could involve a wide scope of devices and potentially many owners and operators for very little improvement in reliability.

Consistancy with the compliance registry and the BES definition is important.
No
No, we believe that the four points are not adequate to describe a unit's capability. FAC-008 and FAC-009 require us to have a normal and emergency rating and the WECC validation policy requires the verification of the unit's capability. Is this standard intended to replace those standards/policies? If so it was not clear in the project documentation. If not, we believe this standard to be redundant to our existing policies and procedures here in WECC.
No
No, if this is intended to verify an emergency reactive capability we believe 15 minutes is sufficient. If this is intended to verify a normal reactive capability then 1 hour is reasonable.
Yes
Yes
Yes
No

What is the technical basis for the 20%? It seems high.
No
No
No conflict, but as stated before, it seems to be redundant with FAC-008, FAC-009 and the existing WECC validation policy.
Yes
1. The language in the Applicability Section 4.2.1, implies that the standard applies to only synchronous condensers in generating facilities. Please clarify. 2. As stated before, we believe that FAC-008 and FAC-009 specify our generator have an normal and emergency rating. The standards should use similar language in requiring validation of capability. However, our regional policy required by MOD-010, specifies validation of the generator reactive capability, thus we believe this standard is redundant and not needed. That is unless MOD-010 is going to be retired. 3. Note 1 in Attachment 1 states that the data point may not match the manufacturer capability curve or the verified values for the MOD-010 standard. We question what the point of this standard is if not to validate. Note 1 mentions other items that might be discovered during the validation required by this standard, but we believe those benefits are achieved by our existing validation policy.
Yes
We believe Black Start units, regardless of size, should be considered in this standard.
No
WECC has an existing model validation policy that is well defined and established. This project documentation does not specifically state that MOD-012 and MOD-013 would be retired. If not, this policy would be redundant with the existing WECC policy.
Yes
Yes
Yes
Yes
No
We believe that the tutorial like language in Section G is not appropriate for a standard. There is an abundance of material available describing the coordination of generator protection equipment, such as textbooks, IEEE tutorials and even NERC tutorials. We believe referencing the documents could be appropriate and helpful. Even though the diagrams are listed as examples, we believe they might be interpreted a recipe to be followed.

Recommend changing Section 4.2 Facilities to match Section 4.2 Facilities as it is written in MOD-026-1 and MOD-027-1 below: 4.2. Facilities For the purpose of this standard, the following Facilities are considered, “applicable units.” Units or plants with an average capacity2factor greater than 5% over the last three calendar years that meet the following: 4.2.1 Generating units connected to the Eastern or Quebec Interconnections with the following characteristics: • Each generating unit with a gross nameplate rating greater than 100 MVA, connected at the point of interconnection3at greater than 100 kV. • For each plant with a gross aggregate nameplate rating greater than 100 MVA, connected at the same point of interconnection at greater than 100 kV: o Each unit with a gross nameplate rating greater than 20 MVA; and o The remainder of the plant as an aggregate. There should also be some allowance for Units which are nearly identical and therefore model the same.
No
The current SERC Regional Criteria requires gross and net reactive capability be determined within the power factor range at which the generating equipment is normally expected to operate. We do not believe anything is gained by testing in power factor ranges where the unit is not expected to operate.
No
First of all “expected value” is not defined. Second any expected value based solely on nameplate data is subject to great variation based on the system the generator is connected to and should not be used to draw conclusions of satisfactory or unsatisfactory test results.
Yes
Attachment 1 Item 1 requires testing of units that are 20 MVA and above to be tested a second time if they are tested as part of the aggregate.

Yes
No
This question seems to have identified the TO in error. MOD025-2 requires data to be submitted to the TP. TP is the appropriate entity to receive the data.
No
The ambient temperature and other factors that influence the ouput should be included. The GO should provide temperature dependent and other data tables/graphs to the TP. Again, the comment form and attachment seem to conflict with R1 and R2 to provide data to the TP not the TO.
Yes
No
Reactive capability cannot be determined, generally, without disturbances to the system. Long-term fault recorders could be installed at all generator high-side buses and verification of generation to any eventual disturbances could be used to get a better picture of the plants reactive power capability.
Yes
Yes
Yes
No
20 MVA seems more consistent with the reasoning in question 4.
Yes
No
The data should be accepted as is unless the data is meaningless.
No
No
Yes
Regarding reactive capability, the SDT has recognized that this standard will not meet the purpose “To ensure that planning entities have accurate generator Real and Reactive Power capability data when assessing Bulk Electric System (BES) reliability.” Should the standard and/or purpose be adjusted to where they match? Reactive capability cannot be determined, generally, without disturbances to the system. Long-term fault recorders could be installed at all generator high-side buses and verification of generation to any eventual disturbances could be used to get a better picture of the plants reactive power capability. R1.3 is unclear we propose: Submit the recorded data to its Transmission Planner within 90 calendar days of the date the data is recorded.
No
Yes

Attachment 1, 2.1 and 2.2: It would be more reasonable to allow for some small variation in real power level around the rated gross real power output and minimum real power outputs, perhaps within +/- 5 percent of these values. This would allow for variability in coal conditions, system voltages, etc. Also, the requirement in 2.1 for 90 percent of wind turbines online may be impractical in many cases. A lower value such as 75 percent may be more reasonable.
No
Yes
Yes
No
No
Yes
It is not clear how this standard would be applied to wind generators. They should perhaps be specifically exempted from these requirements.
Yes
Yes
No
The primary applicability should be to rotating synchronous machines which must have their protection settings and excitation controls properly coordinated with the machine capability. It is not clear how this can be applied to wind generators.
No
Replace the phrase "...preventing tripping..." with "...reducing the potential for tripping..."
Yes
No
The following should be added to the list in Section G: 1. under-excited limiters or minimum excitation limiters 2. over-excited limiters or maximum excitation limiters.
Yes

No
Yes
1. R1.2 needs to be clarified, and more time allowed. The phrase, "within 90 days following the identification or implementation of systems, equipment, or setting changes..." is vague, and should be replaced with "within 120 days of modifications made to systems, equipment, or setting changes...". The requirement should clarify that the clock starts 120 days after the date that the affected generator returned to service following the modifications. 2. It is not clear how wind generators can be subject to this standard. The information in Section G does not relate to wind machines.

Yes
Yes
No
GRE doesn't agree with doing the under and over-excited limits at min. power levels. Mainly for baseload units, this is not representative of where the units run. Also, this would be costly when you are taking a baseload unit to min. load for the testing. There are also many unit specific conditions that exist that may prevent an unit from running at its true minimum load. If they want it at different points I think they should leave it up to the GO/GOP's to decide at what other load point they want to run the test.
Yes
GRE would object to doing this at URGE because URGE is not our normal operating condition. The reactive power testing should be done at normal full load (normal operating conditions) to be representative of how much reactive power the unit can put out or absorb during normal running conditions. GRE doesn't agree with doing the under and over-excited limits at min. power levels. Mainly for baseload units, this is not representative of where the units run. Also, this would be costly when you are taking a baseload unit to min. load for the testing. There are also many unit specific conditions that exist that may prevent an unit from running at its true minimum load.

Not clear why would data be submitted to TO. Based on Functional Model, TP, TOP or PC would be more applicable.
No
Generating facilities are already designed and ratings determined based on maximum expected ambient temperatures. Besides, equipment cooling may not be directly dependent on ambient temperature. Providing the details to other entities would be of no practical value. GOs have to meet declared capabilities as registered or derate their facilities if needed.
No
In principle, using compliance registry as a sole criteria for applicability of Reliability Standards removes technical evaluation and justification from the process. The value that technical experts participating in SDTs may add becomes limited, which ultimately does not benefit the industry.
No
Technically, only verification at the maximu rated active power output has practical value since it is the most limiting operating condtion in terms of reactive power capability. Verifying reactive power capability at lower active power outputs is redundant because: 1. The capability will obviously be somewhat higher than at maximum active power output 2. Registration data normally include only Qmax and Qmin, which are determined at unit's rated active power output. 3. Reactive capability does not depend on unit's active power output as much as on other factors, such as system or station service voltages D curve is developed based on calculated data. The purpose of this should not be verification of the curve
Yes
It may be better to specify a particular rate of change of measured temperature determining that heating has stabilized instead of selecting an arbitrary time period.
Yes
Only verification of (1) has practical significance; (2) and (3) are redundant. Please see Comment 5.
Yes
Not clear why would verification be required for generating units over 20 MVA while for SCs the threshold is over 50 MVA, especially having in mind that SCs are specifically used to provide reactive support
Yes

No
Such a wide margin seems to defeat the purpose of verifications. If such margin is technically acceptable to planners, the question is why even requiring verifications, especially for smaller units. It is hard to immagine that actual capability (active or reactive) of generating units/facilities would ever be lower than 80% of declared.
No
No
No
No
Yes
This standard would not apply to SCs in any case
No
No
Yes
The standard apparently favours ambient monitoring as a verification method. While this method has certain advantages over methods traditionally used to verify response of turbine-governors (off-line and on-line step tests), it should be well understood that its implemention is associated with additional costs and difficulties. The question is how would GOs make use of ambient monitoring data to verify the models? GOs are responsible only for equipment models and would not normally have overall system models which are necessary to evaluate the results of ambient monitoring. That puts the focus back on traditional approaches.
Yes
No
Yes
Yes
Yes
Yes
No
Yes
The note in section G may have to be revisited. The main issue is that active excitation limiters can prevent a unit from unneccessary tripping during system transients. The standard should encourage activation and proper setting of avaiable excitation limiters
Individual

Northeast Utilities

Yes
No
The Transmission Operator (TOP) and Transmission Planner (TP) are far more likely to need and use the data and models identified and dispatch the units in their market area. In New York, the NYISO as the TOP is responsible for real-time modeling and dispatch (specifying both real and reactive schedules), and as TP the longer term modeling. The Transmission Owners (TO's) do not have this type of relationship with the Generation Owners (GO's) and Generation Operators (GOP's). R1: A standard should be developed that makes reactive power testing mandatory for all units above 75 MVA. This standard will provide the TOP with critical information on the total dynamic reactive capability of dispatched generation.
Yes
Real and reactive power output is affected by the thermal conditions in effect a t the time of testing and dispatch. The output of a generator, and therefore the model of its output, can be more or less temperature dependent, e.g., a combustion turbine with versus the same combustion turbine without inlet chillers. Attachment 1 specifies that the temperature only be recorded at the end of the verification period. Temperatures can vary significantly over the course of the verification period, and at a minimum the ambient temperatures at the beginning and end of a verification period should be recorded. It would also be meaningful and helpful to record ambient temperatures at intermediate points during a verification period. The Real Power data submitted should not be adjusted to a temperature other than ambient. When collecting real time data, it should be "what you see is what you get"; adjustments should not be accepted.
No
Generally, only units larger 75 MVA are impactful. It is recommended making 75 MVA the reporting floor [regardless of connected voltage]. This is consistent with current draft BES definition being prepared by the BES SDT.
Yes
Yes
No
Regarding Part 2.1, in the NYISO reactive power is tested at a real power level above 90% of maximum. The tariff was designed in this manner for a few reasons: (1) not to be simultaneous test with 100% real power test and (2) provide a reliable maximum reactive test when the unit is stressed, but is still capable of providing reserve power. Recommend providing some flexibility in this requirement by stating that reactive power can be tested above 90% of maximum real power.
Yes
Yes
Yes
Yes
No
No
No
No

No
A Planning Coordinator should be able to request a review of turbine/governor and load control or active power/frequency control system model even though response is not consistent from one frequency excursion event to the next from any unit connected to the power system. If not being listed in the Applicability section is an issue, then the wording should be changed in the Applicability section so as not to preclude the Planning Coordinator from collecting necessary data.
No
Can’t generators be operated as synchronous condensers if needed?
No
No
Yes
In the Applicability Section, why the differences between the Eastern Interconnection/Quebec and WECC in generating unit and plant sizes specified?
No
This draft standard appears to have been written from a traditional steam or combustion turbine generator perspective. It may not work for a photovoltaic or wind generator installation.
No
Generally only units larger 75 MVA are impactful. Recommend making 75 MVA the reporting floor [regardless of connected voltage]. This is consistent with the current draft BES definition being prepared by BES SDT.
Yes
Only units larger 75 MVA are generally impactful. We recommend making 75 MVA the reporting floor [regardless of connected voltage]. Coordination will be needed. Static VAR Compensators are typically self protected by the vendor. As long as the interface point (transformer) is properly and redundantly protected and the Static VAR Compensator safely shuts down for internal faults or out of spec operation, there should be minimal need for coordination with transmission system protection. However, this issue would have to be researched with the vendor of the equipment. Coordination with the Transmission Operator will have to be reviewed for pre and post protection system operation conditions.
No
Modify the wording to reflect all ‘real and reactive power sources,’ not limiting it exclusively to traditional rotating machinery.
Yes
Yes
No
The data retention section of the standard is vague with respect to responsibilities of the various parties. It would appear that the data retention responsibility falls to either the Generator Owner or the Transmission Owner with a synchronous condenser on its system. If, however, the Transmission Owner is also required to retain compliance data of generator and transmission system coordination, a substantial amount of time may be required to gather this information as it does not exist today. At the very least, once this standard becomes effective an effort with generators will be needed to assemble the appropriate information demonstrating the proper coordination of transmission system and generator relaying. This could take a considerable amount of time to complete. Responsibility for data retention should be placed on the owner of the equipment.
No
Yes
Related to the “Examples of Coordination”, the P-Q diagram, the R-X diagram, and the Inverse Time

Diagram are not all interchangeable. For this Standard only the P-Q Diagram can be used for compliance because it provides both under and over excitation capabilities of the machine. This curve is commonly used in industry and is readily understood by Engineers, System Operators and Generator Operators. The R-X Diagram example should be considered optional if impedance relays are used that reach beyond the generator-transformer protection zones. However, the R-X Diagram should not be mandatory. Concerning the Inverse Time Diagram, this example should be deleted since it only provides information on machine overexcitation capabilities and does not address underexcitation settings.

PPL Generation
Annette Bannon
No
MOD-024 has already been incorporated into a regional standard by RFC (MOD-024-RFC); and, as is implicit in the term "standard," these documents should change only infrequently.
No
PPL Generation, LLC's Registered Entities are already performing VAR testing and reporting the results to our RTO (PJM), in accordance with Manual PJM-14D, and PJM then makes this information available to other entities. It would be very confusing to have to conduct two different VAR tests (PJM and NERC), possibly resulting in two different values (depending on the final wording of MOD-025), reported to two different entities.
No
The correction of real power capability to other-than-tested ambient conditions, as is currently performed by PPL Generation Registered Entities for MOD-024-RFC, is a complex matter involving the wet-bulb temperature, condenser cleanliness and other factors beyond simply the dry-bulb temperature, especially when using a total-unit thermodynamic computer model for this purpose. One must also consider low-ambient limitations; wintertime predicted capabilities must be truncated if they would otherwise exceed the generator or GSU rating. Corrections to other-than-tested ambients should be performed by the GO, using an on-request basis.
No
The applicability of this standard should include, "and having a capacity factor for the past three years averaging over 10%." As presently written this standard would require VAR testing of a small, emergency genset if located in a baseload facility interconnected > 100 kV.
Yes
The proposed verification at multiple points over a unit's operating range appears to derive from a belief that the verification test results will follow the generator OEM's D-curve; and, owing to the abnormal voltages created by VAR testing and aux bus drop-out limitations; this will not be the case.
No
The one-hour period appears to derive from D-curve (thermal limiting) expectations; and, as explained above, this will not be the case
Yes
Yes
Yes
Yes
Yes
Note however that the expectation, as discussed above, is (for certain PPL Generation Registered Entities' units) derived form the aux bus limits, not the D-curve.
No
Yes
Ref. the inputs made above, there should be just one VAR test, with a single set of results going to all parties.
Yes
PPL offers the following comments on Attachment 1: Att. 1, para. 2: Change the final sentence to

end, "within 20% of the expected real and reactive power values." Reason: Clarification Att.1, footnote to para. 2.1: Change "normal expected maximum" to "normal," and "at the time of the verification" to "for the ambient conditions during the verification." Reason: Clarification. The normal output of a unit is often not its (emergency) maximum generation, and the word "ambient" works better than "time." Att. 1, para. 2.1, 1st sentence: Change "at rated gross Real Power capability" to "within 20% of the Real Power capability." Reason: Clarification, see the comment above to para. 2. Also, the terms capability and rating have different meanings. Att. 1, para. 2.1, last sentence: Change "possible" to "practical" Att. 1, para. 2.2: Change exception in 1st sentence to "other than wind, photovoltaic and peaking (capacity factor < 10%)." Reason: Given that peaking units typically operate only during periods of maximum demand, it can be difficult to establish a realistic min power expectation, this exercise would add little or no value, and such testing would be unnecessarily economically burdensome. Att.1, para. 2.3: Add at end, "for baseload units. Values for peaking units (<10% capacity factor) may be recorded as soon as they are reached. Reason: The dispatch volatility of peaking units can make a one-hour hold-period unnecessarily economically burdensome. Att. 1, para. 2.5: Add at end, "if attainable. Otherwise a 10% variation is acceptable" Reason: Hydrogen pressure can vary, and minor disturbances should not disquality an otherwise-acceptable test. Att. 1, para. 3.2: Clarification is needed. Is the standard saying that a special-for-test voltage schedule should be established with the RTO? Att. 1, para. 3.3: Add at the end, "one or the other of these values may be calculated, if metering is not present at both locations." Reason: Same concept as para. 4.1. Att. 1, Note 1, 1st sentence: Add at the end, "or unit auxiliary system voltage limits or facility operational practices." Make the same change also for "transmission system conditions" in the third sentence. Reason: VAR testing involves creating abnormal voltages at the generator terminals and in the feeds to auxiliary equipment. Drop-out of aux motors can constitute the practical test limit. It is appropriate to apply safety margins in this respect (ref. facility operational practices), lest units be at risk of tripping in the course of conducting a reliability test. Att. 1, Note 2: Clarification is needed regarding the less-restrictive conditions being referred-to. Att. 1, para 3.4: Replace "and a correction factor...if needed" with "and, if requested, correction to other ambient conditions." Reason: Correction often involves more than a simple multiplication factor, especially when using a thermodynamic computer model for this purpose. This exercise includes truncating corrections to lower ambients for GSU and generator limits, if necessary. General: The generator OEM D-curve constitutes a rating, not a capability, and is applicable only at rated voltage. VAR testing involves identifying a capability at abnormal voltages, and is thus likely to rarely if ever match the D-curve. General: Where the RTO has an effective VAR testing program in place (as is the case for PJM) the results should be acceptable as-is for NERC compliance purposes, lest there be created two different tests, resulting in reporting of two different reactive capabilities to two different entities.
No
Yes
Yes
No
No
Yes
PPL Generation suggests the following changes: 1. Increase the capacity factor threshold identified in the Applicability Section from the current 5% to 10%. Otherwise, ambient monitoring may be required for an excessively long period. 2. Allow the use of OEM-provided governor models and, if adequate, existing models to satisfy the requirement in R2. OEM models can have equivalent-or-better validity than on-line testing. 3. Define what response is expected to be documented for Requirement 2.1.1 (as pertaining to a time-frame of 30 seconds or less, and to sudden frequency dips, not step-increases). Units have an immediate response (e.g. opening the control valves) and a long-term response (e.g. ramping-up the coal feed). Governors (the subject of this standard) deal only with the former category. Ambient monitoring should eventually provide a frequency-dip event to analyze, but the same is not true for opposite-direction events. 4. Should the recorded response in

Requirement 2.1.1 be the predicted response? It appears that the on-line response and the recorded response are the same thing. 5. In Requirement 2.1.1, clarify under what circumstances a lack of response constitutes suitable verification, e.g. experiencing a frequency drop for units running valves-wide-open or CTGs at baseload firing temperature.
Yes
No
See item 1 in Question 9 Response.
No
No
As stated in comment 2 for item 9 below, NERC is not being consistent in using the term "capability." It refers in other standards to that which can be achieved, not to the condition at which tripping is needed.
Yes
No
Yes
No
See comment 2 for item 9 below.
Yes
PPL Generation suggests the following changes: 1. Consider making this standard applicable to generation facilities having a capacity factor for the past three years averaging over 10%. The basis for this request: As presently written this Applicability would require compliance for a small, emergency genset if located in a baseload facility interconnected > 100 kV. 2. In Requirements R.1, R1.1.1, R1.2 and elsewhere where the term "capability" is used, consider using the term "trip limit". As currently written, it appears that Requirement 1.1.1 is semantically misdirected in requiring protectives to be set below equipment capabilities. A capability is what the unit can actually do (ref. MOD-024 and 025). It is not the limit beyond which damage, instability or other problems may occur. A unit with a 875 MVA GSU and 900 MVA generator, for example, may have a real power capability of only 750 MW based on boiler and turbine limitations. It is not possible to have trips set below a unit's capability, unless PRC and MOD apply different meanings for this term, which would not be suitable. Confusion may be caused by generator D-curves also being called “capability curves,” but here also one would not want to require that generator never be operated at the D-curve value.

Constellation Power Generation
Yes
Yes
No
Constellation Power Generation (CPG) agrees with this approach.
No
Although CPG agrees with the approach of applying this standard to all generation facilities in the compliance registry, mimicking it in the standard is redundant and problematic. Should the compliance registry change, then this standard may include facilities not registered with NERC. Conversely, this standard could potentially exclude facilities in the registry should the compliance registry change.
Yes

CPG agrees that the points chosen would provide a sufficient approximation of a unit's capabilities. However, these capabilities will never match a generator's capability curve for a multitude of reasons, and as such, some verbiage should be included in the attachment under item 2 instead of as a note at the end of the document. Further, the limitations on the unit that may not allow the unit to perform to its capability curve are most likely designed into the control system as limiters or protection system components so as to not allow damage to the unit. These designed controls should not be "investigated for resolution" as stated in Note 1.
Yes
Yes
Yes
Yes
Yes
Yes
No
No
Yes
CPG is concerned with the general wording of Attachment 1 as the verbiage is not auditable. For example, Item 2.1 states "Maintain as steady as possible Real and Reactive Power output during verification." The term "steady as possible" is extremely subjective and open to a multitude of interpretations. From a technical perspective, item 3.3 is not auditable because it is assuming that the voltages and the high and low side of the GSU are metered. This is usually not the case. A statement allowing for an entity to report on the requested metered points based on their configuration and allowing for some points to not be answered would be preferable. Likewise, Attachment 2 would require a similar statement.
No
No. CPG believes that the use of capacity factor, a variable data point, in the applicability of a standard is too problematic. Capacity factor is a market a function that is dependent on many variables outside of reliability and therefore does not belong in a reliability standard. CPG is also unsure as to how the SDT arrived at the MVA thresholds in each of the Interconnections, and is requesting that a technical justification of those thresholds be submitted along with the response of comments.
Yes
Yes
No
No
Yes
CPG is unsure as to what Requirement 2.1.1 is actually requiring. Please explain the difference between an on-line response to a frequency excursion vs. a recorded response. This sub requirement seems to be implying that each GO has the necessary equipment to capture an on line or recorded response. Is it the intent of the drafting team to force GOs to install equipment in order to comply

with R2.1.1 along with the conditions found in Attachment 1? CPG would also like clarification on Requirement 2.1.5. Outer loop controls don't affect the governor control (frequency loop). Lastly, CPG would like the SDT to describe how a GO will know that a frequency excursion event occurred on the BES if their facility was unaffected and the facility did not have equipment sensitive enough to measure within .15 Hz.
No
Although CPG agrees with the approach of applying this standard to all generation facilities in the compliance registry, mimicking it in the standard is redundant and problematic. Should the compliance registry change, then this standard may include facilities not registered with NERC. Conversely, this standard could potentially exclude facilities in the registry should the compliance registry change.
No

Consolidated Edison Co. of NY, Inc.
Yes
No
The Transmission Operator (TOP) and Transmission Planner (TP) are far more likely to need and use the data and models identified and dispatch the units in their market area. In New York, the NYISO as the TOP is responsible for real-time modeling and dispatch (specifying both real and reactive schedules), and as TP the longer term modeling. The Transmission Owners (TO's) do not have this type of relationship with the Generation Owners (GO's) and Generation Operators (GOP's). R1: A standard should be developed that makes reactive power testing mandatory for all units above 75 MVA. This standard will provide the TOP with critical information on the total dynamic reactive capability of dispatched generation.
Yes
Real and reactive power output is affected by the thermal conditions in effect a t the time of testing and dispatch. The output of a generator, and therefore the model of its output, can be more or less temperature dependent, e.g., a combustion turbine with versus the same combustion turbine without

inlet chillers. Attachment 1 specifies that the temperature only be recorded at the end of the verification period. Temperatures can vary significantly over the course of the verification period, and at a minimum the ambient temperatures at the beginning and end of a verification period should be recorded. It would also be meaningful and helpful to record ambient temperatures at intermediate points during a verification period. The Real Power data submitted should not be adjusted to a temperature other than ambient. When collecting real time data, it should be “what you see is what you get”; adjustments should not be accepted.
No
Generally, only units larger 75 MVA are impactful. It is recommended making 75 MVA the reporting floor [regardless of connected voltage]. This is consistent with current draft BES definition being prepared by BES SDT.
Yes
Yes
No
We recommend allowing the Transmission Operator (TOP) flexibility in determine the specific detailed nature of the reactive power tests performed in support its modeling. Regarding Part 2.1, in the NYISO, the maximum reactive power is tested at a real power level above 90% of maximum real power capability. The test was designed in this manner for a two reasons: (1) not to be a simultaneous test with 100% real power test and (2) to provide a reliable maximum reactive power test when the unit is stressed, but is still capable of providing reserve power. We recommend providing the TOP flexibility in this requirement by allowing reactive power to be tested above 90% of maximum real power capability. The NYISO Ancillary Services Manual also contemplates that GO’s will test lagging and leading reactive power during time periods more appropriate to their use. On p. 28 and p. 34 the manual states: • Lagging MVAr capability testing will normally be performed during on-peak hours. The VSS Supplier must operate at maximum Lagging MVAr for at least one hour for the test to be acceptable. • The Leading MVAr testing will normally be performed during off-peak hours. The Leading MVAr test shall be scheduled with the corresponding TO, who will inform the NYISO. Ref: http://www.nyiso.com/public/webdocs/documents/manuals/operations/ancserv.pdf Presumably, under the NYISO tariff the leading and lagging Reactive Power tests would not be performed at the same time or necessarily at the same “rated gross Real Power capability.” ISO-NE also notes that maximum leading and lagging reactive power may not be at the same real power output level. • Points #4 and #9 in Figure #1, the two [lagging and leading] break points, do not necessarily correspond to the same MW output of the Generator. Ref: http://www.iso-ne.com/rules_proceds/operating/isone/op14/op14b_rto_final.pdf Proposed language change to MOD-025 Attachment 1: 2.1. Perform verification of Real and Reactive Power capability of all generating units at maximum over-excited (lagging) and under-excited (leading) reactive capability at rated gross Real Power capability1, or at the Real Power level stipulated by the Transmission Operator. ...

No
No
A Planning Coordinator should be able to request a review of turbine/governor and load control or active power/frequency control system model even though response is not consistent from one frequency excursion event to the next from any unit connected to the power system. If not being listed in the Applicability section is an issue, then the wording should be changed in the Applicability section so as not to preclude the Planning Coordinator from collecting necessary data.
No
Can't generators be operated as synchronous condensers if needed?
No
No
Yes
In the Applicability Section, why the differences between the Eastern Interconnection/Quebec and WECC in generating unit and plant sizes specified?
No
This draft standard appears to have been written from a traditional steam or combustion turbine generator perspective. It may not work for a photovoltaic or wind generator installation.
No
Generally only units larger than 75 MVA are impactful. Recommend making 75 MVA the reporting floor [regardless of connected voltage]. This is consistent with the current draft BES definition being prepared by the BES SDT.
Yes
Only units larger 75 MVA are generally impactful. We recommend making 75 MVA the reporting floor [regardless of connected voltage]. Coordination will be needed. Static VAR Compensators are typically self protected by the vendor. As long as the interface point (transformer) is properly and redundantly protected and the Static VAR Compensator safely shuts down for internal faults or out of spec operation, there should be minimal need for coordination with transmission system protection. However, this issue would have to be researched with the vendor of the equipment. Coordination with the Transmission Operator will have to be reviewed for pre and post protection system operation conditions.
No
Modify the wording to reflect all 'real and reactive power sources,' not limiting it exclusively to traditional rotating machinery.
Yes
Yes
No
The data retention section of the standard is vague with respect to responsibilities of the various parties. It would appear that the data retention responsibility falls to either the Generator Owner or the Transmission Owner with a synchronous condenser on its system. If, however, the Transmission Owner is also required to retain compliance data of generator and transmission system coordination, a substantial amount of time may be required to gather this information as it does not exist today. At the very least, once this standard becomes effective an effort with generators will be needed to assemble the appropriate information demonstrating the proper coordination of transmission system and generator relaying. This could take a considerable amount of time to complete. Responsibility for data retention should be placed on the owner of the equipment.
No

Yes
Related to the “Examples of Coordination”, the P-Q diagram, the R-X diagram, and the Inverse Time Diagram are not all interchangeable. For this Standard only the P-Q Diagram can be used for compliance because it provides both under and over excitation capabilities of the machine. This curve is commonly used in industry and is readily understood by Engineers, System Operators and Generator Operators. The R-X Diagram example should be considered optional if impedance relays are used that reach beyond the generator-transformer protection zones. However, the R-X Diagram should not be mandatory. Concerning the Inverse Time Diagram, this example should be deleted since it only provides information on machine overexcitation capabilities and does not address underexcitation settings.

Thad Ness
American Electric Power
Yes
In general, AEP is not opposed to combining MOD-024-1 and MOD-025-1 into a single MOD-025-2 standard.
Yes
Draft Standard MOD-025-2 provisions 1.3 and 2.3 both state that the data be provided to the Transmission Planner, rather than the Transmission Owner as stated within this question #2. We agree that the Transmission Planner is the correct recipient for this data.
Yes
Again, we believe the question should be associated with the providing of ambient temperature and correction factor information to the Transmission Planner and the Resource Planner rather than the Transmission Owner. We believe the Resource Planner should provide the ambient temperature value, while the Generator Owner should provide the correction.
Yes
Yes
The results of the test may not accurately reflect the VAR capability due to system conditions or alarm stopping the test and not reflect the actual generator limit in a real time scenario. This is discussed in Notes 1 and 2 of Attachment 1.
Yes
This requirement is stated in Attachment 1, section 2.3.
Yes
This is stated in Attachment 1, section 2.4. A clarification could be in order to relate the recording of the time when the limit is reached to the requirement that the test be conducted over a one hour interval. For example, if a limit is reached in 15 minutes, is the verification test completed or is the expectation that the unit is held at that level for the balance of the one hour test window. Also, it is curious why this question excludes the condition of over-excited reactive capability at the rated gross real power per Attachment 1, section 2.1.
Yes
Yes
The current draft of the standard in section 4.2.1 proposes that the size of synchronous condensers to be verified be limited to those greater than 20 MVA, not 50MVA as stated in this question. Regardless, either limit would be acceptable.
Yes
No
System conditions greatly affect the expected reactive power values as stated in Attachment 1, Notes 1 and 2. While 20% appears reasonable for the real power verification, there needs to be flexibility as to this value for reactive power, given that system conditions are not constant.

No
With respect to reactive power, AEP is not aware of any regional variances that would be required for this standard.
No
AEP is not aware of any conflicts between the proposed standard and any regulatory function, rule, order, tariff, rate schedule, legislative requirement, or agreement.
No
No
Yes
Yes
Synchronous condensers respond to changes in voltage and not frequency, and as a result, have no place within the scope of this standard.
No
AEP is not aware of the need for any regional variances that might be required as a result of MOD-027-1.
No
AEP is not aware of any conflicts between the proposed MOD-027-1 and any regulatory function, rule, order, tariff, rate schedule, legislative requirement, or agreement.
Yes
Standard models may not be available for wind units and wind facilities (which appear to be within scope of 4.2), particularly aggregate reactive and frequency response controls. As a result, it might be difficult to obtain and provide such information.
Yes
Though we agree that the standard as written is “technology neutral”, its apparent neutrality might well be impacted by the definition of BES which is currently being revised. This topic might need to be revisited once the revised definition of BES has been approved.
No
It needs to be explicitly stated whether or not a Transmission Owner is held under R1 if they do not own synchronous condensers. This might be achieved by adding additional language to 4.1.2 stating that the standard applies to those who own facilities as specified in 4.2. Usage of the words “coordinate” and “coordination” seems ambiguous, and might be open to interpretation. In other standards these words are often used to describe communication between NERC functions rather than ensuring that necessary and sufficient settings exist among equipment types to permit them to operate in a pre-determined sequence. The threshold of 50MVA is not mentioned in the draft standard. Rather, 4.2.1 specifies a threshold of 20MVA. It appears the term “synchronous condenser” has been omitted from R1. Suggest using "Each Generator Owner and Transmission Owner with applicable Facilities shall coordinate its generating unit, generating Facility, or synchronous condenser voltage regulating system controls, including limiters and protection functions with the generating unit and Facility or synchronous condenser capabilities and protective system settings; to include as applicable".
No
AEP sees no benefit to the reliability of the BES in adding to this standard the controls associated with static reactive resources.
No
We are concerned by the inclusion of “protection system settings” in how it might differ from, or be confused with, the NERC defined term Protection System. The term “generator capabilities” should be removed from the purpose statement (as well as the requirements), as it is general enough of a term to make proving compliance difficult.
No

In light of the many other changes to standards currently proposed, and their implementations, AEP would suggest an additional year to the proposed implementation schedule to ensure a successful adaptation to PRC-019-1. The effective date for the 20% compliance milestone is inconsistent between the draft standard and the implementation plan, with one document allowing one year for compliance and the other allowing two years.
No
There appear to be inconsistencies between the standard and appendix G. the standard uses the term “protective system settings” and “protection system settings” while the appendix uses the term “protection function”.
Yes
No
AEP is not currently aware of any need for regional variances to this standard.
Yes
Measure 1 states the need for “one previous dated set of evidence that demonstrates the latest coordination review has been done within the intervals specified in Requirement R1, Section 1.2.”, yet this would not be required by the standard until five years following the initial coordination.
Individual
Michelle D'Antuono
Ingleside Cogeneration LP
Yes
Ingleside Cogeneration LP agrees that generator reactive testing necessarily requires validation at the real power extremes. This means there is no benefit to require separate testing.
No
Cogeneration LP believes that the proper recipient is the Transmission Planner. The Transmission Planner in turn must supply the information to the Planning Authority, Reliability Coordinator, and/or Transmission Operator as needed. There is no apparent reason why the Transmission Owner should be in the loop. Attachment 1, Item 3.4 seems to be the only place in MOD-025-2 that the Transmission Owner is shown as the recipient of generator verification data. It should be changed to Transmission Planner – consistent with the rest of the standard.
Yes
As with question #2, we believe the appropriate recipient of generator verification data is the Transmission Planner, not the Transmission Owner. Secondly, the Generator Owner providing the validation data must also be responsible for any corrections based on ambient temperature – as there may complexities beyond temperature correction factors. In these cases, if the TP performs the calculation, they may otherwise assume more capacity is available in their contingency assessments. The GO should have the option to provide the actual validation results to the TP with a temperature correction factor, but ultimately that decision rests with them. Third, the Transmission Planner must provide the required operating temperature range necessary for their system models. This will assure consistency among generators operating within their planning jurisdiction. If there are any discrepancies between the GO’s and TP’s expected range of operation, they can work that out through an iterative resolution process – similar to the structure suggested in MOD-026-1 and MOD-027-1.
Yes
These applicability criteria are consistent within the Regions that Ingleside Cogeneration has familiarity with (TRE, WECC, and SERC).
Yes
These operating points are more than sufficient to validate reactive capability in accordance with FERC’s directive. However, Ingleside Cogeneration LP believes that it is sufficient and far less risky to perform the validation at the TOP’s reactive capability schedule limits. In addition, there needs to be an allowance for known equipment limitations which prevent testing at the four test points. Similarly, unforeseen limitations which are determined during testing may prevent the validation at every extreme.
No

Ingleside agrees in principle that one hour is sufficient at this test point, but believes it should take place at the limit identified in the Transmission Operator’s reactive capability schedule.
No
Ingleside agrees in principle that a demonstration that the generator can reach these test points is sufficient, and reduces the risk to the equipment. However, the limits identified in the Transmission Operator’s reactive capability schedule should be verified, not the generator’s operational limits.
No
There is a significant body of work underway defining the extent of the Bulk Electric System, which this proposal bypasses. This determination should rest with the project team responsible for that effort.
No
There is a significant body of work underway defining the extent of the Bulk Electric System, which this proposal bypasses. This determination should rest with the project team responsible for that effort.
Yes
There is no reason to preclude the use of actual operations data in validation exercises.
No
The real and reactive capacities should be validated to be within 20% of expectation at the limits identified in the Transmission Operator’s reactive capability schedule, not the generator’s operational limits.
Yes
TRE, WECC, and SERC have similar but slightly different requirements. It is Ingleside’s expectation that these regions would align their processes to MOD-025-2 when it takes effect.
No
No
No
Yes
MOD-027-1 already takes Ingleside Cogeneration LP out of its comfort zone by requiring the ownership and validation of interconnected system performance simulations. This is normally a Transmission Planner or Transmission Operator function, not a Generator Owner. Although we understand the benefit of modeling validations, it is appropriate to begin with only the most critical facilities. If anything, we believe the applicability criteria should be consistent with those generation facilities which have DME installed as required by their Regional Entity. This is a reasonable, in-place means to identify those generators which are important to BES frequency response – and have already the recording equipment needed to validate performance.
Yes
There is already a significant body of work underway defining the extent of the Bulk Electric System. This determination should rest with the project team responsible for that effort.
Yes
In the TRE region, there is already a generator governor/frequency response standard under development. It is not obvious to us that the TRE standard aligns with MOD-027-1.
No
Yes
Like many Generator Owners, Ingleside Cogeneration LP has limited experience with transmission system modeling and scenario planning. Although in general we have a good working relationship with our Transmission Planner, MOD-027-1 may border on exchanging information which either entity may consider to be proprietary. In addition, the extra costs required to deploy recording equipment and to engage external experts to assist with frequency response planning are not budgeted. With

this in mind, a priority deployment may be more appropriate – where the most critical facilities in each Region are evaluated first.
Yes
Ingleside Cogeneration LP's gas and steam turbine units use voltage limiting and protection system technologies which are clearly referenced under PRC-019-1.
No
PRC-019-1 is appropriate for generating units and facilities identified under the compliance registry criteria. Since synchronous condensers are not part of those criteria, they should be not be considered applicable to any NERC standard at this time. There is a project team presently modifying the definition of the Bulk Electric System – this determination should rest with them.
No
Ingleside Cogeneration LP is hesitant to require validation of components which have not been clearly identified as a reliability imperative under either the revised definition of the BES or CIP-002-4's bright-line criteria.
Yes
Yes
The five year phased-in validation of settings is sufficient for Ingleside Cogeneration LP.
No
Ingleside Cogeneration LP agrees with the concept of establishing a mode of operation that allows voltage regulators and limiters the first opportunity to deal with a voltage transient well before the corresponding Protection Systems are activated. However, we are concerned that protective relay settings must be always set in accordance with the Steady State Stability Limit (SSSL) as defined by NERC. There may be factors that are more limiting which require more sensitive settings – which should be acceptable if demonstrated on a P-Q, R-X or similar graph.
Yes

Louis Slade
Yes
No
R1.3 and R2.3 require submittal to Transmission Planner, not Transmission Owner. We believe it is also appropriate to submit these results to the Resource Planner as we are unaware of an existing reliability standard that requires this information be provided to that entity (even though aware that version 5 of the Functional Model (on page 28) states the Resource Planner "Coordinates with Transmission Planners, Transmission Service Providers, Reliability Coordinators, and Planning Coordinators on resource adequacy plans." Further, we believe it is also appropriate to submit these results to the Balancing Authority and Transmission Operator despite the fact that they may request verification pursuant to TOP-002a @R13. We believe that, given the owner is being required to verify real and reactive capability, and report the results to one entity, requiring reporting to additional entities who could find the information useful in its reliability assessment (whether in the planning or operating time horizon) adds significant value at little additional effort.
Yes
We believe that, if the Resource Planner or Transmission Planner desire use of any correction factor, other than ambient, they be allowed to request the GO or TO adjust for that (those) correction factor(s) but that compliance with this standard be based solely upon the requirements contained

within. If a RE desires to impose additional correction factor(s), it should file for a regional variance to this standard.
Yes
No
We believe that, if the Resource Planner or Transmission Planner desire use of any correction factor, other than ambient, they be allowed to request the GO or TO adjust for that (those) correction factor(s) but that compliance with this standard be based solely upon the requirements contained within. If a RE desires to impose additional correction factor(s), it should file for a regional variance to this standard.
Yes
No
For items 2 and 3 see comments in question 5. We agree with item 1.
Yes
No
First, we would like to state that we did not see the 50 MVA threshold in the posted version of this standard. And, if we had, we would not have agreed. If 20 MVA is the appropriate threshold for a generator, it is appropriate for a synchronous condenser.
Yes
No
If the question was meant to ask whether we agree with the sentence that reads" Operational data from within the year prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is within 20% of the expected value:" (Attachment 1, @2) tehn we respond affirmatively. However, we do not agree that a verification MUST be within 20%. It is possible that a physical change to either the asset being verified or the system it is interconnected with may result in its inability to perform to within 20%. If this is true, then we could agree that any such variance must be accompanied by an explanation as to why the verification did not fall with the 20% 'boundary' There should be no requirement for percent of expected value.
No
No
Yes
Test form needs to be improved. Provide the form in format that can be electronically completed by the user.
No
Yes
Yes
No
No
Yes
While we understand that a significant portion of the industry supports the 5% capacity factor threshold, we believe that this term is subject to different uses by various entities and parties,

particularly biased as to whether one is discussing capacity or energy. We suggest that, for the purpose of this standard, capacity factor be described as defined by NERC GADS. Please elaborate on Requirement 2.1.5. Also, we believe that “Load Control” and “AGC” are the same. R3, the third bullet, we suggest that “did not match the recorded response for three or more transmission system events be changed to “did not approximate the recorded response for three or more transmission system events “ We believe there needs to be an exception allowed if a frequency event does not occur in 10 years. What is “staged test” mentioned on Attachment 1? Also Attachment 1 is very confusing and should be rewritten.
Yes
Yes
No
Yes
No
The effective date implementation schedules contained in the standard and the associated Implementation Plan do not agree. Specifically, the standard indicates one year following regulatory and/or Board of Trustee approval where as the Implementation Plan indicates two year. Additionally, the standard at Step 5.2 does not include a sub-step for 100% of applicable units.
Yes
Yes
No
Yes
1) the phrase “Generating equipment”, in the 3rd bullet of R1, be changed to “Generator” to be consistent with the usage under bullets 1 & 2. 2) The title and purpose of the document do not address synchronous condensers as addressed in Requirement R1; 3) if the standard includes synchronous condensers, why are static VAR compensators not included? The following bullets under R1 are too generic. Should specifically outline required parameters. In-service 1excitation system and voltage regulating system control, limiters and protection functions • In-service generator or synchronous condenser protection system settings • Generating equipment or synchronous condenser capabilities • Steady state stability limit We recommend replacing the bullets with the following: • Generator or syn. Condenser capability curves. • Steady state stability limit. • Loss of field zone 1. • Loss of field zone 2. • Loss of field trip. • Under excitation limiter. • Over excitation limiter. • Power factor line. • Backup over current settings. • Instantaneous field current trip. • Instantaneous field current limit. • Volts per hertz.

Synchronous condensers are specifically for local area voltage regulation purposes. Units between the sizes of 20MVA to 50MVA could be significant to an area's dynamic performance under contingencies.
Yes
No comment.
No
No
No
No
Yes
We agree with this proposal as being in line with our overall concern that model verification requirements should be based on cost efficiency and practicality. Facilities outside of the Applicability Section are already judged to be of minimal significance in dynamic impact, and are also typically of vintages and origins whose modeling data and parameters are difficult or impossible to obtain. For facilities of minor dynamic impact in a locality, typical or surrogate model data would serve the simulation purposes the vast majority of times.
Yes
It is our opinion that synchronous condensers, when in operation, are intended to regulate local voltages but not for regional frequency control.
No
No
Yes
We have a number of questions and concerns as follows: • While the Standard uses the word “verified” and “verification” loosely, it is not precisely clear what a GO would have to do to satisfy the

verification requirements in R2. Would each of the Time Constants, Forward and/or Feedback Gains, Dead-band Excitation Limits, Saturation Characteristics, etc. to be determined separately each on its own? Or are these parameters taken as a whole so long as their combined effect produces a response characteristic in a simulation that matches the recorded test response during an off-line step-input test? • The response of a unit is dependent on the instantaneous conditions of the external system to which it is connected at the time of the disturbance, in addition to the inherent response characteristics as built. This may result in the modeling parameters derived based on on-line frequency/Load excursion test not being unique. • If a simulation study results in response characteristics that does not match an on-line step input test response, can the GO arbitrarily adjust one or more of the model parametric values to produce a matching response, and send the Transmission Planner these adjusted values as the model data? • We have concern about whether this Standard is cost efficient to the industry. The transient stability dynamic modeling for turbine/governor was developed under the assumption of limited bandwidth validity and approximations. The other equipment models in the simulation, e.g. generators, excitation controls, SVCs, HVDC Converters, boiler/burner controls, etc. are all approximations without any correlated degree of accuracies in comparison to each other. On the other hand, the verification efforts are expected to cost quite a bit to GOs, especially for older units whose vendors/manufacturers may not even be in existence any more.
Group
FirstEnergy
Sam Ciccone
Yes
We agree that a “one-stop-shop” approach is appropriate for Real and Reactive Generator Verification requirements.
No
The standard in Subpart 1.3 says that the Transmission Planner is the entity that shall receive this information. We agree that it should be the TP. Also, we question whether or not the Planning Coordinator should also receive this information. Furthermore, with respect to how this information will be used by the planning entities, the team needs to assure that there is no duplication of efforts with MOD-010-0 and MOD-011-0. We suggest that MOD-010-0 and MOD-011-0 get revised to remove redundancies, or make it clear the the entity may supply existing MOD-010/-011 compliance evidence to show compliance with MOD-025-2.
No
We believe that it is the responsibility of the Generator Owner to have an appropriate Ambient Adjustment Methodology and make the necessary corrections to the data per its methodology before submitting it to the Transmission Owner. We suggest similar requirement regarding ambient ajustments as found in regional standards MOD-024-RFC-01 and MOD-025-RFC-01.
Yes
We agree that this standard should be consistent with the NERC Compliance Registry.
No
As a TO, we rank the importance to the modeling effort as follows: (1) Pmax, Qmax; (2) Pmin, Qmin; (3)) Pmax, Qmin. We believe that the Pmin, Qmax is of little value to a Planning Engineer.
Yes
Although we are OK with the 1 hour interval, we are not convinced this will meet the reliability goals

of the standard. Just being able to hit a specific reactive output is one thing, but that does not assure Reliability. Most large generators and large main transformers have only reached one, possibly two, thermal time constants within an hour timeframe There are many thermal problems that can be identified if the electrical equipment is permitted to be operated at high load levels over an extended period of time. It may be necessary to show that reactive output can be maintained over a longer period of time.
Yes
Yes
Yes, we believe they should be verified because they are the same type of dynamic, voltage independent, source of reactive power as is a real power generator. We also believe that they certainly are generators, generators of reactive power. In fact, they are identical in function, design and equipment as a real power generator, minus the prime mover. A synchronous condenser, like its sister the real power generator, can be continuously adjusted for the desired output and contains equipment that must be properly adjusted to provide the desired range of reactive output.
Yes
The applicability section does not mention the 50 MVA threshold.
Yes
No
If the generating unit is capable of reaching 20% of the "expected value", than why should verification be concluded at that point? (We could potentially be missing out on fully realizing the potential of a reactive resource by pre-maturely ending the verification. A very important dimension of this verification (that was touched on in the Standard) is the recognition of equipment conditions or voltage regulator settings that could be improved when a staged test is performed. It is difficult if not impossible to capture equipment shortcomings or limitations which can be very useful to improving operations when verifying through the use of Operational data. Also, we need clarification regarding what would be considered “within 20% of expected value” if your leading reactive limit was 0 MVAR (unity)?
No
Yes
Regional Entities such as RFC currently have Real and Reactive standards in place for its members and will need to evaluate the need to keep their standard or revise it to remove any inconsistencies that may exist. One inconsistency is the periodicity of verification for real power.
Yes
Regarding Notes 1 & 2 in the standard: Generally we have found that reactive power limitations that originate inside the generating station (hydrogen pressure, thermally sensitive generator, voltage regulator settings, and excitation problems) usually cannot be overcome through engineering analysis on the part of the transmission planning engineer. These types of conditions can only be addressed by the GO. On the other hand, Generator Terminal Voltage limits, or Transmission System voltage Limits can be eliminated using engineering analysis to simulate a more stressed system. Attachment 1, R2 – Assuming there are no transmission system related limitations, how close does the test value for VARs have to come from the expected value to be considered “verified”? Attachment 1, R2.2 – Nuclear units should be exempt from having to test leading VAR capability as this would challenge the plant’s licensing limits for safety bus minimum voltage. MOD-025-RFC-01 currently allows this exemption for nuclear plants. Attachment 1, NOTE 1 – For clarity, nuclear plant safety bus voltage limits should mentioned as a reason why D-Curve values may not be met during a test.
No
Yes
Yes

No
No
Yes
As a result of the 2010 NERC Generator Governor Survey, it became clear that many nuclear units (and I believe all of the BWR units) do not respond to changes grid frequency because their governors are controlling steam pressure. The standard should have a specific exclusion for nuclear generating units which have governors that operate to control steam pressure and which do not respond to grid frequency deviations. This is consistent with the Eastern Interconnection Reliability Assessment Group (ERAG) Multi-Regional Modeling Working Group Procedure Manual version 5, May 6, 2010 which states in Appendix II, Section B Dynamic Modeling Requirements, Paragraph 2b) that "Turbine-governor representation shall be omitted for units that do not regulate frequency such as base load nuclear units, pumped storage units…". For those nuclear units that are able to respond to overfrequency events there is a possibility that a response to a system transient may not be seen during a ten year period. Since responding to an overfrequency event will result in a drop in unit load and a corresponding change in reactivity, the governor control dead band, which is set to minimize the possibility of a spurious reactivity change, could be large enough to ignore an event that meets the frequency excursion threshold (for example a 0.1 Hz dead band would ride through on a 0.07 Hz excursion). Likewise a nuclear unit would not perform a frequency reference change input test with the unit on-line because of the resulting change in reactivity. Would injecting a frequency signal to the EHC during off-line calibration and noting the response be acceptable?
Yes
Yes
Although we agree with the applicability, the standard that was posted does not mention the 50 MVA threshold.
No
Yes
Yes
At the moment we do not have comments on the proposed measures. We will review the proposed measures on the next draft and provide out input.
No
Section 1.2 of the Compliance section is missing a time frame for data retention. Timeframes consistent with CEA routine audit cycles should be added to this section.
No
We are not aware of the need for a variance at this time.
Yes
M1 requires that the GO will have evidence that "…voltage regulating system controls and protection functions are coordinated with the generating unit and generating Facility capabilities and protective system settings applied to in-service equipment as specified in Requirement R1, Section 1.1, and one previous dated set of evidence that demonstrates the latest coordination review has been done within the intervals specified in Requirement R1, Section 1.2." For the first verification cycle this would require that units would have to prove compliance as much as 4 years before the standard became enforceable. This is akin to setting up a traffic camera in a 35 mph zone in March, changing the speed limit in that zone to 25 mph in July, and going back and writing tickets for every car that exceeded 25 mph from March through June. This needs to be clarified. Requirement R2 (shown as 1.2 in the standard) should have a violation risk factor of MEDIUM instead of HIGH. Furthermore, it seems that the phrase "within 90 days of making a change to the generating equipment, voltage control limiter

settings, or protective function settings that would affect the coordination” is not necessary because a change to equipment setting would already require coordination per Requirement R1. We suggest removing this part of 1.2 (or R2).

Yes
The second bullet, in part B “Requirements,” section R1, page 4: The word “library” should be removed from the phrase “system model library block diagrams,” since not all wind manufacturers have standard library models.
The fourth bullet in Part G “Reference,” paragraph beginning with “Equipment limits,”, page 6: The word “stator” should be removed, in order to make the over voltage protection limits applicable to non-synchronous machines.

Yes
No

The data from MOD-25-2 should be submitted to the Transmission Operator. The Transmission Owner does not appear to be the correct functional entity. The Transmission Owner may not have the area view required for this testing. Real and Reactive Power Testing must be coordinated with the Transmission Operator to ensure that the system remains within all operating limits.
No
We maintain that temperature correction should be performed as required by the Transmission Operator. The standard must ensure that accurate data for gas turbine and combined cycle generators is obtained which can be adjusted to reflect the ambient temperature presumed in Planning Assessments.
Yes
Yes, however the standard should not rewrite the Compliance Registry as attempted in section 4.2. The registry language of section IIIc.3 and IIIc.4 is more precise and differs from what is proposed in the standard. For instance, the registry's wording on Black Start generators applies to a blackstart unit material to and designated as part of a transmission operator entity's restoration plan. All that is needed is to have the standard applicable to Generator Owners and let the Registry dictate those who must register and comply.
No
Performing testing for lagging capability at minimum real power output especially would require an inordinate amount of planning to ensure that transmission voltage levels in the local area are not exceeded. Testing requirements should be changed to two points, one for an hour to verify over-excited reactive capability at rated Real Power and one at minimum Real Power output to verify under-excited capability. Also the test of leading capability at minimum real power loading should be held for five minutes. These tests are adequate to verify critical characteristics of the generator for use in studies. The four point tests may be difficult to obtain given system configuration and operation.
Yes
Yes, the standard should also require a recording of generator vibration during the test and require that the Generator Owner report an increase in vibration over the test period indicating the presence of rotor shorted turns that would limit long term generator MVAR loading. One hour may be enough time to determine if rotor shorted turns are present as indicated by vibration but the vibration must be recorded. The reactive power output data recording should be at 5 minute intervals and use the average for the hour. Also testing leading capability at minimum real power loading should be held for five minutes.
No
These types of tests should require remaining at the point for a length of time. Under-excited power verification at minimum power output for five minutes should be adequate. Testing requirements for over-excited reactive capability at minimum real power output and under-excited capability at maximum power should be removed. These tests lead to transmission system voltage concerns.
Yes
Yes, but as written the standard is not clear as to how the testing is to be performed for a synchronous condenser.
No
There is no technical justification supporting the 50 MVA criterion. Absent this, we propose to use the Compliance Registry criteria for generators of 20 MVA as a general criterion for data being verified for synchronous condensers over 20 MVA as well.
Yes
No
As we interpret the language, we do not agree with the 20% requirement. In the assessments performed in our area our goal is to use data that is much more accurate than what appears to be required under the standard. Allowing verification to be up to 20% inaccurate may result in inaccurate system assessments, potentially leading to overlooking potential system problems or to unnecessary system investment to address system concerns which are not really present. This value should be changed to a maximum of 5%.

No
No
The obligations set by this Standard are less stringent for Generator Owners/Operators than those contained in ISO-NE's Tariff. In addition, FERC's Standard Generation Interconnection Rules make clear that material changes to generation facilities (which would include changes to reactive power capabilities) must be reported to the Transmission Service Provider prior to the change being made. The Standard Drafting Team should consider whether language is appropriate to make clear that the Standard is not meant to displace obligations to report reactive power capabilities already contained in Transmission Service Providers' tariffs.
Yes
• Effective Dates: This proposal is not well explained and very well may not work. Some concerns that arise: (a) For those GOs that have units in multiple control areas, are they supposed to apply the Implementation Plan for their entire fleet or for their fleet on a per Region basis? This same issue can apply to TOs which may be in multiple areas. This seems impossible to track and may leave some areas without any verification for 5 years after the standard has been approved. The Transmission Operator should be given the discretion to require and approve a test schedule within it's area. (b) For those GOs with only one or two facilities in a region, how will the 5-year implementation plan work? Will the GO with one facility in a region have 5 years to implement (i.e., the 100% rule would not "kick" in until 5 years out, or will the GO with one facility in a region have only 1 year to implement (since 20% of 1 unit would arguably capture the unit). • R1.2 and 2.2 All entities should use the same submittal form. Please delete the option for a Generator Owner to develop its own form. • R1.3… 90 days is too long for reporting data. Recommend 30 days for providing verification data. • VSL for R2 should mirror VSL for R1. Specifically R2 doesn't mention submitting >120 days as R1 does. • Attachment 1: 1. specify that the AVR must be in service and in automatic controlling voltage if required by the TOP 2. If AVR is not required by the TOP, does the unit still have to test? Under the VAR-001 standard an entity may be exempted by the Transmission Operator from having a functional AVR. Under such an exemption the need for testing should not be required. • Attachment 2: move the check boxes to the top so that that someone looking at form knows immediately what type of audit was performed. • There should be VSLs in regards to going more than 66 months between verifications. • Periodicity should be captured in Requirements, not in the Attachment • If each test is done on different days, does each test have its own verification date? • Please clarify what footnote 1 of Attachment 1 is intended to describe with "normal" with respect to the unit's normal expected maximum Real Power at the time of the verification. • Attachment 1, Section 2.1 states that during wind turbine and photovoltaic verification, 90% must be on line. This should read "with AT LEAST ninety percent of the…"
Yes
Generators sized well over 100 MVA with a capacity factor under 5% are numerous in our area of the Eastern Interconnection. These older large generators with a capacity factor below 5% will have a significant impact on electric system performance during stressed conditions with high loads. These generators must not be excluded from the verification requirement. Generators sized under 100 MVA may also be important, what is the justification for the cutoff from the verification requirement at 100 MVA? This applicability criteria in this standard should be the same as the Compliance Registry requirements.
No
NERC is largely concerned with the declining frequency response of the Eastern Interconnection and this proposal seems completely at odds with that concern. The Planning Coordinator (or Transmission Planner) should definitely be allowed to request verification of selected governors. In addition to generators that have governor effect overridden by outer control loops (Distributed Control System, DCS) there may be a dead band within the governor. The Transmission Planner must be able to request verification of selected governor models that may fall outside of the standard. The question mentions Planning Coordinator but the standard itself is applicable to the Transmission Planner.
Yes
No

Yes
Requirement R4 is a direct violation of the Large Generator Interconnection portion of the ISO Tariff that requires generators to request permission and provide models prior to making changes to the equipment characteristics. As currently written, this appears to allow generators to submit models after making the changes. Such changes may have been detrimental to system performance and therefore need to be reviewed prior to implementation.
Yes
In requirement R2.1.1 what is meant by frequency excursion/reference change? This standard must require that all models provided are non-proprietary, otherwise a major reason (NERC MMG) for model collection will be undermined. This will prevent coordination of studies across regions which may undermine reliability. We are not sure if we have the correct version of draft MOD-027-1. In the “Differences also exist between MOD-026-1 and MOD-027-1” Section of this Comment Form, there are several mentions of Requirement R1 Part 1.x which we are unable to find in the draft standard. For example, Requirement R1 Part 1.2.1 in (5), R1 Part 1.3 in (6), R1 Part 1.4 in (7), and R1 Parts 1.1, 1.3, 1.4 in the “Compliance Elements for MOD-027-1” Section. Also, the referenced MOD-026-1 does not have the parts mentioned in this Comment Form. Is the background provided in this comment form incorrect, or are the posted versions of MOD-026 and MOD-027 out of date? In requirement R5.3: It stipulates as a criterion that a disturbance simulation results in the turbine/governor and Load control or active power/frequency control model exhibiting positive damping. We do not agree with the condition that the simulate must exhibits positive damping. Even with an accurate turbine/governor and Load control or active power/frequency control model, system damping is affected by a many other dynamic performance contributors such as other generators, system topology, power flow levels, voltage levels, excitation system and power system stabilizer settings, etc. In short, having an accurate turbine/governor and Load control or active power/frequency control model does not necessary guarantee or equate to positive damping.
Yes
Yes, however the standard should not rewrite the Compliance Registry as attempted. The registry language of section IIIc.3 and IIIc.4 is more precise and differs from what is proposed in the standard. For instance, the registry’s wording on Black Start generators applies to a blackstart unit material to and designated as part of a transmission operator entity’s restoration plan. If the NERC standards become effective for non-material 9 MVA black start units those units will likely drop out of the program. All that is needed is to have the standard applicable to Generator Owners and let the Registry dictate those who must register and comply.
