Exhibit A

Proposed Reliability Standards Submitted for Approval

A. Introduction

1. **Title:** Verification and Data Reporting of Generator Real and Reactive Power Capability and Synchronous Condenser Reactive Power Capability

2. **Number:** MOD-025-2

3. **Purpose:** To ensure that accurate information on generator gross and net Real and Reactive Power capability and synchronous condenser Reactive Power capability is available for planning models used to assess Bulk Electric System (BES) reliability.

4. **Applicability:**

 4.1. Functional entities

  4.1.1 Generator Owner

  4.1.2 Transmission Owner that owns synchronous condenser(s)

 4.2. Facilities:

 For the purpose of this standard, the term, "applicable Facility" shall mean any one of the following:

  4.2.1 Individual generating unit greater than 20 MVA (gross nameplate rating) directly connected to the Bulk Electric System.

  4.2.2 Synchronous condenser greater than 20 MVA (gross nameplate rating) directly connected to the Bulk Electric System.

  4.2.3 Generating plant/Facility greater than 75 MVA (gross aggregate nameplate rating) directly connected to the Bulk Electric System.

5. **Effective Date:**

 5.1. In those jurisdictions where regulatory approval is required[1]:

  5.1.1 By the first day of the first calendar quarter, two calendar years following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified at least 40 percent of its applicable Facilities.

  5.1.2 By the first day of the first calendar quarter, three calendar years following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified at least 60 percent of its applicable Facilities.

  5.1.3 By the first day of the first calendar quarter, four calendar years following applicable regulatory approval, or as otherwise made effective pursuant to

[1] Wind Farm Verification - If an entity has two wind sites, and verification of one site is complete, the entity is 50% complete regardless of the number of turbines at each site. A wind site is a group of wind turbines connected at a common point of interconnection or utilizing a common aggregate control system.

the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified at least 80 percent of its applicable Facilities.

5.1.4 By the first day of the first calendar quarter, five calendar years following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified 100 percent of its applicable Facilities.

5.2. In those jurisdictions where regulatory approval is not required[2]:

5.2.1 By the first day of the first calendar quarter, two calendar years following Board of Trustees approval, each Generator Owner and Transmission Owner shall have verified at least 40 percent of its applicable Facilities.

5.2.2 By the first day of the first calendar quarter, three calendar years following Board of Trustees approval, each Generator Owner and Transmission Owner shall have verified at least 60 percent of its applicable Facilities.

5.2.3 By the first day of the first calendar quarter, four calendar years following Board of Trustees approval, each Generator Owner and Transmission Owner shall have verified at least 80 percent of its applicable Facilities.

5.2.4 By the first day of the first calendar quarter, five calendar years following Board of Trustees approval, each Generator Owner and Transmission Owner shall have verified 100 percent of its applicable Facilities.

Note: The verification percentage above is based on the number of applicable units owned.

[2] Wind farm verification - If an entity has two wind sites, and verification of one site is complete, the entity is 50% complete regardless of the number of turbines at each site. A wind site is a group of wind turbines connected at a common point of interconnection or utilizing a common aggregate control system.

Requirements

R1. Each Generator Owner shall provide its Transmission Planner with verification of the Real Power capability of its applicable Facilities as follows: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

1.1. Verify the Real Power capability of its generating units in accordance with Attachment 1.

1.2. Submit a completed Attachment 2 (or a form containing the same information as identified in Attachment 2) to its Transmission Planner within 90 calendar days of either (i) the date the data is recorded for a staged test; or (ii) the date the data is selected for verification using historical operational data.

R2. Each Generator Owner shall provide its Transmission Planner with verification of the Reactive Power capability of its applicable Facilities as follows: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

2.1. Verify, in accordance with Attachment 1, (i) the Reactive Power capability of its generating units and (ii) the Reactive Power capability of its synchronous condenser units.

2.2. Submit a completed Attachment 2 (or a form containing the same information as identified in Attachment 2) to its Transmission Planner within 90 calendar days of either (i) the date the data is recorded for a staged test; or (ii) the date the data is selected for verification using historical operational data.

R3. Each Transmission Owner shall provide its Transmission Planner with verification of the Reactive Power capability of its applicable Facilities as follows: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

3.1. Verify, in accordance with Attachment 1, the Reactive Power capability of its synchronous condenser units.

3.2. Submit a completed Attachment 2 (or a form containing the same information as identified in Attachment 2) to its Transmission Planner within 90 calendar days of either (i) the date the data is recorded for a staged test; or (ii) the date the data is selected for verification using historical operational data.

B. Measures

M1. Each Generator Owner will have evidence that it performed the verification, such as a completed Attachment 2 or the Generator Owner form with the same information or dated information collected and used to complete attachments, and will have evidence that it submitted the information within 90 days to its Transmission Planner; such as dated electronic mail messages or mail receipts in accordance with Requirement R1.

M2. Each Generator Owner will have evidence that it performed the verification, such as a completed Attachment 2 or the Generator Owner form with the same information, or dated information collected and used to complete attachments and will have evidence that it submitted the information within 90 days to its Transmission Planner; such as dated electronic mail messages or mail receipts in accordance with Requirement R2.

M3. Each Transmission Owner will have evidence that it performed the verification, such as a completed Attachment 2 or the Transmission Owner form with equivalent information or dated information collected and used to complete attachments, and will have evidence that it submitted the information within 90 days to its Transmission Planner; such as dated electronic mail messages or mail receipts in accordance with Requirement R3.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

The Regional Entity shall serve as the Compliance enforcement authority unless the applicable entity is owned, operated, or controlled by the Regional Entity. In such cases the ERO or a Regional entity approved by FERC or other applicable governmental authority shall serve as the CEA.

1.2. Evidence Retention

The following evidence retention periods identify a period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention specified below is shorter than the time since the last compliance audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Generator Owner and Transmission Owner shall each keep the data or evidence to show compliance as identified below, unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

- The Generator Owner shall retain the latest MOD-025 Attachment 2 and the data behind Attachment 2 or Generator Owner form with equivalent information and submittal evidence for Requirements R1 and R2, Measures M1 and M2 for the time period since the last compliance audit.
- The Transmission Owner shall retain the latest MOD-025 Attachment 2 and the data behind Attachment 2 or Transmission Owner form with equivalent information and submittal evidence for Requirement R3, Measure M3 for the time period since the last compliance audit.

If a Generator Owner or Transmission Owner is found noncompliant, it shall keep information related to the noncompliance until mitigation is complete or for the time specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes

Compliance Audit

Self-Certification

Spot Checking

MOD-025 Attachment 1 – Verification of Generator Real and Reactive Power Capability and Synchronous Condenser Reactive Power Capability

Periodicity for conducting a new verification:

The periodicity for performing Real and Reactive Power capability verification is as follows:

1. For staged verification; verify each applicable Facility at least every five years (with no more than 66 calendar months between verifications), or within 12 calendar months of the discovery of a change that affects its Real Power or Reactive Power capability by more than 10 percent of the last reported verified capability and is expected to last more than six months. The first verification for each applicable Facility under this standard must be a staged test.
2. For verification using operational data; verify each applicable Facility at least every five years (with no more than 66 calendar months between verifications), or within 12 calendar months following the discovery that its Real Power or Reactive Power capability has changed by more than 10 percent of the last reported verified capability and is expected to last more than six months. If data for different points is recorded on different days, designate the earliest of those dates as the verification date, and report that date as the verification date on MOD-025, Attachment 2 for periodicity purposes.
3. For either verification method, verify each new applicable Facility within 12 calendar months of its commercial operation date. Existing units that have been in long term shut down and have not been tested for more than five years shall be verified within 12 calendar months.

It is intended that Real Power testing be performed at the same time as full load Reactive Power testing, however separate testing is allowed for this standard. For synchronous condensers, perform only the Reactive Power capability verifications as specified below.

If the Reactive Power capability is verified through test, it is to be scheduled at a time advantageous for the unit being verified to demonstrate its Reactive Power capabilities while the Transmission Operator takes measures to maintain the plant's system bus voltage at the scheduled value or within acceptable tolerance of the scheduled value.

Verification specifications for applicable Facilities:

1. For generating units of 20 MVA or less that are part of a plant greater than 75 MVA in aggregate, record data either on an individual unit basis or as a group. Perform verification individually for every generating unit or synchronous condenser greater than 20 MVA (gross nameplate rating).

2. Verify with all auxiliary equipment needed for expected normal operation in service for both the Real Power and Reactive Power capability verification. Perform verification with the automatic voltage regulator in service for the Reactive Power capability

verification. Operational data from within the two years prior to the verification date is acceptable for the verification of either the Real Power or the Reactive Power capability, as long as a) that operational data meets the criteria in 2.1 through 2.4 below and b) the operational data demonstrates at least 90 percent of a previously staged test that demonstrated at least 50 percent of the Reactive capability shown on the associated thermal capability curve (D-curve). If the previously staged test was unduly restricted (so that it did not demonstrate at least 50 percent of the associated thermal capability curve) by unusual generation or equipment limitations (e.g., capacitor or reactor banks out of service), then the next verification will be by another staged test, not operational data:

2.1. Verify Real Power capability and Reactive Power capability over-excited (lagging) of all applicable Facilities at the applicable Facilities' normal (not emergency) expected maximum Real Power output at the time of the verifications.

2.1.1 Verify synchronous generating unit's maximum real power and lagging reactive power for a minimum of one hour.

2.1.2 Verify variable generating units, such as wind, solar, and run of river hydro, at the maximum Real Power output the variable resource can provide at the time of the verification. Perform verification of Reactive Power capability of wind turbines and photovoltaic inverters with at least 90 percent of the wind turbines or photovoltaic inverters at a site on-line. If verification of wind turbines or photovoltaic inverter Facility cannot be accomplished meeting the 90 percent threshold, document the reasons the threshold was not met and test to the full capability at the time of the test. Reschedule the test of the facility within six months of being able to reach the 90 percent threshold. Maintain, as steady as practical, Real and Reactive Power output during verifications.

2.2. Verify Reactive Power capability of all applicable Facilities, other than wind and photovoltaic, for maximum overexcited (lagging) and under-excited (leading) reactive capability for the following conditions:

2.2.1 At the minimum Real Power output at which they are normally expected to operate collect maximum leading and lagging reactive values as soon as a limit is reached.

2.2.2 At maximum Real Power output collect maximum leading reactive values as soon as a limit is reached.

2.2.3 Nuclear Units are not required to perform Reactive Power verification at minimum Real Power output.

2.3. For hydrogen-cooled generators, perform the verification at normal operating hydrogen pressure.

2.4. Calculate the Generator Step-Up (GSU) transformer losses if the verification measurements are taken from the high side of the GSU transformer. GSU

transformer real and reactive losses may be estimated, based on the GSU impedance, if necessary.

3. Record the following data for the verifications specified above:

3.1. The value of the gross Real and Reactive Power generating capabilities at the end of the verification period.

3.2. The voltage schedule provided by the Transmission Operator, if applicable.

3.3. The voltage at the high and low side of the GSU and/or system interconnection transformer(s) at the end of the verification period. If only one of these values is metered, the other may be calculated.

3.4. The ambient conditions, if applicable, at the end of the verification period that the Generator Owner requires to perform corrections to Real Power for different ambient conditions such as:

- Ambient air temperature
- Relative humidity
- Cooling water temperature
- Other data as determined to be applicable by the Generator Owner to perform corrections for ambient conditions.

3.5. The date and time of the verification period, including start and end time in hours and minutes.

3.6. The existing GSU and/or system interconnection transformer(s) voltage ratio and tap setting.

3.7. The GSU transformer losses (real or reactive) if the verification measurements were taken from the high side of the GSU transformer.

3.8. Whether the test data is a result of a staged test or if it is operational data.

4. Develop a simplified key one-line diagram (refer to MOD-025, Attachment 2) showing sources of auxiliary Real and Reactive Power and associated system connections for each unit verified. Include GSU and/or system Interconnection and auxiliary transformers. Show Reactive Power flows, with directional arrows.

4.1. If metering does not exist to measure specific Reactive auxiliary load(s), provide an engineering estimate and associated calculations. Transformer Real and Reactive Power losses will also be estimates or calculations. Only output data are required when using a computer program to calculate losses or loads.

5. If an adjustment is requested by the Transmission Planner, then develop the relationships between test conditions and generator output so that the amount of Real Power that can be expected to be delivered from a generator can be determined at different conditions, such as peak summer conditions. Adjust MW values tested to the ambient conditions specified by the Transmission Planner upon request and submit them to the Transmission Planner within 90 days of the request or the date the data was recorded/selected whichever is later.

Note 1: Under some transmission system conditions, the data points obtained by the Mvar verification required by the standard will not duplicate the manufacturer supplied thermal capability curve (D-curve). However, the verification required by the standard, even when conducted under these transmission system conditions, may uncover applicable Facility limitations; such as rotor thermal instability, improper tap settings or voltage ratios, inaccurate AVR operation, etc., which could be further analyzed for resolution. The Mvar limit level(s) achieved during a staged test or from operational data may not be representative of the unit's reactive capability for extreme system conditions. See Note 2.

Note 2: While not required by the standard, it is desirable to perform engineering analyses to determine expected applicable Facility capabilities under less restrictive system voltages than those encountered during the verification. Even though this analysis will not verify the complete thermal capability curve (D-curve), it provides a reasonable estimate of applicable Facility capability that the Transmission Planner can use for modeling.

Note 3: The Reactive Power verification is intended to define the limits of the unit's Reactive Power capabilities. If a unit has no leading capability, then it should be reported with no leading capability; or the minimum lagging capability at which it can operate.

Note 4: Synchronous Condensers only need to be tested at two points (one over-excited point and one under-excited point) since they have no Real Power output.

MOD-025 Attachment 2

One-line Diagram, Table, and Summary for Verification Information Reporting

Note: If the configuration of the applicable Facility does not lend itself to the use of the diagram, tables, or summaries for reporting the required information, changes may be made to this form, provided that all required information (identified in MOD-025, Attachment 1) is reported.

Verification Data

Provide data by unit or Facility, as appropriate

Data Type	Data Recorded	Last Verification (Previous Data; will be blank for the initial verification)
Gross Reactive Power Capability (*Mvar)		
Aux Reactive Power (*Mvar)		
Net Reactive Power Capability (*Mvar) equals Gross Reactive Power Capability (*Mvar) minus Aux Reactive Power connected at the same bus (*Mvar) minus tertiary Reactive Power connected at the same bus(*Mvar)		
Gross Real Power Capability (*MW)		
Aux Real Power (*MW)		
Net Real Power Capability (*MW) equals Gross Real Power Capability (*MW) minus Aux Real Power connected at the same bus (*MW) minus tertiary Real Power connected at the same bus(*MW)		
* Note: Enter values at the end of the verification period.		
GSU losses (only required if verification measurements are taken on the high side of the GSU - Mvar)		

Summary of Verification

- Date of Verification _________,Verification Start Time _____, Verification End Time ______
- Scheduled Voltage _______________
- Transformer Voltage Ratio: GSU ______, Unit Aux _____, Station Aux _____, Other Aux _____
- Transformer Tap Setting: GSU ______, Unit Aux _____, Station Aux _____, Other Aux _____
- Ambient conditions at the end of the verification period:

  Air temperature: _________

  Humidity: _________

  Cooling water temperature: _________

  Other data as applicable: _________

- Generator hydrogen pressure at time of test (if applicable) _____________

Date that data shown in last verification column in table above was taken _____________

Remarks :

Note: If the verification value did not reach the thermal capability curve (D-curve), describe the reason.

A. Introduction

1. **Title:** Verification of Models and Data for Generator Excitation Control System or Plant Volt/Var Control Functions

2. **Number:** MOD-026-1

3. **Purpose:** To verify that the generator excitation control system or plant volt/var control function[1] model (including the power system stabilizer model and the impedance compensator model) and the model parameters used in dynamic simulations accurately represent the generator excitation control system or plant volt/var control function behavior when assessing Bulk Electric System (BES) reliability.

4. **Applicability:**

   4.1. Functional Entities:

   4.1.1 Generator Owner

   4.1.2 Transmission Planner

   4.2. Facilities:

   For the purpose of the requirements contained herein, Facilities that are directly connected to the Bulk Electric System (BES) will be collectively referred as an "applicable unit" that meet the following:

   4.2.1 Generation in the Eastern or Quebec Interconnections with the following characteristics:

   4.2.1.1 Individual generating unit greater than 100 MVA (gross nameplate rating).

   4.2.1.2 Individual generating plant consisting of multiple generating units that are directly connected at a common BES bus with total generation greater than 100 MVA (gross aggregate nameplate rating).

   4.2.2 Generation in the Western Interconnection with the following characteristics:

   4.2.2.1 Individual generating unit greater than 75 MVA (gross nameplate rating).

   4.2.2.2 Individual generating plant consisting of multiple generating units that are directly connected at a common BES bus with total generation greater than 75 MVA (gross aggregate nameplate rating).

---

[1] Excitation control system or plant volt/var control function:

a. For individual synchronous machines, the generator excitation control system includes the generator, exciter, voltage regulator, impedance compensation and power system stabilizer.

b. For an aggregate generating plant, the volt/var control system includes the voltage regulator & reactive power control system controlling and coordinating plant voltage and associated reactive capable resources.

4.2.3 Generation in the ERCOT Interconnection with the following characteristics:

4.2.3.1 Individual generating unit greater than 50 MVA (gross nameplate rating).

4.2.3.2 Individual generating plant consisting of multiple generating units that are directly connected at a common BES bus with total generation greater than 75 MVA (gross aggregate nameplate rating).

4.2.4 For all Interconnections:

- A technically justified[2] unit that meets NERC registry criteria but is not otherwise included in the above Applicability sections 4.2.1, 4.2.2, or 4.2.3 and is requested by the Transmission Planner.

5. Effective Date:

5.1. For Requirements R1, and R3 through R6, the first day of the first calendar quarter beyond the date that this standard is approved by applicable regulatory authorities or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities. In those jurisdictions where regulatory approval is not required, the standard shall become effective on the first day of the first calendar quarter beyond the date this standard is approved by the NERC Board of Trustees, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

5.2. For Requirement R2, 30 percent of the entity's applicable unit gross MVA for each Interconnection on the first day of the first calendar quarter that is four years following applicable regulatory approval or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter that is four years following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

5.3. For Requirement R2, 50 percent of the entity's applicable unit gross MVA for each Interconnection on first day of the first calendar quarter that is six years following applicable regulatory approval or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter that is six years following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

5.4. For Requirement R2, 100 percent of the entity's applicable unit gross MVA for each Interconnection on the first day of the first calendar quarter that is 10 years

[2] Technical justification is achieved by the Transmission Planner demonstrating that the simulated unit or plant response does not match the measured unit or plant response.

following applicable regulatory approval or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter that is 10 years following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

B. Requirements

R1. Each Transmission Planner shall provide the following requested information to the Generator Owner within 90 calendar days of receiving a written request : *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*

- Instructions on how to obtain the list of excitation control system or plant volt/var control function models that are acceptable to the Transmission Planner for use in dynamic simulation,
- Instructions on how to obtain the dynamic excitation control system or plant volt/var control function model library block diagrams and/or data sheets for models that are acceptable to the Transmission Planner, or
- Model data for any of the Generator Owner's existing applicable unit specific excitation control system or plant volt/var control function contained in the Transmission Planner's dynamic database from the current (in-use) models, including generator MVA base.

R2. Each Generator Owner shall provide for each applicable unit, a verified generator excitation control system or plant volt/var control function model, including documentation and data (as specified in Part 2.1) to its Transmission Planner in accordance with the periodicity specified in MOD-026 Attachment 1. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

2.1. Each applicable unit's model shall be verified by the Generator Owner using one or more models acceptable to the Transmission Planner. Verification for individual units less than 20 MVA (gross nameplate rating) in a generating plant (per Section 4.2.1.2, 4.2.2.2, or 4.2.3.2) may be performed using either individual unit or aggregate unit model(s), or both. Each verification shall include the following:

2.1.1. Documentation demonstrating the applicable unit's model response matches the recorded response for a voltage excursion from either a staged test or a measured system disturbance,

2.1.2. Manufacturer, model number (if available), and type of the excitation control system including, but not limited to static, AC brushless, DC rotating, and/or the plant volt/var control function (if installed),

2.1.3. Model structure and data including, but not limited to reactance, time constants, saturation factors, total rotational inertia, or equivalent data for the generator,

2.1.4. Model structure and data for the excitation control system, including the closed loop voltage regulator if a closed loop voltage regulator is installed or the model structure and data for the plant volt/var control function system,

2.1.5. Compensation settings (such as droop, line drop, differential compensation), if used, and

2.1.6. Model structure and data for power system stabilizer, if so equipped.

R3. Each Generator Owner shall provide a written response to its Transmission Planner within 90 calendar days of receiving one of the following items for an applicable unit:

- Written notification from its Transmission Planner (in accordance with Requirement R6) that the excitation control system or plant volt/var control function model is not usable,
- Written comments from its Transmission Planner identifying technical concerns with the verification documentation related to the excitation control system or plant volt/var control function model, or
- Written comments and supporting evidence from its Transmission Planner indicating that the simulated excitation control system or plant volt/var control function model response did not match the recorded response to a transmission system event.

The written response shall contain either the technical basis for maintaining the current model, the model changes, or a plan to perform model verification[3] (in accordance with Requirement R2). *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*

R4. Each Generator Owner shall provide revised model data or plans to perform model verification[4] (in accordance with Requirement R2) for an applicable unit to its Transmission Planner within 180 calendar days of making changes to the excitation control system or plant volt/var control function that alter the equipment response characteristic.[5] *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*

---

[3] If verification is performed, the 10-year period as outlined in MOD-026 Attachment 1 is reset.

[4] Ibid

[5] Exciter, voltage regulator, plant volt/var or power system stabilizer control replacement including software alterations that alter excitation control system equipment response, plant digital control system addition or replacement, plant digital control system software alterations that alter excitation control system equipment response, plant volt/var function equipment addition or replacement (such as static var systems, capacitor banks, individual unit excitation systems, etc), a change in the voltage control mode (such as going from power factor control to automatic voltage control, etc), exciter, voltage regulator, impedance compensator, or power system stabilizer settings change. Automatic changes in settings that occur due to changes in operating mode do not apply to Requirement R4.

R5. Each Generator Owner shall provide a written response to its Transmission Planner, within 90 calendar days following receipt of a technically justified[6] unit request from the Transmission Planner to perform a model review of a unit or plant that includes one of the following: *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*

- Details of plans to verify the model (in accordance with Requirement R2), or
- Corrected model data including the source of revised model data such as discovery of manufacturer test values to replace generic model data or updating of data parameters based on an on-site review of the equipment.

R6. Each Transmission Planner shall provide a written response to the Generator Owner within 90 calendar days of receiving the verified excitation control system or plant volt/var control function model information in accordance with Requirement R2 that the model is usable (meets the criteria specified in Parts 6.1 through 6.3) or is not usable.

6.1. The excitation control system or plant volt/var control function model initializes to compute modeling data without error,

6.2. A no-disturbance simulation results in negligible transients, and

6.3. For an otherwise stable simulation, a disturbance simulation results in the excitation control and plant volt/var control function model exhibiting positive damping.

If the model is not usable, the Transmission Planner shall provide a technical description of why the model is not usable. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

C. Measures

M1. The Transmission Planner must have and provide the dated request for instructions or data, the transmitted instructions or data, and dated evidence of a written transmittal (e.g., electronic mail message, postal receipt, or confirmation of facsimile) as evidence that it provided the request within 90 calendar days in accordance with Requirement R1.

M2. The Generator Owner must have and provide dated evidence it verified each generator excitation control system or plant volt/var control function model according to Part 2.1 for each applicable unit and a dated transmittal (e.g., electronic mail message, postal receipt, or confirmation of facsimile) as evidence it provided the model, documentation, and data to its Transmission Planner, in accordance with Requirement R2.

M3. Evidence for Requirement R3 must include the Generator Owner's dated written response containing the information identified in Requirement R3 and dated evidence

---

[6] Technical justification is achieved by the Transmission Planner demonstrating that the simulated unit or plant response does not match the measured unit or plant response.

of transmittal (e.g., electronic mail message, postal receipt, or confirmation of facsimile) of the response.

M4. Evidence for Requirement R4 must include, for each of the Generator Owner's applicable units for which system changes specified in Requirement R4 were made, a dated revised model data or plans to perform a model verification and dated evidence (e.g., electronic mail message, postal receipt, or confirmation of facsimile) it provided the revised model and data or plans within 180 calendar days of making changes.

M5. Evidence for Requirement R5 must include the Generator Owner's dated written response containing the information identified in Requirement R5 and dated evidence (e.g., electronic mail message, postal receipt, or confirmation of facsimile) it provided a written response within 90 calendar days following receipt of a technically justified request.

M6. Evidence of Requirement R6 must include, for each model received, the dated response indicating the model was usable or not usable according to the criteria specified in Parts 6.1 through 6.3 and for a model that is not usable, a technical description; and dated evidence of transmittal (e.g., electronic mail message, postal receipt, or confirmation of facsimile) that the Generator Owner was notified within 90 calendar days of receipt of model information.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

The Regional Entity shall serve as the Compliance Enforcement Authority unless the applicable entity is owned, operated, or controlled by the Regional Entity. In such cases the ERO or a Regional entity approved by FERC or other applicable governmental authority shall serve as the CEA.

1.2. Data Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Generator Owner and Transmission Planner shall each keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

- The Transmission Planner shall retain the information/data request and provided response evidence of Requirements R1 and R6, Measures M1 and M6 for three calendar years from the date the document was provided.

- The Generator Owner shall retain the latest excitation control system or plant volt/var control function model verification evidence of Requirement R2, Measure M2.
- The Generator Owner shall retain the information/data request and provided response evidence of Requirements R3 through R5, and Measures M3 through M5 for three calendar years from the date the document was provided.

If a Generator Owner or Transmission Planner is found non-compliant, it shall keep information related to the non-compliance until mitigation is complete or approved or for the time specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes

Compliance Audit

Self-Certification

Spot Checking

Compliance Investigation

Self-Reporting

Complaints

1.4. Additional Compliance Information

None

2. Violation Severity Levels

R #	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The Transmission Planner provided the instructions and data to the Generator Owner more than 90 calendar days but less than or equal to 120 calendar days of receiving a written request.	The Transmission Planner provided the instructions and data to the Generator Owner more than 120 calendar days but less than or equal to 150 calendar days of receiving a written request.	The Transmission Planner provided the instructions and data to the Generator Owner more than 150 calendar days but less than or equal to 180 calendar days of receiving a written request.	The Transmission Planner failed to provide the instructions and data to the Generator Owner within 180 calendar days of receiving a written request.
R2	The Generator Owner provided its verified model(s), including documentation and data to its Transmission Planner after the timeframe specified in MOD-026 Attachment 1 but less than or equal to 90 calendar days late; OR The Generator Owner provided the Transmission Planner verified models that omitted one of the six Parts identified in Requirement R2, Parts 2.1.1 through 2.1.6.	The Generator Owner provided its verified model(s), including documentation and data to its Transmission Planner more than 90 calendar days but less than or equal to 180 calendar days late as specified by the periodicity timeframe in MOD-026 Attachment 1. OR The Generator Owner provided the Transmission Planner verified models that omitted two of the six Parts identified in Requirement R2, Parts 2.1.1 through 2.1.6.	The Generator Owner provided its verified model(s), including documentation and data to its Transmission Planner more than 180 calendar days but less than or equal to 270 calendar days late as specified by the periodicity timeframe in MOD-026 Attachment 1. OR The Generator Owner provided the Transmission Planner verified models that omitted three of the six Parts identified in Requirement R2, Parts 2.1.1 through 2.1.6.	The Generator Owner provided its verified model(s), including documentation and data more than 270 calendar days late to its Transmission Planner in accordance with the periodicity specified in MOD-026 Attachment 1. OR The Generator Owner failed to use model(s) acceptable to the Transmission Planner as specified in Requirement R2, Part 2.1. OR The Generator Owner provided the Transmission Planner verified model(s) but omitted four or more of the six parts identified in Requirement R2, Subparts 2.1.1 through 2.1.6.

R #	Lower VSL	Moderate VSL	High VSL	Severe VSL
R3	The Generator Owner provided a written response more than 90 calendar days but less than or equal to 120 calendar days of receiving written notice.	The Generator Owner provided a written response more than 120 calendar days but less than or equal to 150 calendar days of receiving written notice.	The Generator Owner provided a written response more than 150 calendar days but less than or equal to 180 calendar days of receiving written notice.	The Generator Owner failed to provide a written response within 180 calendar days of receiving written notice. OR The Generator Owner's written response failed to contain either the technical basis for maintaining the current model, or a list of future model changes, or a plan to perform another model verification.
R4	The Generator Owner provided revised model data or plans to perform model verification more than 180 calendar days but less than or equal to 210 calendar days of making changes to the excitation control system or plant volt/var control function that altered the equipment response characteristic.	The Generator Owner provided revised model data or plans to perform model verification more than 210 calendar days but less than or equal to 240 calendar days of making changes to the excitation control system or plant volt/var control function that altered the equipment response characteristic.	The Generator Owner provided revised model data or plans to perform model verification more than 240 calendar days but less than or equal to 270 calendar days of making changes to the excitation control system or plant volt/var control function that altered the equipment response characteristic.	The Generator Owner failed to provide revised model data or failed to provide plans to perform model verification within 270 calendar days of making changes to the excitation control system or plant volt/var control function that altered the equipment response characteristic.
R5	The Generator Owner provided a written response more than 90 calendar days but less than or equal to 120 calendar days to the Transmission Planner following receipt of a technically justified request to perform a model review of an applicable unit.	The Generator Owner provided a written response more than 120 calendar days but less than or equal to 150 calendar days to the Transmission Planner following receipt of a technically justified request to perform a model review of an applicable unit.	The Generator Owner provided a written response more than 150 calendar days but less than or equal to 180 calendar days to the Transmission Planner following receipt of a technically justified request to perform a model review of an applicable unit.	The Generator Owner failed to provide a written response to the Transmission Planner within 180 calendar days following receipt of a technically justified request to perform a model review of an applicable unit. OR The Generator Owner's written response failed to include one of the sub bullets of Requirement R5.

R #	Lower VSL	Moderate VSL	High VSL	Severe VSL
R6	The Transmission Planner provided a written response to the Generator Owner indicating whether the model is usable or not usable; including a technical description if the model is not usable, more than 90 calendar days but less than or equal to 120 calendar days of receiving verified model information.	The Transmission Planner provided a written response to the Generator Owner indicating whether the model is usable or not usable; including a technical description if the model is not usable, more than 120 calendar days but less than or equal to 150 calendar days of receiving the verified model information. OR The Transmission Planner's written response omitted confirmation for one of the specified model criteria listed in Requirement R6, Parts 6.1 through 6.3.	The Transmission Planner provided a written response to the Generator Owner indicating whether the model is usable or not usable; including a technical description if the model is not usable, more than 150 calendar days but less than or equal to 180 calendar days of receiving the verified model information. OR The Transmission Planner's written response omitted confirmation for two of the specified model criteria listed in Requirement R6, Parts 6.1 through 6.3.	The Transmission Planner failed to provide a written response to the Generator Owner within 180 calendar days of receiving the verified model information. OR The Transmission Planner's written response omitted confirmation for all specified model criteria listed in Requirement R6, Parts 6.1 through 6.3.

MOD-026 Attachment 1 Excitation Control System or Plant Volt/Var Function Model Verification Periodicity		
Row Number	**Verification Condition**	**Required Action**
1	Establishing the initial verification date for an applicable unit. (Requirement R2)	Transmit the verified model, documentation and data to the Transmission Planner on or before the Effective Date. Row 4 applies when calculating generation fleet compliance during the 10-year implementation period. See Section A5 for Effective Dates.
2	Subsequent verification for an applicable unit. (Requirement R2)	Transmit the verified model, documentation and data to the Transmission Planner on or before the 10-year anniversary of the last transmittal (per Note 1).
3	Initial verification for a new applicable unit or for an existing applicable unit with new excitation control system or plant volt/var control function equipment installed. (Requirement R2)	Transmit the verified model, documentation and data to the Transmission Planner within 365 calendar days after the commissioning date.

MOD-026 Attachment 1 Excitation Control System or Plant Volt/Var Function Model Verification Periodicity		
Row Number	**Verification Condition**	**Required Action**
4	Existing applicable unit that is equivalent to another unit(s) at the same physical location. AND Each applicable unit has the same MVA nameplate rating. AND The nameplate rating is ≤ 350 MVA. AND Each applicable unit has the same components and settings. AND The model for one of these equivalent applicable units has been verified. (Requirement R2)	Document circumstance with a written statement and include with the verified model, documentation and data provided to the Transmission Planner for the verified equivalent unit. Verify a different equivalent unit during each 10-year verification period. Applies to Row 1 when calculating generation fleet compliance during the 10-year implementation period.
5	The Generator Owner has submitted a verification plan. (Requirement R3, R4 or R5)	Transmit the verified model, documentation and data to the Transmission Planner within 365 calendar days after the submittal of the verification plan.

MOD-026 Attachment 1 Excitation Control System or Plant Volt/Var Function Model Verification Periodicity		
Row Number	**Verification Condition**	**Required Action**
6	New or existing applicable unit does not include an active closed loop voltage or reactive power control function. (Requirement R2)	Requirement 2 is met with a written statement to that effect transmitted to the Transmission Planner. Perform verification per the periodicity specified in Row 3 for a "New Generating Unit" (or new equipment) only if active closed loop function is established. See Footnote 1 (see Section A.3) for clarification of what constitutes an active closed loop function for both conventional synchronous machines (reference Footnote 1a) and aggregate generating plants (reference Footnote 1b).
7	Existing applicable unit has a current average net capacity factor over the most recent three calendar years, beginning on January 1 and ending on December 31 of 5% or less. (Requirement R2)	Requirement 2 is met with a written statement to that effect transmitted to the Transmission Planner. At the end of this 10-year timeframe, the current average three year net capacity factor (for years 8, 9, and 10) can be examined to determine if the capacity factor exemption can be declared for the next 10-year period. If not eligible for the capacity factor exemption, then model verification must be completed within 365 calendar days of the date the capacity factor exemption expired. For the definition of net capacity factor, refer to Appendix F of the GADS Data Reporting Instructions on the NERC website.

MOD-026 Attachment 1 Excitation Control System or Plant Volt/Var Function Model Verification Periodicity		
Row Number	**Verification Condition**	**Required Action**

NOTES:

NOTE 1: Establishing the recurring 10-year unit verification period start date:

The start date is the actual date of submittal of a verified model to the Transmission Planner for the most recently performed unit verification.

NOTE 2: Consideration for early compliance:

Existing generator excitation control system or plant volt/var control function model verification is sufficient for demonstrating compliance for a 10-year period from the actual transmittal date if either of the following applies:

- The Generator Owner has a verified model that is compliant with the applicable regional policies, guidelines or criteria existing at the time of model verification.
- The Generator Owner has an existing verified model that is compliant with the requirements of this standard.

A. Introduction

1. Title: Verification of Models and Data for Turbine/Governor and Load Control or Active Power/Frequency Control Functions

2. Number: MOD-027-1

3. Purpose: To verify that the turbine/governor and load control or active power/frequency control[1] model and the model parameters, used in dynamic simulations that assess Bulk Electric System (BES) reliability, accurately represent generator unit real power response to system frequency variations.

4. Applicability:

4.1. Functional entities

4.1.1 Generator Owner

4.1.2 Transmission Planner

4.2. Facilities

For the purpose of the requirements contained herein, Facilities that are directly connected to the Bulk Electric System (BES) will be collectively referred to as an "applicable unit" that meet the following:

4.2.1 Generation in the Eastern or Quebec Interconnections with the following characteristics:

4.2.1.1 Individual generating unit greater than 100 MVA (gross nameplate rating).

4.2.1.2 Individual generating plant consisting of multiple generating units that are directly connected at a common BES bus with total generation greater than 100 MVA (gross aggregate nameplate rating).

4.2.2 Generation in the Western Interconnection with the following characteristics:

4.2.2.1 Individual generating unit greater than 75 MVA (gross nameplate rating).

4.2.2.2 Individual generating plant consisting of multiple generating units that are directly connected at a common BES bus with total generation greater than 75 MVA (gross aggregate nameplate rating).

4.2.3 Generation in the ERCOT Interconnection with the following characteristics:

[1] Turbine/governor and load control or active power/frequency control:

a. Turbine/governor and load control applies to conventional synchronous generation.

b. Active power/frequency control applies to inverter connected generators (often found at variable energy plants).

4.2.3.1 Individual generating unit greater than 50 MVA (gross nameplate rating).

4.2.3.2 Individual generating plant consisting of multiple generating units that are directly connected at a common BES bus with total generation greater than 75 MVA (gross aggregate nameplate rating).

5. Effective Date:

5.1. For Requirements R1, and R3 through R5, the first day of the first calendar quarter beyond the date that this standard is approved by applicable regulatory authorities or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities. In those jurisdictions where regulatory approval is not required, the standard shall become effective on the first day of the first calendar quarter beyond the date this standard is approved by the NERC Board of Trustees, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

5.2. For Requirement R2, 30 percent of the entity's applicable unit gross MVA for each Interconnection on the first day of the first calendar quarter that is four years following applicable regulatory approval or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter that is four years following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

5.3. For Requirement R2, 50 percent of the entity's applicable unit gross MVA for each Interconnection on first day of the first calendar quarter that is six years following applicable regulatory approval or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter that is six years following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

5.4. For Requirement R2, 100 percent of the entity's applicable unit gross MVA for each Interconnection on the first day of the first calendar quarter that is 10 years following applicable regulatory approval or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter that is 10 years following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

B. Requirements

R1. Each Transmission Planner shall provide the following requested information to the Generator Owner within 90 calendar days of receiving a written request: *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*

- Instructions on how to obtain the list of turbine/governor and load control or active power/frequency control system models that are acceptable to the Transmission Planner for use in dynamic simulation,
- Instructions on how to obtain the dynamic turbine/governor and load control or active power/frequency control function model library block diagrams and/or data sheets for models that are acceptable to the Transmission Planner, or
- Model data for any of the Generator Owner's existing applicable unit specific turbine/governor and load control or active power/frequency control system contained in the Transmission Planner's dynamic database from the current (in-use) models.

R2. Each Generator Owner shall provide, for each applicable unit, a verified turbine/governor and load control or active power/frequency control model, including documentation and data (as specified in Part 2.1) to its Transmission Planner in accordance with the periodicity specified in MOD-027 Attachment 1. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

2.1. Each applicable unit's model shall be verified by the Generator Owner using one or more models acceptable to the Transmission Planner. Verification for individual units rated less than 20 MVA (gross nameplate rating) in a generating plant (per Section 4.2.1.2, 4.2.2.2, or 4.2.3.2) may be performed using either individual unit or aggregate unit model(s) or both. Each verification shall include the following:

2.1.1. Documentation comparing the applicable unit's MW model response to the recorded MW response for either:

- A frequency excursion from a system disturbance that meets MOD-027 Attachment 1 Note 1 with the applicable unit on-line,
- A speed governor reference change with the applicable unit on-line, or
- A partial load rejection test,[2]

2.1.2. Type of governor and load control or active power control/frequency control[3] equipment,

---

[2] Differences between the control mode tested and the final simulation model must be identified, particularly when analyzing load rejection data. Most controls change gains or have a set point runback which takes effect when the breaker opens. Load or set point controls will also not be in effect once the breaker opens. Some method of accounting for these differences must be presented if the final model is not validated from on-line data under the normal operating conditions under which the model is expected to apply.

[3] Turbine/governor and load control or active power/frequency control:

2.1.3. A description of the turbine (e.g. for hydro turbine - Kaplan, Francis, or Pelton; for steam turbine - boiler type, normal fuel type, and turbine type; for gas turbine - the type and manufacturer; for variable energy plant - type and manufacturer),

2.1.4. Model structure and data for turbine/governor and load control or active power/frequency control, and

2.1.5. Representation of the real power response effects of outer loop controls (such as operator set point controls, and load control but excluding AGC control) that would override the governor response (including blocked or nonfunctioning governors or modes of operation that limit Frequency Response), if applicable.

R3. Each Generator Owner shall provide a written response to its Transmission Planner within 90 calendar days of receiving one of the following items for an applicable unit.

- Written notification, from its Transmission Planner (in accordance with Requirement R5) that the turbine/governor and load control or active power/frequency control model is not "usable,"
- Written comments from its Transmission Planner identifying technical concerns with the verification documentation related to the turbine/governor and load control or active power/frequency control model, or
- Written comments and supporting evidence from its Transmission Planner indicating that the simulated turbine/governor and load control or active power/frequency control response did not approximate the recorded response for three or more transmission system events.

The written response shall contain either the technical basis for maintaining the current model, the model changes, or a plan to perform model verification[4] (in accordance with Requirement R2). *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*

R4. Each Generator Owner shall provide revised model data or plans to perform model verification[5] (in accordance with Requirement R2) for an applicable unit to its Transmission Planner within 180 calendar days of making changes to the turbine/governor and load control or active power/frequency control system that alter the equipment response characteristic[6]. *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*

---

a. Turbine/governor and load control applies to conventional synchronous generation.

b. Active power/frequency control applies to inverter connected generators (often found at variable energy plants).

[4] If verification is performed, the 10 year period as outlined in MOD-027 Attachment 1 is reset.

[5] Ibid.

[6] Control replacement or alteration including software alterations or plant digital control system addition or replacement, plant digital control system software alterations that alter droop, and/or dead band, and/or frequency response and/or a change in the frequency control mode (such as going from droop control to constant MW control, etc).

R5. Each Transmission Planner shall provide a written response to the Generator Owner within 90 calendar days of receiving the turbine/governor and load control or active power/frequency control system verified model information in accordance with Requirement R2 that the model is usable (meets the criteria specified in Parts 5.1 through 5.3) or is not usable.

5.1. The turbine/governor and load control or active power/frequency control function model initializes to compute modeling data without error,

5.2. A no-disturbance simulation results in negligible transients, and

5.3. For an otherwise stable simulation, a disturbance simulation results in the turbine/governor and load control or active power/frequency control model exhibiting positive damping.

If the model is not usable, the Transmission Planner shall provide a technical description of why the model is not usable. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

C. Measures

M1. The Transmission Planner must have and provide the dated request for instructions or data, the transmitted instruction or data, and dated evidence of a written transmittal (e.g., electronic mail message, postal receipt, or confirmation of facsimile) as evidence that it provided the request within 90 calendar days in accordance with Requirement R1.

M2. The Generator Owner must have and provide dated evidence it verified each generator turbine/governor and load control or active power/frequency control model according to Part 2.1 for each applicable unit and a dated transmittal (e.g., electronic mail message, postal receipt, or confirmation of facsimile) as evidence it provided the model, documentation, and data to its Transmission Planner, in accordance with Requirement R2.

M3. Evidence for Requirement R3 must include the Generator Owner's dated written response containing the information identified in Requirement R3 and dated evidence of transmittal (e.g., electronic mail message, postal receipt, or confirmation of facsimile) of the response.

M4. Evidence for Requirement R4 must include, for each of the Generator Owner's applicable units for which system changes specified in Requirement R4 were made, dated revised model data or dated plans to perform a model verification and dated evidence of transmittal (e.g., electronic mail message, postal receipt, or confirmation of facsimile) within 180 calendar days of making changes.

M5. Evidence of Requirement R5 must include, for each model received, the dated response indicating the model was usable or not usable according to the criteria specified in Parts 5.1 through 5.3 and for a model that is not useable, a technical description is the model is not usable, and dated evidence of transmittal (e.g., electronic mail messages, postal receipts, or confirmation of facsimile) that the Generator Owner was notified within 90 calendar days of receipt of model information in accordance with Requirement R5.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

The Regional Entity shall serve as the Compliance Enforcement Authority unless the applicable entity is owned, operated, or controlled by the Regional Entity. In such cases the ERO or a Regional entity approved by FERC or other applicable governmental authority shall serve as the CEA.

1.2. Data Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Generator Owner and Transmission Planner shall each keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

- The Transmission Planner shall retain the information/data request and provided response evidence of Requirements R1 and R5, Measures M1 and M5 for 3 calendar years from the date the document was provided.
- The Generator Owner shall retain the latest turbine/governor and load control or active power/frequency control system model verification evidence of Requirement R2, Measure M2.
- The Generator Owner shall retain the information/data request and provided response evidence of Requirements R3, and R4 Measures M3 and M4 for 3 calendar years from the date the document was provided.

If a Generator Owner or Transmission Planner is found non-compliant, it shall keep information related to the non-compliance until mitigation is complete and approved or for the time specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes

Compliance Audit

Self-Certification

Spot Checking

Compliance Investigation

Self-Reporting

Complaint

1.4. Additional Compliance Information

None

2. Violation Severity Levels

R #	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The Transmission Planner provided the instructions and data to the Generator Owner more than 90 calendar days but less than or equal to 120 calendar days of receiving a written request.	The Transmission Planner provided the instructions and data to the Generator Owner more than 120 calendar days but less than or equal to 150 calendar days of receiving a written request.	The Transmission Planner provided the instructions and data to the Generator Owner more than 150 calendar days but less than or equal to 180 calendar days of receiving a written request.	The Transmission Planner failed to provide the instructions and data to the Generator Owner within 180 calendar days of receiving a written request.
R2	The Generator Owner provided its verified model(s) to its Transmission Planner after the periodicity timeframe specified in MOD-027 Attachment 1 but less than or equal to 90 calendar days late; OR The Generator Owner provided the Transmission Planner a verified model that omitted one of the five Parts identified in Requirement R2, Subparts 2.1.1, through 2.1.5.	The Generator Owner provided its verified model(s) to its Transmission Planner more than 90 calendar days but less than or equal to 180 calendar days late as specified by the periodicity timeframe in MOD-027 Attachment 1; OR The Generator Owner provided the Transmission Planner a verified model that omitted two of the five Parts identified in Requirement R2, Subparts 2.1.1, through 2.1.5.	The Generator Owner provided its verified model(s) to its Transmission Planner more than 180 calendar days but less than or equal to 270 calendar days late as specified by the periodicity timeframe in MOD-027 Attachment 1; OR The Generator Owner provided the Transmission Planner verified models that omitted three of the five Parts identified in Requirement R2, Subparts 2.1.1, through 2.1.5.	The Generator Owner provided its verified model(s) more than 270 calendar days late to its Transmission Planner in accordance with the periodicity specified in MOD-027 Attachment 1; OR The Generator Owner failed to use model(s) acceptable to the Transmission Planner as specified in Requirement R2, Part 2.1; OR The Generator Owner provided the Transmission Planner verified model(s) that omitted four or more of the five Parts identified in Requirement R2, Subparts 2.1.1, through 2.1.5.

R #	Lower VSL	Moderate VSL	High VSL	Severe VSL
R3	The Generator Owner provided a written response more than 90 calendar days but less than or equal to 120 calendar days of receiving written notice.	The Generator Owner provided a written response more than 120 calendar days but less than or equal to 150 calendar days of receiving written notice.	The Generator Owner provided a written response more than 150 calendar days but less than or equal to 180 calendar days of receiving written notice.	The Generator Owner failed to provide a written response within 180 calendar days of receiving written notice; OR The Generator Owner's written response failed to contain either the technical basis for maintaining the current model, or a list of future model changes, or a plan to perform another model verification.
R4	The Generator Owner provided revised model data or plans to perform model verification more than 180 calendar days but less than or equal to 210 calendar days of making changes to the turbine/governor and load control or active power/frequency control system that alter the equipment response characteristic.	The Generator Owner provided revised model data or plans to perform model verification more than 210 calendar days but less than or equal to 240 calendar days of making changes to the turbine/governor and load control or active power/frequency control system that alter the equipment response characteristic.	The Generator Owner provided revised model data or plans to perform model verification more than 240 calendar days but less than or equal to 270 calendar days of making changes to the turbine/governor and load control or active power/frequency control system that alter the equipment response characteristic.	The Generator Owner failed to provide revised model data or failed to provide plans to perform model verification within 270 calendar days of making changes to the turbine/governor and load control or active power/frequency control system that altered the equipment response characteristic.

R #	Lower VSL	Moderate VSL	High VSL	Severe VSL
R5	The Transmission Planner provided a written response to the Generator Owner indicating whether the model is usable or not usable, including a technical description if the model is not usable, more than 90 calendar days but less than or equal to 120 calendar days of receiving verified model information;	The Transmission Planner provided a written response to the Generator Owner indicating whether the model is usable or not usable, including a technical description if the model is not usable, more than 120 calendar days but less than or equal to 150 calendar days of receiving the verified model information; OR The Transmission Planner’s written response omitted confirmation for one of the specified model criteria listed in Requirement R5, Parts 5.1 through 5.3.	The Transmission Planner provided a written response to the Generator Owner indicating whether the model is usable or not usable, including a technical description if the model is not usable, more than 150 calendar days but less than or equal to 180 calendar days of receiving the verified model information; OR The Transmission Planner’s written response omitted confirmation for two of the specified model criteria listed in Requirement R5, Parts 5.1 through 5.3.	The Transmission Planner failed to provide a written response to the Generator Owner within 180 calendar days of receiving the verified model information; OR The Transmission Planner provided a written response without including confirmation of all specified model criteria listed in Requirement R5, Parts 5.1 through 5.3.

MOD-027 Attachment 1

Turbine/Governor and Load Control or Active Power/Frequency Control Model Periodicity

Row Number	Verification Condition	Required Action
1	Establishing the initial verification date for an applicable unit. (Requirement R2)	Transmit the verified model, documentation and data to the Transmission Planner on or before the Effective Date. Row 5 applies when calculating generation fleet compliance during the 10year implementation period. See Section A5 for Effective Dates.
2	Subsequent verification for an applicable unit. (Requirement R2)	Transmit the verified model, documentation and data to the Transmission Planner on or before the 10-year anniversary of the last transmittal (per Note 2).
3	Applicable unit is not subjected to a frequency excursion per Note 1 by the date otherwise required to meet the dates per Rows 1, 2, 4, or 6. (This row is only applicable if a frequency excursion from a system disturbance that meets Note 1 is selected for the verification method and the ability to record the applicable unit's real power response to a frequency excursion is installed and expected to be available). (Requirement R2)	Requirement 2 is met with a written statement to that effect transmitted to the Transmission Planner. Transmit the verified model, documentation and data to the Transmission Planner on or before 365 calendar days after a frequency excursion per Note 1 occurs and the recording equipment captures the applicable unit's real power response as expected.
4	Initial verification for a new applicable unit or for an existing applicable unit with new turbine/governor and load control or active power/frequency control equipment installed. (Requirement R2)	Transmit the verified model, documentation and data to the Transmission Planner within 365 calendar days after the commissioning date.

MOD-027 Attachment 1 Turbine/Governor and Load Control or Active Power/Frequency Control Model Periodicity		
Row Number	**Verification Condition**	**Required Action**
5	Existing applicable unit that is equivalent to another applicable unit(s) at the same physical location; AND Each applicable unit has the same MVA nameplate rating; AND The nameplate rating is ≤ 350 MVA; AND Each applicable unit has the same components and settings; AND The model for one of these equivalent applicable units has been verified. (Requirement R2)	Document circumstance with a written statement and include with the verified model, documentation and data provided to the Transmission Planner for the verified equivalent unit. Verify a different equivalent unit during each 10-year verification period. Applies to Row 1 when calculating generation fleet compliance during the 10-year implementation period.
6	The Generator Owner has submitted a verification plan. (Requirement R3 or R4)	Transmit the verified model, documentation and data to the Transmission Planner within 365 calendar days after the submittal of the verification plan.

MOD-027 Attachment 1

Turbine/Governor and Load Control or Active Power/Frequency Control Model Periodicity

Row Number	Verification Condition	Required Action
7	Applicable unit is not responsive to both over and under frequency excursion events (The applicable unit does not operate in a frequency control mode, except during normal start up and shut down, that would result in a turbine/governor and load control or active power/frequency control mode response.); OR Applicable unit either does not have an installed frequency control system or has a disabled frequency control system. (Requirement R2)	Requirement 2 is met with a written statement to that effect transmitted to the Transmission Planner. Perform verification per the periodicity specified in Row 4 for a "New Generating Unit" (or new equipment) only if responsive control mode operation for connected operations is established.
8	Existing applicable unit has a current average net capacity factor over the most recent three calendar years, beginning on January 1 and ending on December 31 of 5% or less. (Requirement R2)	Requirement 2 is met with a written statement to that effect transmitted to the Transmission Planner. At the end of this 10 calendar year timeframe, the current average three year net capacity factor (for years 8, 9, and 10) can be examined to determine if the capacity factor exemption can be declared for the next 10 calendar year period. If not eligible for the capacity factor exemption, then model verification must be completed within 365 calendar days of the date the capacity factor exemption expired. For the definition of net capacity factor, refer to Appendix F of the GADS Data Reporting Instructions on the NERC website.

MOD-027 Attachment 1 Turbine/Governor and Load Control or Active Power/Frequency Control Model Periodicity		
Row Number	**Verification Condition**	**Required Action**

NOTES:

NOTE 1: Unit model verification frequency excursion criteria:

- ≥ 0.05 hertz deviation (nadir point) from scheduled frequency for the Eastern Interconnection with the applicable unit operating in a frequency responsive mode
- ≥ 0.10 hertz deviation (nadir point) from scheduled frequency for the ERCOT and Western Interconnections with the applicable unit operating in a frequency responsive mode
- ≥ 0.15 hertz deviation (nadir point) from scheduled frequency for the Quebec Interconnection with the applicable unit operating in a frequency responsive mode

NOTE 2: Establishing the recurring ten year unit verification period start date:

- The start date is the actual date of submittal of a verified model to the Transmission Planner for the most recently performed unit verification.

NOTE 3: Consideration for early compliance:

Existing turbine/governor and load control or active power/frequency control model verification is sufficient for demonstrating compliance for a 10 year period from the actual transmittal date if either of the following applies:

- The Generator Owner has a verified model that is compliant with the applicable regional policies, guidelines or criteria existing at the time of model verification
- The Generator Owner has an existing verified model that is compliant with the requirements of this standard

A. Introduction

1. **Title:** Coordination of Generating Unit or Plant Capabilities, Voltage Regulating Controls, and Protection

2. **Number:** PRC-019-1

3. **Purpose:** To verify coordination of generating unit Facility or synchronous condenser voltage regulating controls, limit functions, equipment capabilities and Protection System settings.

4. **Applicability:**

4.1. Functional Entities

4.1.1 Generator Owner

4.1.2 Transmission Owner that owns synchronous condenser(s)

4.2. Facilities

For the purpose of this standard, the term, "applicable Facility" shall mean any one of the following:

4.2.1 Individual generating unit greater than 20 MVA (gross nameplate rating) directly connected to the Bulk Electric System.

4.2.2 Individual synchronous condenser greater than 20 MVA (gross nameplate rating) directly connected to the Bulk Electric System.

4.2.3 Generating plant/ Facility consisting of one or more units that are connected to the Bulk Electric System at a common bus with total generation greater than 75 MVA (gross aggregate nameplate rating).

4.2.4 Any generator, regardless of size, that is a blackstart unit material to and designated as part of a Transmission Operator's restoration plan.

5. **Effective Date:**

5.1. In those jurisdictions where regulatory approval is required:

5.1.1 By the first day of the first calendar quarter, two calendar years following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified at least 40 percent of its applicable Facilities.

5.1.2 By the first day of the first calendar quarter, three calendar years following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified at least 60 percent of its applicable Facilities.

5.1.3 By the first day of the first calendar quarter, four calendar years following applicable regulatory, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, approval each

Generator Owner and Transmission Owner shall have verified at least 80 percent of its applicable Facilities.

5.1.4 By the first day of the first calendar quarter, five calendar years following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified 100 percent of its applicable Facilities.

5.2. In those jurisdictions where regulatory approval is not required:

5.2.1 By the first day of the first calendar quarter, two calendar years following Board of Trustees approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified at least 40 percent of its applicable Facilities.

5.2.2 By the first day of the first calendar quarter, three calendar years following Board of Trustees approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified at least 60 percent of its applicable Facilities.

5.2.3 By the first day of the first calendar quarter, four calendar years following Board of Trustees approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified at least 80 percent of its applicable Facilities.

5.2.4 By the first day of the first calendar quarter, five calendar years following Board of Trustees approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified 100 percent of its applicable Facilities.

B. Requirements

R1. At a maximum of every five calendar years, each Generator Owner and Transmission Owner with applicable Facilities shall coordinate the voltage regulating system controls, (including in-service[1] limiters and protection functions) with the applicable equipment capabilities and settings of the applicable Protection System devices and functions. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

1.1. Assuming the normal automatic voltage regulator control loop and steady-state system operating conditions, verify the following coordination items for each applicable Facility:

---

[1] Limiters or protection functions that are installed and activated on the generator or synchronous condenser.

1.1.1. The in-service limiters are set to operate before the Protection System of the applicable Facility in order to avoid disconnecting the generator unnecessarily.

1.1.2. The applicable in-service Protection System devices are set to operate to isolate or de-energize equipment in order to limit the extent of damage when operating conditions exceed equipment capabilities or stability limits.

R2. Within 90 calendar days following the identification or implementation of systems, equipment or setting changes that will affect the coordination described in Requirement R1, each Generator Owner and Transmission Owner with applicable Facilities shall perform the coordination as described in Requirement R1. These possible systems, equipment or settings changes include, but are not limited to the following *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*:

- Voltage regulating settings or equipment changes;
- Protection System settings or component changes;
- Generating or synchronous condenser equipment capability changes; or
- Generator or synchronous condenser step-up transformer changes.

C. Measures

M1. Each Generator Owner and Transmission Owner with applicable Facilities will have evidence (such as examples provided in PRC-019 Section G) that it coordinated the voltage regulating system controls, including in-service[2] limiters and protection functions, with the applicable equipment capabilities and settings of the applicable Protection System devices and functions as specified in Requirement R1. This evidence should include dated documentation that demonstrates the coordination was performed.

M2. Each Generator Owner and Transmission Owner with applicable Facilities will have evidence of the coordination required by the events listed in Requirement R2. This evidence should include dated documentation that demonstrates the specified intervals in Requirement R2 have been met.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

The Regional Entity shall serve as the Compliance enforcement authority unless the applicable entity is owned, operated, or controlled by the Regional Entity. In such cases the ERO or a Regional entity approved by FERC or other applicable governmental authority shall serve as the CEA.

[2] Limiters or protection functions that are installed and activated on the generator or synchronous condenser.

1.2. Evidence Retention

The following evidence retention periods identify a period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention specified below is shorter than the time since the last compliance audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Generator Owner and Transmission Owner shall retain evidence of compliance with Requirements R1 and R2, Measures M1 and M2 for six years.

If a Generator Owner or Transmission Owner is found non-compliant, the entity shall keep information related to the non-compliance until mitigation is complete and approved or for the time period specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last periodic audit report and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes

G. Reference

Examples of Coordination

The evidence of coordination associated with Requirement R1 may be in the form of:

- P-Q Diagram (Example in Attachment 1), or
- R-X Diagram (Example in Attachment 2), or
- Inverse Time Diagram (Example in Attachment 3) or,
- Equivalent tables or other evidence

This evidence should include the equipment capabilities and the operating region for the limiters and protection functions

Equipment limits, types of limiters and protection functions which could be coordinated include (but are not limited to):

- Field over-excitation limiter and associated protection functions.
- Inverter over current limit and associated protection functions.
- Field under-excitation limiter and associated protection functions.
- Generator or synchronous condenser reactive capabilities.
- Volts per hertz limiter and associated protection functions.
- Stator over-voltage protection system settings.
- Generator and transformer volts per hertz capability.
- Time vs. field current or time vs. stator current.

NOTE: This listing is for reference only. This standard does not require the installation or activation of any of the above limiter or protection functions.

For this example, the Steady State Stability Limit (SSSL) is the limit to synchronous stability in the under-excited region with fixed field current.

On a P-Q diagram using X_d as the direct axis saturated synchronous reactance of the generator, X_s as the equivalent reactance between the generator terminals and the "infinite bus" including the reactance of the generator step-up transformer and V_g as the generator terminal voltage (all values in per-unit), the SSSL can be calculated as an arc with the center on the Q axis with the magnitude of the center and radius described by the following equations

$$C = V^2_g/2*(1/X_s-1/X_d)$$

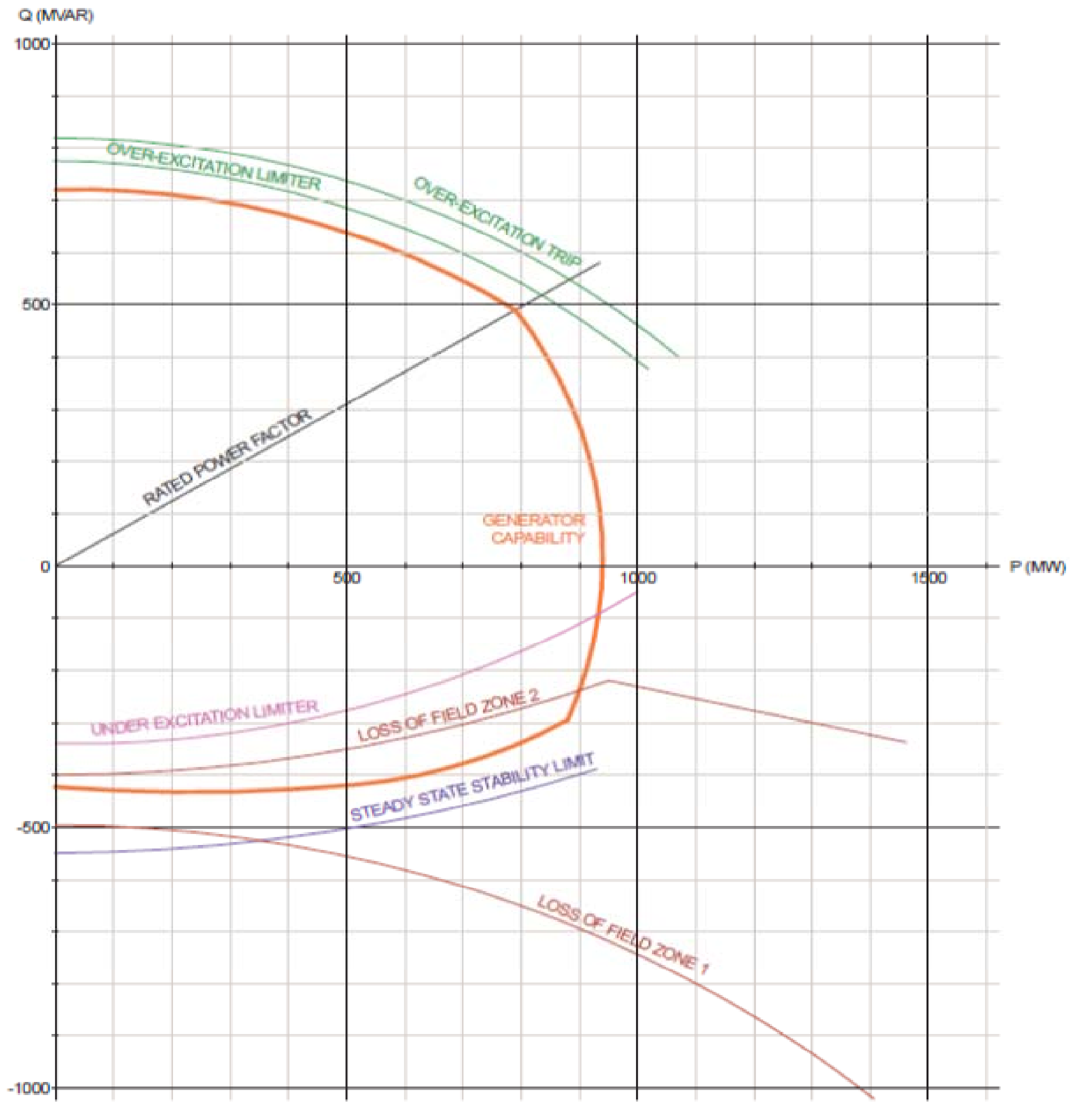
$$R = V^2_g/2*(1/X_s+1/X_d)$$

On an R-X diagram using X_d as the direct axis saturated synchronous reactance of the generator, and X_s as the equivalent reactance between the generator terminals and the "infinite bus" including the reactance of the generator step-up transformer the SSSL is an arc with the center on the X axis with the center and radius described by the following equations:

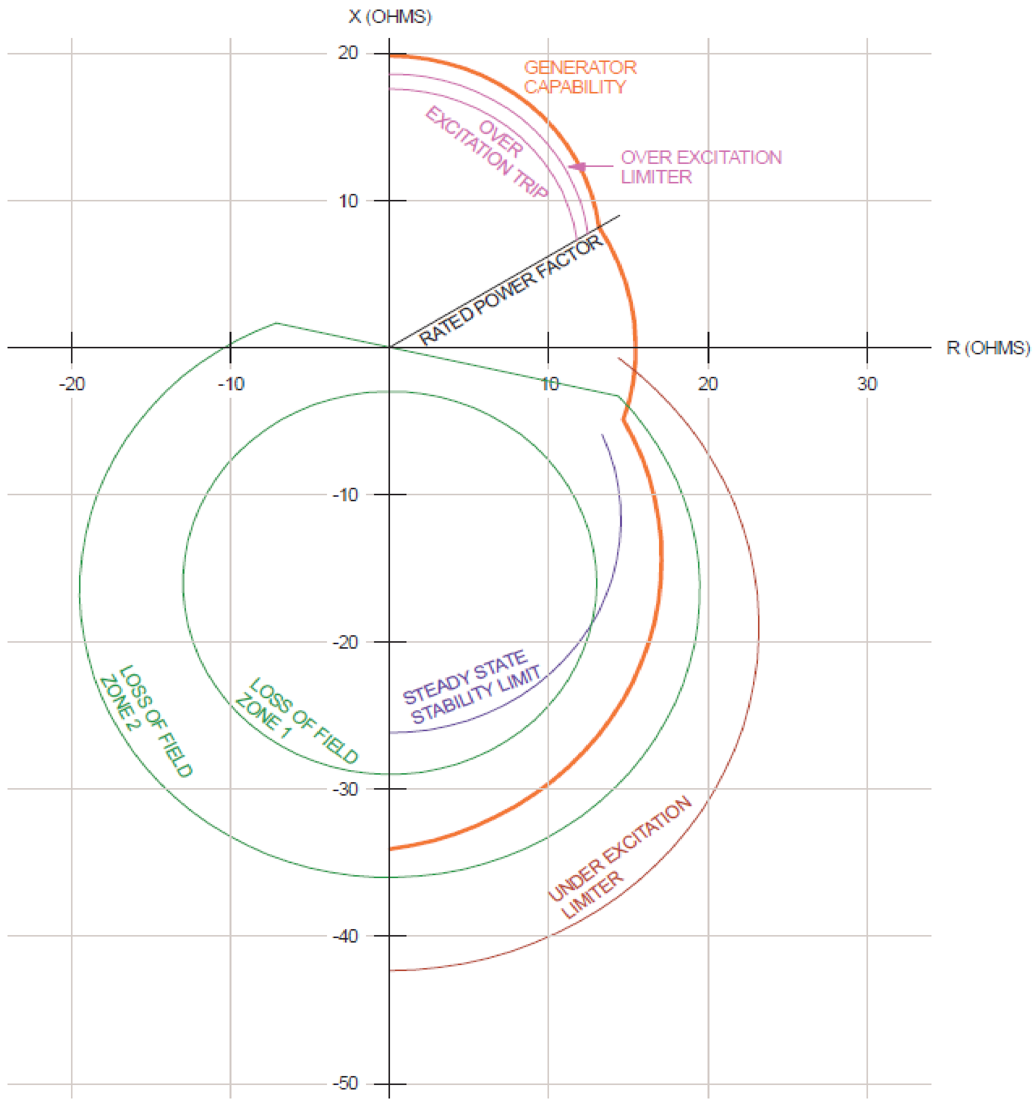
$$C = (X_d-X_s)/2$$

$$R = (X_d+X_s)/2$$

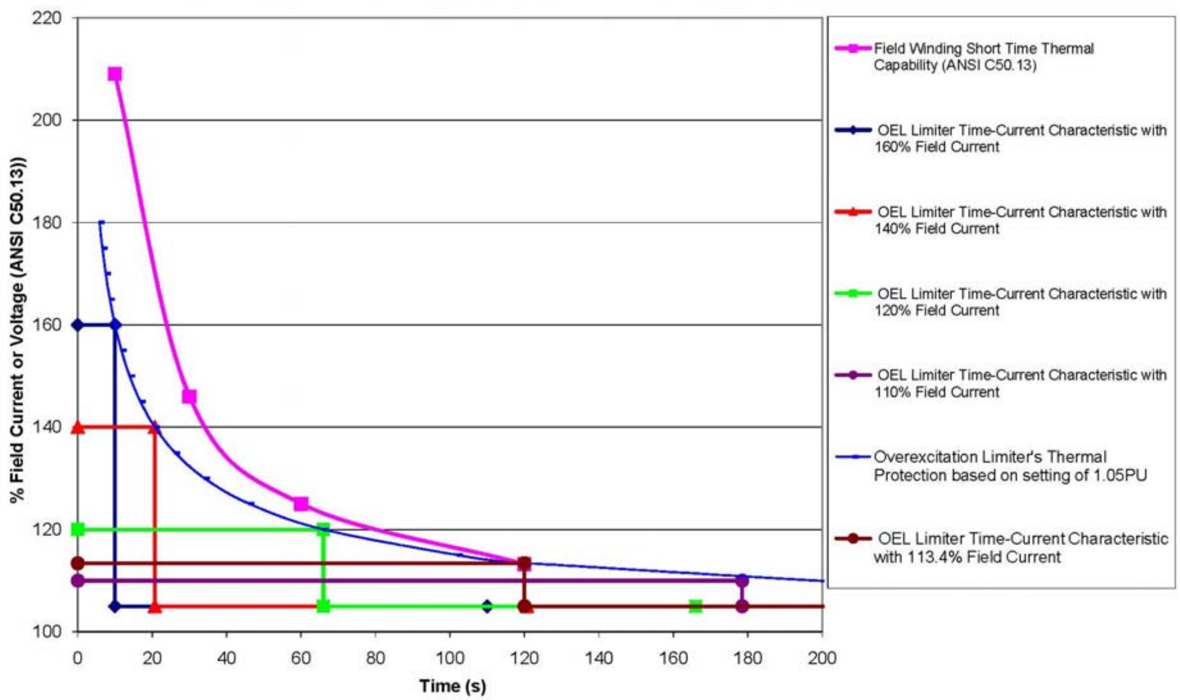
Section G Attachment 1 – Example of Capabilities, Limiters and Protection on a P-Q Diagram at nominal voltage and frequency



Section G Attachment 2 – Example of Capabilities, Limiters, and Protection on an R-X Diagram at nominal voltage and frequency



Section G Attachment 3 - Example of Capabilities, Limiters, and Protection on an Inverse Time Characteristic Plot



A. Introduction

1. Title: Generator Frequency and Voltage Protective Relay Settings

2. Number: **PRC-024-1**

3. Purpose: Ensure Generator Owners set their generator protective relays such that generating units remain connected during defined frequency and voltage excursions.

4. Applicability:

4.1. Generator Owner

5. Effective Date:

5.1. In those jurisdictions where regulatory approval is required:

5.1.1 By the first day of the first calendar quarter, two calendar years following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner shall have verified at least 40 percent of its Facilities are fully compliant with Requirements R1, R2, R3, and R4.

5.1.2 By the first day of the first calendar quarter, three calendar years following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner shall have verified at least 60 percent of its Facilities are fully compliant with Requirements R1, R2, R3, and R4.

5.1.3 By the first day of the first calendar quarter, four calendar years following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner shall have verified at least 80 percent of its Facilities are fully compliant with Requirements R1, R2, R3, and R4.

5.1.4 By the first day of the first calendar quarter, five calendar years following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner shall have verified 100 percent of its Facilities are fully compliant with Requirements R1, R2, R3, and R4.

5.2. In those jurisdictions where regulatory approval is not required:

5.2.1 By the first day of the first calendar quarter, two calendar years following Board of Trustees approval, each Generator Owner shall have verified at least 40 percent of its Facilities are fully compliant with Requirements R1, R2, R3, and R4.

5.2.2 By the first day of the first calendar quarter, three calendar years following Board of Trustees approval, each Generator Owner shall have verified at least 60 percent of its Facilities are fully compliant with Requirements R1, R2, R3, and R4.

5.2.3 By the first day of the first calendar quarter, four calendar years following Board of Trustees approval, each Generator Owner shall have verified at least 80 percent of its Facilities are fully compliant with Requirements R1, R2, R3, and R4.

5.2.4 By the first day of the first calendar quarter, five calendar years following Board of Trustees approval, each Generator Owner shall have verified 100 percent of its Facilities are fully compliant with Requirements R1, R2, R3, and R4.

B. Requirements

R1. Each Generator Owner that has generator frequency protective relaying[1] activated to trip its applicable generating unit(s) shall set its protective relaying such that the generator frequency protective relaying does not trip the applicable generating unit(s) within the "no trip zone" of PRC-024 Attachment 1, subject to the following exceptions: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

- Generating unit(s) may trip if the protective functions (such as out-of-step functions or loss-of-field functions) operate due to an impending or actual loss of synchronism or, for asynchronous generating units, due to instability in power conversion control equipment.
- Generating unit(s) may trip if clearing a system fault necessitates disconnecting (a) generating unit(s).
- Generating unit(s) may trip within a portion of the "no trip zone" of PRC-024 Attachment 1 for documented and communicated regulatory or equipment limitations in accordance with Requirement R3.

R2. Each Generator Owner that has generator voltage protective relaying[1] activated to trip its applicable generating unit(s) shall set its protective relaying such that the generator voltage protective relaying does not trip the applicable generating unit(s) as a result of a voltage excursion (at the point of interconnection[2]) caused by an event on the transmission system external to the generating plant that remains within the "no trip zone" of PRC-024 Attachment 2. If the Transmission Planner allows less stringent voltage relay settings than those required to meet PRC-024 Attachment 2, then the Generator Owner shall set its protective relaying within the voltage recovery characteristics of a location-specific Transmission Planner's study. Requirement R2 is subject to the following exceptions: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

- Generating unit(s) may trip in accordance with a Special Protection System (SPS) or Remedial Action Scheme (RAS).
- Generating unit(s) may trip if clearing a system fault necessitates disconnecting (a) generating unit(s).
- Generating unit(s) may trip by action of protective functions (such as out-of-step functions or loss-of-field functions) that operate due to an impending or actual loss of synchronism or, for asynchronous generating units, due to instability in power conversion control equipment.

---

[1] Each Generator Owner is not required to have frequency or voltage protective relaying (including but not limited to frequency and voltage protective functions for discrete relays, volts per hertz relays evaluated at nominal frequency, multi-function protective devices or protective functions within control systems that directly trip or provide tripping signals to the generator based on frequency or voltage inputs) installed or activated on its unit.

[2] For the purposes of this standard, point of interconnection means the transmission (high voltage) side of the generator step-up or collector transformer.

- Generating unit(s) may trip within a portion of the "no trip zone" of PRC-024 Attachment 2 for documented and communicated regulatory or equipment limitations in accordance with Requirement R3.

R3. Each Generator Owner shall document each known regulatory or equipment limitation[3] that prevents an applicable generating unit with generator frequency or voltage protective relays from meeting the relay setting criteria in Requirements R1 or R2 including (but not limited to) study results, experience from an actual event, or manufacturer's advice. *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

3.1. The Generator Owner shall communicate the documented regulatory or equipment limitation, or the removal of a previously documented regulatory or equipment limitation, to its Planning Coordinator and Transmission Planner within 30 calendar days of any of the following:

- Identification of a regulatory or equipment limitation.
- Repair of the equipment causing the limitation that removes the limitation.
- Replacement of the equipment causing the limitation with equipment that removes the limitation.
- Creation or adjustment of an equipment limitation caused by consumption of the cumulative turbine life-time frequency excursion allowance.

R4. Each Generator Owner shall provide its applicable generator protection trip settings associated with Requirements R1 and R2 to the Planning Coordinator or Transmission Planner that models the associated unit within 60 calendar days of receipt of a written request for the data and within 60 calendar days of any change to those previously requested trip settings unless directed by the requesting Planning Coordinator or Transmission Planner that the reporting of relay setting changes is not required. *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*

C. Measures

M1. Each Generator Owner shall have evidence that generator frequency protective relays have been set in accordance with Requirement R1 such as dated setting sheets, calibration sheets or other documentation.

M2. Each Generator Owner shall have evidence that generator voltage protective relays have been set in accordance with Requirement R2 such as dated setting sheets, voltage-time curves, calibration sheets, coordination plots, dynamic simulation studies or other documentation.

M3. Each Generator Owner shall have evidence that it has documented and communicated any known regulatory or equipment limitations (excluding limitations noted in footnote 3) that resulted in an exception to Requirements R1 or R2 in accordance with Requirement

---

[3] Excludes limitations that are caused by the setting capability of the generator frequency and voltage protective relays themselves but does not exclude limitations originating in the equipment that they protect.

R3 such as a dated email or letter that contains such documentation as study results, experience from an actual event, or manufacturer's advice.

M4. Each Generator Owner shall have evidence that it communicated applicable generator protective relay trip settings in accordance with Requirement R4, such as dated e-mails, correspondence or other evidence and copies of any requests it has received for that information.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

The Regional Entity shall serve as the Compliance Enforcement Authority (CEA) unless the applicable entity is owned, operated, or controlled by the Regional Entity. In such cases, the ERO or a Regional Entity approved by FERC or other applicable governmental authority shall serve as the CEA.

1.2. Data Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Generator Owner shall retain evidence of compliance with Requirement R1 through R4; for 3 years or until the next audit, whichever is longer.

If a Generator Owner is found non-compliant, the Generator Owner shall keep information related to the non-compliance until mitigation is complete and approved for the time period specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes

Compliance Audit

Self-Certification

Spot Checking

Compliance Investigation

Self-Reporting

Complaint

1.4. Additional Compliance Information

None

2. Violation Severity Levels

R #	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	N/A	N/A	N/A	The Generator Owner that has frequency protection activated to trip a generating unit, failed to set its generator frequency protective relaying so that it does not trip within the criteria listed in Requirement R1 unless there is a documented and communicated regulatory or equipment limitation per Requirement R3.
R2	N/A	N/A	N/A	The Generator Owner with voltage protective relaying activated to trip a generating unit, failed to set its voltage protective relaying so that it does not trip as a result of a voltage excursion at the point of interconnection, caused by an event external to the plant per the criteria specified in Requirement R2 unless there is a documented and communicated regulatory or equipment limitation per Requirement R3.
R3	The Generator Owner documented the known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2 and communicated the documented limitation to its Planning Coordinator and Transmission Planner	The Generator Owner documented the known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2 and communicated the documented limitation to its Planning Coordinator and Transmission Planner	The Generator Owner documented the known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2 and communicated the documented limitation to its Planning Coordinator and Transmission Planner	The Generator Owner failed to document any known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2. OR The Generator Owner failed to communicate

R #	Lower VSL	Moderate VSL	High VSL	Severe VSL
	more than 30 calendar days but less than or equal to 60 calendar days of identifying the limitation.	more than 60 calendar days but less than or equal to 90 calendar days of identifying the limitation.	more than 90 calendar days but less than or equal to 120 calendar days of identifying the limitation.	the documented limitation to its Planning Coordinator and Transmission Planner within 120 calendar days of identifying the limitation.
R4	The Generator Owner provided its generator protection trip settings more than 60 calendar days but less than or equal to 90 calendar days of any change to those trip settings. OR The Generator Owner provided trip settings more than 60 calendar days but less than or equal to 90 calendar days of a written request.	The Generator Owner provided its generator protection trip settings more than 90 calendar days but less than or equal to 120 calendar days of any change to those trip settings. OR The Generator Owner provided trip settings more than 90 calendar days but less than or equal to 120 calendar days of a written request.	The Generator Owner provided its generator protection trip settings more than 120 calendar days but less than or equal to 150 calendar days of any change to those trip settings. OR The Generator Owner provided trip settings more than 120 calendar days but less than or equal to 150 calendar days of a written request.	The Generator Owner failed to provide its generator protection trip settings within 150 calendar days of any change to those trip settings. OR The Generator Owner failed to provide trip settings within 150 calendar days of a written request.

		>59.4	Continuous operation

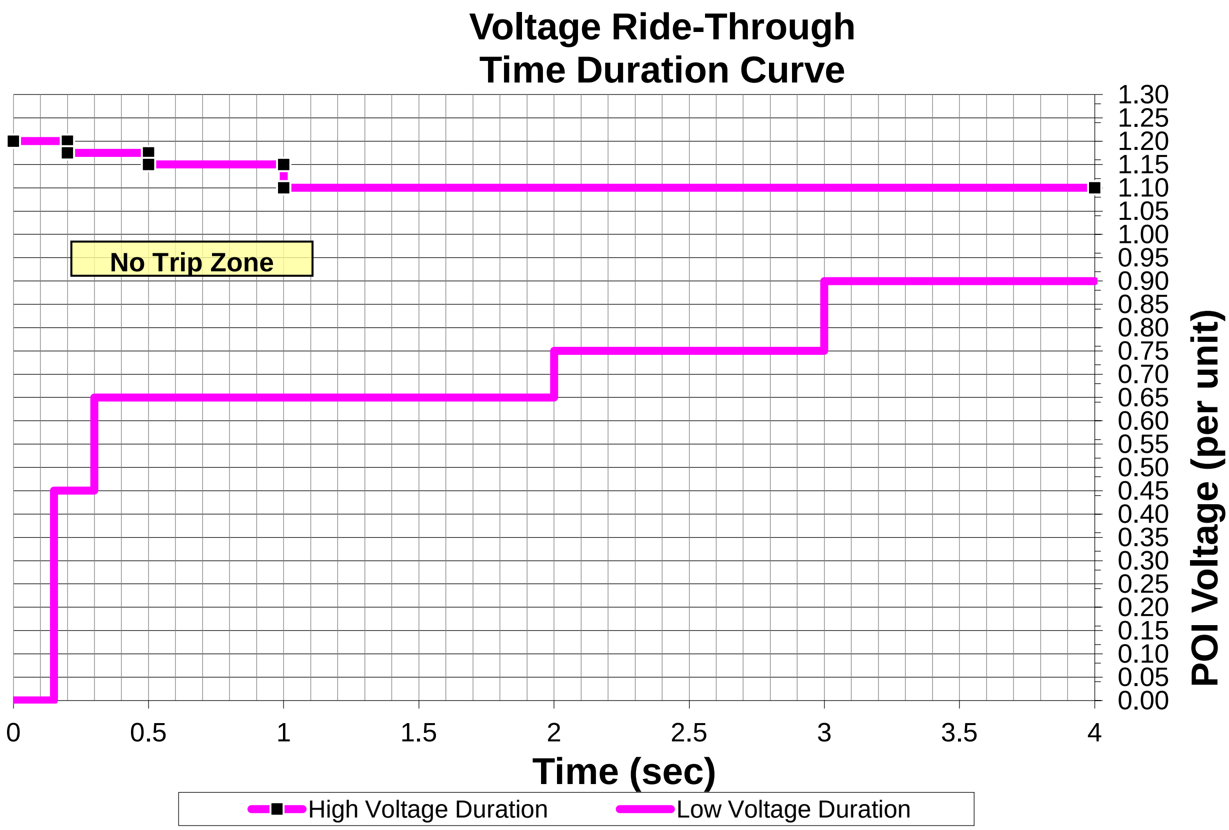
PRC-024— Attachment 2



Ride Through Duration:

High Voltage Ride Through Duration		Low Voltage Ride Through Duration	
Voltage (pu)	**Time (sec)**	**Voltage (pu)**	**Time (sec)**
≥1.200	Instantaneous trip	<0.45	0.15
≥1.175	0.20	<0.65	0.30
≥1.15	0.50	<0.75	2.00
≥1.10	1.00	<0.90	3.00

Voltage Ride-Through Curve Clarifications

Curve Details:

1. The per unit voltage base for these curves is the nominal operating voltage specified by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission Systems at the point of interconnection to the Bulk Electric System (BES).
2. The curves depicted were derived based on three-phase transmission system zone 1 faults with Normal Clearing not exceeding 9 cycles. The curves apply to voltage excursions regardless of the type of initiating event.
3. The envelope within the curves represents the cumulative voltage duration at the point of interconnection with the BES. For example, if the voltage first exceeds 1.15 pu at 0.3 seconds after a fault, does not exceed 1.2 pu voltage, and returns below 1.15 pu at 0.4 seconds, then the cumulative time the voltage is above 1.15 pu voltage is 0.1 seconds and is within the no trip zone of the curve.
4. The curves depicted assume system frequency is 60 Hertz. When evaluating Volts/Hertz protection, you may adjust the magnitude of the high voltage curve in proportion to deviations of frequency below 60 Hz.
5. Voltages in the curve assume minimum fundamental frequency phase-to-ground or phase-to-phase voltage for the low voltage duration curve and the greater of maximum RMS or crest phase-to-phase voltage for the high voltage duration curve.

Evaluating Protective Relay Settings:

1. Use either the following assumptions or loading conditions that are believed to be the most probable for the unit under study to evaluate voltage protection relay setting calculations on the static case for steady state initial conditions:
    a. All of the units connected to the same transformer are online and operating.
    b. All of the units are at full nameplate real-power output.
    c. Power factor is 0.95 lagging (i.e. supplying reactive power to the system) as measured at the generator terminals.
    d. The automatic voltage regulator is in automatic voltage control mode.
2. Evaluate voltage protection relay settings assuming that additional installed generating plant reactive support equipment (such as static VAr compensators, synchronous condensers, or capacitors) is available and operating normally.
3. Evaluate voltage protection relay settings accounting for the actual tap settings of transformers between the generator terminals and the point of interconnection.

Implementation Plan for MOD-025-2, Verification and Data Reporting of Generator Real and Reactive Power Capability and Synchronous Condenser Reactive Power Capability

Approvals Required

MOD-025-2, Verification and Data Reporting of Generator Real and Reactive Power Capability and Synchronous Condenser Reactive Power Capability

Prerequisite Approvals

None

Revisions to Glossary Terms

None

Applicable Entities

Generator Owner

Transmission Owner that owns synchronous condenser(s)

Facilities

- Individual generating unit greater than 20 MVA (gross nameplate rating) directly connected to the Bulk Electric System.
- Synchronous condenser greater than 20 MVA (gross nameplate rating) directly connected to the Bulk Electric System.
- Generating plant/facility greater than 75 MVA (gross aggregate nameplate rating) directly connected to the Bulk Electric System.

Conforming Changes to Other Standards

None

Effective Dates

In those jurisdictions where regulatory approval is required:

- By the first day of the next calendar quarter, two calendar years following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO

governmental authorities, each Generator Owner and Transmission Owner shall have verified at least 40 percent of its applicable units.

- By the first day of the next calendar quarter, three calendar years following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified at least 60 percent of its applicable units.
- By the first day of the next calendar quarter, four calendar years following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified at least 80 percent of its applicable units.
- By the first day of the next calendar quarter, five calendar years following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified 100 percent of its applicable units.

In those jurisdictions where regulatory approval is not required:

- By the first day of the next calendar quarter, two calendar years following Board of Trustees approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified at least 40 percent of its applicable units.
- By the first day of the next calendar quarter, three calendar years following Board of Trustees approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified at least 60 percent of its applicable units.
- By the first day of the next calendar quarter, four calendar years following Board of Trustees approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified at least 80 percent of its applicable units.
- By the first day of the next calendar quarter, five calendar years following Board of Trustees approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified 100 percent of its applicable units.

The Implementation Plan phasing proposed is designed to allow large entities with dozens of units requiring verification an adequate amount of time to obtain resources and conduct testing to become fully compliant with standard requirements. The phase in period is set at five years with expectation at least 20 percent of an entities' applicable units will be verified annually with full compliance achieved by the end of the five year period. The 20 percent annual increment threshold was also selected to ensure that small entities with few units have incentive to become fully compliant in a timely manner and not delay verification of its applicable units until the fifth year of the phasing period.

Wind Farm Verification - If an entity has two wind sites, and verification of one site is complete, the entity is 50% complete regardless of the number of turbines at each site. A wind site is a group of wind turbines connected at a common point of interconnection or utilizing a common aggregate control system.

Retirements

MOD-024-1 - Verification of Generator Gross and Net Real Power Capability and MOD-025-1 - Verification of Generator Gross and Net Reactive Power Capability should both be retired at midnight of the day immediately prior to the Effective Date of MOD-025-2 in the particular jurisdiction in which the new standard is becoming effective.

Implementation Plan for MOD-026-1, Verification of Models and Data for Generator Excitation Control System or Plant Volt/Var Control Functions

Approvals Required

MOD-026-1, Verification of Models and Data for Generator Excitation Control System or Plant Volt/Var Control Functions

Prerequisite Approvals

None

Revisions to Glossary Terms

None

Applicable Entities

Generator Owner
Transmission Planner

For the purpose of this standard, the following Facilities are considered, "applicable units."

Units or plants that meet the following:

Generating units connected to the Eastern or Quebec Interconnections with the following characteristics:

- Individual generating unit greater than 100 MVA (gross nameplate rating) directly connected to the Bulk Electric System.
- Each generating plant consisting of multiple units that are directly connected to the Bulk Electric System at a common bus with total generation greater than 100 MVA (gross aggregate rating).

Generating units connected to the Western Interconnection with the following characteristics:

- Individual generating unit greater than 75 MVA (gross nameplate rating) directly connected to the Bulk Electric System.

- Each generating plant consisting of multiple units that are directly connected to the Bulk Electric System at a common bus with total generation greater than 75 MVA (gross aggregate rating).

Generating units connected to the ERCOT Interconnection with the following characteristics:

- Individual generating unit greater than 50 MVA (gross nameplate rating) directly connected to the Bulk Electric System.
- Each generating plant / Facility consisting of multiple units that are connected to the Bulk Electric System at a common bus with total generation greater than 75 MVA (gross aggregate rating).

For all Interconnections:

- Any technically justified[1] unit that meets NERC registry criteria and is requested by the Transmission Planner.

Conforming Changes to Other Standards

None

Effective Dates

In those jurisdictions where regulatory approval is required:

- Each responsible entity shall ensure compliance with Requirements R1, and R3 through R6 By the first day of the first calendar quarter following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
- Each Generator Owner shall ensure at least 30 percent of its applicable unit gross MVA per Interconnection are compliant with Requirement R2 by the first day of the first calendar quarter, four years following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
- Each Generator Owner shall ensure at least 50 percent of its applicable unit gross MVA per Interconnection are compliant with Requirement R2 by the first day of the first calendar quarter, six years following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
- Each Generator Owner shall ensure 100 percent of its applicable unit gross MVA are compliant with Requirement R2 By the first day of the first calendar quarter, 10 years

[1] Technical justification is achieved by demonstrating that the simulated unit or plant response does not match the measured unit or plant response.

following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

In those jurisdictions where no regulatory approval is required:

- Each responsible entity shall ensure compliance with Requirements R1, and R3 through R6 by the first day of the first calendar quarter following Board of Trustees adoption.
- Each Generator Owner shall ensure at least 30 percent of its applicable unit gross MVA per Interconnection is compliant with Requirement R2 by the first day of the first calendar quarter, four years following Board of Trustees adoption.
- Each Generator Owner shall ensure at least 50 percent of its applicable unit gross MVA per Interconnection is compliant with Requirement R2 By the first day of the first calendar quarter, six years following Board of Trustees adoption.
- Each Generator Owner shall ensure 100 percent of its applicable unit gross MVA is compliant with Requirement R2 By the first day of the first calendar quarter, 10 years following Board of Trustees adoption.

Consideration for Early Compliance

Existing excitation control system and plant volt/var control model verification is sufficient for demonstrating compliance for a 10 year period from the actual verification date if either of the following applies:

- The Generator Owner has a verified model that is compliant with the applicable regional entity policies, guidelines or criteria existing at the time of model verification, or
- The Generator Owner has an existing verified model that is compliant with the requirements of this standard.

Justification

This phased implementation supports the 10 year cycle for the collection of generator response data necessary for required verifications and typical generating unit outage schedules.

When a Generator Owner has verified its Excitation Control System and Plant Volt/Var Control model(s) in compliance with its regional entity requirements 10 years or less prior to the approval date of this Standard, these verifications are deemed sufficient for demonstrating compliance with this Standard for a ten year period from the date of the aforementioned verification.

None

Applicable Entities

Generator Owner
Transmission Planner

For the purpose of this standard, the following Facilities are considered, "applicable units." Units or plants that meet the following:

Generating units connected to the Eastern or Quebec Interconnections with the following characteristics:

- Individual generating unit greater than 100 MVA (gross nameplate rating) directly connected to the Bulk Electric System.
- Each generating plant or generating Facility consisting of multiple units that are connected to the Bulk Electric System at a common bus with total generation greater than 100 MVA (gross aggregate rating).

Generating units connected to the Western Interconnection with the following characteristics:

- Individual generating unit greater than 75 MVA (gross nameplate rating) directly connected to the Bulk Electric System.

- Each generating plant or generating Facility consisting of multiple units that are connected to the Bulk Electric System at a common bus with total generation greater than 75 MVA (gross aggregate rating).

Generating units connected to the ERCOT Interconnection with the following characteristics:

- Individual generating unit greater than 50 MVA (gross nameplate rating) directly connected to the Bulk Electric System.
- Each generating plant or generating Facility consisting of multiple units that are connected to the Bulk Electric System at a common bus with total generation greater than 75 MVA (gross aggregate rating).

Conforming Changes to Other Standards

None

Effective Dates

In those jurisdictions where regulatory approval is required:

- Each responsible entity shall ensure compliance with Requirements R1, and R3 through R5 by the first day of the first calendar quarter following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
- Each Generator Owner shall ensure at least 30 percent of its applicable unit gross MVA per Interconnection are compliant with Requirement R2 by the first day of the first calendar quarter, four years following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
- Each Generator Owner shall ensure at least 50 percent of its applicable unit gross MVA per Interconnection are compliant with Requirement R2 by the first day of the first calendar quarter, six years following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
- Each Generator Owner shall ensure at least 100 percent of its applicable unit gross MVA per Interconnection are compliant with Requirement R2 by the first day of the first calendar quarter, 10 years following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

In those jurisdictions where no regulatory approval is required:

- Each responsible entity shall ensure compliance with Requirements R1, and R3 through R5 by the first day of the first calendar quarter following Board of Trustees adoption.

- Each Generator Owner shall ensure at least 30 percent of its applicable unit gross MVA per Interconnection are compliant with Requirement R2 by the first day of the first calendar quarter, four years following Board of Trustees adoption.
- Each Generator Owner shall ensure at least 50 percent of its applicable unit gross MVA per Interconnection are compliant with Requirement R2 by the first day of the first calendar quarter, six years following Board of Trustees adoption.
- Each Generator Owner shall ensure at least 100 percent of its applicable unit gross MVA per Interconnection are compliant with Requirement R2 by the first day of the first calendar quarter, 10 years following Board of Trustees adoption.

Justification

This phased implementation supports the ten year cycle for the collection of generator response data necessary for required verifications and typical generating unit outage schedules, and it also provides ample time for Generator Owners to either purchase new recording equipment as required or to make necessary modifications to existing recording equipment (frequency triggers, length of recordings for frequency excursions, additional event storage capacity, etc).

Consideration for Early Compliance

Existing turbine/governor and load control or active power/frequency control model verification is sufficient for demonstrating compliance for a ten year period from the actual verification date if either of the following applies:

- The Generator Owner has a verified model that is compliant with the applicable regional entity policies, guidelines or criteria existing at the time of model verification.
- The Generator Owner has an existing verified model that is compliant with the requirements of this standard.

Applicable Entities

Generator Owner
Transmission Owner that owns synchronous condenser(s)

Applicable Facilities

For the purpose of this standard, the term, "applicable Facility" shall mean any of the following:

- Individual generating unit greater than 20 MVA (gross nameplate rating) directly connected to the Bulk Electric System;
- Individual synchronous condenser greater than 20 MVA (gross nameplate rating) directly connected to the Bulk Electric System;
- Generating plant/Facility consisting of one or more units that are connected to the Bulk Electric System at a common bus with total generation greater than 75 MVA (gross aggregate nameplate rating);
- Any generator, regardless of size, that is a blackstart unit material to and designated as part of a Transmission Operator's restoration plan.

Conforming Changes to Other Standards
None

Effective Dates
PRC-019-1 shall become effective as follows:

In those jurisdictions where regulatory approval is required:

- By the first day of the first calendar quarter, two calendar years following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified at least 40 percent of its applicable Facilities.
- By the first day of the first calendar quarter, three calendar years following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified at least 60 percent of its applicable Facilities.
- By the first day of the first calendar quarter, four calendar years following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified at least 80 percent of its applicable Facilities.
- By the first day of the first calendar quarter, five calendar years following applicable regulatory approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified 100 percent of its applicable Facilities.

In those jurisdictions where regulatory approval is not required:

- By the first day of the first calendar quarter, two calendar years following Board of Trustees approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified at least 40 percent of its applicable Facilities.
- By the first day of the first calendar quarter, three calendar years following Board of Trustees approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified at least 60 percent of its applicable Facilities.
- By the first day of the first calendar quarter, four calendar years following Board of Trustees approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified at least 80 percent of its applicable Facilities.

- By the first day of the first calendar quarter, five calendar years following Board of Trustees approval, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, each Generator Owner and Transmission Owner shall have verified 100 percent of its applicable Facilities.

Justification for Phasing:

The coordination activities in this standard (PRC-019-1) are most effectively performed just prior to the performance of a reactive capability test, as required by MOD-025-2. Hence, the SDT has followed the same implementation schedule in PRC-019-1 as defined in MOD-025-2.

- By the first day of the first calendar quarter, three calendar years following Board of Trustees approval, each Generator Owner shall have verified at least 60 percent of its applicable Facilities are fully compliant with Requirements R1, R2, R3, and R4.

- By the first day of the first calendar quarter, four calendar years following Board of Trustees approval, each Generator Owner shall have verified at least 80 percent of its applicable Facilities are fully compliant with Requirements R1, R2, R3, and R4.

- By the first day of the first calendar quarter, five calendar years following Board of Trustees approval, each Generator Owner shall have verified 100 percent of its applicable Facilities are fully compliant with Requirements R1, R2, R3, and R4.

Retirements

None

Justification of Phasing

Requirements R1, R2, R3, and R4 involve evaluation of existing protection system settings and equipment capabilities. Typically, generator protection system setting changes are made during scheduled generator outages. The Implementation Plan allows a five-year window for these changes to be made which corresponds to typical outage cycles. Generating units that have outage cycles that extend longer than five years are not typically base loaded and offer opportunities to effect protection system settings changes during economic shut down periods.

Exhibit C

Order No. 672 Criteria

Order No. 672 Criteria

In Order No. 672,[1] the Commission identified a number of criteria it will use to analyze Reliability Standards proposed for approval to ensure they are just, reasonable, not unduly discriminatory or preferential, and in the public interest. The discussion below identifies these factors and explains how the proposed Reliability Standard has met or exceeded the criteria:

1. **Proposed Reliability Standards must be designed to achieve a specified reliability goal and must contain a technically sound means to achieve that goal.[2]**

The proposed Standards achieve the specific reliability goal of ensuring that (i) generators will not trip off-line during specified voltage and frequency excursions or as a result of improper coordination between generator protective relays and generator voltage regulator controls and limit functions (such coordination will include the generating unit's capabilities), and (ii) generator models accurately reflect the generator's capabilities and operating characteristics. Together, these five proposed Reliability Standards address generator verifications needed to support Bulk-Power System reliability and will ensure that accurate data is collected, verified, and made available for planning simulations.

---

[1] *Rules Concerning Certification of the Electric Reliability Organization; and Procedures for the Establishment, Approval, and Enforcement of Electric Reliability Standards*, Order No. 672, FERC Stats. & Regs. ¶ 31,204, *order on reh'g*, Order No. 672-A, FERC Stats. & Regs. ¶ 31,212 (2006).

[2] Order No. 672 at P 321. The proposed Reliability Standard must address a reliability concern that falls within the requirements of section 215 of the FPA. That is, it must provide for the reliable operation of Bulk-Power System facilities. It may not extend beyond reliable operation of such facilities or apply to other facilities. Such facilities include all those necessary for operating an interconnected electric energy transmission network, or any portion of that network, including control systems. The proposed Reliability Standard may apply to any design of planned additions or modifications of such facilities that is necessary to provide for reliable operation. It may also apply to Cybersecurity protection.

Order No. 672 at P 324. The proposed Reliability Standard must be designed to achieve a specified reliability goal and must contain a technically sound means to achieve this goal. Although any person may propose a topic for a Reliability Standard to the ERO, in the ERO's process, the specific proposed Reliability Standard should be developed initially by persons within the electric power industry and community with a high level of technical expertise and be based on sound technical and engineering criteria. It should be based on actual data and lessons learned from past operating incidents, where appropriate. The process for ERO approval of a proposed Reliability Standard should be fair and open to all interested persons.

2. Proposed Reliability Standards must be applicable only to users, owners and operators of the bulk power system, and must be clear and unambiguous as to what is required and who is required to comply.[3]

The proposed Reliability Standards are clear and unambiguous as to what is required and who is required to comply, in accordance with Order No. 672. All of the proposed Reliability Standards apply to Generator Owners. MOD-025-2 and PRC-019-1 also apply to Transmission Owners that own synchronous condenser(s). MOD-026-1 and MOD-027-1 also apply to Transmission Planners.

3. A proposed Reliability Standard must include clear and understandable consequences and a range of penalties (monetary and/or non-monetary) for a violation.[4]

The VRFs and VSLs for the proposed Reliability Standards comport with NERC and Commission guidelines related to their assignment. The assignment of the severity level for each VSL is consistent with the corresponding Requirement and the VSLs should ensure uniformity and consistency in the determination of penalties. The VSLs do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations. For these reasons, the proposed Reliability Standards include clear and understandable consequences in accordance with Order No. 672.

---

[3] Order No. 672 at P 322. The proposed Reliability Standard may impose a requirement on any user, owner, or operator of such facilities, but not on others.

Order No. 672 at P 325. The proposed Reliability Standard should be clear and unambiguous regarding what is required and who is required to comply. Users, owners, and operators of the Bulk-Power System must know what they are required to do to maintain reliability.

[4] Order No. 672 at P 326. The possible consequences, including range of possible penalties, for violating a proposed Reliability Standard should be clear and understandable by those who must comply.

4. A proposed Reliability Standard must identify clear and objective criterion or measure for compliance, so that it can be enforced in a consistent and non-preferential manner. [5]

The proposed Reliability Standards contain Measures that support each Requirement by clearly identifying what is required and how the Requirement will be enforced. These Measures help provide clarity regarding how the Requirements will be enforced, and ensure that the Requirements will be enforced in a clear, consistent, and non-preferential manner and without prejudice to any party.

5. Proposed Reliability Standards should achieve a reliability goal effectively and efficiently — but do not necessarily have to reflect "best practices" without regard to implementation cost or historical regional infrastructure design.[6]

The proposed Reliability Standards achieve the reliability goal effectively and efficiently in accordance with Order No. 672.

6. Proposed Reliability Standards cannot be "lowest common denominator," *i.e.*, cannot reflect a compromise that does not adequately protect Bulk-Power System reliability. Proposed Reliability Standards can consider costs to implement for smaller entities, but not at consequences of less than excellence in operating system reliability.[7]

[5] Order No. 672 at P 327. There should be a clear criterion or measure of whether an entity is in compliance with a proposed Reliability Standard. It should contain or be accompanied by an objective measure of compliance so that it can be enforced and so that enforcement can be applied in a consistent and non-preferential manner.

[6] Order No. 672 at P 328. The proposed Reliability Standard does not necessarily have to reflect the optimal method, or "best practice," for achieving its reliability goal without regard to implementation cost or historical regional infrastructure design. It should however achieve its reliability goal effectively and efficiently.

[7] Order No. 672 at P 329. The proposed Reliability Standard must not simply reflect a compromise in the ERO's Reliability Standard development process based on the least effective North American practice — the so-called "lowest common denominator" — if such practice does not adequately protect Bulk-Power System reliability. Although FERC will give due weight to the technical expertise of the ERO, we will not hesitate to remand a proposed Reliability Standard if we are convinced it is not adequate to protect reliability.

Order No. 672 at P 330. A proposed Reliability Standard may take into account the size of the entity that must comply with the Reliability Standard and the cost to those entities of implementing the proposed Reliability Standard. However, the ERO should not propose a "lowest common denominator" Reliability Standard that would achieve less than excellence in operating system reliability solely to protect against reasonable expenses for supporting this vital national infrastructure. For example, a small owner or operator of the Bulk-Power System must bear the cost of complying with each Reliability Standard that applies to it.

The proposed Reliability Standards do not reflect a "lowest common denominator" approach. To the contrary, the proposed Reliability Standards represent a significant improvement over the previous version as described herein.

7. Proposed Reliability Standards must be designed to apply throughout North America to the maximum extent achievable with a single Reliability Standard while not favoring one geographic area or regional model. It should take into account regional variations in the organization and corporate structures of transmission owners and operators, variations in generation fuel type and ownership patterns, and regional variations in market design if these affect the proposed Reliability Standard.[8]

The proposed Reliability Standards apply throughout North America and do not favor one geographic area or regional model.

8. Proposed Reliability Standards should cause no undue negative effect on competition or restriction of the grid beyond any restriction necessary for reliability.[9]

The proposed Reliability Standards do not restrict the available transmission capability or limit use of the bulk-power system in a preferential manner.

9. The implementation time for the proposed Reliability Standard is reasonable.[10]

The proposed effective dates for the Reliability Standards are just and reasonable and appropriately balance the urgency in the need to implement the standards against the

---

[8] Order No. 672 at P 331. A proposed Reliability Standard should be designed to apply throughout the interconnected North American Bulk-Power System, to the maximum extent this is achievable with a single Reliability Standard. The proposed Reliability Standard should not be based on a single geographic or regional model but should take into account geographic variations in grid characteristics, terrain, weather, and other such factors; it should also take into account regional variations in the organizational and corporate structures of transmission owners and operators, variations in generation fuel type and ownership patterns, and regional variations in market design if these affect the proposed Reliability Standard.

[9] Order No. 672 at P 332. As directed by section 215 of the FPA, FERC itself will give special attention to the effect of a proposed Reliability Standard on competition. The ERO should attempt to develop a proposed Reliability Standard that has no undue negative effect on competition. Among other possible considerations, a proposed Reliability Standard should not unreasonably restrict available transmission capability on the Bulk-Power System beyond any restriction necessary for reliability and should not limit use of the Bulk-Power System in an unduly preferential manner. It should not create an undue advantage for one competitor over another.

[10] Order No. 672 at P 333. In considering whether a proposed Reliability Standard is just and reasonable, FERC will consider also the timetable for implementation of the new requirements, including how the proposal balances any urgency in the need to implement it against the reasonableness of the time allowed for those who must comply to develop the necessary procedures, software, facilities, staffing or other relevant capability.

reasonableness of the time allowed for those who must comply to develop necessary procedures, software, facilities, staffing or other relevant capability. This will allow applicable entities adequate time to ensure compliance with the requirements.

Specifically, the proposed implementation plans for MOD-026-1 and MOD-027-1 are of a longer duration due to the complexity of the tasks involved. Model verification testing on generating units is a relatively specialized and complex task that involves some risk to the operating unit. The reasons for this are as follows:

- The unit must have temporary monitoring equipment connected to record the necessary parameters;
- To install the equipment necessary to obtain shaft position information, a unit shutdown may be required;
- A specialized skill set is required both to perform the test and to process the data obtained during testing. There are not large numbers of these personnel available;
- Each unit takes 2-3 days to instrument, collect data, and then process the data to verify that the model is correct, unlike MOD-025 testing which can typically be accomplished with already installed instruments and within 1 day.

Given that there are many units to test, a long period of time was deemed to be necessary to get all the units complete. Obviously, entities with few units will probably have more time than needed, but entities with large numbers of units may be challenged even by the 10 year period. If the planning entity has a need for a particular unit, they can require that unit to be verified under Requirement R3 of the proposed Standards. The proposed effective dates are explained in the proposed Implementation Plan, attached as **Exhibit C**.

10. The Reliability Standard was developed in an open and fair manner and in accordance with the Commission-approved Reliability Standard development process.[11]

[11] Order No. 672 at P 334. Further, in considering whether a proposed Reliability Standard meets the legal standard of review, we will entertain comments about whether the ERO implemented its Commission-approved Reliability Standard development process for the development of the particular proposed Reliability Standard in a proper manner, especially whether the process was open and fair. However, we caution that we will not be sympathetic to

The proposed Reliability Standards were developed in accordance with NERC's Commission-approved, ANSI- accredited processes for developing and approving Reliability Standards. **Exhibit E** includes a summary of the Reliability Standard development proceedings, and details the processes followed to develop the Reliability Standards.

These processes included, among other things, multiple comment periods, pre-ballot review periods, and balloting periods. Additionally, all meetings of the drafting team were properly noticed and open to the public. The initial and recirculation ballots both achieved a quorum and exceeded the required ballot pool approval levels.

11. NERC must explain any balancing of vital public interests in the development of proposed Reliability Standards.[12]

NERC has identified no competing public interests regarding the request for approval of the proposed Reliability Standards. No comments were received that indicated the proposed Reliability Standards conflict with other vital public interests.

12. Proposed Reliability Standards must consider any other appropriate factors.[13]

No other negative factors relevant to whether the proposed Reliability Standards are just and reasonable were identified.

---

arguments by interested parties that choose, for whatever reason, not to participate in the ERO's Reliability Standard development process if it is conducted in good faith in accordance with the procedures approved by FERC.

[12] Order No. 672 at P 335. Finally, we understand that at times development of a proposed Reliability Standard may require that a particular reliability goal must be balanced against other vital public interests, such as environmental, social and other goals. We expect the ERO to explain any such balancing in its application for approval of a proposed Reliability Standard.

[13] Order No. 672 at P 323. In considering whether a proposed Reliability Standard is just and reasonable, we will consider the following general factors, as well as other factors that are appropriate for the particular Reliability Standard proposed.

Exhibit D

Analysis of how VRFs and VSLs Were Determined Using Commission Guidelines

Violation Risk Factor and Violation Severity Level Assignments

Project 2007-09 Generator Verification

This document provides the drafting team's justification for assignment of Violation Risk Factors (VRFs) and Violation Severity Levels (VSLs) for each requirement in MOD-025-2 — Verification and Data Reporting of Generator Real and Reactive Power Capability.

Each primary requirement is assigned a VRF and a set of one or more VSLs. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability standards, as defined in the ERO Sanction Guidelines.

Justification for Assignment of Violation Risk Factors

The Generator Verification Standard drafting team applied the following NERC criteria when proposing VRFs for the requirements under this project:

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to Bulk Electric System instability, separation, or a cascading sequence of failures; or could place the Bulk Electric System at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could; under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to Bulk Electric System instability, separation, or a cascading sequence of failures; or could place the Bulk Electric System at an unacceptable risk of instability, separation, or cascading failures; or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the Bulk Electric System; or the ability to effectively monitor and control the Bulk Electric System. However, violation of a medium-risk requirement is unlikely to lead to Bulk Electric System instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could; under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the Bulk Electric System; or the ability to effectively monitor, control, or restore the Bulk Electric System. However, violation of a medium-risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to Bulk Electric System instability, separation, or cascading failures; nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the Bulk Electric System; or the ability to effectively monitor and control the Bulk Electric System; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the Bulk Electric System; or the ability to effectively monitor, control; or restore the Bulk Electric System. A planning requirement that is administrative in nature.

The SDT also considered consistency with the FERC Violation Risk Factor Guidelines for setting VRFs:[1]

Guideline (1) — Consistency with the Conclusions of the Final Blackout Report

The Commission seeks to ensure that Violation Risk Factors assigned to Requirements of Reliability standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk Power System.

In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk Power System:[2]

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup Facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and Facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical Facilities
- Appropriate use of transmission Loading relief

Guideline (2) — Consistency within a Reliability Standard

The Commission expects a rational connection between the sub-requirement Violation Risk Factor assignments and the main Requirement Violation Risk Factor assignment.

Guideline (3) — Consistency among Reliability Standards

[1] North American Electric Reliability Corp., 119 FERC ¶ 61,145, order on reh'g and compliance filing, 120 FERC ¶ 61,145 (2007) ("VRF Rehearing Order").
[2] Id. at footnote 15.

The Commission expects the assignment of Violation Risk Factors corresponding to requirements that address similar reliability goals in different reliability standards would be treated comparably.

Guideline (4) — Consistency with NERC's Definition of the Violation Risk Factor Level

Guideline (4) was developed to evaluate whether the assignment of a particular Violation Risk Factor level conforms to NERC's definition of that risk level.

Guideline (5) — Treatment of Requirements that Co-mingle More Than One Obligation

Where a single requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such requirements must not be watered down to reflect the lower risk level associated with the less important objective of the reliability standard.

The following discussion addresses how the SDT considered FERC's VRF Guidelines 2 through 5. The team did not address Guideline 1 directly because of an apparent conflict between Guidelines 1 and 4; whereas Guideline 1 identifies a list of topics that encompass nearly all topics within NERC's reliability standards and implies that these requirements should be assigned a "High" VRF, Guideline 4 directs assignment of VRFs based on the impact of a specific requirement to the reliability of the system. The SDT believes that Guideline 4 is reflective of the intent of VRFs in the first instance; and, therefore, concentrated its approach on the reliability impact of the requirements.

VRF for MOD-025-2:

There are three requirements in MOD-025-2. Each requirement was assigned a "Medium" VRF.

VRF for MOD-025-2, Requirement R1:

- FERC Guideline 2 — Consistency within a reliability standard exists. Each Requirement in MOD-025-1 is assigned a "Medium" VRF. Requirement R1 is similar in scope to Requirements R2 and R3. Each requirement is to perform a verification of capability.
- FERC Guideline 3 — Consistency among reliability standards exists. This requirement is similar with MOD-010-0 and MOD-012-0 Requirements R1 and R2 in concept and they have approved Medium VRFs. A primary difference being MOD-010-0 and MOD-012-0 require data submission for all Facilities, and not merely a single unit, as specified in this standard.
- FERC Guideline 4 — Consistency with NERC's definition of the VRF level selected exists. Failure to verify models in the long-term planning time horizon is a requirement in a planning time frame that, if violated, could, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the Bulk Electric System; or the ability to effectively monitor, control, or restore the Bulk Electric System. Therefore, the assigned "Medium" VRF is appropriate.

- FERC Guideline 5 — Treatment of requirements that co-mingle more than one obligation is satisfactory. The Requirement R1 risk objective is to verify capability. The risk objectives are administrative in nature, consisting of recording and submission requirements for planning studies. The “Medium” VRF assigned is based on the risk objective specified.

VRF for MOD-025-2, Requirement R2:

- FERC Guideline 2 — Consistency within is similar in scope to Requirements R1 and R3. Each Requirement is to perform a verification of capability.
- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar with MOD-010-0 and MOD-012-0 Requirements R1 and R2 in concept, and they have approved Medium VRFs. A primary difference being MOD-010-0 and MOD-012-0 require data submission for all Facilities, and not merely a single unit as specified in this standard.
- FERC Guideline 4 — Consistency with NERC’s Definition of the VRF Level selected exists. Failure to verify models is a requirement in a planning time frame that, if violated, could, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the Bulk Electric System; or the ability to effectively monitor, control, or restore the Bulk Electric System. Therefore, the assigned “Medium” VRF is appropriate.
- FERC Guideline 5 — Treatment of requirements that co-mingle more than one obligation is satisfactory. The Requirement R1 risk objective is to verify capability. The risk objectives are administrative in nature, consisting of recording and submission requirements for planning studies. The “Medium” VRF assigned is based on the risk objective specified.

VRF for MOD-025-2, Requirement R3:

- FERC Guideline 2 — Consistency within a reliability standard exists. Each requirement in MOD-025-1 is assigned a “Medium” VRF. Requirement R3 is similar in scope to Requirements R1 and R2.
- FERC Guideline 3 — Consistency among reliability standards exists. This requirement is similar with MOD-010-0 and MOD-012-0, Requirements R1 and R2, in concept and they have approved Medium VRFs. A primary difference being MOD-010-0 and MOD-012-0 require data submission for all Facilities, and not merely a single unit, as specified in this standard.
- FERC Guideline 4 — Consistency with NERC’s definition of the VRF level selected exists. Failure to verify models in the long-term planning time horizon is a requirement in a planning time frame that, if violated, could, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or

capability of the Bulk Electric System; or the ability to effectively monitor, control, or restore the Bulk Electric System. Therefore, the assigned “Medium” VRF is appropriate.

- FERC Guideline 5 — Treatment of requirements that co-mingle more than one obligation is satisfactory. The Requirement R3 risk objective is to verify capability. The risk objectives are administrative in nature, consisting of recording and submission requirements for planning studies. The “Medium” VRF assigned is based on the risk objective specified.

Justification for Assignment of Violation Severity Levels:

In developing the VSLs for the standards under this project, the SDT anticipated the evidence that would be reviewed during an audit, and developed its VSLs based on the noncompliance an auditor may find during a typical audit. The SDT based its assignment of VSLs on the following NERC criteria:

Lower	Moderate	High	Severe
Missing a minor element (or a small percentage) of the required performance. The performance or product measured has significant value, as it almost meets the full intent of the requirement.	Missing at least one significant element (or a moderate percentage) of the required performance. The performance or product measured still has significant value in meeting the intent of the requirement.	Missing more than one significant element (or is missing a high percentage) of the required performance, or is missing a single vital component. The performance or product has limited value in meeting the intent of the requirement.	Missing most or all of the significant elements (or a significant percentage) of the required performance. The performance measured does not meet the intent of the requirement, or the product delivered cannot be used in meeting the intent of the requirement.

FERC's VSL guidelines are presented below, followed by an analysis of whether the VSLs proposed for each requirement in MOD-025-2 meet the FERC Guidelines for assessing VSLs:

Guideline 1: Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

Compare the VSLs to any prior levels of noncompliance and avoid significant changes that may encourage a lower level of compliance than was required when levels of noncompliance were used.

Guideline 2: Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

A violation of a “binary” type requirement must be a “Severe” VSL.

Do not use ambiguous terms such as “minor” and “significant” to describe noncompliant performance.

Guideline 3: Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

VSLs should not expand on what is required in the requirement.

Guideline 4: Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations

Unless otherwise stated in the requirement, each instance of noncompliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the “default” for penalty calculations.

VSLs for MOD-025-2 Requirement R1:

R#	Compliance with NERC VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R1	The NERC VSL guidelines are satisfied by identifying noncompliance based on the obligation to verify capability and provide data within certain timeframes. The VSLs account for increments of tardiness and incomplete data submissions.	Standard requirements have been significantly revised since MOD-025-1 was approved. Proposed VSL's are binary with additional consideration for the obligation to submit information in a timely fashion; whereas, MOD-025-1 levels of noncompliance only considered completeness of submitted information. As drafted, proposed VSL's raise the current level of compliance.	Proposed VSL's identify noncompliance based on the obligation to verify capability and provide data within certain timeframes. The VSLs account for increments of tardiness and incomplete data submissions. Proposed VSL language does not include ambiguous terms, and ensure uniformity and consistency in the determination of penalties based on binary performance and obligation information submission timeliness.	Proposed VSL's do not expand on what is required in the requirement. The VSL's assigned only consider performing required action, and if information is provided in a timely manner. Proposed VSL's are consistent with the requirement.	Proposed VSL's are based on a single violation, and not a cumulative violation methodology.

VSLs for MOD-025-2 Requirement R2:

R#	Compliance with NERC VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R2	The NERC VSL guidelines are satisfied by identifying noncompliance based on the obligation to verify capability and provide data within certain timeframes. The VSLs account for increments of tardiness and incomplete data submissions.	Standard requirements have been significantly revised since MOD-025-1 was approved. Proposed VSL's are binary with additional consideration for the obligation to submit information in a timely fashion; whereas, MOD-025-1 levels of noncompliance only considered completeness of submitted information. As drafted, proposed VSL's raise the current level of compliance.	Proposed VSL's identify noncompliance based on the obligation to verify capability and provide data within certain timeframes. The VSLs account for increments of tardiness and incomplete data submissions. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on binary performance and obligation information submission timeliness.	Proposed VSL's do not expand on what is required in the requirement. The VSL's assigned only consider performing required action and if information is provided in a timely manner. Proposed VSL's are consistent with the requirement.	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

VSLs for MOD-025-2 Requirement R3:

R#	Compliance with NERC VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R3.	The NERC VSL guidelines are satisfied by identifying noncompliance based on the obligation to verify capability and provide data within certain timeframes. The VSLs account for increments of tardiness and incomplete data submissions.	Standard requirements have been significantly revised since MOD-025-1 was approved. Proposed VSL's are binary with additional consideration for the obligation to submit information in a timely fashion; whereas, MOD-025-1 levels of noncompliance only considered completeness of submitted information. As drafted, proposed VSL's raise the current level of compliance.	Proposed VSL's identify noncompliance based on the obligation to verify capability and provide data within certain timeframes. The VSLs account for increments of tardiness and incomplete data submissions. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on binary performance and obligation information submission timeliness.	Proposed VSL's do not expand on what is required in the requirement. The VSL's assigned only consider performing required action and if information is provided in a timely manner. Proposed VSL's are consistent with the requirement.	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

Violation Risk Factor and Violation Severity Level Assignments

Project 2007-09 Generator Verification

This document provides the drafting team's justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in MOD-026-1 — Verification of Models and Data for Generator Excitation Control System and Plant Volt/Var Control Functions.

Each primary requirement is assigned a VRF and a set of one or more VSLs. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the ERO Sanction Guidelines.

Justification for Assignment of Violation Risk Factors

The Generator Verification Standard Drafting Team applied the following NERC criteria when proposing VRFs for the requirements under this project:

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

The SDT also considered consistency with the FERC Violation Risk Factor Guidelines for setting VRFs:[1]

Guideline (1) — Consistency with the Conclusions of the Final Blackout Report

The Commission seeks to ensure that Violation Risk Factors assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System.

In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:[2]

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief

Guideline (2) — Consistency within a Reliability Standard

The Commission expects a rational connection between the sub-Requirement Violation Risk Factor assignments and the main Requirement Violation Risk Factor assignment.

Guideline (3) — Consistency among Reliability Standards

[1] North American Electric Reliability Corp., 119 FERC ¶ 61,145, order on reh'g and compliance filing, 120 FERC ¶ 61,145 (2007) ("VRF Rehearing Order").
[2] Id. at footnote 15.

The Commission expects the assignment of Violation Risk Factors corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) — Consistency with NERC's Definition of the Violation Risk Factor Level

Guideline (4) was developed to evaluate whether the assignment of a particular Violation Risk Factor level conforms to NERC's definition of that risk level.

Guideline (5) — Treatment of Requirements that Co-mingle More Than One Obligation

Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

The following discussion addresses how the SDT considered FERC's VRF Guidelines 2 through 5. The team did not address Guideline 1 directly because of an apparent conflict between Guidelines 1 and 4. Whereas Guideline 1 identifies a list of topics that encompass nearly all topics within NERC's Reliability Standards and implies that these requirements should be assigned a "High" VRF, Guideline 4 directs assignment of VRFs based on the impact of a specific requirement to the reliability of the system. The SDT believes that Guideline 4 is reflective of the intent of VRFs in the first instance and therefore concentrated its approach on the reliability impact of the requirements.

VRF for MOD-026-1:

There are six requirements in MOD-026-1. Four requirements were assigned a "Lower" VRF while the remaining two were assigned a "Medium" VRF.

VRF for MOD-026-1, Requirement R1:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R1 does not contain Parts. Requirement obligations include actions similar in scope to actions specified in Requirement R6; and all standard requirements specify either an Operations Planning or a Long-term Planning Time Horizon.
- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar to MOD-004-1, Requirement R9 that has an approved Lower VRF. This requirement is also similar to draft standard MOD-027-1 Requirement R1 which also specifies a Lower VRF.
- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to provide requested information is a requirement that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. Therefore the assigned "Lower" VRF is appropriate.

- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R1 high risk objective is to provide requested information. This requirement is administrative in nature for providing instructions and data used for performing model verification. The "Lower" VRF assigned is based on the high risk objective specified.

VRF for MOD-026-1, Requirement R2:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R2 contains Parts specifying supporting obligations for satisfying the main requirement. The VRFs are only applied at the Requirement level and each Requirement Part is treated equally. Requirement obligations include actions similar in scope to actions specified in Requirement R1 and R6; and all standard requirements specify either an Operations Planning or a Long-term Planning Time Horizon.
- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar with MOD-010-0 and MOD-012-0 Requirements R1 and R2 that have approved VRFs of Medium. This requirement is also similar to draft standard MOD-027-1 Requirement R2 which also specifies a Medium VRF.
- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to verify models in the Long-term Planning Time Horizon is a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. Therefore the assigned "Medium" VRF is appropriate.
- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R2 high risk objective is to verify models per specified periodicity. Requirement Parts and obligations are lower risk elements that ensure main requirement completeness which are administrative in nature consisting of documentation, information revision obligation and submission requirements. The "Medium" VRF assigned is based on the high risk objective specified.

VRF for MOD-026-1, Requirement R3:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R3 does not contain Parts. Requirement obligations include actions similar in scope to actions specified in Requirement R1 and R6; and all standard requirements specify either an Operations Planning or a Long-term Planning Time Horizon.

- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar to MOD-004-1, Requirement R7 and R8 that has an approved Lower VRF. This requirement is also similar to draft standard MOD-027-1 Requirement R3 which also specifies a Lower VRF.
- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to verify models in the Long-term Planning Time Horizon is a requirement that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. Therefore the assigned "Lower" VRF is appropriate.
- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R3 high risk objective is to provide a written response after receiving notice. The Requirement is administrative in nature consisting of documentation, information revision obligation and submission requirements. The "Lower" VRF assigned is based on the high risk objective specified.

VRF for MOD-026-1, Requirement R4:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R4 does not contain Parts. Requirement obligations include actions similar in scope to actions specified in Requirement R1 and R6; and all standard requirements specify either an Operations Planning or a Long-term Planning Time Horizon.
- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar to MOD-004-1, Requirement R1 and R2 that has an approved Lower VRF. This requirement is also similar to draft standard MOD-027-1 Requirement R4 which also specifies a Lower VRF.
- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to verify models in the Long-term Planning Time Horizon is a requirement that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. Therefore the assigned "Lower" VRF is appropriate.
- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R4 high risk objective is to provide revised data after making changes to equipment. The Requirement is administrative in nature consisting of documentation, information revision obligation and submission requirements. The "Lower" VRF assigned is based on the high risk objective specified.

VRF for MOD-026-1, Requirement R5:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R5 contains Parts specifying supporting obligations for satisfying the main requirement. The VRFs are only applied at the Requirement level and each Requirement Part is treated equally. Requirement obligations include actions similar in scope to actions specified in Requirement R1 and R6; and all standard requirements specify either an Operations Planning or a Long-term Planning Time Horizon.
- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar to MOD-004-1, Requirement R7 and R8 that has an approved Lower VRF. This requirement is also similar to draft standard MOD-027-1 Requirement R3 which also specifies a Lower VRF.
- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to verify models in the Long-term Planning Time Horizon is a requirement that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. Therefore the assigned "Lower" VRF is appropriate.
- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R5 high risk objective is to provide a written response after receiving a request. Requirement Parts and obligations are lower risk elements that ensure main requirement completeness which are administrative in nature consisting of documentation, information revision obligation and submission requirements. The "Lower" VRF assigned is based on the high risk objective specified.

VRF for MOD-026-1, Requirement R6:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R6 contains Parts specifying supporting obligations for satisfying the main requirement. The VRFs are only applied at the Requirement level and each Requirement Part represents an obligation for ensuring main requirement completeness. Requirement obligations include actions similar in scope to actions specified in Requirement R1; and all standard requirements specify either an Operations Planning or a Long-term Planning Time Horizon.
- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar with MOD-010-0 and MOD-012-0 Requirements R1 and R2 that have approved VRFs of Medium. This requirement is also similar to draft standard MOD-027-1 Requirement R5 which also specifies a Medium VRF.
- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to identify if a model is useable or not is a requirement that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to

effectively monitor, control, or restore the bulk electric system. Therefore the assigned "Medium" VRF is appropriate.

- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R6 high risk objective is to verify if the model is useable or not. Requirement Parts and obligations are lower risk elements that ensure main requirement completeness which are administrative in nature consisting of documentation and submission requirements. The "Medium" VRF assigned is based on the high risk objective specified.

Justification for Assignment of Violation Severity Levels:

In developing the VSLs for the standards under this project, the SDT anticipated the evidence that would be reviewed during an audit, and developed its VSLs based on the noncompliance an auditor may find during a typical audit. The SDT based its assignment of VSLs on the following NERC criteria:

Lower	Moderate	High	Severe
Missing a minor element (or a small percentage) of the required performance The performance or product measured has significant value as it almost meets the full intent of the requirement.	Missing at least one significant element (or a moderate percentage) of the required performance. The performance or product measured still has significant value in meeting the intent of the requirement.	Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital component. The performance or product has limited value in meeting the intent of the requirement.	Missing most or all of the significant elements (or a significant percentage) of the required performance. The performance measured does not meet the intent of the requirement or the product delivered cannot be used in meeting the intent of the requirement.

FERC's VSL guidelines are presented below, followed by an analysis of whether the VSLs proposed for each requirement in MOD-026-1 meet the FERC Guidelines for assessing VSLs:

Guideline 1: Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

Compare the VSLs to any prior levels of non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when levels of non-compliance were used.

Guideline 2: Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

A violation of a "binary" type requirement must be a "Severe" VSL.

Do not use ambiguous terms such as "minor" and "significant" to describe noncompliant performance.

Guideline 3: Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

VSLs should not expand on what is required in the requirement.

Guideline 4: Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations

. . . unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the "default" for penalty calculations.

VSLs for MOD-026-1 Requirement R1:

R#	Compliance with NERC VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R1.	The NERC VSL guidelines are satisfied by incorporating increments for tardiness VSL elements. The SDT has determined a 30 day “Increments for Tardiness” period is appropriate for standard VSLs proposed.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL’s incorporate the increments for tardiness methodology. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on timeliness of the action specified.	Proposed VSL’s do not expand on what is required in the requirement. The VSL’s assigned only consider performing required action and if information submission is timely. Proposed VSL’s are consistent with the requirement.	Proposed VSL’s are based on a single violation and not a cumulative violation methodology.

VSLs for MOD-026-1 Requirement R2:

R#	Compliance with NERC Revised VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R2.	The NERC VSL guidelines are satisfied by incorporating increments for tardiness with completeness of information required for the main Requirement action. The SDT has determined a 30 day "Increments for Tardiness" period is appropriate for standard VSLs proposed.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL's consider completeness of listed parts deemed to possess equal reliability weight and also increments for tardiness. Binary requirements are categorized as severe. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on binary performance, and both completeness and timeliness of the actions and obligations specified.	Proposed VSL's do not expand on what is required in the requirement. The VSL's assigned only consider performing required action and if information submission is complete. Proposed VSL's are consistent with the requirement.	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

VSLs for MOD-026-1 Requirement R3:

R#	Compliance with NERC Revised VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R3.	The NERC VSL guidelines are satisfied by incorporating increments for tardiness VSL elements for the main Requirement action. Actions and obligations specified in the Requirement Parts incorporate a binary element, consideration for omitting required information. The SDT has determined a 30 day "Increments for Tardiness" period is appropriate for standard VSLs proposed.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL's are a combination of a binary element and increments for tardiness. Binary requirements are categorized as severe. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on binary performance, and both completeness and timeliness of the actions and obligations specified.	Proposed VSL's do not expand on what is required in the requirement. The VSL's assigned only consider performing required action and if information submission is both complete and provided in a timely manner. Proposed VSL's are consistent with the requirement.	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

VSLs for MOD-026-1 Requirement R4:

R#	Compliance with NERC Revised VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R4.	The NERC VSL guidelines are satisfied by incorporating increments for tardiness VSL elements for the main Requirement action. The SDT has determined a 30 day "Increments for Tardiness" period is appropriate for standard VSLs proposed.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL's utilize increments for tardiness rationale. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on timeliness of the actions and obligations specified.	Proposed VSL's do not expand on what is required in the requirement. The VSL's assigned only consider performing required action and if information submission is complete and provided in a timely manner. Proposed VSL's are consistent with the requirement.	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

VSLs for MOD-026-1 Requirement R5:

R#	Compliance with NERC Revised VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R5.	The NERC VSL guidelines are satisfied by incorporating equal multiple parts criteria VSL elements for the main Requirement action. Actions and obligations specified in the Requirement Parts also incorporate increments for tardiness consideration. The SDT has determined a 30 day “Increments for Tardiness” period is appropriate for standard VSLs proposed.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL’s are a combination of completeness of listed parts deemed to possess equal reliability weight and also increments for tardiness. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on both completeness and timeliness of the actions and obligations specified.	Proposed VSL’s do not expand on what is required in the requirement. The VSL’s assigned only consider performing required action and if information submission is both complete and provided in a timely manner. Proposed VSL’s are consistent with the requirement.	Proposed VSL’s are based on a single violation and not a cumulative violation methodology.

VSLs for MOD-026-1 Requirement R6:

R#	Compliance with NERC VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R6.	The NERC VSL guidelines are satisfied by incorporating increments for tardiness VSL elements for the Main Requirement action. Actions specified in the Requirement Parts incorporate completeness of the actions and obligations specified. The SDT has determined a 30 day "Increments for Tardiness" period is appropriate for standard VSLs proposed.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL's are a combination of completeness of listed parts and also increments for tardiness. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on both completeness and timeliness of the actions and obligations specified.	Proposed VSL's do not expand on what is required in the requirement. The VSL's assigned only consider performing required action and if information submission is both complete provided in a timely manner. Proposed VSL's are consistent with the requirement.	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

Violation Risk Factor and Violation Severity Level Assignments

Project 2007-09 Generator Verification

This document provides the drafting team's justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in MOD-027-1 — Verification of Models and Data for Turbine/Governor and Load Control or Active Power/Frequency Control Functions.

Each primary requirement is assigned a VRF and a set of one or more VSLs. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the ERO Sanction Guidelines.

Justification for Assignment of Violation Risk Factors

The Generator Verification Standard Drafting Team applied the following NERC criteria when proposing VRFs for the requirements under this project:

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

The SDT also considered consistency with the FERC Violation Risk Factor Guidelines for setting VRFs:[1]

Guideline (1) — Consistency with the Conclusions of the Final Blackout Report

The Commission seeks to ensure that Violation Risk Factors assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System.

In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:[2]

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief

Guideline (2) — Consistency within a Reliability Standard

The Commission expects a rational connection between the sub-Requirement Violation Risk Factor assignments and the main Requirement Violation Risk Factor assignment.

Guideline (3) — Consistency among Reliability Standards

[1] North American Electric Reliability Corp., 119 FERC ¶ 61,145, order on reh'g and compliance filing, 120 FERC ¶ 61,145 (2007) ("VRF Rehearing Order").
[2] Id. at footnote 15.

The Commission expects the assignment of Violation Risk Factors corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) — Consistency with NERC's Definition of the Violation Risk Factor Level

Guideline (4) was developed to evaluate whether the assignment of a particular Violation Risk Factor level conforms to NERC's definition of that risk level.

Guideline (5) — Treatment of Requirements that Co-mingle More Than One Obligation

Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

The following discussion addresses how the SDT considered FERC's VRF Guidelines 2 through 5. The team did not address Guideline 1 directly because of an apparent conflict between Guidelines 1 and 4. Whereas Guideline 1 identifies a list of topics that encompass nearly all topics within NERC's Reliability Standards and implies that these requirements should be assigned a "High" VRF, Guideline 4 directs assignment of VRFs based on the impact of a specific requirement to the reliability of the system. The SDT believes that Guideline 4 is reflective of the intent of VRFs in the first instance and therefore concentrated its approach on the reliability impact of the requirements.

VRF for MOD-027-1:

There are five requirements in MOD-027-1. Three requirements were assigned a "Lower" VRF while the remaining two were assigned a "Medium" VRF.

VRF for MOD-027-1, Requirement R1:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R1 does not contain Parts. Requirement obligations include actions similar in scope to actions specified in Requirement R5; and all standard requirements specify a Long-term Planning Time Horizon.
- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar with MOD-004-1, Requirement R9 that has an approved Lower VRF. This requirement is also similar to draft standard MOD-026-1 Requirement R1 which also specifies a Lower VRF.
- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to provide requested information is a requirement that is administrative in nature for the planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. Therefore the assigned "Lower" VRF is appropriate.
- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R1 high risk objective is to provide requested information. This

requirement is administrative in nature for providing instructions and data used for performing model verification. The "Lower" VRF assigned is based on the high risk objective specified.

VRF for MOD-027-1, Requirement R2:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R2 contains Parts specifying supporting obligations for satisfying the main requirement. The VRFs are only applied at the Requirement level and each Requirement Part is treated equally. Requirement obligations include actions similar in scope to actions specified in Requirement R1 and R5; and all standard requirements specify a Long-term Planning Time Horizon.
- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar with MOD-010-0 and MOD-012-0 Requirements R1 and R2 which have an approved VRF of Medium. This requirement is also similar to draft standard MOD-026-1 Requirement R2 which also specifies a Medium VRF.
- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to verify models in the Long-term Planning Time Horizon is a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. Therefore the assigned "Medium" VRF is appropriate.
- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R2 high risk objective is to verify models per specified periodicity. Requirement Parts and obligations are lower risk elements that ensure main requirement completeness which are administrative in nature consisting of documentation, information revision obligation and submission requirements. The "Medium" VRF assigned is based on the high risk objective specified.

VRF for MOD-027-1, Requirement R3:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R3 does not contains Parts. Requirement obligations include actions similar in scope to actions specified in Requirement R1 and R5; and all standard requirements specify a Long-term Planning Time Horizon.
- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar to MOD-004-1, Requirement R7 and R8 that has an approved Lower VRF. This requirement is also similar to draft standard MOD-026-1 Requirement R3 which also specifies a Lower VRF.
- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to verify models in the Long-term Planning Time Horizon is a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or

capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. Therefore the assigned "Lower" VRF is appropriate.

- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R3 high risk objective is to provide a written response after receiving notice. The Requirement is administrative in nature consisting of documentation, information revision obligation and submission requirements. The "Lower" VRF assigned is based on the high risk objective specified.

VRF for MOD-027-1, Requirement R4:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R4 does not contain Parts. Requirement obligations include actions similar in scope to actions specified in Requirement R1 and R5; and all standard requirements specify a Long-term Planning Time Horizon.
- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar to MOD-004-1, Requirement R1 and R2 that has an approved Lower VRF. This requirement is also similar to draft standard MOD-026-1 Requirement R4 which also specifies a Lower VRF.
- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to verify models in the Long-term Planning Time Horizon is a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. Therefore the assigned "Lower" VRF is appropriate.
- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R4 high risk objective is to provide revised data after making changes to equipment. The Requirement is administrative in nature consisting of documentation, information revision obligation and submission requirements. The "Lower" VRF assigned is based on the high risk objective specified.

VRF for MOD-027-1, Requirement R5:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R5 contains Parts specifying supporting obligations for satisfying the main requirement. The VRFs are only applied at the Requirement level and each Requirement Part represents an obligation for ensuring main requirement completeness. Requirement obligations include actions similar in scope to actions specified in Requirement R1; and all standard requirements specify a Long-term Planning Time Horizon.

- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar with MOD-010-0 and MOD-012-0 Requirements R1 and R2 that have approved VRFs of Medium. This requirement is also similar to draft standard MOD-026-1 Requirement R6 which also specifies a Medium VRF.
- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to identify if a model is useable or not is a requirement that is administrative in nature for the planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. Therefore the assigned "Medium" VRF is appropriate.
- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R5 high risk objective is to verify if the model is useable or not. Requirement Parts and obligations are lower risk elements that ensure main requirement completeness which are administrative in nature consisting of documentation and submission requirements. The "Medium" VRF assigned is based on the high risk objective specified.

Justification for Assignment of Violation Severity Levels:

In developing the VSLs for the standards under this project, the SDT anticipated the evidence that would be reviewed during an audit, and developed its VSLs based on the noncompliance an auditor may find during a typical audit. The SDT based its assignment of VSLs on the following NERC criteria:

Lower	Moderate	High	Severe
Missing a minor element (or a small percentage) of the required performance The performance or product measured has significant value as it almost meets the full intent of the requirement.	Missing at least one significant element (or a moderate percentage) of the required performance. The performance or product measured still has significant value in meeting the intent of the requirement.	Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital component. The performance or product has limited value in meeting the intent of the requirement.	Missing most or all of the significant elements (or a significant percentage) of the required performance. The performance measured does not meet the intent of the requirement or the product delivered cannot be used in meeting the intent of the requirement.

FERC's VSL guidelines are presented below, followed by an analysis of whether the VSLs proposed for each requirement in MOD-027-1 meet the FERC Guidelines for assessing VSLs:

Guideline 1: Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

Compare the VSLs to any prior levels of non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when levels of non-compliance were used.

Guideline 2: Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

A violation of a “binary” type requirement must be a “Severe” VSL.

Do not use ambiguous terms such as “minor” and “significant” to describe noncompliant performance.

Guideline 3: Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

VSLs should not expand on what is required in the requirement.

Guideline 4: Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations

. . . unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the “default” for penalty calculations.

VSLs for MOD-027-1 Requirement R1:

R#	Compliance with NERC VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R1.	The NERC VSL guidelines are satisfied by incorporating increments for tardiness VSL elements. The SDT has determined a 30 day "Increments for Tardiness" period is appropriate for standard VSLs proposed.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL's incorporate the increments for tardiness methodology. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on timeliness of the action specified.	Proposed VSL's do not expand on what is required in the requirement. The VSL's assigned only consider performing required action and if information submission is timely. Proposed VSL's are consistent with the requirement.	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

VSLs for MOD-027-1 Requirement R2:

R#	Compliance with NERC Revised VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R2.	The NERC VSL guidelines are satisfied by incorporating increments for tardiness VSL elements for the main Requirement action. The SDT has determined a 30 day "Increments for Tardiness" period is appropriate for standard VSLs proposed.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL's consider completeness of listed parts deemed to possess equal reliability weight and also increments for tardiness. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on binary performance, and both completeness and timeliness of the actions and obligations specified.	Proposed VSL's do not expand on what is required in the requirement. The VSL's assigned only consider performing required action and if information submission is complete. Proposed VSL's are consistent with the requirement.	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

VSLs for MOD-027-1 Requirement R3:

R#	Compliance with NERC Revised VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R3.	The NERC VSL guidelines are satisfied by incorporating increments for tardiness VSL elements for the main Requirement action. Actions and obligations specified in the Requirement Parts incorporate a binary element, consideration for omitting required information. The SDT has determined a 30 day "Increments for Tardiness" period is appropriate for standard VSLs proposed.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL's are a combination of a binary element and increments for tardiness. Binary requirements are categorized as severe. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on binary performance, and both completeness and timeliness of the actions and obligations specified.	Proposed VSL's do not expand on what is required in the requirement. The VSL's assigned only consider performing required action and if information submission is both complete and provided in a timely manner. Proposed VSL's are consistent with the requirement.	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

VSLs for MOD-027-1 Requirement R4:

R#	Compliance with NERC Revised VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R4.	The NERC VSL guidelines are satisfied by incorporating increments for tardiness VSL elements for the main Requirement action. The SDT has determined a 30 day "Increments for Tardiness" period is appropriate for standard VSLs proposed.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL's utilize increments for tardiness rationale. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on timeliness of the actions and obligations specified.	Proposed VSL's do not expand on what is required in the requirement. The VSL's assigned only consider performing required action and if information submission is complete and provided in a timely manner. Proposed VSL's are consistent with the requirement.	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

VSLs for MOD-027-1 Requirement R5:

R#	Compliance with NERC VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R5.	The NERC VSL guidelines are satisfied by incorporating increments for tardiness VSL elements for the Main Requirement action. Actions specified in the Requirement Parts incorporate completeness of the actions and obligations specified. The SDT has determined a 30 day "Increments for Tardiness" period is appropriate for standard VSLs proposed.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL's are a combination of completeness of listed parts and also increments for tardiness. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on both completeness and timeliness of the actions and obligations specified.	Proposed VSL's do not expand on what is required in the requirement. The VSL's assigned only consider performing required action and if information submission is both complete provided in a timely manner. Proposed VSL's are consistent with the requirement.	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

Violation Risk Factor and Violation Severity Level Assignments

Project 2007-09 Generator Verification

This document provides the drafting team's justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in PRC-019-1 — Coordination of Generating Unit or Plant Capabilities, Voltage Regulating Controls and Protection

Each primary requirement is assigned a VRF and a set of one or more VSLs. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the ERO Sanction Guidelines.

Justification for Assignment of Violation Risk Factors

The Generator Verification Standard Drafting Team applied the following NERC criteria when proposing VRFs for the requirements under this project:

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

The SDT also considered consistency with the FERC Violation Risk Factor Guidelines for setting VRFs:[1]

Guideline (1) — Consistency with the Conclusions of the Final Blackout Report

The Commission seeks to ensure that Violation Risk Factors assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System.

In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:[2]

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief

Guideline (2) — Consistency within a Reliability Standard

The Commission expects a rational connection between the sub-Requirement Violation Risk Factor assignments and the main Requirement Violation Risk Factor assignment.

Guideline (3) — Consistency among Reliability Standards

[1] North American Electric Reliability Corp., 119 FERC ¶ 61,145, order on reh'g and compliance filing, 120 FERC ¶ 61,145 (2007) ("VRF Rehearing Order").

[2] Id. at footnote 15.

The Commission expects the assignment of Violation Risk Factors corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) — Consistency with NERC's Definition of the Violation Risk Factor Level

Guideline (4) was developed to evaluate whether the assignment of a particular Violation Risk Factor level conforms to NERC's definition of that risk level.

Guideline (5) — Treatment of Requirements that Co-mingle More Than One Obligation

Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

The following discussion addresses how the SDT considered FERC's VRF Guidelines 2 through 5. The team did not address Guideline 1 directly because of an apparent conflict between Guidelines 1 and 4. Whereas Guideline 1 identifies a list of topics that encompass nearly all topics within NERC's Reliability Standards and implies that these requirements should be assigned a "High" VRF, Guideline 4 directs assignment of VRFs based on the impact of a specific requirement to the reliability of the system. The SDT believes that Guideline 4 is reflective of the intent of VRFs in the first instance and therefore concentrated its approach on the reliability impact of the requirements.

VRF for PRC-019-1:

There are two requirements in PRC-019-1 and both have been assigned a "Medium" VRF.

VRF for PRC-019-1, Requirement R1:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirements R1 and R2 specify that the responsible entity must verify coordination for applicable Facilities. The standard requirements specify a Long-term Planning Time Horizon and both are assigned a "Medium" VRF.
- FERC Guideline 3 — Consistency among Reliability Standards exists. Requirement R1 is similar in concept with both PRC-012-0 Requirement R1 and PRC-023-1 Requirement R1, both of which require protection coordination or settings. These requirements apply to multiple elements while the requirements of PRC-019-1 apply to a single unit, synchronous condenser or plant. Violation of this requirement by a single generator could not be construed as directly causing or contributing to BES instability, separation or cascading within any time frame. For a single violation to lead to BES instability, separation or cascading would require other standards requirements to be violated. This requirement is assigned a "Medium" VRF.
- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to periodically verify voltage regulation controls, limiters and protection coordinated with unit

and synchronous condenser coordination in the Long-term Planning Time Horizon is a requirement in the planning time frame that, if violated, is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition. Therefore the assigned "Medium" VRF is appropriate.

- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R1 and Part 1.1 have a reliability objective to verify voltage regulation controls, limiters and protection coordinated with unit and synchronous condenser coordination. Failure to verify the coordination for a single applicable Facility is unlikely to, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition. The "Medium" VRF assigned is based on the reliability objective specified.

VRF for PRC-019-1, Requirement R2:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirements R1 and R2 specify that the responsible entity must verify coordination for applicable Facilities. The standard requirements specify a Long-term Planning Time Horizon and both are assigned a "Medium" VRF.
- FERC Guideline 3 — Consistency among Reliability Standards exists. Requirement R2 is similar in concept with both PRC-010-0 Requirement R1 and PRC-014-0 Requirement R1, both of which require 5-year verification of protection coordination or settings. These requirements apply to multiple elements while the requirements of PRC-019-1 apply to a single unit, synchronous condenser or plant. Violation of this requirement by a single generator could not be construed as directly causing or contributing to BES instability, separation or cascading within any time frame. For a single violation to lead to BES instability, separation or cascading would require other standards requirements to be violated. This requirement is assigned a "Medium" VRF.
- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to verify coordination following setting changes affecting unit or synchronous condenser coordination in the Long-term Planning Time Horizon is a requirement that, if violated, is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition Therefore the assigned "Medium" VRF is appropriate.
- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R2 has a high reliability objective to specify the periodicity for verifying voltage regulation controls, limiters and protection coordinated with unit and synchronous condenser coordination following a change to equipment settings. Failure to verify the coordination for a single applicable Facility is unlikely to, under emergency, abnormal,

or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition. . The “Medium” VRF assigned is based on the high risk objective specified.

Justification for Assignment of Violation Severity Levels:

In developing the VSLs for the standards under this project, the SDT anticipated the evidence that would be reviewed during an audit, and developed its VSLs based on the noncompliance an auditor may find during a typical audit. The SDT based its assignment of VSLs on the following NERC criteria:

Lower	Moderate	High	Severe
Missing a minor element (or a small percentage) of the required performance The performance or product measured has significant value as it almost meets the full intent of the requirement.	Missing at least one significant element (or a moderate percentage) of the required performance. The performance or product measured still has significant value in meeting the intent of the requirement.	Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital component. The performance or product has limited value in meeting the intent of the requirement.	Missing most or all of the significant elements (or a significant percentage) of the required performance. The performance measured does not meet the intent of the requirement or the product delivered cannot be used in meeting the intent of the requirement.

FERC's VSL guidelines are presented below, followed by an analysis of whether the VSLs proposed for each requirement in PRC-019-1 meet the FERC Guidelines for assessing VSLs:

Guideline 1: Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

Compare the VSLs to any prior levels of non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when levels of non-compliance were used.

Guideline 2: Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

A violation of a "binary" type requirement must be a "Severe" VSL.

Do not use ambiguous terms such as "minor" and "significant" to describe noncompliant performance.

Guideline 3: Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

VSLs should not expand on what is required in the requirement.

Guideline 4: Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations

. . . unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the "default" for penalty calculations.

VSLs for PRC-019-1 Requirement R1:

R#	Compliance with NERC Revised VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R1.	The NERC VSL guidelines are satisfied by identifying noncompliance based on the obligation to verify coordination within a certain timeframe. VSLs account for increments of tardiness.	This is a new Requirement and does not have a prior level of compliance.	The proposed VSLs are based on increments of tardiness for completing the required verifications. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on binary performance, and completeness of the actions and obligations specified.	Proposed VSLs do not expand on what is required in the requirement. The VSLs assigned only consider performing required action per the procedure specified by listed parts. Proposed VSLs are consistent with the requirement.	Proposed VSLs are based on a single violation and not a cumulative violation methodology.

VSLs for PRC-019-1 Requirement R2:

R#	Compliance with NERC Revised VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R2.	The NERC VSL guidelines are satisfied by identifying noncompliance based on the obligation to verify coordination within a certain timeframe. VSLs account for increments of tardiness.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSLs are based on increments of tardiness for competing required verifications. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on binary performance, and completeness of the actions and obligations specified.	Proposed VSLs do not expand on what is required in the requirement. The VSLs assigned only consider performing required action per the procedure specified by listed parts. Proposed VSLs are consistent with the requirement.	Proposed VSLs are based on a single violation and not a cumulative violation methodology.

RELIABILITY CORPORATION

Violation Risk Factor and Violation Severity Level Assignments

Project 2007-09 Generator Verification

This document provides the drafting team's justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in PRC-024-1 — Generator Frequency and Voltage Protective Relay Settings.

Each primary requirement is assigned a VRF and a set of one or more VSLs. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the ERO Sanction Guidelines.

Justification for Assignment of Violation Risk Factors

The Generator Verification Standard Drafting Team applied the following NERC criteria when proposing VRFs for the requirements under this project:

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

The SDT also considered consistency with the FERC Violation Risk Factor Guidelines for setting VRFs:[1]

Guideline (1) — Consistency with the Conclusions of the Final Blackout Report

The Commission seeks to ensure that Violation Risk Factors assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System.

In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:[2]

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief

Guideline (2) — Consistency within a Reliability Standard

The Commission expects a rational connection between the sub-Requirement Violation Risk Factor assignments and the main Requirement Violation Risk Factor assignment.

Guideline (3) — Consistency among Reliability Standards

[2] Id. at footnote 15.

The Commission expects the assignment of Violation Risk Factors corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) — Consistency with NERC's Definition of the Violation Risk Factor Level
Guideline (4) was developed to evaluate whether the assignment of a particular Violation Risk Factor level conforms to NERC's definition of that risk level.

Guideline (5) — Treatment of Requirements that Co-mingle More Than One Obligation
Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

The following discussion addresses how the SDT considered FERC's VRF Guidelines 2 through 5. The team did not address Guideline 1 directly because of an apparent conflict between Guidelines 1 and 4. Whereas Guideline 1 identifies a list of topics that encompass nearly all topics within NERC's Reliability Standards and implies that these requirements should be assigned a "High" VRF, Guideline 4 directs assignment of VRFs based on the impact of a specific requirement to the reliability of the system. The SDT believes that Guideline 4 is reflective of the intent of VRFs in the first instance and therefore concentrated its approach on the reliability impact of the requirements.

VRF for PRC-024-1:
There are four requirements in PRC-024-1. Two of the Requirements (R1 and R2) were assigned a "Medium" VRF and the remaining two requirements were assigned a "Lower" VRF.

VRF for PRC-024-1, Requirement R1:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R1 contains Parts specifying conditions for satisfying the main requirement. The VRFs are only applied at the Requirement level and each Requirement Part is treated equally. Requirement obligations include actions similar in scope to actions specified in Requirement R2 which were assigned a "Medium" VRF.
- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar in concept with both PRC-012-0 Requirement R1 and PRC-023-1 Requirement R1, both of which require protection coordination or settings. These requirements apply to multiple elements while the requirements of PRC-024-1 apply to a single unit. Violation of this requirement by a single generator could not be construed as directly causing or contributing to BES instability, separation or cascading within any time frame. For a single violation to lead to BES instability, separation or cascading would require other standards requirements to be violated. This requirement is assigned a "Medium" VRF.

- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to ensure a proper frequency "no-trip" operating window is a requirement in the planning time frame that, if violated, is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition. Therefore the assigned "Medium" VRF is appropriate.
- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R1 reliability objective is to ensure a proper frequency "no-trip" operating window. Requirement Parts are lower risk condition elements that establish main requirement criteria for completeness. The "Medium" VRF assigned is based on the reliability objective specified.

VRF for PRC-024-1, Requirement R2:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R2 contains Parts specifying conditions for satisfying the main requirement. The VRFs are only applied at the Requirement level and each Requirement Part is treated equally. Requirement obligations include actions similar in scope to actions specified in Requirement R1 which were assigned a "Medium" VRF.
- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar in concept with both PRC-012-0 Requirement R1 and PRC-023-1 Requirement R1, both of which require protection coordination or settings. These requirements apply to multiple elements while the requirements of PRC-024-1 apply to a single unit. Violation of this requirement by a single generator could not be construed as directly causing or contributing to BES instability, separation or cascading within any time frame. For a single violation to lead to BES instability, separation or cascading would require other standards requirements to be violated. This requirement is assigned a "Medium" VRF.
- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to ensure proper voltage "no-trip" criteria is a requirement in the planning time frame that, if violated, is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition. Therefore the assigned "Medium" VRF is appropriate.
- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R2 reliability objective is to ensure proper voltage "no-trip" criteria. Requirement Parts are lower risk condition elements that establish main requirement criteria for completeness. The "Medium" VRF assigned is based on the reliability objective specified.

NERC

VRF for PRC-024-1, Requirements R3:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R3 contains Parts specifying response expectation and limitation reset conditions for satisfying the main requirement. The VRFs are only applied at the Requirement level and each Requirement Part is treated equally.
- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar in concept with PRC-006-0 Requirement R1 which specifies documentation requirements. In addition, as is generally the case with reliability standard VRF definitions for documentation and administrative requirements, this requirement is assigned a “Lower” VRF.
- FERC Guideline 4 — Consistency with NERC’s Definition of the VRF Level selected exists. Failure to document limitations preventing compliance is a requirement that is administrative in nature for the planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. Therefore the assigned “Lower” VRF is appropriate.
- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R3 reliability objective is to document limitations preventing compliance. Requirement Parts and obligations are lower risk elements that ensure main requirement completeness which are administrative in nature consisting of response submission and limitation reset condition requirements. The “Lower” VRF assigned is based on the reliability objective specified.

VRF for PRC-024-1, Requirement R4:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R4 does not contain Parts. Requirement obligations specify the type of response and response time frame to be observed.
- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar in concept with both PRC-007-0 Requirement R3 and PRC-010-0 Requirement R2, both of which require providing information within a specified time frame on request. In addition, as is generally the case with reliability standard VRF definitions for documentation and administrative requirements, this requirement is assigned a “Lower” VRF.
- FERC Guideline 4 — Consistency with NERC’s Definition of the VRF Level selected exists. Failure to provide setting and limitation information as requested is a requirement that is administrative in nature for the planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. Therefore the assigned “Lower” VRF is appropriate.
- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R4 reliability objective is to provide setting and limitation information as requested. Requirement obligations are lower risk condition elements administrative in nature for ensuring the main requirement is satisfied in a timely manner. The “Lower” VRF assigned is based on the reliability objective specified.

Justification for Assignment of Violation Severity Levels:

In developing the VSLs for the standards under this project, the SDT anticipated the evidence that would be reviewed during an audit, and developed its VSLs based on the noncompliance an auditor may find during a typical audit. The SDT based its assignment of VSLs on the following NERC criteria:

Lower	Moderate	High	Severe
Missing a minor element (or a small percentage) of the required performance The performance or product measured has significant value as it almost meets the full intent of the requirement.	Missing at least one significant element (or a moderate percentage) of the required performance. The performance or product measured still has significant value in meeting the intent of the requirement.	Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital component. The performance or product has limited value in meeting the intent of the requirement.	Missing most or all of the significant elements (or a significant percentage) of the required performance. The performance measured does not meet the intent of the requirement or the product delivered cannot be used in meeting the intent of the requirement.

FERC's VSL guidelines are presented below, followed by an analysis of whether the VSLs proposed for each requirement in PRC-024-1 meet the FERC Guidelines for assessing VSLs:

Guideline 1: Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

Compare the VSLs to any prior levels of non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when levels of non-compliance were used.

Guideline 2: Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

A violation of a "binary" type requirement must be a "Severe" VSL.

Do not use ambiguous terms such as "minor" and "significant" to describe noncompliant performance.

Guideline 3: Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

VSLs should not expand on what is required in the requirement.

Guideline 4: Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations

. . . unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the "default" for penalty calculations.

VSLs for PRC-024-1 Requirement R1:

R#	Compliance with NERC VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R1.	The NERC VSL guidelines are satisfied by incorporating binary VSL elements.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL's are a combination of binary elements and are categorized as severe. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on binary performance, and timeliness of the actions and obligations	Proposed VSL's do not expand on what is required in the requirement. The VSL's assigned only consider performing required action per the conditions specified by listed parts. Proposed VSL's are consistent with the requirement.	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

VSLs for PRC-024-1 Requirement R2:

R#	Compliance with NERC VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R2.	The NERC VSL guidelines are satisfied by incorporating binary VSL elements.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL's are a combination of binary elements and are categorized as severe. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on binary performance, and timeliness of the actions and obligations specified.	Proposed VSL's do not expand on what is required in the requirement. The VSL's assigned only consider performing required action per the conditions specified by listed parts. Proposed VSL's are consistent with the requirement.	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

VSLs for PRC-024-1 Requirement R3:

R#	Compliance with NERC VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R3.	The NERC VSL guidelines are satisfied by incorporating increments for tardiness elements.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL's incorporate the increments for tardiness methodology. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on timeliness of the action specified.	Proposed VSL's do not expand on what is required in the requirement. The VSL's assigned only consider performing required action in a timely manner including response obligation and reset conditions specified by listed parts. Proposed VSL's are consistent with the requirement.	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

VSLs for PRC-024-1 Requirement R4:

R#	Compliance with NERC VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R4.	The NERC VSL guidelines are satisfied by incorporating increments for tardiness elements.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL's incorporate the increments for tardiness methodology. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on timeliness of the action specified.	Proposed VSL's do not expand on what is required in the requirement. The VSL's assigned only consider performing required action in a timely manner. Proposed VSL's are consistent with the requirement.	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

Exhibit E

Summary of the Reliability Standard Development Proceeding and Complete Record of Development of Proposed Reliability Standard

Exhibit E — Summary of the Reliability Standard Development Proceeding and Complete Record of Development of Proposed Reliability Standard

The development record for the proposed Reliability Standards is summarized below.

I. Overview of the Standard Drafting Team

When evaluating proposed Reliability Standard, the Commission is expected to give "due weight" to the technical expertise of the ERO.[1] The technical expertise of the ERO is derived from the standard drafting team. For this project, the standard drafting team consisted of four industry experts with a diversity of experience. A detailed set of biographical information for each of the team members is included along with the drafting team roster in **Exhibit F**.

II. Standard Development History

A. SAR Development

A Standard Authorization Request ("SAR") was submitted on April 3, 2007 and was posed for a 30-day public comment period from April 20, 2007 to May 21, 2007. There were 16 sets of comments, including comments from 63 different individuals from more than 35 organizations representing 7 of the 10 Industry Segments. In response to the comments received, the SAR drafting team revised the SAR for Project 2007-09 Generator Verification as follows:

- Added the Generator Operator and Reliability Coordinator as reliability functions that may have responsibilities in the proposed standards.
- Added language to clarify that the standard drafting team will consider the Phase III & IV field test results when developing the standards associated with this project.

The SAR was modified on June 14, 2007.

B. First Posting

MOD-026-1 and PRC-024-1 were posted for a 45-day formal comment period from February 17, 2009 to April 2, 2009. MOD-026-1 received 45 sets of comments, including comments from more than 100 different people from over 50 companies representing 8 of the 10

[1] Section 215 (d)(2) of the Federal Power Act; 16 U.S.C. §824o(d)(2)(2013).

industry segments. The standard drafting team considered stakeholder comments and made the following changes based on those comments:

- The standard drafting team consulted the Functional Model Working Group (FMWG), who rendered the opinion that the Generator Owner should be responsible for model verification, not the Generator Operator. Based on consultation with the FMWG, and supported by the majority of industry comments, the standard drafting team changed the applicability from the Generator Operator to the Generator Owner.
- The layout and the formatting of the standard were significantly updated. Periodicity has been moved to a separate attachment, as the standard drafting team determined that it is not a stand-alone reliability requirement.

For PRC-024-1, there were 43 sets of comments, including comments from more than 100 different people from over 60 companies representing 9 of the 10 industry segments. The standard drafting team considered stakeholder comments and made the following changes to PRC-024-1 based on those comments:

- The drafting team revised the purpose to clarify that new generators must be capable of riding through voltage and frequency excursions and expected unit performance during frequency and voltage excursions must be communicated to entities that monitor or model the associated generator.
- With respect to applicability, the standard drafting team determined that only the Generator Owner has responsibilities required by this NERC Standard. The "facility applicability" language that duplicated the language from the Compliance Registry Criteria is not necessary to include in the applicability section of the standard, and was removed. The team added a footnote to both Requirements R1 and R2 to clarify that the requirements in the standard do not require any entity to have frequency or voltage protective relaying installed or activated on its units.
- With respect to Requirement R1, the standard drafting team modified the sequence of the wording in the requirement; replaced the range of VRFs based on MVA to a single VRF for consistency with other standards; added the following as an additional criterion under which the generating unit may not trip: when the transmission system frequency rate of change is less than 2.5 Hz/second with a total change of up to 1.0 Hz.
- With respect to Requirement R2, the standard drafting team modified the language to clarify that the intent is to address trippings associated with events external to the generator; added more specificity to each of the criterion under which the generator unit may not trip; and replaced the range of VRFs based on MVA to a single VRF for consistency with other standards.

- Requirements R3 and R4 were merged and moved so that it is the last requirement, R7, so that the sequence of requirements is in chronological order.
- The language of Requirement R5 was modified and simplified for clarify regarding the required documentation of equipment limitations.
- A new Requirement was drafted to require Generator Owners to provide requesting entities with specific documentation to support an estimate of a unit's performance during Frequency/Voltage Excursions for modeling and study accuracy.
- The standard drafting team developed the off nominal frequency curve (Attachment 1) in coordination with the NERC UFLS Standard Drafting Team. The 57.8 Hz setting for generator underfrequency and 58 Hz for UFLS is to ensure that the UFLS will have a chance to arrest the system frequency decline before reaching the minimum permissible frequency for generators. The intent of the curves is to ensure that the generators do not trip when the frequency is within the area bounded by the high and low frequency curves. When the frequency excursion reaches outside the high or low curve, the generator is allowed to trip.
- The standard drafting team updated Attachment 2 to add more clarity on the calculations for the voltage ride through curve.

MOD-024-2 was posted for a 30-day public comment period from January 18, 2010 to February 18, 2010. There were 47 sets of comments, including comments from more than 130 different people from over 60 companies representing 8 of the 10 industry segments. The standard drafting team considered stakeholder comments and made the following changes to MOD-024-2 based on those comments:

- The requirement for the Resource Planner and Planning Coordinator to provide the Generator Owner with schedules and temperature adjustments was deleted, and the applicability section of the standard was revised to omit the Planning Coordinator and Resource Planner.
- The standard drafting team combined the requirements of MOD-024 and MOD-025 into MOD-025. Under the combined standard, all applicable units will be verified for both real and reactive power capability just once every five years. To avoid having many units requiring verification in any one year, the initial implementation period proposed requires verification of 20% of an entity's units each year.

MOD-025-2, MOD-027-1 and PRC-019-1 were posted for a formal 30-day comment period from June 15, 2011 to July 15, 2011. There were 65 sets of comments, including comments from approximately 182 different people from approximately 95 companies representing 9 of the 10 industry segments.

The standard drafting team considered stakeholder comments and made the following changes to MOD-025-2 based on those comments:

- Language was added to recommend that the AVR be in automatic control while conducting reactive capability testing, but that reactive capability testing must be done even if the AVR is not available.

The standard drafting team considered stakeholder comments and made the following changes to MOD-027-1 based on those comments:

- The standard drafting team expanded the applicability of MOD-027-1 to include plants/facilities comprised of multiple small units such as variable energy resource plants/facilities;
- Corrections of various typos in the body of the standard, the VSLs, and in Attachment 1;
- Extended the time to comply with Requirement 1 from 30 to 90 days;
- Modified Attachment 1 (Periodicity Table) to address units which are always base loaded (by definition a base loaded unit is considered verified);
- Modified Attachment 1 (Periodicity Table) to clarify establishing the Initial Ten Year Unit Verification Period Start Date;
- Reduced the maximum time allowed between capture of an event and completing model verification from two years to one year;
- Referenced the NERC GADS document for references to capacity factor in the draft standard; and
- Included partial load rejection as a potential test to obtain a recording of the equipment response to be used in model verification.

The standard drafting team considered stakeholder comments and made the following changes to PRC-019-1 based on those comments:

- The example diagrams added that they are drawn at nominal voltage and frequency;
- The formula for calculating the radius of the SSSL was corrected;
- The items “under-excited limiters or minimum excitation limiters” and “over-excited limiters or maximum excitation limiters” have been placed in the bulleted list of the standard;
- The SDT changed “protective” to “protection” within the standard to be consistent with Section G; and
- The SDT added a reference document for use in calculation of SSSL.

C. Second Posting

MOD-026-1 and PRC-024-1 were posted for a 45-day formal public comment period from June 15, 2011 to August 1, 2011, with an initial ballot and non-binding poll from July 22, 2011 to August 1, 2011. For both standards, there were 66 sets of comments, including comments from approximately 185 different people from approximately 120 companies representing all 10 of the 10 industry segments. MOD-026-1 received a quorum of 90.25% and an approval rating of 46.53%. PRC-024-1 received a quorum of 90.82% and an approval of 18.23%.

The standard drafting team considered stakeholder comments and made the following changes to MOD-026-1 based on those comments:

- Correcting several VSL grammatical errors and ensuring consistency between the VSL "increment for tardiness" time period specified and the Requirement language.
- An additional condition, row 12, was added to Attachment 1 (the Periodicity Table) specifying that validation is not required for an excitation control system or plant volt/var control that does not include an active closed loop voltage regulation function. This condition exempts wind and solar plants that do not have the capability to regulate plant voltage or respond to grid voltage fluctuations other than switching capacitor and reactor banks in and out of service.
- The format and column information of Attachment 1 was revised for clarity.
- The typographical errors in R2.1.1 language was corrected to clearly state expectation that "the unit or plant's model response matches the recorded response for a voltage excursion at the generator or plant point of interconnection from either a staged test or a measured system disturbance."
- The language of R2.1.4 was revised to align with the style of R2.1.6.
- To clarify concerns regarding calculating unit capacity factor, the SDT has incorporated into the standard the capacity factor calculation specified in Appendix F of the GADS Data Reporting Instructions (which can be obtained from the NERC website).
- There was some confusion regarding the treatment of small units at plants. The SDT modified the language in the Applicability / Facilities section for clarity and for consistency to the extent possible with the other draft standards in the Generation Verification effort.

The standard drafting team considered stakeholder comments and made the following changes to PRC-024-1 based on those comments:

- The two new terms proposed in the standard were removed. The voltage and frequency excursion values are now located in the requirements where they apply.
- Attachment 1 (Off Nominal Frequency Capability Curve) was revised to clarify the "no trip" zone.
- Attachment 2 (Voltage Ride-Through Time Duration Curves) has been clarified. The per unit voltage base for these curves is the base voltage specified in the system models used by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission Systems at the point of interconnection to the Bulk Electric System (BES). In addition, the definition was modified to include the phrase, "voltages in the curve assume minimum phase-to-ground or phase-to-phase voltage for the low voltage duration curve and maximum phase-to-ground or phase-to-phase voltage for the high voltage duration curve."
- The Requirement Parts were revised in Requirement R1. Part 1.5 was moved into the body of R1.
- Requirement Part 2.1.1 was removed from Requirement R2. The body of the requirement and the remaining Parts were modified to clarify intent.
- Requirement R3 was changed to clarify the intent of non-protection system limitations and when such limitations must be addressed.

MOD-025-2, MOD-027-1 and PRC-019-1 were posted for a 45-day formal comment period from February 29, 2012 to April 16, 2012 with an initial ballot and non-binding poll from April 6, 2012 to April 16, 2012. There were 57 sets of comments, including comments from approximately 159 different people from approximately 51 companies representing 9 of the 10 industry segments. MOD-025-2 received a quorum of 88.28% with an approval rating of 41.09%. MOD-027-1 received a quorum of 88.04% with an approval rating of 36.84%.

For PRC-019-1, there were 65 sets of comments, including comments from approximately 182 different people from approximately 95 companies representing 9 of the 10 industry segments. PRC-019-1 received a quorum of 88.04% with an approval rating of 48.70%.

D. Third Posting

MOD-026-1 and PRC-024-1 were posted for a formal 30-day public comment period from February 29, 2012 to March 29, 2012 with a successive ballot from March 19, 2012 to March 29, 2012. There were 53 sets of comments, including comments from approximately 127 different people from approximately 88 companies representing 9 of the 10 industry segments. MOD-026-1 received a quorum of 81.45% and an approval rating of 61.21%. PRC-024-1 received a quorum of 80.38% and an approval of 41.09%.

The standard drafting team considered stakeholder comments and made the following changes to MOD-026-1 based on those comments:

- Included the term "impedance compensation" to Footnote 1 in the description of what constitutes an excitation control system for synchronous machines.
- Clarified that the response by the Transmission Planner to the Generator Owner concerning the results of testing the model useability is required to be a written response (R6). Also, for ease of reading, moved the last sentence in the requirement to after the Requirement Parts 1-3.
- Revised the first sentence in R1 to read: "Each Transmission Planner shall provide the following requested information to the Generator Owner within 90 calendar days of receiving a written request:" Stakeholders believed the previous language was not as clear as it could be, so the standard drafting team made this revision.
- Refined sub part 2.1.2 to read: "Manufacturer, model number (if available), and type of the excitation control system including, but not limited to static, AC brushless, DC rotating, and/or the plant volt/var control function (if installed)."

The standard drafting team considered stakeholder comments and made the following changes to PRC-024-1 based on those comments:

- The standard drafting team noted that some stakeholders were still unclear if the activities described in Requirement R4 were to be performed by request only, so the standard drafting team rearranged the sentences to make that more clear. Some stakeholders pointed out the RCs and TOPs can request such information via requirements in other standards (IRO-010-1a and TOP-003-2), so these two functional entities were removed from this requirement.
- Based on comments from a majority of stakeholders, Requirement R5 (along with its associated Measure M5 and VSL's) was removed from the Standard. The standard drafting team believes that Requirement R4 achieves the reliability objective of Paragraph 1787 of FERC Order No. 693 that Requirement R5 was written to address.

MOD-025-2, MOD-027-1 and PRC-019-1 were posted for a 30-day formal public comment period from September 28, 2012 to October 31, 2012 with a successive ballot and non-binding poll from October 19, 2012 to October 31, 2012.

For MOD-025-2, there were 48 sets of comments, including comments from approximately 155 different people from approximately 100 companies representing 8 of the 10 industry segments. MOD-025-2 received a quorum of 83.61% and an approval rating of 68.31%.

For-MOD-027-1, there were 46 sets of comments, including comments from approximately 152 different people from approximately 98 companies representing 9 of the 10 industry segments. MOD-027-1 received a quorum of 82.34% and an approval rating of 71.53%.

For PRC-019-1 there were 47 sets of comments, including comments from approximately 153 different people from approximately 99 companies representing 9 of the 10 industry segments. PRC-019-1 received a quorum of 82.07% and an approval rating of 70.64%.

E. Fourth Posting

MOD-026-1 and PRC-024-1 were posted for a formal comment period from September 28, 2012 to October 31, 2012 with a successive ballot and non-binding poll from October 19, 2012 to October 31, 2012.

MOD-026-1 received a quorum of 75.55% and an approval of 76.50%. PRC-024-1 received a quorum of 75% and an approval rating of 57.24%.

MOD-025-2, MOD-027-1 and PRC-019-1 were posted for a recirculation ballot from December 12, 2012 to December 21, 2012. MOD-025-2 received a quorum of 86.89% and an approval rating of 73.06%. MOD-027-1 received a quorum of 86.68% and an approval rating of 74.27%. PRC-019-1 received a quorum of 85.87% and an approval rating of 73.63%.

F. Fifth Posting

PRC-024-1 was posted for a formal comment period from December 12, 2012 to January 11, 2013 with a successive ballot and non-binding poll from January 2, 2013 to January 11, 2013. PRC-024-1 received a quorum of 78.16% and an approval rating of 60.31%.

The standard drafting team considered stakeholder comments and made the following changes to PRC-024-1 based on those comments:

- Revised the title of the standard to “Generator Frequency and Voltage Protective Relay Settings” and the Purpose Statement to “Ensure Generator Owners set their generator protective relays such that generating units remain connected during defined frequency and voltage excursions.”
- Revised “generating unit(s)” to “applicable generating unit(s)” to reflect that the standard only applies to units that meet the registry criteria.
- Removed Requirement R4 from the standards because of ambiguous language and dubious limited reliability benefit.
- Revised Requirement R5 (now R4) to indicate that the trip settings to be provided are only those “associated with Requirements R1 and R2” and not all relays.
- Revised Requirement R2 so that the sentences were shorter and easier to read, and made conforming language changes in Requirement R1.

MOD-026-1 was posted for a recirculation ballot from December 12, 2012 to December 21, 2012. MOD-026-1 received a quorum of 79% and an approval rating of 79.36%.

G. Sixth Posting

PRC-024-1 was posted for a 30-day public comment period from January 25, 2013 to February 25, 2013, with a successive ballot and non-binding poll from February 15, 2013 to February 28, 2013. PRC-02401 received a quorum of 78.80% and an approval rating of 89.01%.

There were 29 sets of comments, including comments from approximately 90 different people from approximately 63 companies representing 7 of the 10 industry segments

The standard drafting team considered stakeholder comments and made the following changes to PRC-024-1 based on those comments:

- Added page numbers to first section of the standard.

- Added the word “generator” before “frequency protective relaying” (second line) in Requirement R1 and before “voltage protective relaying” (second line) in Requirement R2 so that the language mirrored the first line of each requirement.
- Added the phrase “for asynchronous generating units” to the first bullet of Requirement R1 to match the language in the analogous bullet 3 in Requirement R2.
- Added the phrase “the applicable generating unit(s)” to the third line of Requirement R2 to match the language in Requirement R1.
- Added the phrase “with generator frequency or voltage protective relays” to the second line of Requirement R3 to clarify the language.

H. Board of Trustees Approval

MOD-025-2, MOD-026-1, MOD-027-1 and PRC-019-1 were approved by the NERC Board of Trustees on February 7, 2013. PRC-024-1 was approved by the NERC Board of Trustees on May 9, 2013.

Project 2007-09
Generator Verification

Related Files

Status:
MOD-025-1, MOD-026-1, MOD-027-1, and PRC-019-1 were adopted by the NERC Board of Trustees on February 7, 2013 and PRC-024-1 was adopted on May 9, 2013. All five standards will be filed together with the appropriate regulatory authorities.

Purpose/Industry Need:

- To ensure that generators will not trip off-line during specified voltage and frequency excursions or as a result of improper coordination between generator protective relays and generator voltage regulator controls and limit functions (such coordination will include the generating unit's capabilities).
- To ensure that generator models accurately reflect the generator's capabilities and operating characteristics.

New standards to be finalized as part of this project are:

- PRC-019 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection
- PRC-024 — Generator Performance During Frequency and Voltage Excursions
- MOD-026 — Verification of Models and Data for Generator Excitation System Functions
- MOD-027 — Verification of Generator Unit Frequency Response

Standards to be revised as part of this project are:

- MOD-024 — Verification of Generator Gross and Net Real Power Capability
- MOD-025 — Verification of Generator Gross and Net Reactive Power Capability

All six of the standards included in this project address generator verifications needed to support bulk power system reliability. All six of the standards included in this project were originally "Phase III & IV Planning Measures" that were translated into new or a proposed standards as part of the Version 0 translation effort. Stakeholders have already agreed that there is a reliability-related need for each of these standards as part of the work performed in association with the Phase III & IV Modeling SAR. In addition, each of the standards included in this project has some "fill in the blank" requirements assigned to the Regional Reliability Organization that need to be replaced with more specific "continent-wide" requirements before the standards are approved.

Standard Authorization Request Form

Title of Proposed Standard	Generator Verification (Project 2007-09)
Request Date	April 3, 2007

SAR Requestor Information	**SAR Type** (*Check a box for each one that applies.*)	
Name: Bob Millard	☒	New Standards
Primary Contact: Bob Millard	☒	Revision to existing Standards:
Telephone: (708) 588-9886 Fax:	☐	Withdrawal of existing Standard
E-mail: bob.millard@rfirst.org	☐	Urgent Action

Purpose

The purpose of Project 2007-09 Generator Verification is:

- To ensure that generators will not trip off-line during specified voltage and frequency excursions or as a result of improper coordination between generator protective relays and generator voltage regulator controls and limit functions (such coordination will include the generating unit's capabilities).
- To ensure that generator models accurately reflect the generator's capabilities and operating characteristics.

New standards to be finalized as part of this project are:

PRC-019 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection

PRC-024 — Generator Performance During Frequency and Voltage Excursions

MOD-026 —Verification of Models and Data for Generator Excitation System Functions

MOD-027 — Verification of Generator Unit Frequency Response

Standards to be revised as part of this project are:

MOD-024 — Verification of Generator Gross and Net Real Power Capability

MOD-025 — Verification of Generator Gross and Net Reactive Power Capability

Industry Need

All six of the standards included in this project address generator verifications needed to support bulk power system reliability. All six of the standards included in this project were originally “Phase III & IV Planning Measures” that were translated into new or proposed standards as part of the Version 0 translation effort. Stakeholders have already agreed that there is a reliability-related need for each of these standards as part of the work performed in association with the Phase III & IV Modeling SAR. In addition, each of the standards included in this project has some “fill-in-the-blank” requirements assigned to the Regional Reliability Organization that need to be replaced with more specific “continent-wide” requirements before the standards are approved.

Specifically:

- MOD-024-1 and MOD-025-1 were approved by the NERC Board of Trustees but are “pending” with FERC because they include “fill-in-the-blank” requirements assigned to the Regional Reliability Organization (MOD-024-1 and MOD-025-1 require generator owners to verify the generator’s gross and net real and reactive power capability using an RRO established procedure).

- PRC-019-1, PRC-024-1, MOD-026-1 and MOD-027-1 are draft standards that were developed under the Phase III & IV Modeling SAR that have not been presented to the NERC Board of Trustees yet. These four standards contain “fill-in-the-blank” requirements assigned to the Regional Reliability Organization (RRO) which were appropriate when the standards were initially drafted but are not appropriate under current requirements for approval of enforceable standards. Work on these standards to remove the “fill-in-the-blank” requirements under the Phase III & IV Modeling SAR is not authorized and therefore cannot be completed under the Phase III & IV Modeling SAR because the modifications needed to make the standards enforceable are outside the scope of the original Phase III & IV SARs. To properly complete these standards, a new SAR is needed and the prior SAR need to be terminated (termination of the Phase III & IV Modeling SAR will be performed outside the work of this SAR).
    - This set of standards includes verification of the generator’s excitation system; verification of the generator’s frequency response; verification that the generator can remain connected during specified voltage and frequency excursions; and verification that the generator’s voltage regulator controls and limit functions have been coordinated with the generator’s capabilities and protective relays.
    - The field test for this set of standards has shown that a standard can be written to support these verifications.

Brief Description

The scope of this project includes:

- modifying the six standards associated with this project so they conform to the latest version of NERC’s Reliability Standards Development Procedure and the ERO Rules of Procedure,
- replacing the “fill-in-the-blank” requirements assigned to the Regional Reliability Organization with requirements that can be applied on a continent-wide basis and are assigned to users, owners or operators of the bulk power system, and
- considering and addressing issues identified in FERC orders, including the modifications to MOD-024-1 and MOD-025-1 as proposed in FERC Order 693.

Detailed Description

The standards drafting team (SDT) will bring the six standards into conformance with the latest version of NERC's Reliability Standards Development Procedure and the ERO Rules of Procedure. In addition, the STD will consider and address all applicable FERC Orders, including FERC Order 693, and the following proposed changes for each of the six standards in this set of standards:

Draft PRC-019-1

- Revise the purpose statement to include the reliability-related benefit of the standard
- Provide more details to the applicability section of the standard to identify any generator owners that should be exempt from compliance with the requirements in the standard
- Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of 'continent-wide' criteria for verification that generator voltage regulator controls and limit functions are coordinated with the generator's capabilities and protective relays
- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the Regional Reliability Organization
- Add a 'violation risk factor' and a 'time horizon' for each requirement
- Update all the compliance sections of the standard, including:
    - Update the compliance monitoring section to clarify that the regional entity will be the compliance monitor for the generator owner
    - Replace the 'levels of non-compliance' with 'violation severity levels'

Draft PRC-024-1

- Provide more details to the applicability section of the standard to identify any generators that should be exempt from compliance with the requirements in the standard
- Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of 'continent-wide' criteria for verification that generators will remain connected during specified system frequency and voltage excursions
- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the Regional Reliability Organization
- Add a requirement for the Transmission Owner and Generator Owner to coordinate protection systems
- Add a 'violation risk factor' and a 'time horizon' for each requirement
- Update all the compliance sections of the standard, including:
    - Update the compliance monitoring section to clarify that the regional entity will be the compliance monitor for the generator owner
    - Replace the 'levels of non-compliance' with 'violation severity levels'

MOD-024-1:

- Provide more details to the applicability section of the standard to identify any generators that should be exempt from compliance with the requirements in the standard
- Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of 'continent-wide' criteria for verification of models and data associated with verification of generator gross and net real power capability
    - Consider requiring the generator owner to document the test conditions and the relationships between test conditions and generator output
- Assign responsibility to the appropriate functional entities as a result of updates to

the functional model and the replacement of the requirements assigned to the Regional Reliability Organization
- Add a ‘time horizon’ for each requirement
- Update all the compliance sections of the standard, including:
  - Update the compliance monitoring section to clarify that the regional entity will be the compliance monitor for the generator owner
  - Replace the ‘levels of non-compliance’ with ‘violation severity levels’

MOD-025-1:
- Provide more details to the applicability section of the standard to identify any generators that should be exempt from compliance with the requirements in the standard
- Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of ‘continent-wide’ criteria for verification of models and data associated with verification of generator gross and net Reactive Power capability
  - Consider requiring verification of reactive power capability at multiple points over a unit’s operating range
- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the Regional Reliability Organization
- Add a ‘time horizon’ for each requirement
- Update all the compliance sections of the standard, including:
  - Update the compliance monitoring section to clarify that the regional entity will be the compliance monitor for the generator owner
  - Replace the ‘levels of non-compliance’ with ‘violation severity levels’

Draft MOD-026-1
- Provide more details to the applicability section of the standard to identify any generators that should be exempt from compliance with the requirements in the standard
- Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of ‘continent-wide’ criteria for verification of models and data associated with generator excitation system functions
- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the Regional Reliability Organization
- Add a ‘violation risk factor’ and a ‘time horizon’ for each requirement
- Update all the compliance sections of the standard, including:
  - Update the compliance monitoring section to clarify that the regional entity will be the compliance monitor for the generator owner
  - Replace the ‘levels of non-compliance’ with ‘violation severity levels’

Draft MOD-027-1
- Revise the purpose statement to include the reliability-related benefit of the standard
- Provide more details to the applicability section of the standard to identify any generators that should be exempt from compliance with the requirements in the standard
- Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of ‘continent-wide’ criteria for verification of models and data associated with generator unit frequency response
- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the

Regional Reliability Organization

- Add a 'violation risk factor' and a 'time horizon' for each requirement
- Update all the compliance sections of the standard, including:
  - Update the compliance monitoring section to clarify that the regional entity will be the compliance monitor for the generator owner
  - Replace the 'levels of non-compliance' with 'violation severity levels'

Reliability Functions

The Standard Drafting Team will Consider Applicability to All Functional Entities *(Check box for each one that may apply.)*		
☒	Reliability Coordinator	Responsible for the real-time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator's wide area view.
☐	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within a Balancing Authority Area and supports Interconnection frequency in real time.
☐	Interchange Coordinator	Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced interchange schedules between Balancing Authority Areas.
☒	Planning Coordinator	Assesses the longer-term reliability of its Planning Coordinator Area.
☐	Resource Planner	Develops a >one year plan for the resource adequacy of its specific loads within a Planning Coordinator area.
☒	Transmission Planner	Develops a >one year plan for the reliability of the interconnected Bulk Electric System within its portion of the Planning Coordinator area.
☐	Transmission Service Provider	Administers the transmission tariff and provides transmission services under applicable transmission service agreements (e.g., the pro forma tariff).
☒	Transmission Owner	Owns and maintains transmission facilities.
☒	Transmission Operator	Ensures the real-time operating reliability of the transmission assets within a Transmission Operator Area.
☐	Distribution Provider	Delivers electrical energy to the End-use customer.
☒	Generator Owner	Owns and maintains generation facilities.
☐	Generator Operator	Operates generation unit(s) to provide real and reactive power.
☐	Purchasing-Selling Entity	Purchases or sells energy, capacity, and necessary reliability-related services as required.
☐	Market Operator	Interface point for reliability functions with commercial functions.
☐	Load-Serving Entity	Secures energy and transmission service (and related reliability-related services) to serve the End-use Customer.

Reliability and Market Interface Principles

Applicable Reliability Principles *(Check box for all that apply.)*	
☒	1. Interconnected bulk electric systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
☒	2. The frequency and voltage of interconnected bulk electric systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
☒	3. Information necessary for the planning and operation of interconnected bulk electric systems shall be made available to those entities responsible for planning and operating the systems reliably.
☐	4. Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed, coordinated, maintained and implemented.
☐	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk electric systems.
☐	6. Personnel responsible for planning and operating interconnected bulk electric systems shall be trained, qualified, and have the responsibility and authority to implement actions.
☐	7. The security of the interconnected bulk electric systems shall be assessed, monitored and maintained on a wide area basis.

Does the proposed Standard comply with all of the following Market Interface Principles? *(Select 'yes' or 'no' from the drop-down box.)*
1. A Reliability Standard shall not give any market participant an unfair competitive advantage.Yes
2. A Reliability Standard shall neither mandate nor prohibit any specific market structure. Yes
3. A Reliability Standard shall not preclude market solutions to achieving compliance with that Standard. Yes
4. A Reliability Standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards. Yes

April 18, 2007

TO: REGISTERED BALLOT BODY

Ladies and Gentlemen:

Announcement
Nomination Periods Open for Three Drafting Teams

The Standards Committee (SC) announces the following standards actions:

Nominations for Project 2007-09 Generator Verifications SAR Drafting Team (April 18–May 2, 2007)

The Standards Committee is seeking industry experts to serve on the Generator Verification SAR Drafting Team. This project calls for completing the final four Phase III & IV standards (PRC-019, PRC-024, MOD-026, and MOD-027) and for refinement of two standards that were approved in 2005 (MOD-024 and MOD-025).

- PRC-019 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection
- PRC-024 — Generator Performance During Frequency and Voltage Excursions
- MOD-024 — Verification of Generator Gross and Net Real Power Capability
- MOD-025 — Verification of Generator Gross and Net Reactive Power Capability
- MOD-026 —Verification of Models and Data for Generator Excitation System Functions
- MOD-027 — Verification of Generator Unit Frequency Response

The set of six standards all require generator verifications — either to ensure that generators will not trip off line during specified voltage and frequency excursions or as a result of improper coordination between generator protective relays and generator voltage regulator controls and limit functions or to ensure that generator models accurately reflect the generator's capabilities and operating characteristics.

If you are interested in serving on this team, please complete this nomination form and return it to sarcomm@nerc.net with "GEN VER SARDT Nomination" in the subject line, no later than **May 2, 2007**.

Nominations for Project 2006-03 System Restoration and Blackstart Standard Drafting Team (April 18–May 2, 2007)

The Standards Committee is seeking additional industry experts to serve on the System Restoration and Blackstart Standard Drafting Team. This project calls for the modification of the following standards:

- EOP-005 — System Restoration Plans
- EOP-006 — Reliability Coordination — System Restoration
- EOP-007 — Establish, Maintain, and Document a Regional Blackstart Capability Plan
- EOP-009 — Documentation of Blackstart Generating Unit Test Results

This project involves upgrading the overall quality of the four standards; eliminating some gaps in the requirements; eliminating some ambiguity; and eliminating some "fill-in-the-blank" components. The Standards Committee has appointed the initial standard drafting team, but is seeking additional members, particularly from within the SPP and WECC regions.

If you are interested in serving on this team, please complete this nomination form and return it to sarcomm@nerc.net with "SRBS SDT Nomination" in the subject line, no later than **May 2, 2007**.

Nominations for Project 2007-02 Operating Personnel Communications Protocols SAR Drafting Team (April 18–May 2, 2007)

The Standards Committee is seeking additional industry experts to serve on the Operating Personnel Communications Protocols SAR Drafting Team. This SAR calls for the development of communications protocols for use by real-time system operators to improve situational awareness and shorten response time. The Standards Committee has appointed an initial SAR Drafting Team but is seeking additional nominations, particularly from the FRCC, NPCC, and SPP regions, from Canada, and from the generation and load-serving entity segments that will be affected by the proposed standard.

If you are interested in serving on this team, please complete this nomination form and return it to sarcomm@nerc.net with "OPS COM SARDT Nomination" in the subject line, no later than **May 2, 2007**.

Standards Development Process

The *Reliability Standards Development Procedure* contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate. If you have any questions, please contact me at 813-468-5998 or maureen.long@nerc.net.

Sincerely,

Maureen E. Long

Please briefly describe your experience and qualifications to serve on the Generator Verification SAR Drafting Team. Prefer experience in verifying or modeling generator capabilities or in coordinating generator protection with transmission protection. Previous experience working on or applying NERC or IEEE standards is beneficial, but not a requirement.

I represent the following NERC Reliability Region(s) (check all that apply):		**I represent the following Industry Segment (check one):**
☐ ERCOT	☐	1 — Transmission Owners
☐ FRCC	☐	2 — RTOs, ISOs
☐ MRO	☐	3 — Load-serving Entities
☐ NPCC	☐	4 — Transmission-dependent Utilities
☐ RFC	☐	5 — Electric Generators
☐ SERC	☐	6 — Electricity Brokers, Aggregators, and Marketers
☐ SPP	☐	7 — Large Electricity End Users
☐ WECC	☐	8 — Small Electricity End Users
☐ NA – Not Applicable	☐	9 — Federal, State, and Provincial Regulatory or other Government Entities
	☐	10 – Regional Reliability Organizations and Regional Entities

Which of the following Function(s)[1] do you have expertise or responsibilities:

☐ Reliability Coordinator	☐ Transmission Service Provider
☐ Balancing Authority	☐ Transmission Owner
☐ Interchange Authority	☐ Load Serving Entity
☐ Planning Coordinator	☐ Distribution Provider
☐ Transmission Operator	☐ Purchasing-selling Entity
☐ Generator Operator	☐ Generator Owner
☐ Transmission Planner	☐ Resource Planner
	☐ Market Operator

Provide the names and contact information for two references who could attest to your technical qualifications and your ability to work well in a group.

Standard Authorization Request Form

Title of Proposed Standard	Generator Verification (Project 2007-09)
Request Date	April 3, 2007

SAR Requestor Information	**SAR Type** (*Check a box for each one that applies.*)	
Name: Bob Millard	☒	New Standards
Primary Contact: Bob Millard	☒	Revision to existing Standards:
Telephone: (708) 588-9886 Fax:	☐	Withdrawal of existing Standard
E-mail: bob.millard@rfirst.org	☐	Urgent Action

Purpose

The purpose of Project 2007-09 Generator Verification is:

- To ensure that generators will not trip off-line during specified voltage and frequency excursions or as a result of improper coordination between generator protective relays and generator voltage regulator controls and limit functions (such coordination will include the generating unit's capabilities).
- To ensure that generator models accurately reflect the generator's capabilities and operating characteristics.

New standards to be finalized as part of this project are:

PRC-019 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection

PRC-024 — Generator Performance During Frequency and Voltage Excursions

MOD-026 —Verification of Models and Data for Generator Excitation System Functions

MOD-027 — Verification of Generator Unit Frequency Response

Standards to be revised as part of this project are:

MOD-024 — Verification of Generator Gross and Net Real Power Capability

MOD-025 — Verification of Generator Gross and Net Reactive Power Capability

Industry Need

All six of the standards included in this project address generator verifications needed to support bulk power system reliability. All six of the standards included in this project were originally "Phase III & IV Planning Measures" that were translated into new or proposed standards as part of the Version 0 translation effort. Stakeholders have already agreed that there is a reliability-related need for each of these standards as part of the work performed in association with the Phase III & IV Modeling SAR. In addition, each of the standards included in this project has some "fill-in-the-blank" requirements assigned to the Regional Reliability Organization that need to be replaced with more specific "continent-wide" requirements before the standards are approved.

Specifically:

- MOD-024-1 and MOD-025-1 were approved by the NERC Board of Trustees but are "pending" with FERC because they include "fill-in-the-blank" requirements assigned to the Regional Reliability Organization (MOD-024-1 and MOD-025-1 require generator owners to verify the generator's gross and net real and reactive power capability using an RRO established procedure).

- PRC-019-1, PRC-024-1, MOD-026-1 and MOD-027-1 are draft standards that were developed under the Phase III & IV Modeling SAR that have not been presented to the NERC Board of Trustees yet. These four standards contain "fill-in-the-blank" requirements assigned to the Regional Reliability Organization (RRO) which were appropriate when the standards were initially drafted but are not appropriate under current requirements for approval of enforceable standards. Work on these standards to remove the "fill-in-the-blank" requirements under the Phase III & IV Modeling SAR is not authorized and therefore cannot be completed under the Phase III & IV Modeling SAR because the modifications needed to make the standards enforceable are outside the scope of the original Phase III & IV SARs. To properly complete these standards, a new SAR is needed and the prior SAR need to be terminated (termination of the Phase III & IV Modeling SAR will be performed outside the work of this SAR).
    - This set of standards includes verification of the generator's excitation system; verification of the generator's frequency response; verification that the generator can remain connected during specified voltage and frequency excursions; and verification that the generator's voltage regulator controls and limit functions have been coordinated with the generator's capabilities and protective relays.
    - The field test for this set of standards has shown that a standard can be written to support these verifications.

Brief Description

The scope of this project includes:

- modifying the six standards associated with this project so they conform to the latest version of NERC's Reliability Standards Development Procedure and the ERO Rules of Procedure,
- replacing the "fill-in-the-blank" requirements assigned to the Regional Reliability Organization with requirements that can be applied on a continent-wide basis and are assigned to users, owners or operators of the bulk power system, and
- considering and addressing issues identified in FERC orders, including the modifications to MOD-024-1 and MOD-025-1 as proposed in FERC Order 693.

Detailed Description

The standards drafting team (SDT) will bring the six standards into conformance with the latest version of NERC's Reliability Standards Development Procedure and the ERO Rules of Procedure. In addition, the STD will consider and address all applicable FERC Orders, including FERC Order 693, and the following proposed changes for each of the six standards in this set of standards:

Draft PRC-019-1

- Revise the purpose statement to include the reliability-related benefit of the standard
- Provide more details to the applicability section of the standard to identify any generator owners that should be exempt from compliance with the requirements in the standard
- Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of 'continent-wide' criteria for verification that generator voltage regulator controls and limit functions are coordinated with the generator's capabilities and protective relays
- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the Regional Reliability Organization
- Add a 'violation risk factor' and a 'time horizon' for each requirement
- Update all the compliance sections of the standard, including:
    - Update the compliance monitoring section to clarify that the regional entity will be the compliance monitor for the generator owner
    - Replace the 'levels of non-compliance' with 'violation severity levels'

Draft PRC-024-1

- Provide more details to the applicability section of the standard to identify any generators that should be exempt from compliance with the requirements in the standard
- Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of 'continent-wide' criteria for verification that generators will remain connected during specified system frequency and voltage excursions
- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the Regional Reliability Organization
- Add a requirement for the Transmission Owner and Generator Owner to coordinate protection systems
- Add a 'violation risk factor' and a 'time horizon' for each requirement
- Update all the compliance sections of the standard, including:
    - Update the compliance monitoring section to clarify that the regional entity will be the compliance monitor for the generator owner
    - Replace the 'levels of non-compliance' with 'violation severity levels'

MOD-024-1:

- Provide more details to the applicability section of the standard to identify any generators that should be exempt from compliance with the requirements in the standard
- Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of 'continent-wide' criteria for verification of models and data associated with verification of generator gross and net real power capability
    - Consider requiring the generator owner to document the test conditions and the relationships between test conditions and generator output
- Assign responsibility to the appropriate functional entities as a result of updates to

the functional model and the replacement of the requirements assigned to the Regional Reliability Organization
- Add a 'time horizon' for each requirement
- Update all the compliance sections of the standard, including:
  - Update the compliance monitoring section to clarify that the regional entity will be the compliance monitor for the generator owner
  - Replace the 'levels of non-compliance' with 'violation severity levels'

MOD-025-1:
- Provide more details to the applicability section of the standard to identify any generators that should be exempt from compliance with the requirements in the standard
- Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of 'continent-wide' criteria for verification of models and data associated with verification of generator gross and net Reactive Power capability
  - Consider requiring verification of reactive power capability at multiple points over a unit's operating range
- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the Regional Reliability Organization
- Add a 'time horizon' for each requirement
- Update all the compliance sections of the standard, including:
  - Update the compliance monitoring section to clarify that the regional entity will be the compliance monitor for the generator owner
  - Replace the 'levels of non-compliance' with 'violation severity levels'

Draft MOD-026-1
- Provide more details to the applicability section of the standard to identify any generators that should be exempt from compliance with the requirements in the standard
- Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of 'continent-wide' criteria for verification of models and data associated with generator excitation system functions
- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the Regional Reliability Organization
- Add a 'violation risk factor' and a 'time horizon' for each requirement
- Update all the compliance sections of the standard, including:
  - Update the compliance monitoring section to clarify that the regional entity will be the compliance monitor for the generator owner
  - Replace the 'levels of non-compliance' with 'violation severity levels'

Draft MOD-027-1
- Revise the purpose statement to include the reliability-related benefit of the standard
- Provide more details to the applicability section of the standard to identify any generators that should be exempt from compliance with the requirements in the standard
- Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of 'continent-wide' criteria for verification of models and data associated with generator unit frequency response
- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the

Regional Reliability Organization

- Add a ‘violation risk factor’ and a ‘time horizon’ for each requirement
- Update all the compliance sections of the standard, including:
  - Update the compliance monitoring section to clarify that the regional entity will be the compliance monitor for the generator owner
  - Replace the ‘levels of non-compliance’ with ‘violation severity levels’

Reliability Functions

The Standard Drafting Team will Consider Applicability to All Functional Entities *(Check box for each one that may apply.)*		
☒	Reliability Coordinator	Responsible for the real-time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator's wide area view.
☐	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within a Balancing Authority Area and supports Interconnection frequency in real time.
☐	Interchange Coordinator	Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced interchange schedules between Balancing Authority Areas.
☒	Planning Coordinator	Assesses the longer-term reliability of its Planning Coordinator Area.
☐	Resource Planner	Develops a >one year plan for the resource adequacy of its specific loads within a Planning Coordinator area.
☒	Transmission Planner	Develops a >one year plan for the reliability of the interconnected Bulk Electric System within its portion of the Planning Coordinator area.
☐	Transmission Service Provider	Administers the transmission tariff and provides transmission services under applicable transmission service agreements (e.g., the pro forma tariff).
☒	Transmission Owner	Owns and maintains transmission facilities.
☒	Transmission Operator	Ensures the real-time operating reliability of the transmission assets within a Transmission Operator Area.
☐	Distribution Provider	Delivers electrical energy to the End-use customer.
☒	Generator Owner	Owns and maintains generation facilities.
☐	Generator Operator	Operates generation unit(s) to provide real and reactive power.
☐	Purchasing-Selling Entity	Purchases or sells energy, capacity, and necessary reliability-related services as required.
☐	Market Operator	Interface point for reliability functions with commercial functions.
☐	Load-Serving Entity	Secures energy and transmission service (and related reliability-related services) to serve the End-use Customer.

Reliability and Market Interface Principles

Applicable Reliability Principles *(Check box for all that apply.)*	
☒	1. Interconnected bulk electric systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
☒	2. The frequency and voltage of interconnected bulk electric systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
☒	3. Information necessary for the planning and operation of interconnected bulk electric systems shall be made available to those entities responsible for planning and operating the systems reliably.
☐	4. Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed, coordinated, maintained and implemented.
☐	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk electric systems.
☐	6. Personnel responsible for planning and operating interconnected bulk electric systems shall be trained, qualified, and have the responsibility and authority to implement actions.
☐	7. The security of the interconnected bulk electric systems shall be assessed, monitored and maintained on a wide area basis.

Does the proposed Standard comply with all of the following Market Interface Principles? *(Select 'yes' or 'no' from the drop-down box.)*
1. A Reliability Standard shall not give any market participant an unfair competitive advantage.Yes
2. A Reliability Standard shall neither mandate nor prohibit any specific market structure. Yes
3. A Reliability Standard shall not preclude market solutions to achieving compliance with that Standard. Yes
4. A Reliability Standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards. Yes

SAR Drafting Team Kick-off Meeting
Florida Reliability Coordinating Council Offices
Tampa, FL
June 18-19, 2007

Vance Beauregard, American Electric Power
Jack Thormahlen, Lower Colorado River Authority

Background -- Documents

- ERCOT Protocols
  - Rules of the market
- ERCOT Operating Guides
  - Additional details regarding reliability

Background – Action Plan

- Dynamics Working Group
  - Reviewed Operating Guides to identify where draft requirements were met
  - Prepared Operating Guide revisions to address remaining gaps
  - Submitted Operating Guide Revision Request (OGRR)

Background – Action Plan

- Reliability and Operations Subcommittee (ROS)
  - Tabled Operating Guide Revision Request (OGRR)
  - Formed an ad hoc task force

Background – Action Plan

- Ad Hoc Task Force
  - Composed of 17 market participants
  - Reviewed Operating Guides to identify where draft requirements were met
  - Reviewed OGRR and suggested changes
  - Will resubmit OGRR at appropriate time

Formality of Actions Taken

- ROS directed the formation of the Ad Hoc Task Force
- Market Participants invited to participate
  - Combined cycle plants and steam turbine plants
  - Hydro
  - Coal fired and Nuclear
  - Transmission Providers
- Ad Hoc Task work has not been reviewed by ROS

Different from Normal Process

- Normal Process Approvals
  - Reliability and Operations Subcommittee
  - Technical Advisory Committee
  - ERCOT Board of Directors
- NERC Field Test Request
  - Actions have not gone through the normal reviews and approval processes in order to provide a timely response to NERC

Actual Testing / Verification

- For most of the testing the past experience and testing was sufficient
- Market Participants have revised the OGRR to insure the fidelity of the model
- No actual tests were performed

Executive Summary of Results

- ERCOT Protocols
  - 5.2.2 Operating Standards
    - Comply with Good Utility Practice, NERC and ERCOT standards
  - 5.8.2 Primary Frequency Control Measurements
    - Shall be performed to ensure conformance to criteria

Executive Summary of Results

- ERCOT Protocols (continued)
  - 5.8.1.2 Reporting
    - Tests to be reported to ERCOT in 30 days
  - 6.10.3.5 Reactive Supply
    - Each unit submits a CURL to ERCOT
  - 6.10.2 Capacity Testing Requirements
    - Test of net dependable capability seasonally

Executive Summary of Results

- ERCOT Operating Guides
  - 1.2 Document Relationship
  - 1.3 Process for Operating Guide Revision
  - 2.2.4 Automatic Voltage Regulators and Power System Stabilizers
  - 2.2.5 Turbine Speed Governors
  - 2.2.6 Performance/Disturbance/ Compliance Analysis

Executive Summary of Results

- ERCOT Operating Guides (2)
  - 2.9.1 Automatic Firm Load Shedding
  - 2.9.2 Generators Under-Frequency relay coordination
  - 3.1.4 Power Generation Companies testing and modeling requirements
  - 3.1.4.3.1 Corrected Unit Reactive Limits (CURL)

Executive Summary of Results

- ERCOT Operating Guides (3)
  - 3.1.4.5 Automatic Voltage Regulators and Power System Stabilizers (tests)
  - 3.1.4.6 Protective Relaying Requirement
  - 5.1.6.2 System Modeling Information
  - 7.2.5.3 Specific Application Considerations

Status of References

- ERCOT Protocols and Operating Guides are approved as of May 1, 2007
- Responses to the draft standards were reviewed by the ad hoc task force
- The OGRR is evolving to reflect comments

Difference from Proposed Requirements

- Operating Guides need more specificity
- OGRR will provide necessary language to meet the proposed draft standards

Extent of Actual Checking of Documents

- Review of historical testing processes
- Testing is required under ERCOT Protocols and Operating Guides
- Modeling information is also required
- Gap identified in the feedback loop for model verification
- OGRR will address the issues

Are Procedures Feasible?

- Procedures were deemed to be feasible and reasonable
- Gap in feedback loop needs to be addressed to make sure verification tests produce worthwhile results

Were Verifications Valuable?

- Present tests are valuable for ERCOT purposes, but do not result in model verification
- The OGRR will ensure that models will be verified and improved

Anticipated Cost and Time

- Cost of verifying models is unknown
- Complete implementation of the OGRR could take up to 3 years

Changes to Draft Standards

- No changes needed from ERCOT perspective
- Requirements should not be written in a way to prohibit verification of the models using actual disturbance data

Implementation Plan

- ERCOT has no comments on the implementation plan or timeline
- The final form of the ERCOT OGRR will likely depend on what the final NERC standard looks like

Important Regional Point

- Requirements should not be written in a way to prohibit verification of the models using actual disturbance data

Details/Appendices/Attachments

- Regional documents and procedures
- See attached ERCOT Protocols and Operating Guides

Mapping

- Mapping of the draft standards to the ERCOT Protocols and Operating Guides and OGRR188 is contained in the appendix

Red-lined Draft Standards

- ERCOT does not propose any changes to the draft standards
- Verification will be done primarily by using actual disturbance data

Midwest Reliability Organization

Generator Testing Review Task Force

Phase III – IV Field Testing Results

June 18 - 19, 2007

GTRTF Overview

- MAPP Generator Testing Working Group
  - ✓Formed in 1998
  - ✓Developed MAPP Generator Testing Requirements
- MRO GTRTF
  - ✓Formed in Sept. 2006
  - ✓Developed MRO Generator Testing Guidelines for the four Field Test standards and two approved standards (real and reactive power testing)
  - ✓Participation from American Transmission, Manitoba Hydro, Muscatine W&P, Wisc Public Service, Xcel Energy (NSP)

MIDWEST RELIABILITY ORGANIZATION

MOD-026 Excitation Response Verification

- Field Testing Performed
  - ✓ 31 Units tested to MAPP guidelines
  - ✓ 11 Units tested or to be tested to MRO guidelines
- Requirements reasonable, achievable
- Testing can be costly – $5k to $50k+ (includes 027)
- Initial matching to measured data time consuming
  - ✓ Parameter optimization program would be very helpful.
- Verification through disturbance monitoring
  - ✓ Expected to be less costly, but not field tested
  - ✓ Recommend removing requirement for step response test (R1.4.5) to allow disturbance monitoring

MIDWEST RELIABILITY ORGANIZATION

MOD-027 Frequency Response Verification

- Field Testing Performed
  - ✓ 17 Units tested to MAPP guidelines
  - ✓ 8 Units tested or to be tested to MRO guidelines
- Requirements reasonable, achievable
- Testing can be costly – $5k to $50k+ (includes 026)
- Initial matching to measured data time consuming
  - ✓ Parameter optimization program would be very helpful.
  - ✓ Some units could not match PSS/E model to response – had to use detailed manufacturer model
- Verification through disturbance monitoring
  - ✓ Expected to be less costly, but not field tested
  - ✓ No function in PSS/E for injecting an arbitrary frequency signal at the model speed reference point.

MIDWEST RELIABILITY ORGANIZATION

PRC-019 Coordinating Control & Protection

- Field Testing Performed
  - ✓ 166 Units analyzed, most to the MAPP guidelines
- Requirements reasonable, achievable
- Testing relatively inexpensive
  - ✓ Limiter verification done with MOD-026 testing
  - ✓ Relay verification done per PRC-005
- Several cases of mis-coordination found
  - ✓ Mostly related to UEL, LOF Relay and SSSL
- Recommended changes
  - ✓ R2.1.3 (plot prime mover rating) seems of questionable value.

MIDWEST RELIABILITY ORGANIZATION

PRC-024 Voltage & Frequency Excursions

- Field Testing Performed
  - ✓ No physical testing. 2 Units analyzed for voltage criteria by PSS/E simulation.
- Requirements reasonable, achievable
  - ✓ Frequency criteria must comply with regional UFLS program.
  - ✓ Standardized, reasonable voltage criteria needs to be developed.
- No physical generator testing involved
  - ✓ Frequency relay verification done per PRC-005
  - ✓ Voltage ride-through done by simulation
- Recommended changes
  - ✓ Existing units should be exempt from voltage criteria (beyond IEEE or ANSI mfr req's) until upgrading.

Phase III-IV Field Test Report
Prepared by the SERC EC Generator Standard Field Test Task Force
June 15, 2007

BACKGROUND

The purpose of this report is to document the activities of the SERC EC Generator Standard Field Test Task Force in the NERC Field Tests of proposed Reliability Standards for MOD-026 (Verification of Models and Data for Generator Excitation System Functions); MOD-027 (Verification of Generator Unit Frequency Response); PRC-019 (Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection); and PRC-024 (Generator Performance During Frequency and Voltage Excursions).

SERC EC GSFT-TF members include representatives from the US Army Corps of Engineers-Mobile District (USACE), Dominion, Entergy, SCE&G, and Southern. In support of the Field Test activities by SERC member Generator and Transmission Owners, the GSFT-TF developed the following Field Test Guidelines and Reporting Forms:

1) SERC Field Test Guidelines – Verification of Models and Data for Generator Excitation System Functions - NERC Reliability Standards MOD-026; [SERC MOD-026 Field Test Guideline Rev 1 (1-11-07).doc]

2) MOD-026 SERC Field Test Reporting form; [SERC MOD-026 Field Test Reporting Form Rev 0 (1-11-07).doc]

3) SERC Field Test Guidelines – Verification of Generator Unit Frequency Response – NERC Draft Reliability Standard MOD-027; SERC MOD-027 Field Test Guideline Rev 0 (3-2-07).doc

4) MOD-027 SERC Field Test Reporting Form; SERC MOD-027 Field Test Reporting Form Rev 0 (4-17-07).doc

5) SERC Field Test Guidelines – Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection; SERC PRC-019 Field Test Guideline Rev 0 (8-28-06).doc

6) PRC-019 SERC Field Test Reporting Form; SERC PRC-019 Field Test Reporting Form Rev 1 (11-2-06).doc

7) SERC Field Test Guidelines – Generator Performance during Frequency and Voltage Excursions; SERC PRC-024 Field Test Guidelines Rev 0 (3-2-07).doc

8) Generator Owner PRC-024 SERC Field Test Reporting Form; SERC PRC-024 GO Field Test Reporting Form Draft 0 (3-13-07).doc

9) Transmission Owner PRC-024 SERC Field Test Reporting Form; SERC PRC-024 TO Field Test Reporting Form Draft 0 (3-13-07).doc

The purpose of the aforementioned Field Test Guidelines and Reporting Forms are to provide assistance to the SERC volunteer members that conducted the Field Tests. As such, the documents do not contain content that constitutes a requirement on any SERC entity.

Following is Field Test background information specific to each proposed Reliability Standard:

<u>MOD-026-1: Verification of Models and Data for Generator Excitation System</u>

Generation Owner entities within SERC that participated in this field test include the USACE-Mobile District, Dominion, SCE&G, and Southern. Though the current version of the proposed Reliability Standard does not include applicability to Transmission Owners, TO entities within SERC that participated include the USACE-Mobile District, Dominion, Entergy, and Southern. All of these entities were also represented on the GSFT-TF. Therefore, all were extremely knowledgeable regarding the GSFT-TF developed Field Test Guidelines and Reporting Forms. Even before the start of the Field Test, SERC had approved the Supplement which called for the open step in voltage testing and subsequent excitation model verification over a multi year phase in period. As such, all of the entities had either planned or had performed some exciter model verifications in the past.

<u>MOD-027-1: Verification of Generator Unit Frequency Response</u>

Generation Owner entities within SERC that participated in this field test include the USACE-Mobile District, Dominion, Entergy, SCE&G, and Southern. Though the current version of the proposed Reliability Standard does not include applicability to Transmission Owners, TO entities within SERC that participated include Dominion, Entergy, and Southern. All of these entities were also represented on the GSFT-TF. Therefore, all were extremely knowledgeable regarding the GSFT-TF developed Field Test Guidelines and Reporting Forms.

As documented in the Field Test Guidelines, the GSFT-TF attempted to utilize an event based approach to Validate unit frequency response for a sample number of generators. While it is known that WECC has developed and utilize this type of approach, it has not been previously utilized in SERC. A significant part of the effort was spent finding an appropriate software tool to re-create the frequency event and validate the models. Generator response data for two specific frequency excursion events were compared to unit frequency responses predicted by the unit's speed / load control dynamic models.

<u>PRC-019-1: Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection</u>

Generation Owner entities within SERC that participated in this field test include the USACE-Mobile District, Dominion, Entergy, and Southern. All of these entities were also represented on the GSFT-TF. Therefore, all were extremely knowledgeable of the GSFT-TF developed Field Test Guidelines and Reporting Forms. Though not obligated through any RRO or NERC requirements, Southern Company Generation has been performing generator coordination studies for a few years. The other entities had not recently conducted these coordination studies until this Field Test. As such, they had to implement through significant start up processes.

PRC-024-1: Generator Performance during Frequency and Voltage Excursions

Generation Owner entities within SERC that participated in this field test include Dominion, Southern, and USACE-Mobile District. All of these entities were also represented on the GSFT-TF. Therefore, all were extremely knowledgeable regarding the GSFT-TF developed Field Test Guidelines and Reporting Forms. As part of SERC UFLS studies, efforts have been made in the past to identify units with under frequency turbine protection that would not coordinate with UFLS relays. There has been some limited investigation of low voltage ride through (LVRT) capabilities of units in SERC. Draft frequency excursion and LVRT curves have been drafted and discussed in SERC groups, with the intent of adding them to SERC Supplements in support of Planning Standards. However, the efforts were put on hold with the abolishment of the Planning Standards. Therefore, before these Field Test activities, there has been little formal investigation of unit ride through capability for frequency and voltage excursions within SERC.

EXECUTIVE SUMMARY

MOD-026-1: Verification of Models and Data for Generator Excitation System

The GSFT-TF developed Field Test Guidelines that addresses each of the proposed NERC Reliability Standard Requirements in MOD-026-1. Two SERC Generator Owner entities actually performed the activities detailed in the completed SERC Field Test Guidelines (Attachment 1), while 2 utilized outside consultants to address some of the Requirements. The GSFT-TF believes these activities would constitute compliance with the proposed MOD-026-1 NERC Reliability Standard as currently drafted.

Four Generator Owners, and the associated Transmission Planning entities, within SERC participated in the Field Test of MOD-026. One Generator Owner and Transmission Planning entity have been performing the Open Step in Voltage tests and subsequent exciter model verification for a number of years. Prior to the Field Tests, the other entities had limited experience. Two entities relied on consultants to perform the Open Step in Voltage test, either as part of unit start up activities, or through a specific contract for excitation system model verification. It should be noted that most entities will require the use of consultants to perform these tests and the model validations due to a lack of in-house expertise. It was observed that using consultants is expensive, roughly $20,000 to 30,000 for one unit.

Open Step in Voltage tests are performed when the unit is at synchronous speed but at no load (i.e., functionally, the generator breaker is open). Therefore, it is best performed when the generator is coming off-line or is about to be put on-line. Thus, scheduling of these tests can be problematic.

Satisfactorily completing the requirements in draft Reliability Standard MOD-026-1 does improve the accuracy of the exciter models used in dynamic simulations. But it is noted that the effort required to verify the exciter model with the Open Step in Voltage tests can be laborious and time consuming. While the major dynamic simulation software vendors do have a number of exciter models in their library, it is becoming commonplace for Generator Owners to execute partial excitation system change outs. For example, conversion of a rotating field excitation system from an analog voltage regulator to a static voltage regulator results in an hybrid system that does not fit well with any standard library models. Significant effort, including requests for additional unit data from generator manufacturers, resulting in required use of an exponentially more complicated exciter model was required to obtain good model verification.

It is difficult to accurately project the cost, time, and level of benefits for all applicable entities in the region to implement the procedures to verify excitation system and PSS models. The current amount of actual generating plant capability in Commercial Operation in SERC approaches 260 GW. The GSFT-TF recommends that all units below 75 MVA or interconnected at voltages less than 100 kV should be exempt from the model verification requirements. Also, rigorous configuration control processes and sister units philosophy should be allowed so that model verification efforts can potentially be applicable to multiple units. Assuming the Reliability Standard is developed with reasonable exemption criteria, and allowances for configuration control / sister unit philosophies, the SERC GSFT-TF would recommend a 7 year phase in period (Effective date 2 years after adoption, then 20% per year for 5 years).

As marked up by the GSFT-TF in the redline versions of the current draft of MOD-026 (MOD-026_Draft for Field Test (GSFT-TF revised 5-3-07).doc), the GSFT also recommends:

1) A list of acceptable models be maintained, along with a procedure for revising the list of acceptable models (must be available in the major dynamic simulation software libraries).
2) Additional specificity regarding PSS commissioning tests.

<u>MOD-027-1: Verification of Generator Unit Frequency Response</u>

The GSFT-TF developed Field Test Guidelines that addresses each of the proposed NERC Reliability Standard Requirements in MOD-027-1. Five SERC Generator Owner entities attempted to perform the activities detailed in the completed SERC Field Test Guidelines. Upon inspection of captured event data for both the frequency excursion events, one of the Generator Owners found that none of his units were in an operating state conducive to responding to under frequency events (i.e., units were motoring). The other Generator Owners were able to identify multiple units in a proper operating state for further analysis and completion of all the Requirements as detailed proposed MOD-027-1. While dependent on the operating state of units during frequency events which are subsequently analyzed, the GSFT-TF believes these activities would constitute compliance with the proposed MOD-027-1 NERC Reliability Standard as currently drafted.

Until the Field Test, there have been few dedicated efforts to verify unit speed load control systems. Because of the large number of generators in SERC, the GSFT-TF determined that an event based methodology, similar to that utilized by WECC, was clearly the most practical course to pursue. However, selection of a tool to perform the simulations to replicate actual frequency excursion events was difficult. Software packages conducive to control system block diagram construction and code generation were evaluated. However, to utilize these packages, each type of speed load control system model to be verified would have to be constructed and tested.

At least one dynamic simulation software package contains a “playback” feature, which forces frequency and voltage signatures that can be manipulated to replicate what was recorded during actual transmission system events. The simulated frequency excursions are then applied to the unit frequency response models so that the resulting MW response predicted by the frequency response models could be compared to the actual captured unit MW response event data. Unfortunately, that capability does not exist for the dynamic simulation software package used by the vast majority of Transmission Planners in SERC.

Despite the absence of a “playback feature”, the tool chosen for this Field Test effort was the dynamic simulation software package utilized in SERC. The GSFT-TF developed a small 3 bus loadflow, with a dominant “Eastern Interconnection” machine and the test machine. Source code altering the mechanical power of the dominant machine was developed to force the dominant machine to slow down relative to 60 hertz and create a simulated transmission system frequency to approximately replicate the actual recorded transmission system frequency. The resulting unit MW versus time output produced by the test machine unit frequency response model was compared to the actual unit MW versus time output captured by the event data. Further details can be found in SERC MOD-027 Field Test Reporting Form Rev 0 (4-17-07).doc.

The GSFT-TF volunteer entities investigated multiple models for two separate frequency excursion events. In some cases, good correlation between the event data and model data was not obtained. The field test concluded before issues regarding the poor correlation could be resolved. Once the poor correlations are resolved, the end result will be closer correlation between the models and the actual performance of the installed equipment.

The Field Test was a successful proof of concept exercise. However, the processes would require additional development before becoming a “production grade” activity that would be expected for compliance with an approved NERC Reliability Standard. Following are a list of specific issues that would need to be addressed before it is practical for unit frequency response model verifications be required per an enforceable NERC Reliability Standard:

1) A process would need to be set up to identify frequency excursion events which meet minimum criteria for verifying unit speed load governor systems, and subsequently communicate this information to the appropriate parties.
2) A significant number of units are not equipped with event recording equipment with sufficient resolution, triggering capabilities (if not inherently continuous) and/or data retention. Also, some plants do not have individual recording equipment for each unit (example, CC plants often sum their MW output into one transducer or meter)
3) A tool needs to be developed that can be utilized by the entities responsible for verifying the unit speed load models. While SERC utilized dynamic simulation software predominately used by almost all SERC members with a small loadflow along with flecs code unique to each frequency excursion event. The process was cumbersome and required user expertise in dynamic simulation. It did not exactly replicate the transmission system frequency and the models MW output often had high frequency oscillations associated with numeric instability (note – we were advised by the software vendor to alter the frequency filter, but this resulted in limited positive impact). In summary, the process is not “production grade”.
4) Staged events, at least in the Eastern Interconnection, are impractical. It will probably take significant calendar time before enough events would occur to capture most of the non-exempt units on-line but far enough below maximum power output for governor response to be observed. The GSFT-TF recommends that all units below 75 MVA or interconnected at voltages less than 100 kV should be exempt from the model verification requirements. Also, rigorous configuration control processes should be allowed as a means to demonstrate that validated unit responses are unchanged.

Working through these issues will take considerable time and effort. Therefore, the GSFT-TF recommends that drafting efforts on this standard be delayed until such time as adequate tools be developed and made available.

However, if draft Reliability Standard MOD-027-1 continues through the drafting process and is ultimately successfully balloted, the effective date should be delayed for 2 years, with the requirements phased in over at 20% per year over the next 5 years.

PRC-019-1: Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection

The GSFT-TF developed Field Test Guidelines that addresses each of the proposed NERC Reliability Standard Requirements in PRC-019-1. Five SERC Generator Owners actually performed the activities detailed in the completed SERC Field Test Guidelines. The GSFT-TF believes these activities would constitute compliance with the proposed PRC-019-1 NERC Reliability Standard as currently drafted.

One Generator Owner has been performing these unit coordination studies a number of years. Out of roughly 65 generating units reviewed, only one case of marginal coordination was identified. Prior to the Field Tests, the other entities had limited experience. The other Generator Owners initiated new processes, utilizing the Field Test Guidelines for direction. In all cases, the Generator Owners reported significant startup costs in both manpower and capital costs. Selection of tools, and obtaining equipment limit characteristics from vendors proved to be manpower intensive. No miscoordinations were identified by the other entities participating in this field test. The GSFT-TF estimates this could cost as much as $16 million to meet these requirements for all the applicable generating units in the SERC region. However, even with the high costs the GSFT-TF agrees that this is a beneficial standard.

The GSFT-TF discussed and noted that it may be difficult to obtain start-up test data on older generators, and that re-performing those tests would be a high cost and significant effort. The GSFT-TF agreed that there should be an exemption for older generators. Other GSFT-TF comments, as detailed in the referenced “Redlined” standard, include:

1) In addition to older generators, all units below 75 MVA or interconnected at voltages less than 100 kV should generally be exempt
2) The prime mover limit should be removed as a required plot characteristic – it hardly ever refers to a true physical limit. It is more appropriate to relate this to the MW capability determined in MOD-024.
3) The requirement to plot additional limits that restrict the MW or Mvar capability should be removed as this is an ambiguous requirement
4) The Generator Owner should retain the latest coordination study and provide it to the Compliance Monitor upon request.

The GSFT-TF agrees that this standard should be phased in at 20% per year.

PRC-024-1: Generator Performance during Frequency and Voltage Excursions

The GSFT-TF developed Field Test Guidelines that addresses each of the proposed NERC Reliability Standard Requirements in PRC-024-1. Three SERC entities, consisting of three GOs and two TOs, attempted to perform the activities detailed in the completed SERC Field Test Guidelines.

The task of determining coordination with the SERC draft frequency excursion curve shown in the PRC-024 Field Test Guidelines was a relatively simple task. Coordination of this curve with UFLS relays has been accomplished in past and an ongoing SERC UFLS study. Ignoring tool startup costs, coordination with generator turbine under frequency protective relays was also relatively simple for two of the GOs. The other GO reported that they have plant procedures in place to manually trip the unit if the frequency drops below thresholds which do not coordinate with the SERC draft frequency excursion curve. The GO went on to state that upon further review, they could alter their plant procedures to coordinate with the draft frequency excursion curve without compromising the unit.

The task of determining coordination with the SERC draft LVRT curve was a more daunting task. Plant auxiliary UV relays did not pose a risk of operating for the SERC draft LVRT characteristic. Utilizing steady state techniques with some simplifying assumptions, such as relaxation of steady state Mvar limits, suggested that generator back up impedance relays would not be able to ride through this characteristic. However, one TO utilized dynamic simulations to approximately create the LVRT characteristic through a small bus dynamic case and found that the back up impedance relay would not be expected to operate for the LVRT excursion. The reason why the steady state evaluation produced an incorrect solution was due to the inherent absence of the exciter time constants and exciter ceiling limits.

Based on reviewing the dynamic simulations, the LVRT characteristic should be changed from fault clearing time until one second should be raised from 0.4 to 0.5 per unit. This is required to provide adequate margin from unit transient instability.

The GSFT-TF understands that in order for Transmission Planners to be able to design UF and/or UV safety net schemes, assumptions regarding the UF and LVRT have to be made. Therefore, there is a reliability need to assess the expected ride through capability of units. However, the draft Reliability Standard as written does not address all of the plant systems that could be limiting factors in ride through capability. The GOs have serious concerns regarding the LVRT capability of systems required for operation of generating plants. Coordination of unit protection systems with the LVRT requirements alone will not guarantee the unit will always remain on-line. For example, Boiler Control Systems, systems unique to Nuclear Power Plants, and station service loads will impact ride through capability. The GOs believe that due to the complexity of these systems it is not possible to ensure a generating plant can survive every event. These topics are discussed in more detail in Attachment 6,

The issue of ride through characteristics for generators, especially LVRT, is evolving throughout the industry. The GSFT-TF experience in the field test shows that additional work is required before an effective NERC Reliability Standard can be developed. The GSFT-TF recommends that a process be put in place for additional research into these areas.

SERC Field Test Guidelines

Verification of Models and Data for Generator Excitation System Functions

NERC Reliability Standard MOD-026

SERC Reliability Corporation

Revision History

Revision	Date	Comments
0	October 10, 2006	GSFT-TF finalized SERC MOD-026-1 Guideline for Field Test purposes.
1	January 11, 2007	Revised Attachment 2

Responsible SERC Subgroup & Region Review Group

The Generator Standard Field Test Task Force (GSFT-TF) has been tasked by the Engineering Committee to develop these field test guidelines and to provide assistance to SERC volunteer members. Responsible SERC Subgroup(s) and the Regional Review Group would be assigned only after the successful ballot and NERC B.O.T adoption of draft NERC Reliability Standard MOD-026.

Review and Re-Certification Requirements

Not applicable until the successful ballot and NERC B.O.T adoption of draft NERC Reliability Standard MOD-026.

Effective Dates:

Not applicable until the successful ballot and NERC B.O.T adoption of draft NERC Reliability Standard MOD-026.

List of Attachments

Attachment 1: NERC Reliability Standard MOD-026
Attachment 2: Excitation System Questionnaire

I. Introduction/ Purpose

In order to effectively evaluate the electric system's performance, the accuracy of data for the interconnected transmission network and the associated generating equipment is critical. Accordingly, valid data reflecting generator excitation systems are essential for performing planning and operating studies to assess or evaluate the reliability of the electric system.

This SERC field test guideline for the NERC Reliability Standards MOD-026 is intended to:

1) Provide guidance for SERC Generator Owners/Operators to address verification of generator excitation system, power system stabilizers models, and excitation limit controls.
2) Document the GSFT-TF recommended exemption criteria and sister unit philosophy.
3) Document the GSFT-TF recommended Configuration Controls.

II. Definitions

1. **Confirm (–ed, –ation) –** To assure that plant or equipment conditions (including control settings) that would impact previously provided data has not changed.

2. **Exempt Generation –** Generator(s) that meets the exemption criteria for a particular Validation/test requirement.

3. **Validate (-dated, -dation)** – To establish the accuracy of data used to model electrical equipment. Validation may be achieved through simulation, operating data, field readings, engineering evaluations or reviews, use of manufacturer data, commissioning data, performance tracking, and/or testing where appropriate.

4. **Verify (Verification)** – To establish through Validation or Confirmation.

5. **Standard Model (or Model) –** A model included with the Power System Simulator, Power Technologies, Inc. (PSS/E) dynamic simulation software. Many Institute of Electrical and Electronics Engineers, Inc. (IEEE) models are included in the standard PSS/E models. Complete model information includes both the name of the Standard Model and the value of each parameter.

III. Requirements/Expectations

A. Generator Exemption Criteria [*Ref.MOD-026, R1.1*]

In order to maximize the efficiency of generator testing, it is prudent to exempt generators that are believed to have less significant impact on the reliability of the bulk electric system from data Validation requirements. The exemption criteria specified by these guidelines are based on both the operating voltage of the bulk power system to which the generator is interconnected, and the MVA rating of the generator. When referring to the MVA rating of the generator, at facilities where multiple machines and/or prime movers are required for normal unit operation, the MVA rating refers to the total MVA capacity of the facility. Examples of this include combined cycle or cross compound units.

As documented in the NERC Glossary of Terms, the NERC Board of Trustees approved a definition for the bulk electric system on February 8, 2005 as follows:

> "As defined by the Regional Reliability Organization, the electrical generation resources, transmission lines, interconnections with neighboring systems, and associated equipment, generally operated at voltages of 100 kV or higher. Radial transmission facilities serving only load with one transmission source are generally not included in this definition."

Therefore, for generators interconnected to a power system operated at a voltage of less than 100 kV, Validation is not required. Inasmuch as possible, models and model parameters should be based on the most accurate information available from sources such as the manufacturer, calibration and maintenance records and field inspection (i.e., estimated parameters).

Generators with a nameplate rating less than or equal to 75 MVA or that are not connected to the bulk power system are exempt.

Table 1 summarizes the Generator Exemption Criteria.

Generator Interconnected kV or MVA Size	Validated Models & Data Required
< 100 kV	No
≥ 100kV & ≤ 75 MVA	No
≥100kV & > 75 MVA	Yes

Table 1: Generator Exemption Criteria

B. Sister Unit/Equipment Validation Guidelines

Some units have equipment with the same characteristics such that they respond the same as equipment of other units. If it can be demonstrated that the units, equipment, or systems have identical designs, identical major components and identical significant control system settings, then the units can be considered sisters in regard to that equipment or system. In those situations, an assumption can be made for a sister unit by Validating the excitation system (and PSS system as appropriate) model for one (sample) unit. Equipment or systems that do not impact the equipment or system to be Validated need not be identical. Units that are sisters in one regard may not be sisters for other equipment or systems to be Validated. Documentation must exist to demonstrate that the information about the sample unit can be applied to a sister unit. In future Validations, a different sister unit shall be selected to eventually verify that the sister approach was valid.

C. Configuration Controls

The Generator Owner shall implement a program intended to ensure the condition of the excitation controls (Automatic Voltage Regulator, Limiters, and Power System Stabilizer) remains consistent with the state of the equipment when the latest model Verification was performed. This will normally be performed during a major generator outage, or when setting changes are implemented. [Ref.MOD-026, R1.4.6]

There are several programmatic alternatives that are considered adequate for assuring the generator excitation system models accurately reflect the response of the field equipment. The alternatives are:

1. Periodically repeating the baseline testing and simulation comparisons to assure the model parameters submitted for dynamic simulations are accurate.
2. With the appropriate data collection equipment and excitation system modeling expertise available, the generator owner may want to Validate the model by alternate means.
3. If analog control equipment owners regularly calibrate their controls and have documented excitation system parameters at the time of the baseline test, then future calibration activities can be conducted with the goal of maintaining excitation system parameters in the as-modeled state. This assures and documents that the excitation system modeling parameters are still consistent with the Validated baseline model parameters.
4. For digital excitation systems , once baseline parameters are established through testing, future Validation activities shall consist of ensuring any components that may drift (such as A/D converters) are properly calibrated and ensuring the control system parameters have not changed from the baseline data.
5. In general, hybrid excitation systems (excitation systems that contain both analog and digital subsystems), should be treated as analog control systems.

D. Excitation System Classification:

The generator owner shall provide the Planning Authority and/or Transmission Planner the following excitation system classification information (see Attachment 2) [*Ref.MOD-026, R1.4.1*]:

1. Manufacturer and Type of Excitation System. Examples of excitation system types are static, brushless, alternator rectifier, motor driven dc exciters, etc
2. Manufacturer and Type of Voltage Regulator.

E. Regulator and Excitation Control Systems

1. General Requirements *[Ref.MOD-026, R1.4.2]*

a) The Generator Owner shall provide an appropriate automatic voltage regulator and excitation system Standard Model and associated parameters. The Transmission Planner shall provide assistance in selection and Validation of this Standard Excitation Model[1].

b) The Generator Owner shall provide reactive current or line drop compensation settings where applicable. *[Ref.MOD-026, R1.4.4]*

c) The Generator Owner shall provide open circuit step test data necessary for Validation of the model for the excitation control system.

d) The Transmission Planner will perform a simulation of the open circuit test using the modeling data provided in sections a, b, and c above to verify the generator excitation system model.

e) Due to nuclear licensing requirements and concerns, Transmission Planners and Generator Owners shall coordinate any required studies, assessment, and / or testing of the generator excitation systems that could adversely impact the capacity and/or the capability of the nuclear plant off-site sources and nuclear plant safety.

2. Specific Requirements *[Ref.MOD-026, R1.2]*

a) Validation Process
Adequate Validation requires a baseline model to be established in conjunction with an Open Circuit Step Response (OCSR) test. (Note: Data from an OCSR test itself does not constitute the model, but can be used to adjust the model parameters until the simulation results closely match the OCSR response.) This test consists of collecting data (for data points, see below) on the generator performance during transients when a step in the voltage reference is introduced.

[1] Many times, dynamic simulation software manufacturers wait until a model is approved by IEEE before including it within the library of models provided with the software. Therefore, there can be a significant time lapse between installation/use of something that requires a model and the availability of a Standard Model. Until such time as new models are added to the Transmission Planners' model library, a Standard Model that most closely approximates the actual response shall be used. User Defined Models are usually complicated and troublesome to incorporate into the regional and interregional dynamics databases, and therefore they shall only be used in extraordinary situations

Good correlation between the model and the OCSR test must be achieved. Otherwise, the model along with other variables that affect exciter response must be re-examined.

b) Data Points Required for Validation Tests *[Ref.MOD-026, R1.4.5]*
The following data points shall be monitored for Validation. If signal transducer outputs are used for data collection, any time lags introduced by the transducer must be accounted for in the model Validation process. Otherwise, the response of the transducer output may be inappropriate for model Validation. The test parameters are:

1.) Generator Voltage
2.) Field Voltage (Generator and/or Exciter as appropriate)
3.) Field Current (Generator and/or Exciter as appropriate)
4.) Step input (for voltage step test)

Note, the magnitude of the step input (generally expressed as a percentage of the generator voltage) shall be stated, but shall be no less than 1%. See sample test data below. Some recording equipment allows both graphical and tabular data formats. These data collection systems are preferred since one can visually see the results and can use the tabular data for comparison with simulated results to aid in the validation process.

F. Power System Stabilizers

1. General Requirements *[Ref.MOD-026, R1.4.6]*

All units that have commissioned Power System Stabilizers (PSS) must submit a Validated Standard Model. The Standard Model will normally be Confirmed during a major outage, or when setting changes are implemented. *[Ref.MOD-026, R1.3]*

2. Specific Requirements *[Ref.MOD-026, R1.2]*

a) Units commissioning new PSSs will supply the Transmission Planner applicable test results provided upon commissioning. This includes results of the Gain Margin test, Phase Compensation test, and on-line step in voltage tests with and without the PSS in service.

b) Units that have previously commissioned PSSs will supply the Transmission Planner applicable test results provided from the initial commissioning, if available, including the results of the Gain Margin test, Phase Compensation test, and on-line step in voltage tests with and without the PSS in service. If the aforementioned tests are not available, the Transmission Planner may grant the Generator Owner the option of providing a PSS tuning study report along with field verification of the exciter and PSS settings.

c) Where appropriate, the Standard Model data can be described by block diagrams and/or tables, based on standard IEEE or PSS/E type models.

d) The Phase Compensation Test must include a gain and phase shift Bode plot for the excitation system with and without the stabilizer. Each Bode plot must be formatted as follows:

1) Semi-log type chart
2) Gain magnitude expressed in decibels
3) Phase shift expressed in degrees
4) Frequency expressed in Hertz, typically 0.01 – 5.0 Hz log scale

G. Excitation Limit Controls

1. General Requirements *[Ref.MOD-026, R1.3]*

a) Data concerning excitation limit controls must be submitted for all units. Updated data must be submitted to the Planning Authority and/or Transmission Planner each time changes are made that could affect the limits (such as upgrades and replacements). This data shall be Confirmed during a major generator outage, or when setting changes are implemented.

b) For new or refurbished systems, design data obtained from the vendor and submitted at the time of requisition is sufficient until such time as more accurate data (from commissioning/acceptance testing) can be obtained and submitted to the Transmission Planner.

2. Specific Requirements *[Ref.MOD-026, R1.2 & R1.4.3]*

a) Verification of setpoints may be performed for most of the regulator systems with the generator shutdown by providing simulated inputs (such as PT and CT) of the appropriate magnitude and phase angle and assuring that the regulator responds appropriately when the limit is reached.

b) Underexcition Limiter setpoints could also be checked by lowering excitation with the unit on line until the limiter prevents any further decrease in excitation.

c) If data is retrievable, calibration or maintenance data such as field measurements may be used to calculate limiter characteristics instead of a separate test.

Attachment 1

NERC Reliability Standard MOD-026

A. Introduction

1. **Title:** **Verification of Models and Data for Generator Excitation System Functions**
2. **Number:** MOD-026-1
3. **Purpose:** To ensure accurate information on generator excitation system functions (including voltage regulator controls, limiters, compensators, and power system stabilizers, if applicable) is available for models used to assess Bulk Electric System reliability.
4. **Applicability**
   - **4.1.** Regional Reliability Organization.
   - **4.2.** Generator Owner.
5. **Proposed Effective Date:** To be determined.

B. Requirements

R1. The Regional Reliability Organization shall establish and maintain procedures to address verification of models and data associated with generator excitation system functions including voltage regulator controls, limiters, compensators, and power system stabilizers. These procedures shall include the following:

R1.1. Generating unit exemption criteria including documentation of those units that are exempt from a portion or all of these procedures.

R1.2. Acceptable methods for model and data verification, including any applicable conditions under which the data should be verified. Such methods can include use of manufacturer data, commissioning data, performance tracking, engineering analysis, field verification of equipment settings, testing, simulation and comparison with test results or disturbance monitoring data, etc.

R1.3. Periodicity and schedule of verification and reporting, including a list of report recipients, schedules associated with field changes to existing units, and refurbished units.

R1.4. Information to be reported related to generator excitation system functions:

R1.4.1. Verified manufacturer and type of excitation system/voltage regulator control system (for example, static, brushless, rotating, etc.).

R1.4.2. Verified model for each excitation system/voltage regulator control system with associated gains, time constants, and limits.

R1.4.3. Verified static set points for under and over excitation limiters.

R1.4.4. Verified line drop compensator settings.

R1.4.5. Open circuit test response data showing generator field voltage and generator terminal voltage (exciter field voltage and current data for brushless units).

R1.4.6. Verified model for each power system stabilizer with associated gains, time constants, and limits.

R1.4.7. Confirmation that the verification was conducted with the voltage regulator in the automatic voltage control mode

R1.4.8. Method of verification used.

R1.4.9. Date of verification.

R2. The Regional Reliability Organization shall provide its generator excitation system data verification and reporting procedures, and any changes to those procedures, to the Generator Owners, Generator Operators, Transmission Operators, Planning Authorities, and Transmission Planners affected by the procedure within 30 calendar days of the approval.

R3. The Generator Owner shall follow its Regional Reliability Organization's procedures for verifying and reporting its models and data associated with generator excitation system functions per MOD-026 R1.

C. Measures

M1. The Regional Reliability Organization shall have available for inspection a procedure for the verification and reporting of models and data associated with its generator excitation system functions in accordance with MOD-026 R1.

M2. The Regional Reliability Organization shall have evidence that its procedure for verification and reporting of generator excitation system data, and any revisions to that procedure were provided to affected Generator Owners, Generator Operators, Transmission Operators, Planning Authorities, and Transmission Planners within 30 calendar days of approval.

M3. The Generator Owner shall have evidence it provided verification of the models and data associated with its generator excitation system functions, consistent with the Regional Reliability Organization procedure.

4. Provide the open circuit test data (plots), appropriate voltage regulator and excitation system Standard Model and associated parameters, and documentation/plots showing good correlation between model simulation and OCSR test results.

5. If the unit is equipped with a commissioned PSS, provide the data required in III.F.2.

6. Provide the data required in III.G.2 on Excitation Limit Controls.

MOD-026 SERC Field Test Reporting Form

The purpose of this form is to provide a consistent report format for field testing results after using the SERC Field Test Guideline "Verification of Models and Data for Generator Excitation System Functions". Documentation of the test results will provide feedback showing that the field test was successful and/or will help to enhance the test guideline.

Use the attached SERC Field Test Guideline "Verification of Models and Data for Generator Excitation System Functions" to perform the test (engineering study). Complete one (1) report form for each unit tested.

Provide the following information:

1. How long did it take to perform an Open Circuit Step Response (OCSR) test and collect the relevant data (generator voltage, field voltage and field current) in order to validate the exciter model?
   - Pre-Test Planning & Preparation : ________ Hours
   - Setup of Test Equipment: ________ Hours
   - Time to Prepare Unit for Test: ________ Hours
   - Performance of Test and Data Collection: ________ Hours
2. How long did it take to analyze the test data and get a good correlation between exciter model and the OCSR test? ________ Hours
3. Was a good correlation between the exciter model and the OCSR test obtained? (Yes or No)

   If no please attach additional information as appropriate.
4. What was the magnitude of the step input applied? ________________________
5. List any material costs associated with this testing.

   ____
   ____
6. Were set points (overexcitation and underexcitation) verified on the voltage regulator (Yes or No). If no, please attach additional information as appropriate.
7. Please list any suggested changes to the guideline?

   ____
   ____
   ____
8. Provide a completed Attachment # 2 to the SERC Field Test Guidelines for Verification of Models and Data for Generator Excitation System Functions (MOD-026).
9. Name of the person completing the form:________________ Phone Number_________ Company Name_______________

Send the completed report form, plots, models and documentation to **phuntley@serc1.org**

SERC Field Test Guideline

Verification of Generator Unit Frequency Response

NERC Draft Reliability Standard MOD-027

SERC Reliability Corporation

Revision History

Revision	Date	Comments
0	March 2, 2007	GSFT-TF finalized SERC MOD-027-1 Guideline for Field Test purposes.

Responsible SERC Subgroup & Region Review Group

The Generator Standard Field Test Task Force (GSFT-TF) has been tasked by the Engineering Committee to develop these field test guidelines and to provide assistance to SERC volunteer members. Responsible SERC Subgroup(s) and the Regional Review Group would be assigned only after the successful ballot and NERC B.O.T adoption of draft NERC Reliability Standard MOD-027.

Review and Re-Certification Requirements

Not applicable until the successful ballot and NERC B.O.T adoption of draft NERC Reliability Standard MOD-027.

Attachment 2: Sample Reporting Form: Turbine and Governor (Speed/Load) Controls Questionnaire
Attachment 3: Definitions of Unit Frequency Response

I. Introduction

In order to effectively evaluate the electric system's performance, the accuracy of data for the interconnected transmission network and the associated generating equipment is critical. This document addresses one such item, generating unit frequency response and associated model data. For dynamic planning and operating studies with a time frame of 0 to 60 seconds, unit frequency response of hydro and conventional fossil steam generating units is primarily influenced by the turbine governor system. Thus, valid models for these type units should focus on the governor system. For combustion turbine based generation (CTs and Combined Cycle), unit frequency response for 0 to 60 seconds can be influenced by both the governor system, if active for frequency control, and other plant control systems such as combustion turbine firing temperature controls, etc. Thus, the development of valid models for these units may require additional control functions. Nuclear generating units typically do not provide a frequency response since their governor systems are generally inactive or insensitive regarding frequency control. If this is the case, the development of valid models for those units is not necessary.

This SERC field test guideline for the NERC Reliability Standards MOD-027 is intended to:

1) Provide guidance for SERC Transmission Planners and Generator Owners/Operators to address verification of generator unit frequency response.
2) Document the GSFT-TF recommended exemption criteria and sister unit philosophy.
3) Document the GSFT-TF recommended Configuration Controls.

After this field test has been completed, and if MOD-027 Reliability Standard is approved and implemented, the GSFT-TF recommends that SERC develop a regional procedure identifying future events for which data should be collected and evaluated by SERC members.

II. Definitions

1. **Confirm (–ed, –ation) –** To assure that plant or equipment conditions (including control settings) that would impact previously provided data has not changed.

2. **Exempt Generation –** Generator(s) that meets the exemption criteria for a particular Validation/test requirement.

3. **Validate (-dated, -dation)** – To establish the accuracy of data used to model electrical equipment. Validation may be achieved through simulation,

operating data, field readings, engineering evaluations or reviews, use of manufacturer data, commissioning data, performance tracking, and/or testing where appropriate.

4. **Verify (Verification)** – To establish through Validation or Confirmation.

5. **Standard Model (or Model) –** A model included with the Power System Simulator, Power Technologies, Inc. (PSS/E) dynamic simulation software. Many Institute of Electrical and Electronics Engineers, Inc. (IEEE) models are included in the standard PSS/E models. Complete model information includes both the name of the Standard Model and the value of each parameter.

III. Requirements/Expectations

A. Generator Exemption Criteria [Ref.MOD-027, R1.2]

In order to maximize the use of resources, it is prudent to exempt generators that are believed to have less significant impact on the reliability of the bulk electric system from data Validation requirements. The exemption criteria specified by these guidelines are based on both the operating voltage of the bulk power system to which the generator is interconnected, and the MVA rating of the generator. When referring to the MVA rating of the generator, at facilities where multiple machines and/or prime movers are required for normal unit operation, the MVA rating refers to the total MVA capacity of the facility. Examples of this include combined cycle or cross compound units.

As documented in the NERC Glossary of Terms, the NERC Board of Trustees approved a definition for the bulk electric system on February 8, 2005 as follows:

> "As defined by the Regional Reliability Organization, the electrical generation resources, transmission lines, interconnections with neighboring systems, and associated equipment, generally operated at voltages of 100 kV or higher. Radial transmission facilities serving only load with one transmission source are generally not included in this definition."

Therefore, for generators interconnected to a power system operated at a voltage of less than 100 kV, Validation is not required. Inasmuch as possible, models and model parameters should be based on the most accurate information available from sources such as the manufacturer, calibration and maintenance records, field inspection (i.e., estimated parameters), and event data.

Generators with a nameplate rating less than or equal to 75 MVA or that are not connected to the bulk power system are exempt. Table 1 summarizes the Generator Exemption Criteria.

Table 1:

Generator Interconnected kV or MVA Size	Validated Models & Data Required
< 100 kV	No
≥ 100kV & ≤ 75 MVA	No
≥100kV & > 75 MVA	Yes

Generator Exemption Criteria

B. Sister Unit/Equipment Validation Guidelines

Some units have equipment with the same characteristics such that they respond the same as equipment of other units. If it can be demonstrated that the units, equipment, or systems have identical designs, identical major components and identical significant control system settings, then the units can be considered sisters in regard to that equipment or system. In those situations, an assumption can be made for a sister unit by Validating the unit frequency response model for one (sample) unit. Equipment or systems that do not impact the equipment or system to be Validated need not be identical. Units that are sisters in one regard may not be sisters for other equipment or systems to be Validated. Documentation must exist to demonstrate that the information about the sample unit can be applied to a sister unit. In future Validations, a different sister unit shall be selected to eventually verify that the sister approach was valid.

C. Configuration Controls

The Generator Owner shall implement a program intended to insure the condition of the unit frequency response system (speed / load control system) remains consistent with the state of the equipment when the latest model Validation was performed. This will normally be performed during a major generator outage, or when setting changes are implemented. [Ref.MOD-027, R1.3]

Turbine-Generator speed/load governor systems consist of:

1) a speed signal from the TG
2) a speed load governor controller
3) mechanical (usually hydraulic) actuators and valves (or gates on hydro units)

In general, the speed signal and mechanical portion of the system are not modified unless the overall governor system is being modified. Thus, Configuration Controls do not apply to these two subsystems. The speed load governor controller may vary widely between units due to vintage, retrofit or component modification and thus is the primary focus in the Configuration Controls. The following addresses the key aspects of a Configuration Controls program for the speed load governor controller portion of the system. In cases where the controller is being replaced, the speed/load governor system should be treated like a new governor.

1. Periodically repeating the event based model Validation described in Section D.2 (post-mortem simulation of specific event(s) using dynamics models to validate turbine governor and associated control systems parameters) to assure the existing model parameters for dynamic simulations are accurate.

2. Due to their design, the response of a Mechanical Hydraulic Control (MHC) system is not easily adjustable and thus if properly maintained (replacement of deteriorated components), it is not subject to appreciable performance changes. Thus, no specific Configuration Controls process is necessary.

3. For analog based governor controllers (Electro Hydraulic Control - EHC systems), the Configuration Controls process should consist of a maintenance program that includes regular calibration of the controller to

conform to baseline data (typically previous calibration data) that was used in the previously governor model Validation process described in Section D.2

4. For digital based governor controllers (Digital Electro Hydraulic - DEH systems), the Configuration Controls process should consist of a maintenance program that includes regular calibration of any components that are subject to drift (such as A/D converters) and verification that the configuration files are the same as those utilized in the original Validation activities.

These activities should assure and document that the unit frequency response system modeling parameters are still consistent with the validated baseline model parameters.

D. Turbine and Governor (Speed/Load) Controls [Ref. MOD-027, R1]

1. General Requirements

a) Generator Owners will submit to their Transmission Planner an appropriate speed/load control system Standard Model with associated parameters (based on the most accurate information available from sources such as the manufacturer, calibration and maintenance records, field inspection, operating data and engineering evaluations or reviews) and the Attachment 2 reporting form for each generating unit. The Generator Owner and the Transmission Planner may need to coordinate to determine which Standard Model to use. (Ref.MOD-027, R1.5.1)

b) As detailed in D.2., an event based approach to Validate generator unit frequency response will be utilized.

c) For each new or modified speed/load control system, a Standard Model (based on as-built parameter information available from the vendor) must be submitted in addition to the Attachment 2 questionnaire. The model based on this design data is sufficient until more accurate data (from event analysis or commissioning/acceptance testing) can be obtained and submitted to the Transmission Planner. The Generator Owner and the Transmission Planner may need to coordinate to determine which Standard Model applies and/or what data should be provided. (Ref.MOD-027, R1.4)

d) If there are typical operating modes that have different control parameters, a model must be provided for each mode.

e) Standard Models and/or parameters must be Validated each time changes are made that could affect the model such as upgrades and replacements or Confirmed at least every five years. (Ref.MOD-027, R1.4)

f) SERC shall provide its frequency response verification and reporting procedures, and any changes to those procedures, to the Generator Owners, Generator Operators, Transmission Operators, Planning Authorities, and Transmission Planners affected by the procedures within 30 days of approval. (Ref.MOD-027, R2)

g) The Generator Owner and Transmission Planners shall follow the SERC procedure for verifying and reporting its generator unit frequency response. (Ref.MOD-027, R3)

2. Specific Requirements

An event based approach will be utilized to Validate unit frequency response for each applicable generator. Generator response data for specific frequency excursion event(s) will be compared to the unit frequency response predicted by the Standard Models. Validation of the unit frequency response system is achieved by adjusting (if necessary) the turbine governor and associated control systems parameters[1] in the Standard Model until good correlation with the captured event(s) data is obtained. [Ref.MOD-027, R1.3]

a) Speed/load control system response must be Validated with underfrequency event data. In order for event data to be suitable for Validation, the data must

- Record generator electric power and local system frequency
- Record a frequency drop to 59.96 Hz or below (resolution 0.01 Hz)
- Have a generator power resolution of 1% of the generator Continuous Capability
- Record data every 4 to 6 seconds, or more frequently
- Record data for at least 60 seconds, or more depending on the timeframe of the response

b) Generator event data required is unit MW output versus time. This data may be obtained from SCADA systems, data loggers, excitation/governor event capturing systems, dedicated monitoring systems or test instrumentation.

[1] As reference see Pereira, Undrill, Kosterev, Davies and Patterson, “A New Thermal Governor Modeling Approach in the WECC,” IEEE Trans. Power Syst., vol 18, pp 819-829, May 2003 and other documents located on the WECC website for the Modeling and Validation Work Group (MVWG) at http://www.wecc.biz/committees/PCC/TSS/MVWG/documents/index.html

c) PSS/E dynamic simulation software will be used by SERC for the NERC Field Test activity of Validating the generator's speed/load control models:

1. A loadflow consisting of a large (MVA) unit representing Eastern Interconnection (EI), a large EI load, the unit whose speed/load model is to be Validated, and any other transmission system elements required to replicate the event will be modeled. The loadflow is expected to have ten or less buses.
2. Transmission system frequency versus time event data will be examined as part of the validation process
3. After creating the dynamic "snap" but before compiling and linking the dynamics executable, "flecs" code will be inserted in the "conec" file. The code will alter the mechanical power of the large EI machine. The result is that the large EI machine will speed up or slow down accordingly, thus changing system frequency to reasonably match the event data.
4. The resulting unit MW versus time output produced by the model will be compared to the actual unit MW versus time output captured by the event data. If good correlation[2] is obtained, Validation of the model is complete. If good correlation is not obtained, the following courses of action should be considered:
   i. Modify the parameters of the unit's existing speed/load model and repeat the Validation process.
   ii. A new model with new parameters could be developed.
   iii. The Generator Owner could investigate why good correlation was not obtained, which could result in refining the unit's frequency response controls
5. Care should be taken to consider more than one frequency excursion event before implementing an updated model into the dynamics database.

d) When Validating the generator power output response of an event simulation with actual recorded event data, the response time to be modeled should be 60 seconds, regardless of unit type. If compromises have to be made in the selection of model parameters, there should be emphasis on selecting parameters that best replicate the generator power output response during the first 30 seconds of the event. (Ref.MOD-027, R1.1).

e) It is recognized by the GSFT-TF that other stand alone software programs could be used to replicate a transmission system frequency

[2] As part of the field test activities efforts will be made to quantify "good correlation."

excursion and subsequently Validate generator unit speed/load control models. The GSFT-TF investigated and determined that PSLF ™, EMTP ™, and MAT LAB ™ software programs could be used for this activity. Therefore, upon the successful ballot and NERC B.O.T and FERC adoption of draft NERC Reliability Standard MOD-027, the GSFT-TF would advise SERC that the aforementioned and other commercially available software tools could be utilized to fulfill the applicable NERC requirements.

f) Reporting

A record of the most recent Validation including information specified in NERC Reliability Standard MOD-027-1 R1.5.1 – R.1.5.4 on each generator shall be maintained by the Validating party and reported to SERC or NERC within 30 days of the request. (Ref.MOD-027, R1.4, R1.5.1 - R1.5.4)

g) Examples

Attachment 3 refers to several types of turbine - governor controllers.

Attachment 1

A. Introduction

1. **Title:** **Verification of Generator Unit Frequency Response**
2. **Number:** MOD-027-1
3. **Purpose:** To provide verification of generator unit frequency response (other than Automatic Generation Control) for use in models for reliability studies.
4. **Applicability**
   - **4.1.** Regional Reliability Organization.
   - **4.2.** Generator Owner.
5. **Proposed Effective Date:** To be Determined.

B. Requirements

R1. The Regional Reliability Organization shall establish and maintain procedures to address verification of generator unit frequency response. These procedures shall include the following:

- **R1.1.** Response time to be modeled, e.g. up to 30 seconds for steam units, up to 45 seconds for hydro units, etc.
- **R1.2.** Generating unit exemption criteria including documentation of those units that are exempt from a portion or all of these procedures.
- **R1.3.** Acceptable methods for model and data verification, including any applicable conditions under which the data should be verified. Such methods can include use of manufacturer data, commissioning data, performance tracking, engineering analysis, field verification of equipment settings, testing, simulation and comparison with test results or disturbance monitoring data, etc.
- **R1.4.** Periodicity and schedule of verification and reporting, including a list of report recipients, schedules associated with field changes to existing units, and refurbished units.
- **R1.5.** Information to be reported related to generator unit frequency response:
  - **R1.5.1.** Verified manufacturer and type of speed governor controls.
  - **R1.5.2.** Verified model for each speed governor control with any associated deadband, gains, time constants, and limits (e.g., maximum valve opening velocity, maximum capability of the turbine, etc.).
  - **R1.5.3.** Verified frequency response data of the unit, considering additional plant controls that affect the response of the unit (blocked or nonfunctioning governors or modes of operation that limit frequency response).
  - **R1.5.4.** Method of verification and conditions of the verification including status of controls.

R2. The Regional Reliability Organization shall provide its frequency response verification and reporting procedures, and any changes to those procedures, to the Generator Owners, Generator Operators, Transmission Operators, Planning Authorities, and Transmission Planners affected by the procedures within 30 calendar days of the approval.

R3. The Generator Owner shall follow its Regional Reliability Organization's procedure for verifying and reporting its generator unit frequency response per MOD-027 R1.

Attachment 1

C. Measures

M1. The Regional Reliability Organization shall have available for inspection a procedure for verifying and reporting generator unit frequency response in accordance with MOD-027 R1.

M2. The Regional Reliability Organization shall have evidence that its procedure, and any revisions to that procedure, for verification and reporting generator unit frequency response was provided to affected Generator Owners, Generator Operators, Transmission Operators, Planning Authorities, and Transmission Planners within 30 calendar days of approval.

M3. The Generator Owner shall have evidence it provided verification of the models and data associated with generator unit frequency response, consistent with the Regional Reliability Organization procedure.

Attachment 2

- ☐ PTI Standard Model with Estimated Parameters
- ☐ PTI Standard Model with Parameters derived from event(s) based Validation(s)

Droop Setting (%): ____________

Attachment 3

Definitions of Unit Frequency Response

Steam units may operate in several modes, but for modeling these three will be considered:

Baseload –	Operating at or near maximum output
Setpoint Control –	Operating such that other controls will override automatic action of the governor. Typically the setpoint is related to load and temperature limits.
Responsive –	Operating with typical governor control without other automatic override controls.

Based on the above information and the diagram below, the type of turbine – governor response for thermal units is defined:

<table>
<tr><td></td><td>Thermal</td><td></td><td>Examples†</td></tr>
<tr><td></td><td>Type UC</td><td>Unresponsive, baseload unit (very quickly returns to near baseload after an initial response)</td><td></td></tr>
<tr><td></td><td>Type FC</td><td>Fast controller, shorter response (quickly returns to near baseload)</td><td></td></tr>
<tr><td></td><td>Type SC</td><td>Slow controller, longer response (responds for a short time, then returns to near baseload)</td><td></td></tr>
<tr><td></td><td>Type NC</td><td>No controller, responsive</td><td></td></tr>
</table>

† Just to illustrate what each type may look like, some example charts are given. The event is assumed to occur at 10 seconds and a hypothetical change in generator output is depicted.

Gas turbine units are divided into two categories:

	Gas	
	Type GL	with load controller
	Type GN	no load controller

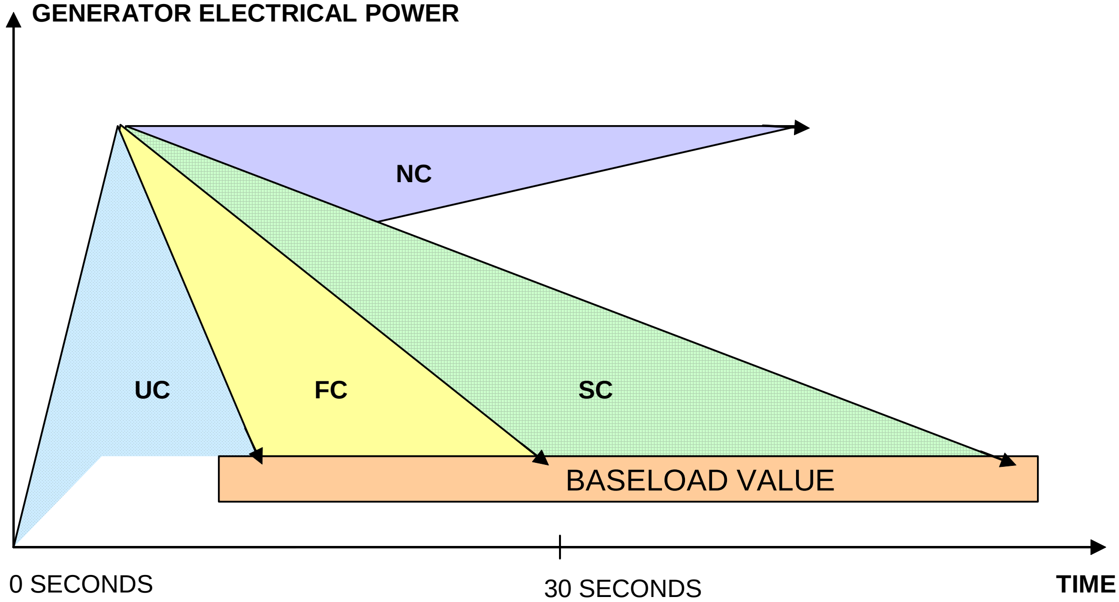

Figure A3-1, General characteristics of each type of turbine – governor response

MOD-027 SERC Field Test Reporting Form

The purpose of this form is to provide a consistent report format for field testing results after using the SERC Field Test Guideline "Verification of Generator Unit Frequency Response". Documentation of the test results will provide feedback showing that the field test was successful and/or will help to enhance the test guideline.

Use the attached SERC Field Test Guideline "Verification of Generator Unit Frequency Response" to perform the test (engineering study). Complete one (1) report form for each unit tested.

Provide the following information:

1. Is there a maintenance management program in place for the turbine speed load governor control system (analog and/or digital based)? (Yes or No)
   - If yes, what is the maintenance interval? (months)
2. Is there a configuration management program in place for the turbine speed load governor control system (analog and/or digital based)? (Yes or No)
3. Was good correlation between the generator output (MW vs. time) and the model obtained? (Yes or No)

   3. A. **If yes:** (Use additional pages if needed to explain.)
   - How long did it take to obtain the generator output data? (hours)
   - How long did it take to set up the model to simulate this event? (hours)
   - How long did it take to compare the generator output data to the model? (hours)
   - Did the model parameters or type need to be changed?

   3. B. **If No:**
   - Use additional pages to explain.
4. List any material costs associated with this study.
5. Please list any suggested changes to the guideline?
6. Provide a completed Attachment # 2 to the SERC Field Test Guidelines for Verification of Generator Unit Frequency Response (MOD-027).

I. Introduction

This SERC field test guideline for the NERC Reliability Standards PRC-019 is intended to:

1) Provide guidance for SERC Generator Owners/Operators in conducting studies to show coordination of generator voltage regulator controls with unit capabilities and protection as specified by the NERC Reliability Standards (Section IIIA).
2) Document the GSFT-TF recommended exemption criteria (Section IIIA) and sister unit philosophy (Section IIIB).

II. Definitions

1. **Generator Capability Curve –**A graphical presentation of data that illustrates the thermal limits of the combined real and reactive power capability of the generator at the specified terminal voltage.
2. **Additional Definitions to be added as needed.**

III. Requirements/Expectations

A. **Generator Exemption Criteria** [*Ref.PRC-019, R2.*]

In order to maximize the use of resources, it is prudent to exempt generators that are believed to have less significant impact on the reliability of the bulk electric system from maintaining rigorous documentation of generator control and protective relay coordination study results. The exemption criteria specified by this guideline are based on both the operating voltage of the bulk power system to which the generator is interconnected, and the MVA rating of the generator. When referring to the MVA rating of the generator, at facilities where multiple machines and/or prime movers are required for normal unit operation, the MVA rating refers to the total MVA capacity of the facility. Examples of this include combined cycle or cross compound units.

As documented in the NERC Glossary of Terms, the NERC Board of Trustees approved a definition for the bulk electric system on February 8, 2005 as follows:

> "As defined by the Regional Reliability Organization, the electrical generation resources, transmission lines, interconnections with neighboring systems, and associated equipment, generally operated at voltages of 100 kV or higher. Radial transmission facilities serving only load with one transmission source are generally not included in this definition."

Therefore, for generators interconnected to a power system operated at a voltage of less than 100 kV, a documented study demonstrating the coordination of generator voltage regulator controls with unit capabilities and protection is not required.

Generators with a nameplate rating less than or equal to 75 MVA or that are not connected to the bulk power system are exempt.

Table 1 summarizes the Generator Exemption Criteria.

Generator Interconnected kV or MVA Size	Study Documentation of Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection Required
< 100 kV	No
> 100kV & ≤ 75 MVA	No
>100kV & > 75 MVA	Yes

Table 1: Generation Exemption Criteria

B. Sister Unit/Equipment Verification Guidelines

If it can be demonstrated that the generators, voltage regulator and exciters along with their control and protection system equipment and settings are all identical, then the units can be considered sisters units. In those situations, an assumption can be made for a sister unit by coordinating the generator voltage regulator controls with unit capabilities and protection for one (sample) unit. Documentation must exist to demonstrate that the information about the sample unit can be applied to a sister unit.

C. Requirements [*Ref. PRC-019, R2.1*]

1. Generator owner/operator to develop (or retrieve from generator manufacturer) the Generator Capability Curve for each non-exempt generating unit. This curve shall include specification of nominal voltage, ambient air or cooling temperature, or hydrogen pressure as appropriate. [*Ref. PRC-019, R2.1.1*]

2. Generator owner/operator to show on the Generator Capability Curve and other appropriate curves (plots) that the coordination of the generator voltage regulator controls and limit functions are coordinated with the generator's capabilities and protective relays. The completed curves (plots) should show the following as appropriate (See Attachments 2 through 5):

   a) Steady state over-excitation and under excitation limiter control characteristics. [*Ref. PRC-019, R2.1.2*]

   b) Power output limit of the unit, as verified per MOD-024. [*Ref. PRC-019, R2.1.3*]

   c) Other factors that could limit megawatt or megavar capability. [*Ref. PRC-019, R2.1.4*] Example: generator step-up transformer MVA rating, generator rotor with shorted turn, steady state transmission and station auxiliary bus voltage limits, etc.

   d) Loss of excitation relay / field protection relay characteristics [*Ref. PRC-019, R2.1.5*]

   e) Coordination of the volts per hertz protection system(s), including limiters, relating to the generator, generator step-up transformer, normal station service transformer. [*Ref. PRC-019, R2.1.6*]

A. Introduction

1. **Title: Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection**

2. **Number:** PRC-019-1

3. **Purpose:** Ensure generator voltage regulator controls and limit functions are coordinated with the generator's capabilities and protective relays.

4. **Applicability**

   4.1. Regional Reliability Organization.

   4.2. Generator Owner.

5. **Proposed Effective Dates:** To be determined:

   One year beyond Board of Trustee adoption for Requirement 1

   Two years beyond Board of Trustee adoption 1st 20% compliant with Requirement 2 and Requirement 3

   Three years beyond Board of Trustee adoption 2nd 20% compliant with R2, R3

   Four years beyond Board of Trustee adoption 3rd 20% compliant with R2, R3

   Five years beyond Board of Trustee adoption 4th 20% compliant with R2, R3

   Six years beyond Board of Trustee adoption 5th 20% compliant with R2, R3

B. Requirements

R1. The Regional Reliability Organization shall establish and maintain criteria for exemptions to any of the Generator Owner requirements in R2.

R2. Unless exempted by the Regional Reliability Organization in accordance with R1, the Generator Owner shall have study results that show it verified that its generator voltage regulator controls and limit functions are coordinated with the generator's capabilities and protective relays. This study shall include the following:

R2.1. Plots, or data that could be plotted for the following:

R2.1.1. Generator capability curve, including specification of nominal voltage, ambient air or cooling temperature, or hydrogen pressure.

R2.1.2. Steady state over-excitation limiter and under-excitation limiter control characteristics.

R2.1.3. MW limit of the prime mover.

R2.1.4. Any other limit that could restrict the megawatt or megavar capability.

R2.1.5. Loss of excitation / field protective relay characteristics.

R2.1.6. Volts-per-hertz protection settings including volts-per-hertz limiters in the automatic voltage regulator.

R3. The Generator Owner shall have the information in R2.1.1 through R2.1.6 available to show to the Regional Reliability Organization upon request (within 30 calendar days).

C. Measures

M1. The Regional Reliability Organization shall, within 30 calendar days of a request, provide to Generator Owners its exemption criteria defined in accordance with R1.

M2. The Generator Owner shall have evidence it showed the Regional Reliability Organization the information identified in R2.1 through R2.1.6 within 30 calendar days of a request.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

NERC for the Regional Reliability Organization.

Regional Reliability Organization for Generator Owners.

1.2. Compliance Monitoring Period and Reset Timeframe

The compliance reset period is one calendar year.

1.3. Data Retention

The Generator Owner shall retain all current information needed to show coordination. The Compliance Monitor shall retain any audit data for three years.

1.4. Additional Compliance Information

The Regional Reliability Organization and Generator Owner shall demonstrate compliance through self-certification or audit (periodic, as part of targeted monitoring or initiated by complaint or event), as determined by the Compliance Monitor.

2. Levels of Non-Compliance

2.1. Level 1: The Regional Reliability Organization did not provide the exemption criteria in accordance with R1.

2.2. Level 2: The Generator Owner information on coordination of the generator voltage regulator controls and limit functions does not address one of the requirements identified in accordance with R2.1.1 through R2.1.6.

2.3. Level 3: Not applicable.

2.4. Level 4: The Generator Owner information on coordination of the generator voltage regulator controls and limit functions does not address two or more of the requirements identified in accordance with R2.1.1 through R2.1.6.

E. Regional Differences

None identified.

SERC PRC-019 Field Test Reporting Form

The purpose of this form is to provide a consistent report format for field testing results after using the SERC Field Test Guideline "Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection". Documentation of the test results (this field test may actually be considered an engineering study) will provide feedback showing that the field test was successful and/or will help to enhance the test guideline.

Use the SERC Field Test Guideline "Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection" to perform the test (engineering study). It is suggested that a newer, more modern generating unit be used for the test, to verify the coordination of more different types of protection relay systems (versus an older unit that may not have as many generator protection relays). Complete one (1) report form for each unit tested (studied).

Provide the following information:

1. How long did it take to assemble (bring together) the technical data (generator capability curve(s), voltage regulator settings, protective relay settings, etc.) needed to perform the engineering study? ________ Hours
2. What methodology / tools were used to perform the coordination studies?

   ☐ Computerized coordination curves

   ☐ Manual coordination curves

   ☐ Combination (computerized / manual)
3. How many man-hours did it take to develop the methodology / tools? _________
4. How long did it take to analyze the technical information and draw the curves (plots)? ________ Hours
5. List any material costs associated with this study.

   ____

   ____
6. Were the voltage regulator settings and the protective relay settings coordinated with the generator capability curve (as found)? ________ (Yes or No)
7. If not, list the devices that needed configuration changes:

   ____

   ____
8. Please list any suggested changes to the guideline or Draft NERC Reliability standard?

   ____

   ____
9. Provide the completed curves (plots). Remove all references that would identify the unit (company, station, and unit names, etc)
10. Name of person completing form: ______________ Phone number ____________

    Company name _________________________________

Send the completed report form and coordination curves electronically to: phuntley@serc1.org.

SERC Field Test Guidelines

Generator Performance During Frequency and Voltage Excursions

NERC Draft Reliability Standards PRC-024

Revision History

Attachment 1: Draft NERC Reliability Standard PRC-024

I. Introduction

In order to effectively evaluate the electric system's performance, Transmission Planners make implicit or explicit assumptions regarding the ability of generators to remain on-line during frequency and voltage excursions. The validity of these assumptions are critical for planning and operating studies of the reliability of the electric system. These assumptions are especially critical for studies used to develop "safety-net" schemes such as Under Frequency Load Shedding (UFLS) and Under Voltage Load Shedding (UVLS). Incorrect assumptions regarding the ability of generators to remain on-line would lead to ineffective or suboptimal load shedding schemes.

This SERC field test guideline for the NERC Reliability Standards PRC-024 is intended to:

1) Provide guidance for SERC Generator Owners to address verification of the capability of generators to remain connected to the electrical grid during defined system frequency and voltage excursions.
2) Provide guidance for SERC Generator and Transmission Owners to:
    a. Address coordination between the generator under frequency protection and SERC's UFLS program.
    b. Address coordination of generator protection with transmission protection systems.
3) Document the GSFT-TF recommended exemption criteria, variance requests, and sister unit philosophy.

It is recognized that any effort to verify the capability of generators to remain connected during defined system frequency and voltage excursions does not constitute a guarantee by the Generator Owner. There are systems in a generation plant where practical means are not readily available to determine how they would respond to the frequency and voltage excursion, and/or if a trip of these systems would subsequently cause an immediate or delayed generator trip. These systems include, but are not limited to, Boiler Control Systems, Adjustable Speed Drives, and station auxiliary loads (motor performance due to undervoltage or underfrequency, and loss of load due to dropout of unlatched contactors).

Therefore, the GSFT-TF is recommending for these field test activities a verification process meant to uncover protection system coordination issues that would almost certainly lead to a generator tripping if exposed to the defined frequency or voltage excursion. As such, the likelihood of the generator remaining on-line during the defined frequency or voltage excursion would be increased and lend some additional validity to study assumptions made by Transmission Planners.

II. Definitions

1. **Exempt Generation –** Generator(s) that meets the exemption criteria for a particular

requirement.

2. **Low Voltage Ride Through (LVRT) Capability –** the ability of a generator to remain on-line when subjected to a defined transmission system voltage excursion.
3. **Variance –** a deviation in the established RRO requirement for a generator to remain on-line during system frequency and/or voltage excursion.

III. Requirements/Expectations

A. Generator Exemption Criteria [*Ref. PRC-024, R3*]

It is prudent to exempt small generators that, if they are unable to stay on-line for certain frequency and voltage excursions, would be expected to have an insignificant impact on the reliability of the bulk electric system. Therefore, generators interconnected to a power system operated at a voltage of less than 100 kV or having a nameplate rating of less than or equal to 75 MVA are exempt from complying with SERC's requirements for generators to remain connected during the defined frequency and voltage excursions. On a case by case basis the Transmission Planner may identify certain generators that are less than 75 MVA, but have a significant impact on transmission voltage security, and cannot be exempted from the low voltage ride-through requirements.

B. Variance Procedures [*Ref. PRC-024, R4*]

It is recognized that efforts to ensure coordination between generator protection systems and the Region's defined voltage and frequency excursion could result in identification of generators who have systems that will be unable to achieve coordination. In those instances, the Generator Owner can request a Variance from SERC. SERC, the Generator Owner, and the Transmission Owner will then work together to determine if the requested Variance would adversely impact bulk power system reliability. In no instances should any protection or control scheme setting be endorsed that exposes a generating unit to damage.

C. Requirements for Generators to Remain Connected During System Frequency and Voltage Excursions

1. Frequency Excursion Requirements

a) To ensure coordination with under-frequency load shed (UFLS) schemes, generator protection schemes are expected to be set such that the generator would remain on-line when subjected to the frequency excursion curve defined in Figure 1 [*Ref. PRC-024, R1*] .

b) The process of determining coordination with the frequency excursion curve defined in Figure 1 assumes that the corresponding transmission system voltage remains within scheduled limits.

c) The Generator Owner can demonstrate coordination with transmission system UFLS schemes through the development of a coordination curve (reference Figure 2).

d) If generator protection schemes are set such that the generator would not be expected to stay on line for the frequency excursion curve shown in Figure 1, the Generator Owner should investigate if the schemes can be relaxed without exposing the generator to potential damage. This could include consultation with the Original Equipment Manufacturer. If the protection schemes cannot be adjusted such that the generator would stay on line for the frequency excursion shown in Figure 1, the Generator Owner should request a Variance (reference Section B).

e) To reasonably assure the generators capability to remain on-line during the frequency excursion defined in Figure 1, expected performance of the following systems should be evaluated:

(1) Turbine Generator protection
Specific protective relays that should be checked for coordination with the frequency excursion defined in Figure 1 include turbine frequency protection and volts per hertz.

(2) Nuclear Power Plant Systems
Systems that are both unique to Nuclear power plant systems and are potentially sensitive to under frequency excursions should be checked for coordination with the frequency excursion defined in Figure 1. These systems include Reactor Coolant Pumps for PWRs and Reactor Recirc Pumps for BWRs.

f) To ensure coordination with generator turbine underfrequency protection schemes, UFLS schemes are expected to be designed to initiate load shed for frequency excursions which are less severe than the curve defined in Figure 1. In order to show the coordination, the Transmission Owner is required to develop a coordination curve – an example is shown in Figure 3. This activity should occur at the same time that the UFLS scheme review of the set points and timing is conducted per NERC Reliability Standard PRC-006 R.1.4.1. [*Ref. PRC-024, R2.1.*]

2. Voltage Excursion Requirements

a) To ensure the interconnected transmission system is planned appropriately per the requirements in TPL-001 through TPL-004, generator protection schemes are expected to be set such that the generator would have sufficient LVRT capability to remain on-line when subjected to the voltage excursion curve defined in Figure 4 [*Ref. PRC-024, R1*]

b) The process of determining coordination with the voltage excursion curve defined in Figure 4 assumes that the corresponding transmission system frequency remains at 60 Hertz.

c) The SERC under-voltage excursion curve, shown in Figure 4, is defined at the generator's highside transmission bus. Note that the time at Voltage 0 in Figure 4 would typically be dictated by transient stability limits. If the LVRT Capability of the generator corresponds to a Voltage 0 time which is less than the transient stability limit, the Generator Owner should work with the Transmission Owner to determine if any additional action is required.

d) The technical drivers dictating the flat and then gradual recovery to 80% within 2 seconds depicted on the generator LVRT curve in Figure 4 include:

(1) Captured event data verify that fault activity resulting in similar voltage signatures as depicted in Figure 4 have occurred in SERC as a result of fault activity.
(2) In order to design secure UVLS safety net schemes, SERC utilities have installed UVLS schemes with logic to trip load include time delays from approximately 1 to just beyond 2.0 seconds. Thus, a minimum LVRT of 2.0 seconds is required.
(3) Detailed dynamic simulations consistently confirm that the transmission system does not have to be significantly further stressed to transition from a delayed voltage recovery of 2 second at the highside of generation plants to a "no recovery" wide area fast voltage collapse scenario. Therefore, if critical generation units trip before UVLS schemes can operate, the transmission system will have exposure to credible wide area voltage collapse scenarios that may or may not be contained to a control area.

e) To reasonably assure the generators LVRT Capability to withstand the voltage excursion defined in Figure 4, expected response to the voltage excursion by the following systems should be evaluated:
(1) Station Service Bus Under Voltage Relays
All station service under voltage relays which protect buses and/or individual loads that contain known loads critical to the generator remaining on-line should coordinate with the under-voltage excursion curve depicted in Figure 4.
(2) Generator Under Voltage Relays
The settings of any generator under voltage relay should coordinate with the under-voltage excursion curve depicted in Figure 4.
(3) Loss of Field and/or Power Potential Source Exciter PPT Secondary Relaying
The setting of any loss of field and/or power potential source exciter PPT secondary relay(s) should be checked for coordination with the under-voltage excursion curve depicted in Figure 4.
(4) Generator Backup relays (Overcurrent and/or Distance)

Suggested screening method for Generator Backup Distance relay: 1) Note the time delay. 2) Note the per unit voltage at the time delay noted in Step 1. 3) Calculate the corresponding impedance seen by the relay. Note that an increase in per unit voltage can generally be assumed on the low side of the generator GSU.

(5) Nuclear Power Plant Loss of Offsite Power Relays.

f) If generators are unable to withstand the under-voltage excursion shown in Figure 4, the Generator Owner should investigate the possibility of increasing the LVRT Capability of the Generators. If the voltage excursion withstand capability cannot be adjusted such that the generator would be expected to remain on line for the under-voltage excursion shown in Figure 4, the Generator Owner should request a Variance (reference Section B).

g) To ensure coordination between generator unit and transmission protection, the Transmission Owner and the Generator Owner should exchange relay setting information and develop coordination plots. These coordination plots should depict generator back-up protection and transmission system back-up protection, including UVLS protection, as appropriate. [Ref. PRC-024, R2.2]

3. SERC Documentation Requirements

a) SERC shall provide documentation of its excursion requirements, exemptions, and variance procedure to the Transmission Owners and Generator Owners within its Region within 30 calendar days of approval. [Ref. PRC-024, R5]

b) SERC shall, at least every five years, review and, as necessary, update its requirements, exemption criteria, and variance procedure. [Ref. PRC-024, R6]

Attachment 1

A. Introduction

1. **Title:** **Generator Performance During Frequency and Voltage Excursions**
2. **Number:** PRC-024-1
3. **Purpose:** To ensure that generators remain connected to the electrical grid during voltage and frequency excursions and are not normally tripped manually or by preset protection schemes during frequency and voltage excursions.
4. **Applicability**
   - **4.1.** Regional Reliability Organizations.
   - **4.2.** Generator Owners.
   - **4.3.** Transmission Owners.
5. **Proposed Effective Dates:** **To be determined:**

   Requirement 1 through Requirement 6 – One year beyond Board of Trustee adoption

   Requirement 7 – Two years beyond Board of Trustee adoption

B. Requirements

R1. The Regional Reliability Organization shall establish requirements for generators to remain connected during system frequency and voltage excursions expressed as a function of:

- **R1.1.** Time duration in seconds or cycles.
- **R1.2.** Amplitude or magnitude of the excursion.
- **R1.3.** Relationship between time and amplitude or magnitude.

R2. The Regional Reliability Organization shall establish and maintain requirements for generators to remain connected during frequency and voltage excursions. These requirements shall include:

- **R2.1.** Coordination between the generator under frequency protection and the regional Under Frequency Load Shedding (UFLS) program.
- **R2.2.** Coordination of generator protection, including back-up protection, with transmission Protection Systems.

R3. The Regional Reliability Organization shall establish and maintain criteria for exemptions to any of the regional requirements established in accordance with R1 and R2.

R4. The Regional Reliability Organization shall establish and maintain a procedure for handling variances (i.e., different criteria or methods) from the Regional Reliability Organization's requirements established in R1 and R2, including steps for requesting and approving such variances.

R5. The Regional Reliability Organization shall provide documentation of its excursion requirements, exemptions, and variance procedure to the Transmission Owners and Generator Owners within its Region within 30 calendar days of approval.

R6. The Regional Reliability Organization shall, at least every five years, review and, as necessary, update its requirements, exemption criteria, and variance procedure.

R7. Generator Owners and Transmission Owners shall comply with the regional requirements for coordination of generator protection defined in R2 and any approved variances.

Attachment 1

A. Measures

M1. The Regional Reliability Organization shall, within 30 calendar days of a request, provide NERC with its requirements, exemption criteria, and variance procedure for generators to withstand excursions in voltage and frequency.

M2. The Regional Reliability Organization shall have evidence it provided the requirements, criteria and procedures to the Transmission Owners and Generator Owners within its Region within 30 calendar days of approval.

M3. The Regional Reliability Organization shall have evidence it reviewed and updated its requirements, criteria and procedures as required in R6.

M4. Generator Owners and Transmission Owners shall, within 30 calendar days of a request, provide the Regional Reliability Organization with documentation that it met the regional requirements for coordination of generator protection defined in R1 and R2 and any approved regional variances.

Generator Owner PRC-024 SERC Field Test Reporting Form

The purpose of this form is to provide a consistent report format for field testing results after using the SERC Field Test Guideline "Generator Performance During Frequency and Voltage Excursions". Documentation of the test results will provide feedback showing that the field test was successful and/or will help to enhance the test guideline.

Use the attached SERC Field Test Guideline "Generator Performance During Frequency and Voltage Excursions" to perform the applicable engineering studies. Complete one (1) report form for each unit tested.

Provide the following information:

1. How long did it take to assemble (bring together) the technical data needed to plot the expected unit frequency withstand capability? Hours
2. If frequency excursion plots were created, what methodology / tools were used to construct the frequency excursion coordination plots?

   ☐ Computerized coordination curves

   ☐ Manual coordination curves

   ☐ Combination (computerized / manual)
3. If frequency excursion plots were not created, please explain the methodology used to demonstrate coordination with the draft SERC frequency excursion characteristic.
4. How many man-hours did it take to develop the methodology / tools?
5. Did the results indicate that the generator would be expected to remain on line for the draft SERC frequency Characteristic? ☐Yes ☐ No

   If no please attach additional information as appropriate.
6. How long did it take to analyze the technical information and draw the frequency curves (plots)? Hours
7. List any material costs associated with the generator frequency withstand capability portion of this field test.
8. How long did it take to assemble (bring together) the technical data needed to plot the expected Low Voltage Ride Through (LVRT) capability? Hours
9. If LVRT plots were created, what methodology / tools were used to construct the frequency excursion coordination plots?

   ☐ Computerized coordination curves

   ☐ Manual coordination curves

   ☐ Combination (computerized / manual)
10. If LVRT plots were not created, please explain the methodology used to demonstrate coordination with the draft SERC LVRT characteristic.
11. How many man-hours did it take to develop the methodology / tools?

Generator Owner PRC-024 SERC Field Test Reporting Form

12. Did the results indicate that the generator would be expected to remain on line for the draft LVRT characteristic? ☐Yes ☐ No

    If no please attach additional information as appropriate.

13. How long did it take to analyze the technical information and draw the LVRT curves (plots)? Hours

14. List any material costs associated with the generator LVRT capability portion of this field test.

15. Please list any suggested changes to the guideline or the draft NERC Reliability Standard.

16. Provide the completed curves (plots) and other applicable documentation. Remove all references that would identify the unit (company, station, and unit names, etc)

17. Name of the person completing the form: Phone Number Company Name

Send the completed report form, plots, models and documentation to **phuntley@serc1.org**

Transmission Owner PRC-024 SERC Field Test Reporting Form

The purpose of this form is to provide a consistent report format for field testing results after using the SERC Field Test Guideline "Generator Performance During Frequency and Voltage Excursions". Documentation of the test results will provide feedback showing that the field test was successful and/or will help to enhance the test guideline.

Use the attached SERC Field Test Guideline "Generator Performance During Frequency and Voltage Excursions" to perform the applicable engineering studies. Complete one (1) report form for each unit tested.

Provide the following information:

1. How long did it take to assemble (bring together) the technical data needed to plot the UFLS characteristics? Hours
2. If frequency plots were created, what methodology / tools were used to construct the frequency coordination plots?

   ☐ Computerized coordination curves

   ☐ Manual coordination curves

   ☐ Combination (computerized / manual)
3. If frequency plots were not created, please explain the methodology used to demonstrate coordination with the draft SERC frequency excursion characteristic.
4. How many man-hours did it take to develop the methodology / tools?
5. Did the results indicate the UFLS characteristic coordinates with the draft SERC frequency Characteristic? ☐Yes ☐ No

   If no please attach additional information as appropriate.
6. How long did it take to analyze the technical information and draw the frequency curves (plots)? Hours
7. List any material costs associated with the generator frequency withstand capability portion of this field test.
8. How long did it take to assemble (bring together) the technical data needed to plot the transmission system backup protection characteristic applicable for the draft SERC LVRT curve? Hours
9. If LVRT plots were created, what methodology / tools were used to construct the frequency excursion coordination plots?

   ☐ Computerized coordination curves

   ☐ Manual coordination curves

   ☐ Combination (computerized / manual)
10. If LVRT plots were not created, please explain the methodology used to demonstrate coordination with the draft SERC LVRT characteristic and associated generator backup relay characteristics.
11. How many man-hours did it take to develop the methodology / tools?

Transmission Owner PRC-024 SERC Field Test Reporting Form

12. Did the results indicate coordination with the draft LVRT characteristic? ☐Yes ☐ No

    If no please attach additional information as appropriate.

13. How long did it take to analyze the technical information and draw the LVRT curves (plots)? Hours

14. List any material costs associated with the transmission LVRT capability portion of this field test.

15. Please list any suggested changes to the guideline or the draft NERC Reliability Standard.

16. Provide the completed curves (plots) and other applicable documentation. Remove all references that would identify the unit (company, station, and unit names, etc)

17. Name of the person completing the form: Phone Number Company Name

Standard Redlines

- **MOD-026_Draft for Field Test (GSFT-TF revised 5-3-07).doc**
- **MOD-027_Draft for Field Test (GSFT-TF revised 5-3-07).doc**
- **PRC-019_Draft for Field Test (GSFT-TF revised 5-3-07).doc**

A. Introduction

1. **Title:** **Verification of Models and Data for Generator Excitation System Functions**
2. **Number:** MOD-026-1
3. **Purpose:** To ensure accurate information on generator excitation system functions (including voltage regulator controls, limiters, compensators, and power system stabilizers, if applicable) is available for models used to assess Bulk Electric System reliability.
4. **Applicability**

   4.1. Regional Reliability Organization.

   4.2. Generator Owner

   4.3. Transmission Planner.

5. **Proposed Effective Date:** ~~To be determined.~~ The effective date should be delayed for 2 years, then phased in over at 20% per year over the next 5 years.

B. Requirements

R1. The Regional Reliability Organization shall establish and maintain procedures to address verification of models and data associated with generator excitation system functions including voltage regulator controls, limiters, compensators, and power system stabilizers. These procedures shall include the following:

R1.1. Generating unit exemption criteria ~~including documentation of those units that are exempt from a portion or all of these procedures~~. [exempt generators 75 MVA or less or generators not directly connected to the 100kV system through their step-up transformer.]

R1.2. Acceptable methods for model and data verification, including any applicable conditions under which the data should be verified. Such methods can include use of manufacturer data, commissioning data, performance tracking, engineering analysis, field verification of equipment settings, testing, simulation and comparison with test results or disturbance monitoring data, etc.

R1.3. A list of acceptable models to be used and procedures for revising the list of acceptable models.

~~**R1.3.**~~**R1.4.** Periodicity and schedule of verification and reporting, including a list of report recipients, schedules associated with field changes to existing units, and refurbished units.

~~**R1.4.**~~**R1.5.** Information to be reported related to generator excitation system functions:

~~**R1.4.1.**~~**R1.5.1.** Verified manufacturer and type of excitation system/voltage regulator control system (for example, static, brushless, rotating, etc.).

~~**R1.4.2.**~~**R1.5.2.** Verified model for each excitation system/voltage regulator control system with associated gains, time constants, and limits.

~~**R1.4.3.**~~**R1.5.3.** Verified static set points for under and over excitation limiters.

~~**R1.4.4.**~~**R1.5.4.** Verified line drop compensator settings.

~~**R1.4.5.**~~**R1.5.5.** Open circuit test response data showing generator field voltage and generator terminal voltage (exciter field voltage and current data for brushless units).

~~R1.4.6.~~R1.5.6. Verified model for each power system stabilizer with associated gains, time constants, and limits. Generator owners commissioning new PSSs will supply the Transmission Planner applicable test results provided upon commissioning. This includes results of the Gain Margin test, Phase Compensation test, and on-line step in voltage tests with and without the PSS in service.

~~R1.4.7. Confirmation that the verification was conducted with the voltage regulator in the automatic voltage control mode~~

~~R1.4.8.~~R1.5.7. Method of verification used.

~~R1.4.9.~~R1.5.8. Date of verification.

R2. The Regional Reliability Organization shall provide its generator excitation system data verification and reporting procedures, and any changes to those procedures, to the Generator Owners, Generator Operators, Transmission Operators, Planning Authorities, and Transmission Planners affected by the procedure within 30 calendar days of the approval.

R3. The Generator Owner shall follow its Regional Reliability Organization's procedures for verifying and reporting its models and data associated with generator excitation system functions per MOD-026 R1.

C. Measures

M1. The Regional Reliability Organization shall have available for inspection a procedure for the verification and reporting of models and data associated with its generator excitation system functions in accordance with MOD-026 R1.

M2. The Regional Reliability Organization shall have evidence that its procedure for verification and reporting of generator excitation system data, and any revisions to that procedure were provided to affected Generator Owners, Generator Operators, Transmission Operators, Planning Authorities, and Transmission Planners within 30 calendar days of approval.

M3. The Generator Owner shall have evidence it provided verification of the models and data associated with its generator excitation system functions, consistent with the Regional Reliability Organization procedure.

A. Introduction

1. **Title:** **Verification of Generator Unit Frequency Response**

2. **Number:** MOD-027-1

3. **Purpose:** To provide verification of generator unit frequency response (other than Automatic Generation Control) for use in models for reliability studies.

4. **Applicability**

   4.1. Regional Reliability Organization.

   4.2. Generator Owner.

   4.3. Transmission Planner

5. **Proposed Effective Date:** To be Determined. Because of the need to develop new tools and methods to capture and analyze the results and time required to validate each generator, the effective date should be delayed for 2 years, then phased in over at 20% per year over the next 5 years.

B. Requirements

R1. The Regional Reliability Organization shall establish and maintain procedures to address verification of generator unit frequency response. These procedures shall include the following:

R1.1. Response time to be modeled, ~~e.g. up to~~at least 60~~30~~ seconds~~ for steam units, up to 45 seconds for hydro units, etc~~.

R1.2. Generating unit exemption criteria~~ including documentation of those units that are exempt from a portion or all of these procedures~~. [exempt generators 75 MVA or less or generators not directly connected to the 100kV system through their step-up transformer.]

R1.3. Acceptable methods for model and data verification, including any applicable conditions under which the data should be verified. Such methods can include use of manufacturer data, commissioning data, performance tracking, engineering analysis, field verification of equipment settings, testing, simulation and comparison with test results or disturbance monitoring data, etc. [Standard should include, but not be limited to, an event based methodology as specified in section III.D.2 of the SERC Field Test Guideline for Verification of Generator Unit Frequency Response (draft NERC Reliability Standard MOD-027).]

R1.4. Periodicity and schedule of verification and reporting, including a list of report recipients, schedules associated with field changes to existing units, and refurbished units.[Standard should allow documented configuration controls as a means of ensuring validated unit response remains applicable]

R1.5. Information to be reported related to generator unit frequency response:

~~**R1.5.1.**Verified manufacturer and type of speed governor controls.~~

~~**R1.5.2.**~~**R1.5.1.** Verified model for each speed governor control~~ with any associated deadband, gains, time constants, and limits (e.g., maximum valve opening velocity, maximum capability of the turbine, etc.)~~.

~~R1.5.3.~~R1.5.2. Verified frequency response data of the unit, considering additional plant controls that affect the response of the unit (blocked or nonfunctioning governors or modes of operation that limit frequency response).

~~R1.5.4.~~R1.5.3. Method of verification and conditions of the verification including status of controls.

R2. The Regional Reliability Organization shall provide its frequency response verification and reporting procedures, and any changes to those procedures, to the Generator Owners, Generator Operators, Transmission Operators, Planning Authorities, and Transmission Planners affected by the procedures within 30 calendar days of the approval.

R3. The Generator Owner shall follow its Regional Reliability Organization's procedure for verifying and reporting its generator unit frequency response per MOD-027 R1.

C. Measures

M1. The Regional Reliability Organization shall have available for inspection a procedure for verifying and reporting generator unit frequency response in accordance with MOD-027 R1.

M2. The Regional Reliability Organization shall have evidence that its procedure, and any revisions to that procedure, for verification and reporting generator unit frequency response was provided to affected Generator Owners, Generator Operators, Transmission Operators, Planning Authorities, and Transmission Planners within 30 calendar days of approval.

M3. The Generator Owner shall have evidence it provided verification of the models and data associated with generator unit frequency response, consistent with the Regional Reliability Organization procedure.

A. Introduction

1. **Title:** **Coordination of Generator Voltage Regulator Controls with ~~Unit~~ Generator Capabilities and Protection**

2. **Number:** PRC-019-1

3. **Purpose:** Ensure generator voltage regulator controls and limit functions are coordinated with the generator's capabilities and protective relays.

4. **Applicability**

   4.1. Regional Reliability Organization.

   4.2. Generator Owner.

5. **Proposed Effective Dates:** To be determined:

   One year beyond Board of Trustee adoption for Requirement 1

   Two years beyond Board of Trustee adoption 1st 20% compliant with Requirement 2 and Requirement 3

   Three years beyond Board of Trustee adoption 2nd 20% compliant with R2, R3

   Four years beyond Board of Trustee adoption 3rd 20% compliant with R2, R3

   Five years beyond Board of Trustee adoption 4th 20% compliant with R2, R3

   Six years beyond Board of Trustee adoption 5th 20% compliant with R2, R3

B. Requirements

R1. The Regional Reliability Organization shall establish and maintain criteria for exemptions to any of the Generator Owner requirements in R2. [exempt generators 75 MVA or less or generators not directly connected to the 100kV system through their step-up transformer.]

R2. Unless exempted by the Regional Reliability Organization in accordance with R1, the Generator Owner shall have study results that show it verified that its generator voltage regulator controls and limit functions are coordinated with the generator's capabilities and protective relays. This study shall include the following:

R2.1. Plots~~, or data that could be plotted for~~ to show the following, if applicable:

R2.1.1. Generator capability curve, including specification of nominal voltage, ambient air or cooling temperature, or hydrogen pressure.

R2.1.2. Steady state over-excitation limiter and under-excitation limiter control characteristics.

R2.1.3. Verified MW ~~limit of the prime mover~~capability of the generating unit [as developed in MOD-024].

R2.1.4. ~~Any other limit that could restrict the megawatt or megavar capability~~.

R2.1.5. Loss of excitation / field protective relay characteristics.

R2.1.6. Volts-per-hertz protection settings including volts-per-hertz limiters in the automatic voltage regulator.

R3. The Generator Owner shall have the information in R2.1.1 through R2.1.6 available to show to the Regional Reliability Organization upon request (within 30 calendar days).

C. Measures

M1. The Regional Reliability Organization shall, within 30 calendar days of a request, provide to Generator Owners its exemption criteria defined in accordance with R1.

M2. The Generator Owner shall have evidence it ~~showed the Regional Reliability Organization the information~~performed the studies identified in R2.1 through R2.1.6 within 30 calendar days of a request.

MOD-026 SERC Field Test Reporting Form

The purpose of this form is to provide a consistent report format for field testing results after using the SERC Field Test Guideline "Verification of Models and Data for Generator Excitation System Functions". Documentation of the test results will provide feedback showing that the field test was successful and/or will help to enhance the test guideline.

Use the attached SERC Field Test Guideline "Verification of Models and Data for Generator Excitation System Functions" to perform the test (engineering study). Complete one (1) report form for each unit tested.

Provide the following information:

1. How long did it take to perform an Open Circuit Step Response (OCSR) test and collect the relevant data (generator voltage, field voltage and field current) in order to validate the exciter model?
   - Pre-Test Planning & Preparation : ____Unknown____ Hours
   - Setup of Test Equipment: ___8_____ Hours
   - Time to Prepare Unit for Test: ___1_____ Hours
   - Performance of Test and Data Collection: ____1____ Hours

Note: The subject testing was performed by an outside contractor. The above numbers are only observed estimates of the contractor time in each area.

2. How long did it take to analyze the test data and get a good correlation between exciter model and the OCSR test? __Unknown __ Hours

Note: The subject testing and data analysis was performed by an outside contractor.

3. Was a good correlation between the exciter model and the OCSR test obtained? (**Yes** or No)

   If no please attach additional information as appropriate.

4. What was the magnitude of the step input applied? _____2 %________________
5. List any material costs associated with this testing. __Currently our organization does not have all of the test equipment, software and testing experience needed to perform the testing and data analysis required by this proposed standard. All testing, data collection and analysis for this field test was performed by an outside contract at a cost of approximately $20, 000.
   ____
   ____
6. Were set points (overexcitation and underexcitation) verified on the voltage regulator (**Yes** or No). If no, please attach additional information as appropriate.
7. Please list any suggested changes to the guideline?
   ____
   ____
   ____

MOD-026 SERC Field Test Reporting Form

8. Provide a completed Attachment # 2 to the SERC Field Test Guidelines for Verification of Models and Data for Generator Excitation System Functions (MOD-026). Attached.

MOD-026 SERC Field Test Reporting Form

The purpose of this form is to provide a consistent report format for field testing results after using the SERC Field Test Guideline "Verification of Models and Data for Generator Excitation System Functions". Documentation of the test results will provide feedback showing that the field test was successful and/or will help to enhance the test guideline.

Use the attached SERC Field Test Guideline "Verification of Models and Data for Generator Excitation System Functions" to perform the test (engineering study). Complete one (1) report form for each unit tested.

Provide the following information:

1. How long did it take to perform an Open Circuit Step Response (OCSR) test and collect the relevant data (generator voltage, field voltage and field current) in order to validate the exciter model?
   - Pre-Test Planning & Preparation : 20 Hours
   - Setup of Test Equipment: 10 Hours
   - Time to Prepare Unit for Test: 8 Hours - Fire in boiler To 3600 RPM
   - Performance of Test and Data Collection: 12 Hours - Testing performed around unit start up
2. How long did it take to analyze the test data and get a good correlation between exciter model and the OCSR test? 4 - 6 Hours
3. Was a good correlation between the exciter model and the OCSR test obtained? (Yes or No)

   If no please attach additional information as appropriate.
4. What was the magnitude of the step input applied? 1 & 2 %
5. List any material costs associated with this testing.

   ____

   ____
6. Were set points (overexcitation and underexcitation) verified on the voltage regulator (Yes or No). If no, please attach additional information as appropriate.
7. Please list any suggested changes to the guideline?

   ____

   ____

   ____
8. Provide a completed Attachment # 2 to the SERC Field Test Guidelines for Verification of Models and Data for Generator Excitation System Functions (MOD-026).
9. Name of the person completing the form:________________ Phone Number________ Company Name______________

Send the completed report form, plots, models and documentation to

4. Provide the open circuit test data (plots), appropriate voltage regulator and excitation system Standard Model and associated parameters, and documentation/plots showing good correlation between model simulation and OCSR test results.

5. If the unit is equipped with a commissioned PSS, provide the data required in III.F.2.

6. Provide the data required in III.G.2 on Excitation Limit Controls.

Notes:

1. I obtained the IEEE exciter model from the vendor, along with the gains and constants. Our Transmission Planner (TP) performed the simulation and we did not get good correlation. The TP recommended a change to a constant and asked me to check with the Vendor. The Vendor agreed to the change and also recommended one more change to a constant. After a couple of iterations, we obtained good correlation between the model and the step response test.

MOD-027 SERC Field Test Reporting Form

The purpose of this form is to provide a consistent report format for field testing results after using the SERC Field Test Guideline "Verification of Generator Unit Frequency Response". Documentation of the test results will provide feedback showing that the field test was successful and/or will help to enhance the test guideline.

Use the attached SERC Field Test Guideline "Verification of Generator Unit Frequency Response" to perform the test (engineering study). Complete one (1) report form for each unit tested.

Provide the following information:

1. Is there a maintenance management program in place for the turbine speed load governor control system (analog and/or digital based)? (Yes or No) No
   - If yes, what is the maintenance interval? (months)
2. Is there a configuration management program in place for the turbine speed load governor control system (analog and/or digital based)? (Yes or No) No
3. Was good correlation between the generator output (MW vs. time) and the model obtained? (Yes or No) No

   3. A. **If yes:** (Use additional pages if needed to explain.)
   - How long did it take to obtain the generator output data? (hours)
   - How long did it take to set up the model to simulate this event? (hours)
   - How long did it take to compare the generator output data to the model? (hours)
   - Did the model parameters or type need to be changed?

   3. B. **If No:**
   - Use additional pages to explain.
4. List any material costs associated with this study. None
5. Please list any suggested changes to the guideline? Most model/parameters available for the turbine-governor control systems are estimated or typical at best (this is more likely an Industry wide concern). Initially, it might be worth to have initially a couple of units field tested for the accuracy of the model/parameters. Once such field test is performed and the model and parameters are validated, then it might provide a better judgment of whether this Field Test Method provides meaningful and consistent comparison between recorded data and the simulated test results for an event or not.
6. Provide a completed Attachment # 2 to the SERC Field Test Guidelines for Verification of Generator Unit Frequency Response (MOD-027).
7. Name of the person completing the form: Kirit Doshi Phone Number: 804-819-2322
   Company Name: Dominion Virginia Power

Send the completed report form and supporting documentation electronically to: phuntley@serc1.org.

Dominion Explanation
Ref. MOD-027 SERC Field Test Reporting Form, Item 3B

The table below compares field observed readings (from SCADA/EMS data) with the simulation test results for six Dominion (F&H) units for the Wansley and the Oconee trip events. If we consider the difference within 1% of Pmax as acceptable, six instances out of total 12 matches reasonably well as far as the MW pick-up amount is concerned. Out of these six, four are for the Wansley event and two are for the Oconee event.

Field Observations Over a 60-Second Period (Maximum reading within this range used for each unit)

Dominion Unit ID	Pmax (MW)	Pre-Event Load (MW)	Max Observed Pick-up within 60 seconds (MW)	Simulated Pick-up MW	Simulated Pick-up % of Pmax	Difference between Pmax and Pgen	MW Diff. in Response (Simulated minus Observed)	Difference as % of Pmax
A	71	62.40	0.18	1.89	2.66	8.60	1.71	2.41
		55.38	0.96	1.88	2.65	15.62	0.92	1.30
B	118	97.48	1.45	3.29	2.79	20.52	1.84	1.56
		100.80	2.52	3.29	2.79	17.20	0.77	0.65
C	103	88.34	0.65	3.04	2.95	14.66	2.39	2.32
		79.92	2.81	3.04	2.95	23.08	0.23	0.22
D								
E	464	454.13	0.75	5.05	1.09	9.87	4.30	0.93
		457.50	0.75	3.64	0.78	6.50	2.89	0.62
F	110	81.32	1.40	2.67	2.43	28.68	1.27	1.15
		99.36	0.88	2.70	2.45	10.64	1.82	1.65
G	170	170.75	0.63	0.71	0.42	(0.75)	0.08	0.05
		169.75	1.00	1.26	0.74	0.25	0.26	0.15

Blue color readings are for Oconee event

Red color readings are for Wansley event

Note: Unit D was later deleted from the test upon finding that this unit is not expected to respond.

As for the MW versus Time comparison, below listed data indicates the recorded elapsed time in seconds from the initiation of each event for each unit to reach the maximum MW pick-up within the observed time range of 60 seconds.

	(a) Wansley Event	(b) Oconee Event
Unit A:	21	20
Unit B:	42	26
Unit C:	35	20
Unit E:	13	18
Unit F:	19	12
Unit G:	19	44

The simulated responses for most cases indicated 85 to 90 % of the total MW pick-up occur in the first 5 to 7 seconds and then gradually creep up over the next 30 to 50 seconds. Overall, the match between the field-observed responses and the simulated responses are less than satisfactory for the units tested.

This is not to say that the field test method developed is wrong. Most models/parameters available for the turbine-governor control systems are estimated or typical at best (this is more likely an Industry wide issue). Initially, it might be worth to have a couple of units field tested for the accuracy of simulation models/parameters and then evaluating this method of Field Testing may provide more accurate evaluation.

MOD-027 SERC Field Test Reporting Form

The purpose of this form is to provide a consistent report format for field testing results after using the SERC Field Test Guideline "Verification of Generator Unit Frequency Response". Documentation of the test results will provide feedback showing that the field test was successful and/or will help to enhance the test guideline.

Use the attached SERC Field Test Guideline "Verification of Generator Unit Frequency Response" to perform the test (engineering study). Complete one (1) report form for each unit tested.

Provide the following information:

1. Is there a maintenance management program in place for the turbine speed load governor control system (analog and/or digital based)? (Yes or No) yes
    - If yes, what is the maintenance interval? 84 (months)
2. Is there a configuration management program in place for the turbine speed load governor control system (analog and/or digital based)? (Yes or No) no
3. Was good correlation between the generator output (MW vs. time) and the model obtained? (Yes or No) Yes

    3. A. **If yes:** (Use additional pages if needed to explain.)
    - How long did it take to obtain the generator output data? 1 (hours)
    - How long did it take to set up the model to simulate this event? 3 (hours)
    - How long did it take to compare the generator output data to the model? 1 (hours)
    - Did the model parameters or type need to be changed? no

    3. B. **If No:**
    - Use additional pages to explain.
4. List any material costs associated with this study. none
5. Please list any suggested changes to the guideline? none
6. Provide a completed Attachment # 2 to the SERC Field Test Guidelines for Verification of Generator Unit Frequency Response (MOD-027).
7. Name of the person completing the form: Sujit Mandal Phone Number: 504 576 2342 Company Name: Entergy

Send the completed report form and supporting documentation electronically to: phuntley@serc1.org.

MOD-027 SERC Field Test Reporting Form

The purpose of this form is to provide a consistent report format for field testing results after using the SERC Field Test Guideline "Verification of Generator Unit Frequency Response". Documentation of the test results will provide feedback showing that the field test was successful and/or will help to enhance the test guideline.

Use the attached SERC Field Test Guideline "Verification of Generator Unit Frequency Response" to perform the test (engineering study). Complete one (1) report form for each unit tested.

Provide the following information:

1. Is there a maintenance management program in place for the turbine speed load governor control system (analog and/or digital based)? (Yes or No) NOT SURE
   - If yes, what is the maintenance interval? (months)
2. Is there a configuration management program in place for the turbine speed load governor control system (analog and/or digital based)? (Yes or No) NOT SURE
3. Was good correlation between the generator output (MW vs. time) and the model obtained? (Yes or No) We were not able to perform this test. Our EMS currently does not log individual Unit MWs at 6 seconds or less intervals. I was able to get MWs for some units from unit controllers, but unit control system clocks were not synchronized with the EMS clock. Our TO was also tied up gathering material for the NERC compliance filing.

   3. A. **If yes:** (Use additional pages if needed to explain.)
   - How long did it take to obtain the generator output data? (hours)
   - How long did it take to set up the model to simulate this event? (hours)
   - How long did it take to compare the generator output data to the model? (hours)
   - Did the model parameters or type need to be changed?

   3. B. **If No:**
   - Use additional pages to explain.
4. List any material costs associated with this study.
5. Please list any suggested changes to the guideline?
6. Provide a completed Attachment # 2 to the SERC Field Test Guidelines for Verification of Generator Unit Frequency Response (MOD-027).
7. Name of the person completing the form: Pat Longshore Phone Number: 803-217-7490 Company Name: SCE&G

Send the completed report form and supporting documentation electronically to: phuntley@serc1.org.

SERC PRC-019 Field Test Reporting Form

The purpose of this form is to provide a consistent report format for field testing results after using the SERC Field Test Guideline "Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection". Documentation of the test results (this field test may actually be considered an engineering study) will provide feedback showing that the field test was successful and/or will help to enhance the test guideline.

Use the SERC Field Test Guideline "Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection" to perform the test (engineering study). It is suggested that a newer, more modern generating unit be used for the test, to verify the coordination of more different types of protection relay systems (versus an older unit that may not have as many generator protection relays). Complete one (1) report form for each unit tested (studied).

Provide the following information:

1. How long did it take to assemble (bring together) the technical data (generator capability curve(s), voltage regulator settings, protective relay settings, etc.) needed to perform the engineering study? ___40_____ Hours
2. What methodology / tools were used to perform the coordination studies?

   ☐ Computerized coordination curves

   ☐ Manual coordination curves

   ☒ Combination (computerized / manual)
3. How many man-hours did it take to develop the methodology / tools? ___320______
4. How long did it take to analyze the technical information and draw the curves (plots)? __40______ Hours
5. List any material costs associated with this study. ____Curve plotting Software $1,810.____
   ____
6. Were the voltage regulator settings and the protective relay settings coordinated with the generator capability curve (as found)? __Yes______ (Yes or No)
7. If not, list the devices that needed configuration changes: ___The settings were coordinated with the capability curve; however the Volts/Hz limit and trip were set to high.
   ____
8. Please list any suggested changes to the guideline or Draft NERC Reliability standard?
   ____
9. Provide the completed curves (plots). Remove all references that would identify the unit (company, station, and unit names, etc). Attached.
10. Name of person completing form: _David Williams__ Phone number _706.643.0313__Company name __Corps of Engineers – Mobile District

Generator Owner PRC-024 SERC Field Test Reporting Form

The purpose of this form is to provide a consistent report format for field testing results after using the SERC Field Test Guideline "Generator Performance During Frequency and Voltage Excursions". Documentation of the test results will provide feedback showing that the field test was successful and/or will help to enhance the test guideline.

Use the attached SERC Field Test Guideline "Generator Performance During Frequency and Voltage Excursions" to perform the applicable engineering studies. Complete one (1) report form for each unit tested.

Provide the following information:

1. How long did it take to assemble (bring together) the technical data needed to plot the expected unit frequency withstand capability? 8 Hours
2. If frequency excursion plots were created, what methodology / tools were used to construct the frequency excursion coordination plots?

   ☐ Computerized coordination curves

   ☐ Manual coordination curves

   ☒ Combination (computerized / manual)
3. If frequency excursion plots were not created, please explain the methodology used to demonstrate coordination with the draft SERC frequency excursion characteristic.
4. How many man-hours did it take to develop the methodology / tools? 4
5. Did the results indicate that the generator would be expected to remain on line for the draft SERC frequency Characteristic? ☒Yes ☐ No

   If no please attach additional information as appropriate.
6. How long did it take to analyze the technical information and draw the frequency curves (plots)? 2Hours
7. List any material costs associated with the generator frequency withstand capability portion of this field test. Curve ploting software $1,810.
8. How long did it take to assemble (bring together) the technical data needed to plot the expected Low Voltage Ride Through (LVRT) capability? Hours
9. If LVRT plots were created, what methodology / tools were used to construct the frequency excursion coordination plots?

   ☐ Computerized coordination curves

   ☐ Manual coordination curves

   ☒ Combination (computerized / manual)
10. If LVRT plots were not created, please explain the methodology used to demonstrate coordination with the draft SERC LVRT characteristic.
11. How many man-hours did it take to develop the methodology / tools? 16

12. Did the results indicate that the generator would be expected to remain on line for the draft LVRT characteristic? ☒Yes ☐ No Note: The current Unit and Bus under voltage relay settings will ride through the draft LVRT curve. Presently our organization does not have sufficient data to determine if the current excitation and AVR settings will ride through the draft LVRT curve.

    If no please attach additional information as appropriate.

13. How long did it take to analyze the technical information and draw the LVRT curves (plots)? Hours

14. List any material costs associated with the generator LVRT capability portion of this field test. Curve ploting software $1,810.

15. Please list any suggested changes to the guideline or the draft NERC Reliability Standard.

16. Provide the completed curves (plots) and other applicable documentation. Remove all references that would identify the unit (company, station, and unit names, etc). See attached.

Generator Owner PRC-024 SERC Field Test Reporting Form

The purpose of this form is to provide a consistent report format for field testing results after using the SERC Field Test Guideline "Generator Performance During Frequency and Voltage Excursions". Documentation of the test results will provide feedback showing that the field test was successful and/or will help to enhance the test guideline.

Use the attached SERC Field Test Guideline "Generator Performance During Frequency and Voltage Excursions" to perform the applicable engineering studies. Complete one (1) report form for each unit tested.

Provide the following information:

1. How long did it take to assemble (bring together) the technical data needed to plot the expected unit frequency withstand capability? **2 Hours**
2. If frequency excursion plots were created, what methodology / tools were used to construct the frequency excursion coordination plots?

   ☐ Computerized coordination curves

   ☐ Manual coordination curves

   ☐ Combination (computerized / manual)
3. If frequency excursion plots were not created, please explain the methodology used to demonstrate coordination with the draft SERC frequency excursion characteristic. **Most of our generating units would be tripped manually during frequency excursions. Each control room has three Annunciator alarms for frequency changes; 59.8 Hz, 58.1 Hz, and 57.6 Hz. The 59.8 Hz alarm alerts the control room operator (CRO) that there is an issue with the frequency. The CRO will manually trip the unit if the frequency is at 58.1 Hz for 30 seconds or at 57.6 Hz for 1 second.**
4. How many man-hours did it take to develop the methodology / tools?
5. Did the results indicate that the generator would be expected to remain on line for the draft SERC frequency Characteristic? ☐ Yes ☒ No

   If no please attach additional information as appropriate. **See number 15**.
6. How long did it take to analyze the technical information and draw the frequency curves (plots)? **0 Hours**
7. List any material costs associated with the generator frequency withstand capability portion of this field test. **$0**
8. How long did it take to assemble (bring together) the technical data needed to plot the expected Low Voltage Ride Through (LVRT) capability? Hours
9. If LVRT plots were created, what methodology / tools were used to construct the frequency excursion coordination plots?

   ☐ Computerized coordination curves

   ☐ Manual coordination curves

   ☐ Combination (computerized / manual)

Generator Owner PRC-024 SERC Field Test Reporting Form

10. If LVRT plots were not created, please explain the methodology used to demonstrate coordination with the draft SERC LVRT characteristic. **One of our relay engineers evaluated the characteristics of the back-up impedance relay. Determined that the generating unit would not stay on line for a voltage profile shown on the "Proposed SERC Generator Voltage Excursion Curve". Also, see the attached example showing that other types of generating unit equipment can force a unit off line during voltage excursions.**

11. How many man-hours did it take to develop the methodology / tools? **1 hour**.

12. Did the results indicate that the generator would be expected to remain on line for the draft LVRT characteristic? ☐ Yes ☒ No

    If no please attach additional information as appropriate. **See number 15.**

13. How long did it take to analyze the technical information and draw the LVRT curves (plots)? **2 Hours**.

14. List any material costs associated with the generator LVRT capability portion of this field test. **$0**

15. Please list any suggested changes to the guideline or the draft NERC Reliability Standard.

<u>Proposed UF Excursion Curve</u>:

After a review by our turbine engineers and equipment vendors, the operating limits for frequency excursions could possible be adjusted to comply with the proposed curve.

<u>Proposed UV Excursion Curve</u>:

I suggest that the implementation of this standard be delayed until:

- **A.** **Industry specialists analyze, develop, and provide a method(s) for reviewing generating equipment and protective relay characteristics to guide generator operators on how to comply with the proposed standard.**
- **B.** **A cost benefit analysis should be performed to determine the most economical and logical way to achieve the desired end result; should generator owners perform engineering studies and equipment/protective relay changes or should transmission owners/planners/operators change the system models and/or install new transmission equipment/relays or both?**

16. Provide the completed curves (plots) and other applicable documentation. Remove all references that would identify the unit (company, station, and unit names, etc)

17. Name of the person completing the form: **Larry Whanger** Phone Number **804.273.3576** Company Name **Dominion.**

Send the completed report form, plots, models and documentation to **phuntley@serc1.org**

TECHNICAL REPORT

[redacted]

Loss of Generation

Due to

Transmission Fault Event

Technical Report
Loss of Generation Due to Transmission Fault

1. EXECUTIVE SUMMARY

This report is prepared due to an event that occurred on January 31,2006 that caused three of four generating units at the [redacted] to trip. The event that took place involved a rare type of fault combined with a rare equipment failure. The fault that occurred suppressed the voltage at the station and the circuit breaker failure prolonged the duration of the event to the extent that station equipment malfunctioned and could not be overcome before most of the generating units were lost.

This Technical Report provides data calculated by the Transmission Department reflecting a fault study and the associated Voltages that can be expected to occur at the [redacted] Switchyard for various fault scenarios. Using this data, and reliability data published in the IEEE Std 493 (Recommended Practice for the Design of Reliable Industrial and Commercial Power Systems) for similar equipment and faults, the probabilities associated with different events are calculated. Each such event, will cause varying degrees of Voltage Sags and impacts to the Station Auxiliaries Electrical System and operating Units.

The impacts from various fault conditions for each transmission line are projected in a somewhat subjective manner based on the prior impact and expected operating conditions that will occur and the lack of a uniform standard for equipment tolerance to Voltage Sag events for which to base a solid predictive model. These impacts are based on traditional design philosophies of power stations in general, and a full detailed assessment and testing program are required to improve the confidence factor of these assessments.

The costs of Generation losses resulting from an event on the Transmission system are calculated by using replacement power costs for the year 2006, averaged across all four units with each unit at maximum capacity, multiplied by the various probabilities and the expected impact that each event occurrence should produce. The expected annual costs for this type of event is [redacted].

Based on the Reliability Data published, and the characteristics of the transmission lines connected, the transmission lines connected to [redacted] should expect 4.06 outages (momentary or sustained) per year.
The cost of replacement power for all units is based on a six-hour loss for each for a combined total of 3750 MWH at [redacted].

Recognizing that the most economical alternatives for corrective action should be focused at specific equipment, recommendations are offered for the known equipment and suggestions regarding testing techniques are provided for the unknown equipment. Future critical equipment upgrades should include voltage tolerance requirements as part of the equipment specification and as conditions warrant.

Other factors for future consideration that are beyond the scope of this report, include Voltage Profile Studies of the Station Auxiliary Electrical System to determine that all transformers are being operated at their optimum taps, and Switchyard upgrades that may improve specific risks, but at increased costs.

2. INTRODUCTION

On January 31, 2006, the [redacted] sustained a voltage sag of approximately 45% for 26 cycles as indicated in the attached exhibits. The voltage sag resulted from a double line to ground fault caused by a lightning strike approximately 6.9 miles from the station on Line 164. The terminal Breaker at Reeves Ave substation failed to trip and initiated the Breaker Failure Scheme. As a direct result, the power station lost three of four generating units that were operating at the time.

2.1. Purpose

One objective for this document is to provide some insight and understanding regarding the previous event, and understand the consequences/probabilities of future events.

Another objective is to determine the risk of exposure to a similar event that will happen in the future, identify weaknesses in the existing protection against these events. Recommend measures that may be appropriate to mitigate these risks and to quantify these measures by providing an economic evaluation based on the likelihood of experiencing a future event.

2.2. References

The following publications have been used to derive data and information

ANSI/IEEE Std 493-1997 493 Recommended Practice for the Design of Reliable Industrial and Commercial Power Systems
ANSI C84.1-1982 American National Standard for Electric Power Systems and Equipment (60 Hz)– Voltage Ratings
ANSI/IEEE Std 666-1991 Design Guide for Electric Power Service Systems for Generating Stations
ANSI/IEEE Std 1159-1995 IEEE Recommended Practice for Monitoring Electric Power Quality

3. [redacted] UNIT TRIPS

The following information is based on a report issued by the station concerning the events that occurred January 31, 2006

[redacted] summary of events observed/recorded for each unit, 01/31/06

At approximately 06:21:15 a line fault occurs in the system (at Reeves Ave). 115KV voltage at [redacted] substation drops to about ½ (~65KV) for 4 cycles and does not fully recover for at least 26 cycles; total time about ½ of a second. See Exhibit 1.

The affect on each of the generating unit is reproduced from a station report repeated here.

3.1. Unit 1

06:21:15 (PI) All 3 coal feeder motors in service stopped running (480V feed to Merrick controls). No alarms are received in the control room. Running status was not removed in logic. Approximately 1.5 minutes after motors stop the unit trips on loss of flame scanners, black furnace.

3.2. Unit 2

06:21:15 (PI) All 3 coal feeder motors in service stopped running (480V feed to Merrick controls). No alarms are received in the control room. Running status was not removed in logic. Approximately 1.5 minutes after motors stop the unit trips on loss of flame scanners, black furnace.

Note: The coal feeder running status issue was verified on restart of unit 2 A mill feeder. The feeder motor stopped but no notification to the control room operator occurred. The feeder running status was still 'proven' but the motor was not on. If the feeder status worked correctly the units' would have tripped on 'loss of fuel' and not 'black furnace'. Removal of all fuel sources to the boiler is an MFT condition.

3.3. Unit 3

06:21:15 (SOE) 'C' coal feeder motor stopped (480V supply). Coal feeder stopped is recorded on the sequence of events recorder (SOE). The unit goes into runback mode after approximately 2 minutes due to loss of fuel from 'C' mill. The Control Room operator who was consumed with unit 4's related issues determines that unit 4 is not recoverable and switches attention to unit 3 and recovers the unit.

The unit 3 turbine board recorder reboots due to the electrical fault as indicated by loss of turbine data in PI.

3.4. Unit 4

3.4.1. 06:21:15 (SOE) 'C' coal feeder not running (480V supply to speed controller)

3.4.2. 06:21:15 (PI) BFPT main LO pump stopped (480V motor)

3.4.3. 06:21:15 (PI) 'A' dil. air fan on the SCR stopped (480V motor)

3.4.4. 06:21:16 (SOE) 'C' coal feeder running. It appears that the fault knocked 'C' feeder motor out but it came back due to a maintaining contact to run from Modicon.

3.4.5. The feeder speed in PI drops in half and then recovers.

3.4.6. 06:21:16 (SOE) BFPT tripped. The BFPT tripped after the BFPT main LO pump motor stopped. The Aux LO pump and DC back up pump started within two seconds of the main pump stopped. The Aux pump did not catch the autostop oil pressure from dropping below 60 psi. At 60 psi the low autostop oil pressure switches tripped the BFPT.

3.4.7. 06:22:29 (SOE) Low Drum Level Trip

3.4.8. 06:24:18 (SOE) Unit is taken off line by the CRO (opened breakers). The turbine solenoid trip was at 06:22:29, throttle valves recorded closed at 06:22:30.

3.5. Root Cause of Motors Stopping

The probable cause of the various motors stopped was the large drop in system voltage which also dropped the units' 480V buses to either drop out motor starter contactors or fault motors due to a voltage drop below minimum required running voltage.

5. STATION EQUIPMENT

5.1. Industry Standards

IEEE Standard C84.1 establishes Nominal voltages for Power System Equipment and also defines recommended ranges for equipment to operate. Voltage tolerance limits are based on the ANSI/NEMA MG-1, which established the criteria for standard induction motors at +/- 10% of nameplate ratings 230V, 460V, etc. Since motors represent a large component of utilization equipment, they were given primary consideration in establishing the standard. However, there is no national standard that requires particular immunity for voltage sags that may occur on the system. Some specialized interests such as the semi-conductor industry have established specification criteria for tolerance against Voltage Sags for equipment manufactured for their plants (See Exhibit 11).

It should be noted that Generating Stations are not typical in regard to the Voltage Sags that equipment should be expected to operate satisfactorily. Generating station Voltage Limits have always required tolerance against the starting duty of very large motors connected to the system, and consequently, design criteria is to allow starting of this large equipment without dropping out relays and contactors for lower voltage motors and equipment. It is also acceptable to have lower voltages because of the high degree of instrumentation used to monitor process conditions. Most station equipment originally installed with the unit should continue to operate with Voltage sags to 75 – 80% of nominal voltage.

5.2. Equipment Vulnerable to Voltage Disturbances

Equipment that is most vulnerable to voltage disturbances include solid state equipment including Control equipment specifically DCS and PLCs, Soft Start Motor Controllers, and Adjustable Speed Drives. To a lesser degree, electromechanical components such as relays, solenoids and contactors, since these all react slightly slower due to the inherent energy storage characteristics.

The ability of an individual piece of equipment varies from manufacturer to manufacturer. The Voltage Ride-through times must be evaluated for eash specific equipment suspected of being sensitive to the voltage variation.

Some examples of typical equipment –

- Solenoids 10% overvoltage and 15% undervoltage.
- Control Relays and Motor contactors are required by standrds to operate at + 10% and –15% voltage, however most will hold in down to 65% and some event to 50%.

5.3. Techniques for Improving Tolerances to Disturbances

Three-phase equipment is less susceptible to transmission events than single-phase equipment and while most power station equipment is supplied from three-phase sources, there are some equipment supplied from single-phase systems including panels feeding instruments and controls.

Control Transformers used for motor control, if oversized, provide better ride-through capability for the motor contactor. Control Transformers located in the same MCC should be connected to alternating primary phases, A-B, B-C, C-A, to reduce the chances of losing all of the equipment as opposed to just a third of the equipment.

Constant Voltage Transformers (CVT) also known as ferroresonant transformers can provide an economical solution for small loads which are fairly constant.

All solid state controls and instrumentation equipment such as embedded controllers within a equipment package should be fed from the UPS if the equipment is critical to production.

5.4. Specific Recommendations for Limited Station Equipment

Test and verify alarms from Coal system weigh feeders
This testing should incorporate the validity of an alarm, for example, a Weigh Feeder flow alarm should incorporate or prove both, conveyor movement and load. Models that have a paddle switch activation only, may not provide an alarm if the belt just stops with coal on it.

If the Weigh Feeder Controller is not fed from UPS, a Vital Bus Circuit should be supplied to it.

Consider changing out the existing DC adjustable speed drive with 1980 vintage rectification equipment, with an AC Variable Frequency Drive with much better ride-through capability.

Survey equipment and bus operating voltages at various station and system loading conditions in order to determine that transformers so equipped, are set at taps conducive to providing better voltage during Voltage Sags.

Consider implementing a testing program that incorporates the use of a Voltage Sag Generator to identify equipment that may be susceptible to Voltage Sags.

5.5. Future Considerations

The most economical solutions are almost always associated with the individual components that make up a system. System alternatives provide less economical solutions.

Identifying the weakest link in various critical systems will provide the most economical results.

System studies for obtaining the most beneficial Voltage profiles for the operating systems should be considered, and may not be cost prohibitive after the current efforts to construct accurate models of all of the stations is complete.

Future transmission considerations should include replacing old equipment if the age is associated with failures, particularly at the [redacted] Switchyard. These replacements could provide opportunities to further sectionalize the bus to provide better reliability if economically justifiable.

Generator Owner PRC-024 SERC Field Test Reporting Form

SC Generation and Transmission Submittal   Date: 6-07-2007

The purpose of this form is to provide a consistent report format for field testing results after using the SERC Field Test Guideline "Generator Performance During Frequency and Voltage Excursions". Documentation of the test results will provide feedback showing that the field test was successful and/or will help to enhance the test guideline.

Use the attached SERC Field Test Guideline "Generator Performance During Frequency and Voltage Excursions" to perform the applicable engineering studies. Complete one (1) report form for each unit tested.

<u>Provide the following information:</u>

1. How long did it take to assemble (bring together) the technical data needed to plot the expected unit frequency withstand capability? **2 Hours**
2. If frequency excursion plots were created, what methodology / tools were used to construct the frequency excursion coordination plots?

   ☐ Computerized coordination curves

   ☒ Manual coordination curves

   ☐ Combination (computerized / manual)
3. If frequency excursion plots were not created, please explain the methodology used to demonstrate coordination with the draft SERC frequency excursion characteristic. **See Curve #2 of the first attachment.**
4. How many man-hours did it take to develop the methodology / tools? **2 Hours**
5. Did the results indicate that the generator would be expected to remain on line for the draft SERC frequency Characteristic?   **<u>X</u>** Yes   No

   If no please attach additional information as appropriate.
6. How long did it take to analyze the technical information and draw the frequency curves (plots)? **2 Hours**
7. List any material costs associated with the generator frequency withstand capability portion of this field test. **Minimal**
8. How long did it take to assemble (bring together) the technical data needed to plot the expected Low Voltage Ride Through (LVRT) capability? **2 Hours**
9. If LVRT plots were created, what methodology / tools were used to construct the frequency excursion coordination plots?

   Computerized coordination curves

   ☐ Manual coordination curves

   ☒ Combination (computerized / manual)

10. If LVRT plots were not created, please explain the methodology used to demonstrate coordination with the draft SERC LVRT characteristic. **For the first attempt, calculated the high side voltage required for the unit to absorb**

enough Mvars to operate the Back-up Over Current Relay (BUOC) via steady state evaluation with steady state Mvar limits relaxed. A small bus loadflow was created for dynamic simulations – with the test machine and a large dominant "Eastern Interconnection" machine with high inertia and constant excitation. Fault impedances were varied to approximate the LVRT characteristic in the Field Test guidelines at the highside of the GSU for the test machine. MVA was plotted from the test machine to see if the BUOC relay, set at 1.3 times unit MVA with a 70 cycle time delay, would pick up and time out. Other less severe faults within the LVRT characteristic were also assessed to ensure exciter dynamics, when presented with higher voltages at the exciter PPTs, would not result in operation of the aforementioned BUOC relay.

11. How many man-hours did it take to develop the methodology / tools? **N/A**
12. Did the results indicate that the generator would be expected to remain on line for the draft LVRT characteristic? ☐ Yes ☒ No **(No, per steady state simulations)**

    ☒ Yes No **(Yes, per dynamic simulations- see second attachment)**

    If no please attach additional information as appropriate. **See Curve #1 of first attachment.**
13. How long did it take to analyze the technical information and draw the LVRT curves (plots)? **4.5 Hours (steady state) + 8.0 Hours (dynamics)**
14. List any material costs associated with the generator LVRT capability portion of this field test. **Minimal**
15. Please list any suggested changes to the guideline or the draft NERC Reliability Standard. **Back-up Over Current setting can not be relaxed without compromising the generator protection. If units are identified where the BUOC is limiting, application of a very inverse time over-current relay and an impedance relay could <u>possibly</u> be set to provide adequate generation protection.**
16. Provide the completed curves (plots) and other applicable documentation. Remove all references that would identify the unit (company, station, and unit names, etc)

    See attached Curve #1 (Voltage) and Curve #2 (Frequency) of first attachment.

Comments Related to Balance of Plant Performance for SERC Proposed Frequency and Voltage Ride thru Curves
Rev. 0
Date: 6/11/2007

The proposed Under Frequency (UF) and Under Voltage (UV) requirements in "SERC Field Test Guidelines- Generator Performance during Frequency and Voltage Excursions" developed from the draft version of NERC Standard PRC-024 have been under review by power plant design engineers to access the impact on plant continuous performance. Due to the complexity of todays power generating stations this review is incomplete. However, the following does address a significant portion of the components and systems that can be impacted by the proposed UF and UV ride thru curves contained in the SERC document.

A. Under Frequency Ride Through Curves (Figure 1 of SERC Field Test Guidelines):

The ability of a unit/plant to ride through the proposed Under Frequency requirements depends on the under frequency response characteristics of the following equipment, systems and protective devices.

Note, in evaluating the effects of UF we assumed that in general the voltage also decreases in a similar manner as the frequency and thus the V/Hz does not increase significantly.

1. <u>Turbine Generators:</u> The primary units of concern are the turbo-generators and Combustion Turbines (CTs). Turbo-generators have under frequency limits established by the manufacturers due to turbine blade vibration (resonance) limitations. For most turbo-generating units, the subject limits are fairly well defined and typically are used to establish turbine under frequency protective and Under Frequency Load Shedding (UFLS) relay set-points. Based on the technical reviews to date, turbo-generator under frequency limitations are not expected to be a problem with the proposed curve and should coordinate.

Similar data on CTs needs to be developed but no published under frequency limits have been found. Finally, conventional hydro turbine-generators don't have under frequency limitations.

2. <u>Boiler Control Systems:</u> The comments on Boiler Control Systems (BCS) are primarily relating to the under voltage effects, however the issues are related. Most of the newer BCS's utilize UPS's which should minimize concerns with UF events. However, without reviewing the complete system, it cannot be confirmed that the BCS remote devices (instrument sending units and actuators) are

powered from dc or UPS supplies. On older plant designs, the BCS is typically fed from redundant ac sources (non UPS). Since both sources will see the same level of UF, one cannot generalize its performance during the UF event. Thus, this will require further study.

3. Nuclear Power Plants: The following relates to Pressurized Water Reactor (PWR) designs that utilize Reactor Coolant Pumps (RCPs). A critical part of the reactor protection system is to maintain flow through the reactor and the steam generators. This is accomplished with the RCPs. This is so critical that the subject pumps are equipped with flywheels to insure they will continue to turn for a specific period of time without ac power to the motors. The subject motors have under-frequency protection that will trip the ac supply breakers to the motors if the frequency drops (low frequency results in a slow down of the motor and thus the pump) below a specified set-point. A review of at least two PWR plants shows the proposed UF limit curve coordinates with the UF ride-thru curve. It is recommended that other PWR owner/operators review these set points to insure proper coordination.

Please note that Boiling Water Reactor (BWR) plants and systems were not reviewed and it is recommended that a detailed review be performed.

Another unique sub-system employed in Nuclear Power Plants that should be reviewed is the Emergency Diesel Generator (EDG). Each EDG typically has under frequency relays that protect it if a severe UF event occurs while the EDG is paralleled with the system for testing. A review of one plant showed the EDG UF relays to be set to trip in 20 cycles at 59.5 Hz. Thus, the EDG would likely trip for a severe UF event. However, this should not cause a unit trip or have any other adverse impact to the plant and, therefore, does not represent a coordination issue with the proposed UF requirements. Other Nuclear Plant owners/operators should review the EDG systems and the associated UF set points to ensure no adverse impacts are discovered.

Finally, it is recommended that the Reactor Trip System M-G Sets for a PWR nuclear unit be evaluated to determine if they could ride through the proposed under frequency excursion curve and maintain adequate power to the nuclear reactor rod controls. Time did not permit this review to be complete but if they are unable to ride thru, a reactor trip and, hence, unit trip will occur.

4. Generating Plant Protection Systems: A review of the protective relaying schemes applied at several generating stations was performed for the proposed UF curve. Of the units reviewed only one UF protection coordination problem was discovered. The subject coordination problem could be corrected to resolve the mis-coordination. Thus, the initial assessment is that the proposed UF requirements can be coordinated with plant protection.

Note: The above assumes the plant/system voltage will also decrease in a similar manner to the frequency. Otherwise, Volts per Hertz protection will need to be considered.

5. Station Service Loads: For station service loads, only induction motors and Adjustable Speed Drives (ASDs) were considered. In the case of an induction motor, the industry standards permit deviations of +/- 5% frequency deviation provided the voltage remains at rated. This operating limit is generally a continuous capability and would not apply for the short time period under consideration. If the frequency drops, the motor speed would be expected to drop in proportion to the frequency drop. Since the frequency drop is less than 5% motor loads are not expected to exhibit any significant short time performance problems.

For ASDs, more research is needed but, it is believed that they are also required to meet the +/- 5% deviation in rated frequency.

B. Under Voltage Ride Through (Figure 4 of SERC Field Test Guidelines):

1. Turbine-Generators: No specific short-time under voltage limits have been identified for turbine generators. On newer units or retrofit application that utilized static excitation systems powered from the generator or plant bus voltage, the proposed voltage transient would result in a reduction in excitation during the fault and voltage recovery period. Typically static systems are purchased with a minimum of 1.5 per unit ceiling voltage which means these systems would provide full excitation for generator bus voltages down to 75 % of rated. At voltages below this level, the excitation voltage would decrease during the fault profile given in the supplement. Calculations have been performed of expected generator and station service bus voltage for a sample plant which shows the generator bus voltage drops to approximately 30% for the switchyard fault (see Attachment A.) This would result in a maximum excitation voltage of 45% during the initial fault. Please note, even though the field voltage decreases almost instantaneously, the field current {terminal voltage producer} will take longer to decay from pre-fault levels.

Assessing the overall impact of the voltage profile further, would require dynamic studies of the unit/plant for the proposed transmission voltage profile.

2. Boiler Control Systems: The severity of the voltage transient and the resulting plant ac distribution system voltages would significantly impact the BCS even if it is powered from a UPS. The assessment to date indicates that some BCSs might require configuration changes and/or power supply changes to improve the possibility of survival of the subject event. As discussed above for UF events, each owner would need to evaluate the survivability of the BCS, actuators, transmitters, etc. for the stated voltage profile.

3. Station Service Loads: In general the station service loads are either unit connected (fed from transformers connected to the generator terminals) or fed from transformers supplied by the plant switchyard. Some plants designs have loads served from both sources (generator and switchyard) during normal operation. Examples of plants with some or all of station service loads normally supplied from the switchyard are nuclear power plants, many Combined Cycle plants, and plants with new scrubber loads.

To judge the overall impact of the proposed voltage ride through curve, two different plant distribution systems were modeled. A unit where all of the station service load is directly served from the generator was modeled first. The attachment titled "Typical Fossil Unit" (Attachment A) shows the generator bus voltage drops to approximately 30% for a high side fault. The corresponding station service bus voltages are also in the 30% range. It is judged that most of the station service load should ride thru the initial fault event of 15 cycles, but the performance and ride thru capability for the recovery phase of the proposed voltage profile curve cannot be predicted. A dynamic simulation would be required to determine if the station service loads would fully recover. This phase of the analysis was not completed.

Another issue identified for PWR Nuclear power units is the RCP under voltage protection. These under voltage relays are designed to trip the unit by tripping the rod control system in the event of a loss of voltage to the RCPs. A typical trip setting for these relays is less than 67% of the rated bus voltage (4160V) for 0.5 seconds. These relays would likely trip for the proposed voltage excursion curve, thus tripping these unit(s).

The second distribution system modeled is for a typical CC plant where all or a portion of the station service load is supplied from the switchyard. This arrangement also applies to the emergency buses for most Nuclear Power Plants. The results of this analysis are provided in Attachment B. For a high side fault the station service bus voltage drops to zero as one would expect. Again, it is expected that most of the loads would remain connected to the supply buses during the initial fault (approximately 15 cycles), but the long term response which would occur during the voltage recovery phase can not be assessed without dynamically modeling the system.

A special case for this configuration is the emergency buses for Nuclear Power Plants. For these buses, special protective relaying schemes are employed to detect loss of off-site voltage. If these relays operate, the buses are isolated from the transmission system, the EDGs will start and safety related loads are sequenced onto the isolated sources. This action is highly undesirable but within the design basis of the plant. If this event occurred it would be very unlikely that either type of unit (Nuclear or CC unit) would remain connected to the grid. In fact, for the two nuclear plants reviewed, it was determined that the proposed voltage excursion curve would cause the loss-of-offsite-power (LOSP/LOOP) relays to actuate and trip the unit. Due to the very short time delays employed for nuclear plant LOSP/LOOP protection, it is believe that these relays would operate for most Nuclear units for the proposed curve. However, it is recommended that each nuclear unit be evaluated to determine if the proposed voltage ride thru would actuate the LOSP/LOOP relays and automatically trip the unit.

The final configuration to consider is where new scrubber systems are being installed and the station service load for the scrubber is fed from the switchyard. This configuration is also representative of the system shown in Attachment B. The consequence of momentary loss of supply voltage and slow voltage recovery time has not been fully evaluated. However, on some designs, initial reviews indicates that these units may survive the proposed voltage transient (lose the scrubber but not the unit.)

4. Generating Plant Protection Systems: Relay engineers have done a review of typical protection schemes utilized on most generating units in regard to protection responses to the voltage profile. The following addresses typical generator and station service protection. Special protective schemes for nuclear power stations (degraded grid, LOSP, Reactor Protection Systems) are not included except as noted above. The following relays are highlighted:

a. Generator Under voltage Relays: There are some units equipped with relays which trip for under voltage on the generator bus. Assuming the generator bus voltage follows the high-side transmission voltage exactly, there are a couple of these relays that were found to be marginal. However, since the generator voltage does not drop to zero for a transmission high side fault and the regulator will be attempting to boost the generator voltage back normal, the voltage seen by the relays should be less severe than a total loss of voltage the relays probably will not operate. A detailed model of the generator and exciter/voltage regulator would be required to determine the exact response of the relays to give a more definitive answer.

b. Power Potential Source Exciter PPT Secondary Relaying: Several units reviewed have under voltage relays connected on the low side of the exciter Power Potential Transformer (PPT) secondary which are intended to operate for close in faults if the excitation should collapse. The intended setting for these relays is 2 seconds at zero volts. Dynamic simulations show that the exciter would be expected to sustain itself for a fault on the transmission system since its voltage will not drop to zero.

c. Station Service Bus Under Voltage Relays: Some units have bus under voltage relays that trip motor loads for cases of extended under voltage. For the cases reviewed the time delay was found to be much longer than the UV excursion lasted.

d. Backup Overcurrent Relays: Initially it was thought that these relays pose a potential problem. For the distance relay types, the trip setting is typically 75-120 cycles. Utilizing steady state solution techniques and the transmission voltages as shown on the LVRT curve, the generators would be supplying significant reactive current into the system for at least 90 cycles, which would cause the distance relays to trip. However, dynamic analysis has shown that the expected excitation system dynamics results in an expectation that these relays would not trip for the voltage excursion. The response of the voltage-restrained overcurrent type applied to some units would be even more difficult to obtain but could also be an issue.

C. Conclusion:

Overall, our review indicates more significant concerns with a unit/plant being able to remain on line during the UV event than the UF event. The overall opinion is for the proposed voltage profile that many generating units may potentially trip. However, a unit by unit study would be required to evaluate the probability.

SERC Phase III-IV Field Test Results

Roger Green
Sharma Kolluri
Lee Taylor

June 18 - 19, 2007

Tampa, FL

Background

- SERC Volunteered for Phase III-IV Field Test in February 2006
- SERC Engineering Committee formed the Generator Standards Field Test Task Force
- NERC effort and SERC GSFT-TF activities officially began late May 06
  – SERC member entities volunteering include U.S. Army Corp of Engineers, Dominion, Entergy, South Carolina Electric & Gas, and Southern Company

Background

- GSFT-TF developed Field Test Guidelines and Reporting Forms for each draft Reliability Standard
  - These are <u>not</u> approved SERC procedures, standards, processes, etc.
  - Guidelines do contain details on “how” to implement the draft Reliability Standard requirements
  - Reference Attachment 1 in GSFT-TF Field Test Report
- Volunteer SERC entities used Reporting Forms as the basis of reporting their results

MOD-026-1 — Verification of Models and Data for Generator Excitation System Functions

- All SERC volunteer entities attempted to participate
  - 1 GO was unable to schedule Open Step in Voltage test
- Noteworthy Observations include:
  - In general, the end result is more accurate excitation system models
  - Process is expensive if Consultants are utilized

MOD-026-1 — Verification of Models and Data for Generator Excitation System Functions

- Noteworthy Observations continued:
  - After the Open Step in Voltage test, significant effort can be required to subsequently validate the model
    - Example – new static VR with existing rotating field exciter
  - To keep human and capital costs reasonable, GSFT recommends:
    - Exempt 75 MVA units and those interconnected < 100 kV
    - Allow sister unit and configuration controls

MOD-026-1 — Verification of Models and Data for Generator Excitation System Functions

- Noteworthy Observations continued:
  - Standard should include a list of acceptable models
  - Standard should list TP as an Applicable entity
- The GSFT-TF recommends a 7 year phase in period
  - 2 years effective date after adoption, then 20% a year for 5 years

PRC-019-1 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection

- All SERC GO volunteers participated
- 1 GO has been performing studies for a number of years
  - Found one limiter mis-coordination out of 130 studies
- Other GOs only performed study on one unit for proof of concept
  - Significant start up cost (manpower and tools)
  - no mis-coordination found
- Total cost for SERC anticipated to be up to $16M

PRC-019-1 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection

- Noteworthy Observations
  - GSFT recommends exemptions should include:
    - 75 MVA units and those interconnected < 100 kV
    - Older units
  - Requirement to plot prime mover limit adds no value
  - Requirement to plot additional limits that restrict MW or Mvar capability is ambiguous

PRC-019-1 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection

- Other Noteworthy Observations
  - GO should retain latest study and provide it to the Compliance Monitor upon request
  - Phase in period as currently drafted is acceptable (20% per year for 5 years)
  - Though costs are high, GSFT-TF recognizes the merit in moving the draft Reliability Standard forward

MOD-027-1 — Verification of Generator Unit Frequency Response

- All SERC volunteer entities attempted to participate
- Event Based methodology chosen
  - Small bus dynamics ready load flow and dynamics code developed to re-create the actual recorded Transmission System frequency excursion
  - Simulated governor model MW output is compared to actual unit MW event data
  - 2 Eastern Interconnection frequency excursion events evaluated

MOD-027-1 — Verification of Generator Unit Frequency Response

- Noteworthy Observations:
  - GSFT-TF believed that “proof of concept” was achieved
  - Not yet a “production grade” process required for a NERC Reliability Standard
    - Tool development
    - Recording Equipment (excluded participation by one GO)
  - Other obstacles to overcome
    - Process for identifying events in the Eastern Interconnection
    - Periodicity of frequency excursions relative to units being on-line but below Pmax (reason why one GO was not able to participate)

MOD-027-1 — Verification of Generator Unit Frequency Response

- GSFT-TF recommends this standard be "delayed" until issues with tools and processes are worked out
  - If Reliability Standard moves forward, recommend
    - a minimum 2 year delay after adoption, then 20% per year for the next 5 years with allowances for units not being on-line between Pmin and Pmax during identified frequency excursions
    - Exempt 75 MVA units and those interconnected < 100 kV
    - List TP as an Applicable entity

PRC-024-1 — Generator Performance During Frequency and Voltage Excursions

- 3 GOs and corresponding TOs participated
- Draft UF Ride Through Curve developed
  - UFLS relays need to be set above curve, and generation protection or operational limits below the curve
  - A curve acceptable to all the participants was developed
    - Disclaimer – other GOs would need to perform their own evaluations

Figure 4

PRC-024-1 — Generator Performance During Frequency and Voltage Excursions

- Generator relay of most concern is Backup Impedance
  - Steady state evaluation resulted in incorrect conclusion that relay would operate for LVRT curve
  - Dynamic simulation showed that the expected exciter dynamics would not result in operation of relay

Proposed SERC

Generator Voltage Excursion Curve

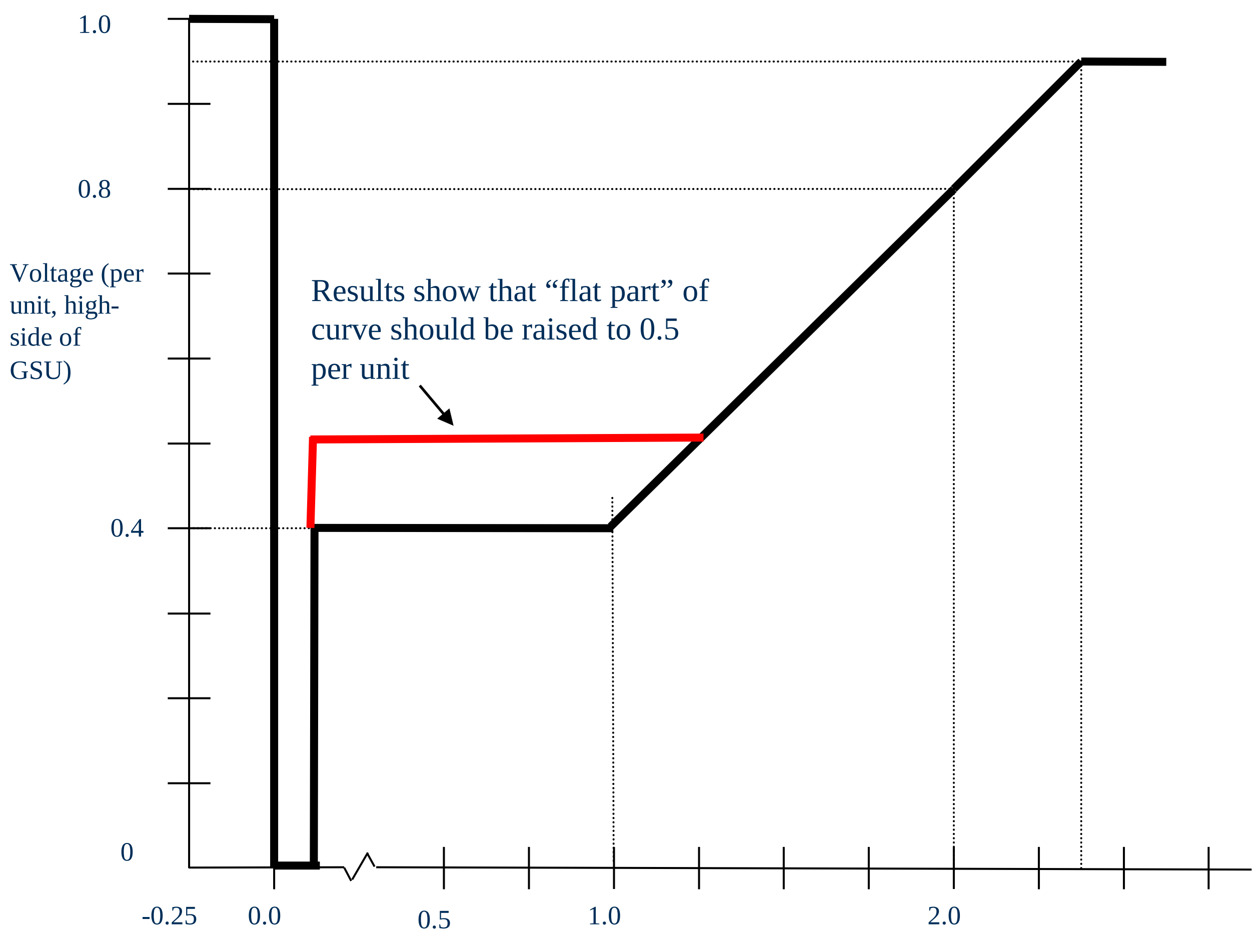

Figure 4

PRC-024-1 — Generator Performance During Frequency and Voltage Excursions

- Noteworthy Observations
  - For design of applicable UV schemes, Transmission Planners really need affirmation of assumption that unit can ride through a voltage excursion
  - As written, the draft Standard addresses only generation protective relays coordination and ride through
  - Standard does not address plant systems that could be limiting factor for ride through capability
  - However, assessment of these plant systems to ensure ride through capability is impractical
- Bottom line – additional research is required

WECC compliance with NERC draft Standards for 2006 Field Test

Mod-026, Mod -027, Prc-019, PRC-024

<table>
<tr><td>NERC Standard Requirement</td><td>WECC Document Reference</td></tr>
<tr><td>From Mod-026-1

R1. The Regional Reliability Organization shall establish and maintain procedures to address verification of models and data associated with generator excitation system functions including voltage regulator controls, limiters, compensators, and power system stabilizers. These procedures shall include the following:

R1.1. Generating unit exemption criteria including documentation of those units that are exempt from a portion or all of these procedures.

R1.2. Acceptable methods for model and data verification, including any applicable conditions under which the data should be verified. Such methods can include use of manufacturer data, commissioning data, performance tracking, engineering analysis, field verification of equipment settings, testing, simulation and comparison with test results or disturbance monitoring data, etc.</td><td>From the WECC Generating Unit Model Validation Policy (Policy) approved July 2006

A.3. Applicability:

A.3.1. Facilities Affected: This policy statement applies to generating facilities connected to the Western Electricity Coordinating Council (WECC) transmission grid at 60 kV or higher voltage (both new and existing, synchronous and non-synchronous) with single unit capacity of 10 MVA and larger, or facilities with aggregate capacity of 20 MVA and larger.

A.3.2. Baseline Testing

A.3.2.1. The Generator Owner shall test the generating unit and validate its model data.

The associated reference documents (with the Policy) titled Generating Unit Baseline Test Requirements and Generating Facility Model Validation Requirements describe methods for verification of the various data items and conditions under which they must be verified.</td></tr>
</table>

R1.3. Periodicity and schedule of verification and reporting, including a list of report recipients, schedules associated with field changes to existing units, and refurbished units.	According to the policy, generator owners are required to perform initial tests to validate data, then they are required to validate the data after changes to generator systems, and verify the data every 5 years or if the transmission planner has reason to suspect the data. They are required to provide the reports to the transmission planner, who review the report and provide it to WECC
R1.4. Information to be reported related to generator excitation system functions: **R1.4.1.** Verified manufacturer and type of excitation system/voltage regulator control system (for example, static, brushless, rotating, etc.). **R1.4.2.** Verified model for each excitation system/voltage regulator control system with associated gains, time constants, and limits. **R1.4.3.** Verified static set points for under and over excitation limiters. **R1.4.4.** Verified line drop compensator settings. **R1.4.5.** Open circuit test response data showing generator field voltage and generator terminal voltage (exciter field voltage and current data for brushless units). **R1.4.6.** Verified model for each power system stabilizer with associated gains, time constants, and limits. **R1.4.7.** Confirmation that the verification was conducted with the voltage regulator in the automatic voltage control mode **R1.4.8.** Method of verification used. **R1.4.9.** Date of verification.	The reference document titled *Generating Facility Data Requirements* section 2.2 describes requirements for data to be reported regarding the excitation system. All of these items are mentioned.

R2. The Regional Reliability Organization shall provide its generator excitation system data verification and reporting procedures, and any changes to those procedures, to the Generator Owners, Generator Operators, Transmission Operators, Planning Authorities, and Transmission Planners affected by the procedure within 30 calendar days of the approval. **R3.** The Generator Owner shall follow its Regional Reliability Organization's procedures for verifying and reporting its models and data associated with generator excitation system functions per MOD-026 R1.	The generator test policy is posted on the public WECC web site to assure availability to those that need it.
From Mod-027-1 **R1.** The Regional Reliability Organization shall establish and maintain procedures to address verification of generator unit frequency response. These procedures shall include the following: **R1.1.** Response time to be modeled, e.g. up to 30 seconds for steam units, up to 45 seconds for hydro units, etc. **R1.2.** Generating unit exemption criteria including documentation of those units that are exempt from a portion or all of these procedures. **R1.3.** Acceptable methods for model and data verification, including any applicable conditions under which the data should be verified. Such methods can include use of	Covered in the documents titled *Generating Unit Baseline Test Requirements* and *Generating Facility Model Validation Requirements* **A.3. approval. **R3.** The Generator Owner shall follow its Regional Reliability Organization's procedure for verifying and reporting its generator unit frequency response per MOD-027 R1.	
From PRC-019-1 **R1.** The Regional Reliability Organization shall establish and maintain criteria for exemptions to any of the Generator Owner requirements in R2.	**A.3. Applicability:** A.3.1. **Facilities Affected:** This policy statement applies to generating facilities connected to the Western Electricity Coordinating Council (WECC) transmission grid at 60 kV or higher voltage (both new and existing, synchronous and non-synchronous) with single unit capacity of 10 MVA and larger, or facilities with aggregate capacity of 20 MVA and larger.
R2. Unless exempted by the Regional Reliability Organization in accordance with R1, the Generator Owner shall have study results that show it verified that its generator voltage regulator controls and limit functions are coordinated with the generator's capabilities and protective relays. This study shall include the following: **R2.1.** Plots, or data that could be plotted for the following: **R2.1.1.** Generator capability curve, including specification of nominal voltage, ambient air or cooling temperature, or hydrogen pressure. **R2.1.2.** Steady state over-excitation limiter and under-excitation limiter control characteristics. **R2.1.3.** MW limit of the prime mover. **R2.1.4.** Any other limit that could restrict the megawatt or megavar capability. **R2.1.5.** Loss of excitation / field	Covered in the document titled *WECC Generating Facility Data Requirements*

protective relay characteristics. **R2.1.6.** Volts-per-hertz protection settings including volts-per-hertz limiters in the automatic voltage regulator. **R3.** The Generator Owner shall have the information in R2.1.1 through R2.1.6 available to show to the Regional Reliability Organization upon request (within 30 calendar days).	
From PRC-024-1 **R1.** The Regional Reliability Organization shall establish requirements for generators to remain connected during system frequency and voltage excursions expressed as a function of: **R1.1.** Time duration in seconds or cycles. **R1.2.** Amplitude or magnitude of the excursion. **R1.3.** Relationship between time and amplitude or magnitude.	Frequency requirements are covered by the WECC Coordinated Off-Nominal Frequency Load Shedding and Restoration Requirements. Reference A section X. Proposed Voltage Standards cover these items for faults and there is a proposed voltage versus fault clearing time curve. Voltage is also listed with regard to coordination with the WECC Coordinated Off-Nominal Frequency Load Shedding and Restoration Requirements in Section XII.
R2. The Regional Reliability Organization shall establish and maintain requirements for generators to remain connected during frequency and voltage excursions. These requirements shall include: **R2.1.** Coordination between the generator under frequency protection and the regional Under Frequency Load Shedding (UFLS) program.	This is covered in the WECC Coordinated Off-Nominal Frequency Load Shedding and Restoration Requirements. Section X
R2.2. Coordination of generator protection, including back-up protection, with transmission Protection Systems.	WECC policy including the *NERC/WECC Planning Standards* and the *Minimum Operating Reliability Criteria* specify that these be coordinated.
R3. The Regional Reliability Organization shall establish and maintain criteria for exemptions to any of the regional requirements established in accordance with R1 and R2. **R4.** The Regional Reliability Organization shall establish and maintain a procedure for handling variances (i.e., different criteria or	In the Off-Nominal Plan the exemption method is listed in Section X Recommendation 5B. It specifies that load must be tripped to match generation that trips too quick. A similar requirement may be needed in the Voltage Standard. The currently proposed voltage standard indicates a 10 MVA size threshold.

methods) from the Regional Reliability Organization's requirements established in R1 and R2, including steps for requesting and approving such variances. **R5.** The Regional Reliability Organization shall provide documentation of its excursion requirements, exemptions, and variance procedure to the Transmission Owners and Generator Owners within its Region within 30 calendar days of approval. **R6.** The Regional Reliability Organization shall, at least every five years, review and, as necessary, update its requirements, exemption criteria, and variance procedure. **R7.** Generator Owners and Transmission Owners shall comply with the regional requirements for coordination of generator protection defined in R2 and any approved variances.	WECC has had organizations that requested variances by submitting a request to the appropriate WECC Committees – Subcommittees and work groups. The documents should be reviewed to assure that they specifically indicate the process for obtaining variances.

WESTERN ELECTRICITY COORDINATING COUNCIL

GENERATING UNIT MODEL VALIDATION POLICY

A. Introduction

A.1. Title: Generating Unit Model Validation Policy

A.2. **Purpose:** Accurate models of generators and associated controls are necessary for realistic simulations of the electric power system of the western interconnection. Baseline testing and periodic performance validation are required to ensure that the dynamic models and databases that are used in the grid simulations are accurate and up to date.

A.3. Applicability:

A.3.1. **Facilities Affected:** This policy statement applies to generating facilities connected to the Western Electricity Coordinating Council (WECC) transmission grid at 60 kV or higher voltage (both new and existing, synchronous and non-synchronous) with single unit capacity of 10 MVA and larger, or facilities with aggregate capacity of 20 MVA and larger.

A.3.2. Entity Responsible:

A.3.2.1. Generator Owner
A.3.2.2. Transmission Planner
A.3.2.3. Regional Reliability Organization

A.4. References: The following documents referred to in this Policy are posted in the "Generator Testing Program" area on the WECC website at [www.wecc.biz]:

A.4.1. Generating Facility Data Requirements
A.4.2. Generating Unit Baseline Test Requirements
A.4.3. Generating Unit Model Validation Requirements
A.4.4. List of WECC-Approved Models

A.5. Effective Date: Approved by the Board at the meeting July 26-28, 2006.

B. Requirements

B.1. Generator Owner Responsibilities

B.1.1. Generating Facility Data

B.1.1.1. The Generator Owner shall provide to the Transmission Planner the information for the Generating Facility as specified in the *Generating Facility Data Requirements* document.

B.1.1.2. The Generator Owner shall review, verify and update the Generating Facility data when any of the following conditions occur:

B.1.1.2.1. No later than 180 days after the new Generating Facility is released for Commercial Operation.

B.1.1.2.2. No later than 180 days after an existing generating unit re-starts Commercial Operation with modified equipment, control settings, or software that influences the behavior of the plant with respect to the grid (e.g. excitation retrofit, additional control function within a controller, turbine modification, voltage regulator and power system stabilizer tuning modification, etc.)

B.1.1.2.3. At least once every five years.

B.1.2. Baseline Testing

B.1.2.1. The Generator Owner shall test the generating unit and validate its model data.

B.1.2.2. The Generator Owner shall provide test and validation reports to its Transmission Planner.

B.1.2.2.1. For guidance on the test requirements, refer to the current *Generating Unit Baseline Test Requirements* document.

B.1.2.3. The testing and associated validation by simulation shall be performed on a generating unit when any of the following conditions have occurred:

B.1.2.3.1. If the generating project has not been certified by WECC under Generator Testing Program since January 1997.

B.1.2.3.2. No later than 180 days after the new Generating Facility is released for Commercial Operation. In the meantime, the Generator Owner will provide the best available model data supplied by the equipment manufacturer using the WECC approved models including commissioning reports.

B.1.2.3.3. No later than 180 days after an existing generating unit re-starts Commercial Operation with modified equipment, control settings, or software that influences its behavior with respect to the grid (e.g. excitation retrofit, additional control function within a controller, turbine modification, voltage regulator and power system stabilizer tuning modification, etc.), only those portions of the generating unit model that can be influenced by the modifications need to be tested and validated.

B.1.2.3.4. No later than 180 days after the Generator Owner is notified by WECC that there is evidence that the modeled response of a Generating Facility does not correlate with the actual response, except in instances where the lack of correlation was caused by equipment problems that were subsequently corrected.

B.1.3. Model Data Validation

B.1.3.1. The Generator Owner shall perform model data validation and provide a report to its Transmission Planner at least once every five years. Schedule of model validation shall be coordinated between the Generator Owner, Transmission Planner and Transmission Operator

B.1.3.1.1. The *"Generating Facility Model Data Validation Requirements"* document describes acceptable methods of model data validation by performance comparison.

B.1.3.2. Generator Owner shall verify that generator control limiters, protection and equipment capabilities are consistent with those reported in the model(s).

B.2. Transmission Planner Responsibilities

B.2.1. Model Data Validation

B.2.1.1. The Transmission Planner shall maintain a current list of all Generating Facilities in its planning area that are subject to testing and model data validation.

B.2.1.1.1. This list shall be made available to WECC upon request.

B.2.1.1.2. For each Generating Facility, the list shall include the status of compliance with this Generating Unit Model Validation Policy, including report dates.

B.2.1.2. The Transmission Planner shall notify Generator Owner when generating unit re-testing and validation are required to maintain compliance with this policy.

B.2.1.3. Disturbance data recorded either at the generator or at the point of interconnection can be used for model data validation.

B.2.1.3.1. If the Transmission Planner has performance monitoring equipment at the point of interconnection, the data shall be made available to the Generator Owner, upon request.

B.2.2. Facility Data and Validation Reports

B.2.2.1. The Transmission Planner shall collect Generating Facility data and model data validation reports from Generator Owners.

B.2.2.2. The Transmission Planner shall verify that the WECC-approved model parameters provided by the Generator Owner are adequately validated by comparing the simulated response of the unit against either the recorded baseline tests or a disturbance response as the case may be, within 30 calendar days after receipt from the Generator Owner.

B.2.2.2.1. The Transmission Planner will work with the Generator Owner on resolving the differences between simulated and actual responses of the Generating Facility to grid disturbances. The Transmission Planner will inform WECC if the differences cannot be resolved.

B.2.2.3. The Transmission Planner shall submit the accepted validated models to WECC and shall notify the Generator Owner that the models are accepted.

B.2.2.4. If a model data validation report is rejected, the Transmission Planner shall inform the Generator Owner of the reason(s) for the rejection. The Transmission Planner will work with the Generator Owner to expedite resolution of any issues preventing acceptance of the model data validation report. The Transmission Planner will inform WECC if the issues cannot be resolved.

B.3. WECC Responsibilities

B.3.1. WECC shall maintain a master data file with the current validated models.

B.3.2. WECC shall review and approve the generator testing and model validation reports.

B.3.3. WECC shall verify that the models are stable and that the modeled system responses reasonably match power system performance.

B.3.4. WECC shall verify compliance with the certification requirements, issue certificates to the Generator Owners and notify Transmission Planner.

B.3.5. WECC has the final authority to determine the suitability of testing and validation of the models.

B.3.6. WECC periodically shall audit the Generator Owners and Transmission Planners on the status of generator testing and model validation.

B.3.7. WECC periodically shall review technical requirements listed in section A4. Any changes in the requirements will go through a WECC "due process."

B.4. Exemptions

B.4.1. WECC may grant exemptions to the Generator Owners in rare situations where a unique condition or equipment configuration exists that would preclude or delay testing and model data validation.

B.4.2. The Generator Owner may request an exemption by submittal to WECC through the Transmission Planner. The request shall include justification for the exemption. WECC shall respond to the request within 90 days after receipt.

C. Definitions

Generator Owner is defined in NERC Reliability Functional Model.

Transmission Planner is defined in NERC Reliability Functional Model.

Commercial Operation is defined in FERC 2003-A Standardization of Generator Interconnection Agreements and Procedures.

Generating Facility is defined in FERC 2003-A Standardization of Generator Interconnection Agreements and Procedures.

Validation. Within the context of this policy and associated documents, Validation is used synonymously with verification and refers to the process of selecting parameters for the appropriate WECC-approved models for generating units and demonstrating that the model behavior is consistent with the generating unit behavior by comparison of simulation to test recording.

Western Electricity Coordinating Council

Generating Facility Data Requirements

1. Principal one-line electrical diagram of the generating facility

Provide a principal one-line diagram of the generating facility, identifying individual generating units, transformers (main step-up, unit auxiliaries, excitation source), transmission lines associated with the generation facility, station service loads, and any other relevant electrical equipment (e.g. power-factor capacitors, static var compensators).

2. Generating Unit Data

Label the generating unit number or identifier in the plant diagram

2.1. Synchronous Generator Data

Provide synchronous generator nameplate data, including rated MVA, kV, stator Amps, power factor, RPM, exciter voltage, rotor Amps.

Provide synchronous generator parameters:

Impedance Data in per unit on machine rated MVA and kV		
Synchronous direct axis reactance – unsaturated	Xdi	
Synchronous quadrature axis reactance– unsaturated	Xqi	
Transient direct axis reactance – unsaturated	X'di	
Transient quadrature axis reactance – unsaturated (*)	X'qi	
Subtransient direct axis reactance – unsaturated	X"di	
Subtransient quadtaure axis reactance – unsaturated (*)	X"qi	
Leakage reactance	Xl	
Positive sequence resistance	Ra	
Field Time Constants		
Open circuit transient time constant – direct axis	T'do	
Open circuit transient time constant – quadrature axis (*)	T'qo	
Open circuit subtransient time constant – direct axis	T"do	
Open circuit subtransient time constant– quadrature axis	T"qo	
Combined Turbine-Generator(-Exciter) Inertia		
Inertia Constant	H	
Open-Circuit Saturation		
Saturation at 1.0 pu generator voltage	S1.0	
Saturation at 1.2 pu generator voltage	S1.2	

(*) not required for salient pole generators

Provide generator open circuit saturation curve with air-gap line.

Air gap field current at rated generator voltage ________________ Amps

Measured field winding resistance __________ Ohms

Field winding temperature or generator hot air/gas temperature at which the field winding resistance was measured __________ C

2.2. Excitation System Data

2.2.1. Exciter and Voltage Regulator

Excitation system type (static, ac rotating, brushless, dc generator, etc) and manufacturer: ____________________________________

Provide nameplate information on excitation equipment (such as excitation transformer in static exciters, dc generator and amplidyne in dc rotating exciters, main and pilot ac generators in ac rotating exciters)

Voltage regulator type and manufacturer (e.g., GE EX 2100, ABB Unitrol-F, etc)
____

Provide a block diagram and completed data forms for the corresponding WECC-approved model (document “WECC Approved Models”).

2.2.2. Line Drop Compensation/Reactive Current Compensation

Indicate whether the voltage regulator has a line drop compensation or reactive current compensation, and provide settings in per unit on machine rated MVA and kV.

2.2.3. Power System Stabilizer

PSS type and manufacturer (e.g., GE EX2000, Basler)
____

Provide a block diagram and completed data forms for the corresponding WECC-approved model (document “WECC Approved Models”).

2.2.4. Over-Excitation Limiter (OEL)

Provide fullest available information on OEL.

Indicate OEL type and manufacturer (e.g. Westinghouse MXL/OXP).

Describe OEL time characteristic (definite time, inverse time).

Provide pickup vs. time characteristic curve

Describe OEL actions (e.g., reduce field current below continuous current rating, trip voltage regulator into manual field current control, trip the generator.)

2.2.5. Under-Excitation Limiter (UEL)

Provide fullest available information on UEL.

UEL type (conventional or voltage sensitive, PQ-limiter, etc).

Describe UEL actions.

Provide limit settings as a curve of real and reactive power.

2.2.6. Stator Current Limiter

Is a stator current limiter incorporated into the excitation system?

Provide fullest available information on stator current limiter

2.2.7. High Voltage Bus Controllers, VAR limiters and Power factor controllers

Provide fullest available information on these controllers.

Indicate which of these controllers are active in normal operation.

2.3. Generator Reactive Capability Curves

Continuous field current rating ____________ Amps

For hydrogen-cooled generators, indicate hydrogen pressure during normal operating conditions ______ psi.

Provide machine reactive capability curves at rated voltage and nominal hydrogen pressure).

Superimpose generator control, limiter and protection curves on the machine reactive capability curve.

Define the operating reactive capability of the generator.

Provide information on reactive power limits implemented by plant or unit supervisory controls (e.g. plant DCS, GE Mark V/ Mark VI / Ovation, GDACS).

3. Turbine-Governor Data

3.1 Hydro-turbine generators

Hydraulic Turbine

Turbine type (e.g., Francis, Kaplan, Pelton) ____________________________

Nominal head ____________ ft   Typical range of operating heads__________ ft

Turbine capacity at full gate opening, nominal head ____________ MW

Provide the "Power versus Gate Position" characteristic at expected operating heads (for Kaplan turbines with blade on the cam). For Kaplan turbines, provide the "Blade angle versus Gate Position" characteristic at expected operating heads.

Provide contact information for a person for reference regarding hydraulic profile of the plant.

Water inertia starting time Tw___________ sec

Hydro Governor

Hydro governor type (e.g. Asea analog electronic, Woodward dash-pot, Woodward 505H, Voest Alpine electronic) ______________________

Provide a block diagram and completed data forms for the WECC-approved models (document "WECC Approved Models").

For Kaplan turbines, provide block diagram with relevant data for a blade controller.

3.2 Steam-Turbine

Boiler type (drum-type or once through) ____________________

Normal fuel type (coal, oil, gas, other) ______________________

Indicate whether the turbine is tandem-compound or cross-compound

Turbine capacity at rated steam throttle pressure, full valve opening
____________ MW

Rated steam pressure (HP) ____________________ psi

Governor type and manufacturer ____________________________

Boiler controller type and manufacturer ____________________________

Describe the normal turbine control and operating practice (base loaded, turbine follow, boiler follow, coordinated controller, sliding pressure, etc)

Provide a block diagram and completed data forms for the WECC-approved models (document "WECC Approved Models").

3.3. Gas Turbines

Gas turbine type and manufacturer (e.g. GE Frame 7, W-501, GE LM6000, etc)
____

Provide the maximum generator output as a function of ambient temperature.

For combined cycle plants,
If the plant has a steam cycle, describe how steam is used from a heat recovery steam generator (HRSG), e.g.

- all steam is used by a steam-turbine generator, or
- 40% of steam is for industrial use, or
- the project is using supplementary duct firing, all steam is used by a steam-turbine generator

Provide a block diagram and completed data forms for the WECC-approved models (document "WECC Approved Models.").

4. Power Plant Controls (e.g. GE Mark V, Ovation,)

4.1. Load or MW controller

Indicate whether the plant has an active load controller (e.g. Process Coordinated Controller).

Describe load controller functions:

- Does it keep the MW output of the plant at a specified set-point?
- Does it have a frequency bias and dead-band?

Provide recordings of plant response to system frequency excursions, if available.

Provide information on AGC capability, ramp rates (up and down), and ranges (low and high). Provide ramp rate recordings, if available.

4.2. Reactive Power Controller

Indicate whether the plant has any reactive power controller (high-side voltage controller, reactive power balancing among units, etc).

Describe the reactive power controller functions:

- Does the controller balance reactive power among generators in the plant?
- Does the controller perform high-side voltage control automatically and how fast it starts and completes response?
- Does the controller limit generator terminal voltage (e.g. +/- 5% of nominal)?

Provide SCADA recordings of plant response to system voltage deviations, if available, showing the effect of the plant reactive power controller.

5. Transformers

Provide the following information for each of the transformers identified in the principal one-line diagram of the generating facility.

Application *(GSU/CSU/LT):* _________________
Number of Windings *(2 or 3):* ________________
Indicate whether the unit is an autotransformer: __________
Note: Subsequent data in rows identified with asterisk (*)are required only for 3-winding transformers

Winding Data

Winding	Nominal	Configuration	Nameplate MVA Ratings		
	[kV]	[Δ, Y, YG]	FA	FO	FOA
Primary – H					
Secondary – X					
(*) Tertiary – Y					

Impedance Data (base MVA= ______ base kV= _____) :

Windings	R1	X1	R0	X0
H to X				
(*) H to Y				
(*) X to Y				

Tap Changer

Tap Changer	Tap Position [kV or Percent]			
Winding	Operating	Min	Max	Step
(H, X, or Y)				

For on-load tap changers, specify the following:

- Regulated voltage: ____________ percent, or Volts
- Controlled bus: ____________
- Dead-band: ____________ percent, or Volts
- Tap changer time constant: _____________ sec

6. Line Data

Provide the following data for each of the lines and feeders identified in the principal one-line diagram of the generating facility:

Nominal operating voltage, kV	
Line length, mi	
Positive sequence line resistance, Ω	
Positive sequence line reactance, Ω	

Please indicate whether the line is overhead or underground.

7. Auxiliary Load

Provide auxiliary load MW and MVAR at minimum stable and maximum power output.

Auxiliary load may be identified as any load at utilization voltage less than the transmission system interconnection voltage, including station service load and unit service load.

Western Electricity Coordinating Council

Generating Facility Model Validation Requirements

Dynamic response validation

The essential principle of dynamic response validation is that the chosen model of the generating facility in the PSS/E or PSLF program must reproduce the results of tests or reproduce recorded disturbances within normally acceptable levels of accuracy.

This principle must be met by executing simulations of the tests or recorded system events in the PSS/E or PSLF program so as to demonstrate that:

- signals from the tests or recorded events are used as reference data
- clearly identifiable variations of input variables are presented to the model to impose the test or recorded disturbance on the model
- the result signals obtained from the simulation are compared to and agree with the reference data

The measure of success of the validation is the quality of the agreement between the recorded and simulated results. Important response characteristics include the following:

- general shape of the curves, including magnitude and rate of the response;
- rise time, overshoot and bandwidth;
- dead-bands and delays;
- initial and final values.

Option 1. Validation using Recordings taken at the Point of Interconnection of the Generating Facility.

Validation is performed using disturbance recordings taken at the Point Of Interconnection (POI) of the Generating Facility (see Figure 1).

The dynamic response of the Generating Facility is driven by the voltage and frequency at the POI and the control inputs (e.g. due to voltage and power schedules from the Control Area Operator).

The POI voltage (V), POI frequency (f), and the unit control signals are used as the model inputs. The real (P) and reactive (Q) power are the measures of the model performance. The validation shall be done for events of voltage and frequency deviations and oscillations at the point of interconnection.

The minimum sampling rate is 20 samples per second. The minimum disturbance record length is 30 seconds.

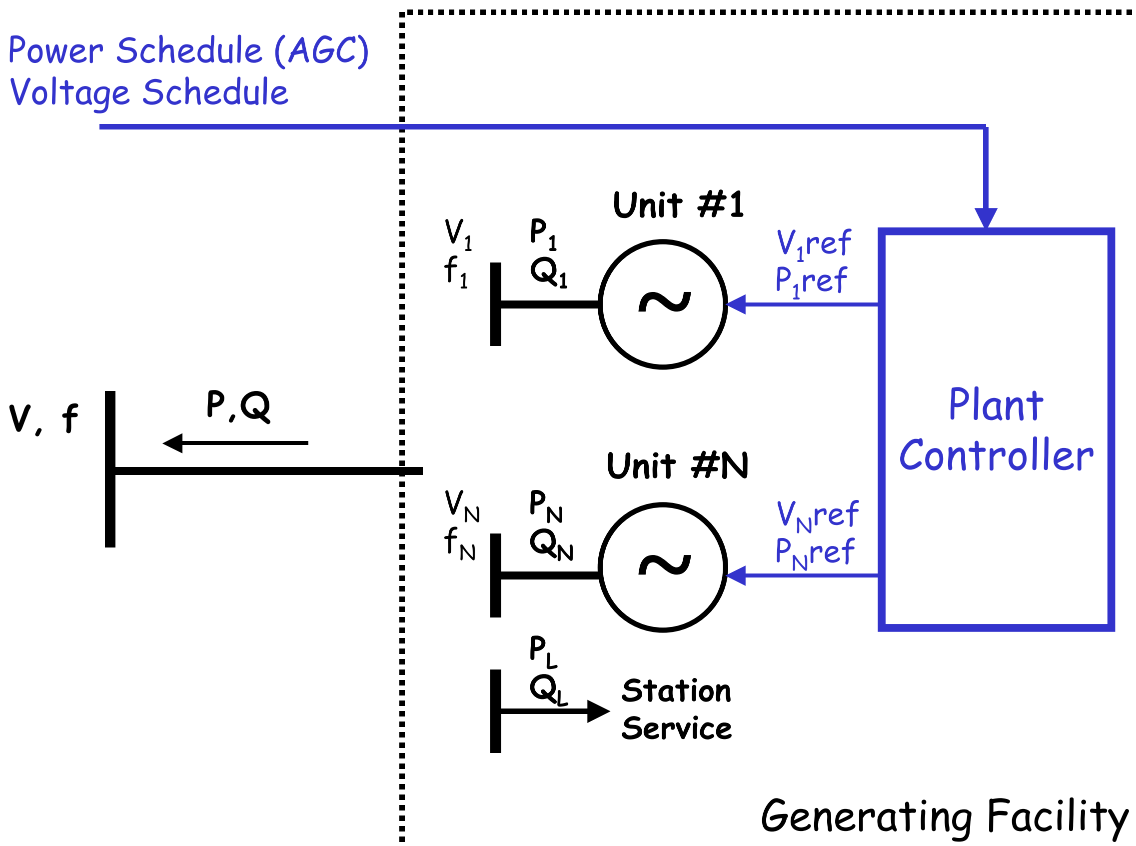

Figure 1: validation performed using disturbance recordings taken at the Generating Facility POI

Acceptable validation methods for generator – excitation models:

Event	Input to Model	Validation Signal
(i) Sudden change in voltage at point of interconnection (greater than 2%) due to a disturbance	- voltage at point of interconnection - frequency at point of interconnection - control signals	- power at point of interconnection - reactive power at point of interconnection
(ii) Sudden change in Generator reactive power (greater than 10% of rated MVA) due to a disturbance	- voltage at point of interconnection - frequency at point of interconnection - control signals	- power at point of interconnection - reactive power at point of interconnection

Acceptable validation methods for governor-turbine models:

Event	Input to Model	Validation Signal
(i) Sudden frequency changes (greater than 0.05 Hz) due to disturbance	- frequency at point of interconnection - control signals	- power at point of interconnection

Examples of governor response validation are described in the following IEEE papers:

1. Les Pereira, John Undrill, Dmitry Kosterev, Donald Davies and Shawn Patterson, “A New Thermal Governor Modeling in WECC,” *IEEE Transactions on Power Systems*, vol.18, no.2, pp.819-829, May 2003.

2. Les Pereira, Dmitry Kosterev, Donald Davies and Shawn Patterson, “New Thermal Governor Model Selection and Validation in the WECC,” *IEEE Transactions on Power Systems*, vol.19, no.1, pp.517-523, February 2004.

3. Dmitry Kosterev, “Hydro Turbine-Governor Model Validation in Pacific Northwest,” IEEE Transactions on Power Systems, vol.19, no.2, pp.1144-1149, May 2004.

Option 2. Validation using Recordings taken at the Generating Unit.

Validation is performed using disturbance and/or test recordings taken at the Generator (see Figure 2). This should be done for every Generator in the Generating Facility.

The dynamic response of the Generator is driven by the stator voltage and frequency (or real and reactive load). The response can be also initiated by the control inputs such as voltage reference and speed reference.

Validation shall be done for the following events:
a) disturbances or tests that result in generator stator voltage and reactive power changes.
b) disturbances that result in generator frequency changes or tests that result in generator real power changes.

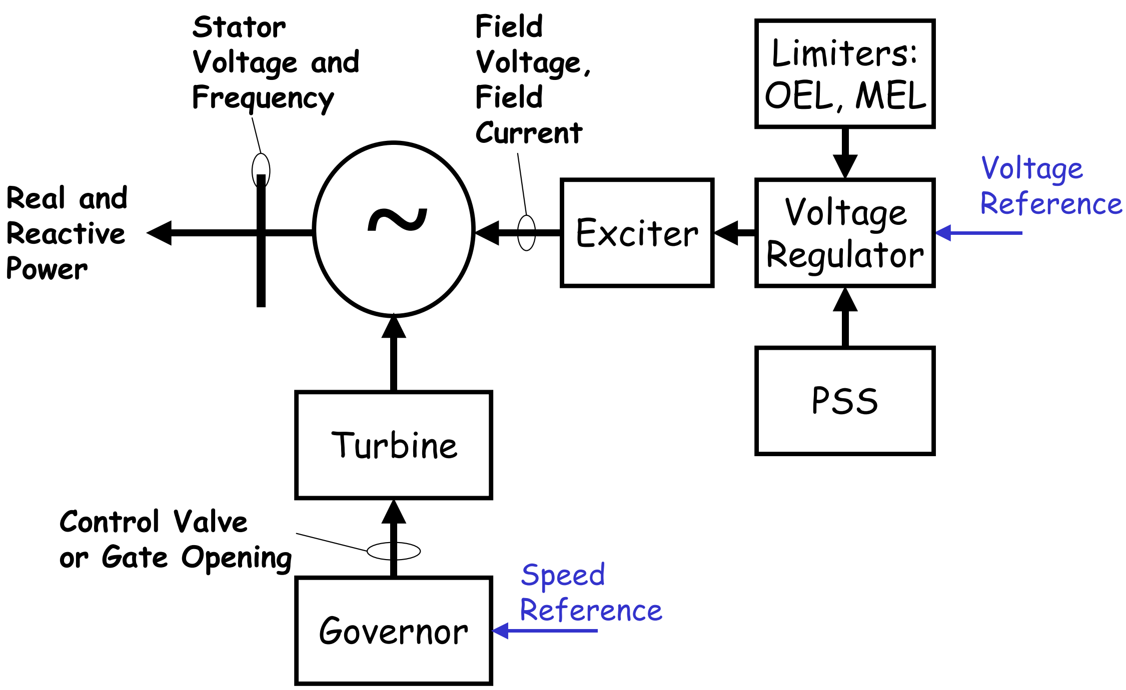

Figure 2: Validation is performed using disturbance and test recordings taken at the Generator

Acceptable validation methods for generator – excitation models:

Event	Input to Model	Validation Signal
(i) Voltage Reference step (typically 2%) with Generator on-line	- Voltage reference step - Generator real power - Generator reactive power	- Stator Voltage - Field Voltage (or Exciter Field Current for rotating exciters)
(ii) Voltage Reference step (typically 2%) with Generator off-line	- Voltage reference step	- Stator Voltage - Field Voltage (or Exciter Field Current for rotating exciters)
(iii) Sudden change in Generator reactive power (greater than 10% of rated MVA) due to a disturbance with Generator on-line	- Generator real power - Generator reactive power	- Stator Voltage - Field Voltage (or Exciter Field Current for rotating exciters)
(iv) reactive load rejection	- Generator reactive power	- Stator Voltage - Field Voltage (or Exciter Field Current for rotating exciters)
(v) Frequency response of Vt/ Vref	- Voltage reference swept sine	- Stator Voltage

The minimum sampling rate is 20 samples per second.

Acceptable validation methods for governor-turbine models:

Event	Input to Model	Validation Signal
(i) Speed Reference steps with generator on-line	- Speed Reference - Frequency	- Generator real power
(ii) Sudden frequency changes (greater than 0.05 Hz) due to disturbance with Generator on-line	- Frequency	- Generator real power

The maximum sampling period is 4 seconds – data available from SCADA or plant DCS.

Western Electricity Coordinating Council
Generating Unit Baseline Test Requirements

A great amount of technical information on methods of generator testing is provided in WSCC 1997 Generator Test Request Letter and Guidelines posted on WECC web-site [www.wecc.biz].

1. Synchronous Generators

The following tests shall be done:

a. Open Circuit Saturation: Measurement of the steady state variation of generator field current versus generator stator voltage from the minimum achievable generator stator voltage to at least 105 percent of the rated stator voltage with the generator circuit breaker open. For machines with brushless exciters the field current measurement shall be the field current of the exciter.

b. Inertia: A test that reasonably confirms the inertia constant of the turbine-generator.

For example, recording of the rotor speed following opening of the generator circuit breaker with the generator running at a moderate real power output.

c. Synchronous Machine Impedances and Time Constants: Tests that reasonably confirm the d-axis reactances (Xd, X'd, X"d) and time constants (T'do and T"do) of the synchronous generator.

For example, recording of terminal voltage and field current following opening of the generator circuit breaker with the generator running at near-zero real power and under-excited so as to absorb substantial reactive power with the excitation system in manual field voltage control.

2. Excitation Systems

Tests of the excitation system shall be such that they reasonably confirm the characteristics of the voltage regulator and the exciter from dc to 5 Hz. The test recordings shall include generator terminal voltage, field voltage or exciter field current for brushless excitation systems. These tests shall be done with the excitation system in automatic voltage control.

One or more of the following tests can meet the above requirement:

a. VAR Rejection Test: Recording of stator voltage, field voltage (exciter field current for brushless exciters) following opening of the generator circuit breaker with the generator running at near-zero real power and under-excited so as to absorb substantial reactive power.

b. Open Circuit Voltage Reference Step: Recording of stator voltage, field voltage (exciter field current for brushless exciters) following a clearly identifiable step change of voltage regulator reference with the generator circuit breaker open.

c. On-Line Voltage Reference Step: Recording of stator voltage, field voltage (exciter field current for brushless exciters) following a clearly identifiable step change of voltage regulator reference with the generator circuit breaker closed and the generator at normal real power output.

d. Open Circuit Frequency Response Test: Gain and phase angle measurement of stator voltage / voltage reference using a swept sign input from 0.05 Hz to 10 Hz.

3. Power System Stabilizer (PSS)

Tests of the PSS shall be such that they identify the PSS transfer function up to 10 Hz. Approaches for PSS testing are described in *WECC Power System Stabilizer Tuning Guidelines* and *WECC Power System Stabilizer Design and Performance Criteria.*

4. Over-Excitation Limiter (OEL)

Update OEL model data as necessary. Approaches for OEL testing are described in *Guidelines for Over-Excitation Limiter (OEL) and Over-Excitation Protection (OEP) Testing.*

5. Turbine Control

5.1 Hydro Unit

Tests of the governor and turbine shall be such that they reasonably confirm the characteristics from dc to 1 Hz.

The following test is acceptable:
On-Line Speed Reference Step: Recording of generator speed, generator speed reference, gate (valve) position, blade angle if applicable, and generator power following a clearly identifiable step change in speed reference with the generator circuit breaker closed and the generator at normal real power output.

The following measurements should also be made:

a. Measurement of turbine-governor steady-state droop.
b. Measurement of steady-state generator power versus gate position (and blade angle versus gate position for Kaplan turbines) at typical operating heads.

5.2 Steam Turbine Units and Gas Turbine Units

The turbine-governor model should be representative of the actual behavior of the unit the majority of the time. Provide recordings of generator power (resolution of 0.5% or better and 4 second sampling time or shorter) for events including frequency deviations. Sources of the data include, but not limited to, plant DCS, SCADA, digital event recorders. Simulated behavior should reasonably match the recorded data.

The methodology for thermal governor response validation is described in IEEE papers prepared by the members of WECC Governor Modeling Task Force:

1. Les Pereira, John Undrill, Dmitry Kosterev, Donald Davies and Shawn Patterson, “A New Thermal Governor Modeling in WECC,” *IEEE Transactions on Power Systems*, vol.18, no.2, pp.819-829, May 2003.

2. Les Pereira, Dmitry Kosterev, Donald Davies and Shawn Patterson, “New Thermal Governor Model Selection and Validation in the WECC,” *IEEE Transactions on Power Systems*, vol.19, no.1, pp.517-523, February 2004.

A. Introduction

1. Title: WECC Voltage Ride-Through Standard

2. Number: XXX-XXX-XXX-X

3. Purpose: Provide voltage ride-through standards for synchronous and induction generating plants of 10 MVA or more.

4. Applicability
   4.1 Generator Owners
   4.2 Generator Operators

5. Effective Date: ______, 2006

B. Requirements

The following sections describe requirements for both synchronous and induction generating units interconnected at WECC transmission voltages of 60 kV or higher.

B1. Existing and Future Generators Except for Pre-2008 Wind Generators

The following requirements are applicable to existing and future individual generating units at plant sites with an installed capability of 10 MVA or more.[1] Wind generating units operative prior to 2008 or earlier are addressed in Section B2, "Transition Period Wind Generators," and Section B3 "Other Wind Generators."

WR1. Generating units are required to remain in-service as follows:

a) Fault period – During the fault and for a period not to exceed normal clearing times, generating units shall ride through voltage excursions as measured at the high side of plant step-up transformer[2] of 0 per unit volts for 0.15 seconds (9 cycles) increasing to 0.9 per unit volts for 1.75 seconds as shown on Figure 1.

b) Post–fault Period -- Following fault clearing, generating units shall ride through voltage excursions as measured at the high side of the generating plant step-up transformer that are within the voltages and time periods defined in the table below and shown on Figure 2:

---

[1] 20 MVA per FERC Order 661

[2] FERC Order 2003 specifies all measurements would be at the Point of Interconnection. However, FERC Order 661A, which was issued after FERC Order 2003 specifies the point of measurement to be high side of the plant step-up transformer.

Post-Fault Time (Sec)	Voltage ≥ (per unit)	Voltage ≤ (per unit)
0.0	0.50	1.30
0.3		1.30
0.3		1.15
1.0		1.15
1.0		1.10
5.0	0.90	1.10
>5.0	0.90	1.10

WR2. It is not acceptable for generating units to trip except under the following conditions:
- a) For faults that when cleared, effectively disconnect the generating unit from the system.
- b) For clearing times and voltage during faults that exceed the levels indicated on Figure 2.
- c) After the fault period if this action is intended as part of a special protection system.

B2. Transition Period Wind Generators

Transition Period Wind Generators (TPWG) are those wind generating units at generating plants with an installed capacity of 10 MVA or more,[3] are subject to FERC Order 661 (or 661A-check), and have either: (i) interconnection agreements signed and filed with the Commission, filed with the Commission in unexecuted form, or filed with the Commission as non-conforming agreements between January 1, 2006 and December 31, 2006, with a scheduled in-service date no later than December 31, 2007, or (ii) wind generating units subject to a wind turbine procurement contract executed prior to December 31, 2005, for delivery through 2007.

WR3. Generating units are required to remain in-service as follows:
- a) Fault period: During the fault and for a period not to exceed normal clearing times, generating units shall ride through voltage excursions as measured at the high side of plant step-up transformer[4] of 0.15 per unit volts for 0.15 seconds (9 cycles) increasing to 0.9 per unit volts for 1.75 seconds as shown on Figure 3.
- b) Post–fault Period: Refer to Section B1, WR1b.

WR4 It is not acceptable for TPWG generating units to trip except under the following conditions:
- a) For faults that occur between the generator terminals and the POI.

[3] 20 MVA per FERC Order 661

[4] FERC Order 2003 specifies all measurements would be at the Point of Interconnection. However, FERC Order 661A, which was issued after FERC Order 2003 specifies the point of measurement to be high side of the plant step-up transformer.

b) For faults that when cleared effectively disconnect the generating plant from the system.
c) After the fault period if this action is intended as part of a special protection system.
d) For times and voltage excursions that exceed the levels indicated on Figures 2 and 3.

B3. All Other Wind Generators
Wind generating units at generating plants with an installed capacity of 10 MVA or more not covered by Sections B1 and B2 are subject to the following requirements.

WR5. Individual wind generating units that are replaced (for example, wind turbine, anything else ?) are required to meet the requirements described in Section B1, for "Generators other than Transition Period Wind Generators."

C. Measures

WM1. Maintain records of all generator trips and the reason for the trip and report any trips that do not meet this Standard to the Reliability Authority.

WM2. See WM1.

WM3 Maintain records of all TPWG trips reporting any trips that do not meet this Standard.

WM4 See WM3.

WM5. Maintain records of when a TPWG unit is replaced and report any replacement to the Reliability Authority.

D. Compliance

E. Guides

It is acceptable for generating plants subject to this Voltage Ride-Through Standard to meet requirements of this standard by the performance of the generators or by installing additional equipment (e.g., Static VAR Compensator) within the generating plant or by a combination of generator performance and additional equipment.

F. Version History

WECC Voltage Ride-Through Standard

A. Introduction

1. **Title:** **Verification of Models and Data for Generator Excitation System Functions**

2. **Number:** MOD-026-1

3. **Purpose:** To ensure accurate information on generator excitation system functions (including voltage regulator controls, limiters, compensators, and power system stabilizers, if applicable) is available for models used to assess Bulk Electric System reliability.

4. **Applicability**

   4.1. Regional Reliability Organization.

   4.2. Generator Owner.

5. **Proposed Effective Date:** To be determined.

B. Requirements

R1. The Regional Reliability Organization shall establish and maintain procedures to address verification of models and data associated with generator excitation system functions including voltage regulator controls, limiters, compensators, and power system stabilizers. These procedures shall include the following:

R1.1. Generating unit exemption criteria including documentation describing characteristics of those units that are exempt from a portion or all of these procedures.

R1.2. Acceptable methods for model and data verification, including any applicable conditions under which the data should be verified. Such methods can include use of manufacturer data, commissioning data, performance tracking, engineering analysis, field verification of equipment settings, testing, simulation and comparison with test results or disturbance monitoring data, etc.

R1.3. A list of acceptable models to be used and procedures for revising the list of acceptable models.

~~R1.3.~~R1.4. Periodicity and schedule of verification and reporting, including a list of report recipients, schedules associated with field changes to existing units, and refurbished units.

~~R1.4.~~R1.5. Information to be reported related to generator excitation system functions:

~~R1.4.1.~~R1.5.1. Verified manufacturer and type of excitation system/voltage regulator control system (for example, static, brushless, rotating, etc.).

~~R1.4.2.~~R1.5.2. Verified model from the acceptable model list for each excitation system/voltage regulator control system with associated gains, time constants, and limits.

~~R1.4.3.~~R1.5.3. Verified static set points for under and over excitation limiters.

~~R1.4.4.~~R1.5.4. Verified line drop compensator settings.

~~R1.4.5.~~R1.5.5. Open circuit test response data showing generator field voltage and generator terminal voltage (exciter field voltage and current data for brushless units).

~~R1.4.6.~~R1.5.6. Verified model from the acceptable model list for each power system stabilizer with associated gains, time constants, and limits.

~~R1.4.7.~~R1.5.7. Confirmation that the verification was conducted with the voltage regulator in the automatic voltage control mode

~~**R1.4.8.**~~**R1.5.8.** Method of verification used.

~~**R1.4.9.**~~**R1.5.9.** Date of verification.

R2. The Regional Reliability Organization shall provide its generator excitation system data verification and reporting procedures, and any changes to those procedures, to the Generator Owners, Generator Operators, Transmission Operators, Planning Authorities, and Transmission Planners affected by the procedure within 30 calendar days of the approval.

R3. The Generator Owner shall follow its Regional Reliability Organization's procedures for verifying and reporting its models and data associated with generator excitation system functions per MOD-026 R1.

C. Measures

M1. The Regional Reliability Organization shall have available for inspection a procedure for the verification and reporting of models and data associated with its generator excitation system functions in accordance with MOD-026 R1.

M2. The Regional Reliability Organization shall have evidence that its procedure for verification and reporting of generator excitation system data, and any revisions to that procedure were provided to affected Generator Owners, Generator Operators, Transmission Operators, Planning Authorities, and Transmission Planners within 30 calendar days of approval.

M3. The Generator Owner shall have evidence it provided verification of the models and data associated with its generator excitation system functions, consistent with the Regional Reliability Organization procedure.

A. Introduction

1. **Title:** **Verification of Generator Unit Frequency Response**

2. **Number:** MOD-027-1

3. **Purpose:** To provide verification of generator unit frequency response (other than Automatic Generation Control) for use in models for reliability studies.

4. **Applicability**

   4.1. Regional Reliability Organization.

   4.2. Generator Owner.

5. **Proposed Effective Date:** To be Determined.

B. Requirements

R1. The Regional Reliability Organization shall establish and maintain procedures to address verification of generator unit frequency response. These procedures shall include the following:

R1.1. Response time to be modeled, e.g. up to 30 seconds for steam units, up to 45 seconds for hydro units, etc.

R1.2. Generating unit exemption criteria including documentation describing characteristics of those units that are exempt from a portion or all of these procedures.

R1.3. Acceptable methods for model and data verification, including any applicable conditions under which the data should be verified. Such methods can include use of manufacturer data, commissioning data, performance tracking, engineering analysis, field verification of equipment settings, testing, simulation and comparison with test results or disturbance monitoring data, etc.

R1.4. A list of acceptable models to be used and procedures for revising the list of acceptable models.

~~R1.4.~~R1.5. Periodicity and schedule of verification and reporting, including a list of report recipients, schedules associated with field changes to existing units, and refurbished units.

~~R1.5.~~R1.6. Information to be reported related to generator unit frequency response:

~~R1.5.1.~~R1.6.1. Verified manufacturer and type of speed governor controls.

~~R1.5.2.~~R1.6.2. Verified model from the acceptable model list for each speed governor control with any associated deadband, gains, time constants, and limits (e.g., maximum valve opening velocity, maximum capability of the turbine, etc.).

~~R1.5.3.~~R1.6.3. Verified frequency response data of the unit, considering additional plant controls that affect the response of the unit (blocked or nonfunctioning governors or modes of operation that limit frequency response).

~~R1.5.4.~~R1.6.4. Method of verification and conditions of the verification including status of controls.

R2. The Regional Reliability Organization shall provide its frequency response verification and reporting procedures, and any changes to those procedures, to the Generator Owners, Generator Operators, Transmission Operators, Planning Authorities, and Transmission Planners affected by the procedures within 30 calendar days of the approval.

R3. The Generator Owner shall follow its Regional Reliability Organization's procedure for verifying and reporting its generator unit frequency response per MOD-027 R1.

C. Measures

M1. The Regional Reliability Organization shall have available for inspection a procedure for verifying and reporting generator unit frequency response in accordance with MOD-027 R1.

M2. The Regional Reliability Organization shall have evidence that its procedure, and any revisions to that procedure, for verification and reporting generator unit frequency response was provided to affected Generator Owners, Generator Operators, Transmission Operators, Planning Authorities, and Transmission Planners within 30 calendar days of approval.

M3. The Generator Owner shall have evidence it provided verification of the models and data associated with generator unit frequency response, consistent with the Regional Reliability Organization procedure.

WECC Low Voltage Ride Through Standard

This Standard was developed to address reliability concerns associated with un-planned generation tripping resulting from low voltage excursions following disturbances.

New Standard

1. Generators are required to remain in-service during system faults (three phase faults with normal clearing and single line to ground faults with delayed clearing) unless clearing the fault effectively disconnects the generator from the system. This requirement does not apply to faults that would occur between the generator terminals and the high side of the generator step-up transformer or to faults that would result in a voltage lower than 0.15 per unit on the high side of the generator step-up transformer.
2. In the post–fault transient period, generators are required to remain in-service for the low voltage excursions specified in WECC Table W-1 as applied to a load bus. These performance criteria are applied to the generator interconnection point, not the generator terminals.
3. Generators may be tripped after the fault period if this action is intended as part of a special protection system
4. This Standard does not apply to a site where the sum of the installed capabilities of all machines is less than 10MVA, unless it can be proven that reliability concerns exist.
5. This Standard applies to any generation independent of the interconnected voltage level.
6. This Standard can be met by the performance of the generators or by installing additional equipment (e.g., SVC, etc.).
7. Existing individual generator units that are interconnected to the network at the time of the adoption of this Standard are exempt from meeting this Standard for the remaining life of the existing generation equipment. Existing individual generator units that are replaced are required to meet this Standard.

WECC Approved Dynamic Model Library

Version 09/06

NOTES:

WECC needs to input the data to the PSLF program, with conversion to the PSS/E program. Therefore, model data must be submitted that can be input to PSLF.

* The PSLF models are converted to these PSS/E models by PTI's conversion program

Acceptable models for the WECC Master Dynamics file (MDF) are highlighted in yellow and indicated in the status column

These models are used in the 06hw3 case and aren't converted, and should be evaluated

EXCITATION SYSTEM MODELS

GE PSLF	PTI PSS/E*	IEEE Standard	Status	Comments	Modifications/Actions Needed	PTI/GE Comments
exac1	EXAC1	AC1A	approved	Brushless AC		Differs from IEEE AC1A -- does not have OEL/UEL inputs and multiplies output by speed.
[esac1a]		AC1A	future	in next PSLF release	New Model	in next PSLF release
exac1a	EXAC1A		approved	exac1 with altered rate feedback source		
exac2	EXAC2		approved	HIR Brushless		Differs from IEEE AC2A -- no OEL/UEL inputs; different field current limit; speed multiplier
esac2a	Not used	AC2A	future	new in GE PSLF	New Model	
exac3	Not used					
exac3a	ESAC3A		approved	GE Alterrex		Differs from IEEE AC3A -- no OEL/UEL inputs; different field current limit; speed multiplier
esac3a	Not used	AC3A	future	new in GE PSLF	New Model	
exac4	EXAC4	AC4A	approved	Some differences from IEEE model		Differs from IEEE AC4A -- no OEL/UEL inputs
[esac4a]		AC4A	future		New Model	in next PSLF release
[esac5a]		AC5A	future	Brushless exciter	New Model	in next PSLF release
exac6a	Not used	AC6A		Alternator, noncontrolled rectifier, lead-lag		Differs from IEEE AC6A -- no OEL/UEL inputs; speed multiplie r
[esac6a]		AC6A	future		New Model	in next PSLF release
esac7b	Not used	AC7B	future	new in GE PSLF	New Model	
exac8b	ESAC8B	AC8B	approved	Brushless exciter with PID voltage regulator i.e. ("SEL" digital excitation system of Basler Electric)		Differs from IEEE AC8B -- no exciter upper limit; added input limits and speed multiplie r
[esac8b]		AC8B	future		New Model	in next PSLF release
exbbc	BBSEX1		approved	Static with ABB regulator		
exdc1	IEEEX1	DC1A	approved	Rotating DC		Differs from IEEE DC1A -- no UEL inputs; speed multiplier
[esdc1a]		DC1A	future		New Model	in next PSLF release
exdc2	EXDC2		approved	Rotating DC with terminal fed pilot, alternate feedback		
exdc2a	EXDC2	DC2A	approved	Rotating DC with terminal fed pilot		Differs from IEEE DC2A -- no UEL inputs; speed multiplier
[esdc2a]		DC2A	future		New Model	in next PSLF release
exdc4	IEEET4	DC3A	approved	Rotating, noncontinuous - minor differences between models		If Kr = 0, should convert to IEEEX4 (IEEE DC3A).
[esdc3a]		DC3A	future		New Model	in next PSLF release
[esdc4b]		DC4B	future	Rotating DC with PID	New Model	in next PSLF release
exeli	EXELI		approved	Static PI transformer fed excitation system		
exst1	EXST1	ST1A	approved	Static with double lead/lag		Differs from IEEE ST1A -- no OEL/UEL inputs; added Xe Ifd loading; RFB before field current limiter.
[esst1a]		ST1A	future		New Model	in next PSLF release
exst2	EXST2	ST2	approved	SCPT - lead/lag block (Tc, Tb) added		
exst2a	ESST2A	ST2A	approved	lead/lag block (Tc, Tb) is included to match the WECC FM		Differs from IEEE ST2A -- no UEL inputs; added lead/lag.
[esst2a]		ST2A	future		New Model	in next PSLF release
exst3	EXST3	ST3	approved			
exst3a	ESST3A	ST3A	approved	Use this model for GE Generex		Differs from IEEE ST2A -- no UEL inputs; fewer time constants.
[esst3a]		ST3A	future		New Model	in next PSLF release
exst4b	ESST4B	ST4B	approved	GE EX2000 bus fed potential source, static compound and Generrex-PPS or -CPS, and SILCOmatic 5 excitation systems, with proportional plus integral (PI) voltage controller		Differs from IEEE ST2A -- no OEL/UEL inputs
[esst4b]		ST4B	future		New Model	in next PSLF release
[esst5b]		ST5B	future	Variation of ST1A (New IEEE Model)	New Model	in next PSLF release
[esst6b]		ST6B	future	Variation of ST4B with field current limit (New IEEE model)	New Model	in next PSLF release
[esst7b]		ST7B	future	Static with limiters (Alstom) (New IEEE model)	New Model	in next PSLF release
exwtg1	Not converted (1)			Excitation system model for wound-rotor induction wind-turbine generator	replace with new wind models	We need details of this model This is crude Vestas V80 model. This will be obsolete after generic Type 2 model is available.
exwtge	Not used			Excitation (converter) control model for GE wind-turbine generators	replace with new wind models	
ieeet1	IEEET1		approved	Old type 1		
mexs	Not used			Manual excitation control with field circuit resistance		
pfqrg	Not used			Power factor / Reactive power regulator		
rexs	REXSYS		approved	General Purpose Rotating Excitation System Model		
scrx	SCRX		approved	intended for use where negative field current may be a problem		
sexs	Not used			for use where details of the actual excitation system are unknown and/or unspecified		PSS/E has a SEXS (simplified excitation system) model (which is similar to the PSLF sexs model but without the PI control block)

texs	Not converted (9)			Transformer Fed Excitation System Model	replace with esst6b	we don't convert this. Per our notes from previous M&V mettings, this model was not to be used in WECC.
oel1	Not converted (277)			Over excitation limiter	Use new model	Please note that this is not an IEEE standard model. GE developed this model for WECC use. If we have to provide a corresponding PSS/E model, we have to get the block diagram from GE This should be replaced by IEEE model.
[oel]		OEL	future	New IEEE model	New Model	in next PSLF release
[uel1]		UEL1	future	New IEEE model	New Model	in next PSLF release
[uel2]		UEL2	future	New IEEE model	New Model	in next PSLF release

GENERATOR MODELS

GE PSLF	PTI PSS/E*	IEEE Standard	Status	Comments	Modifications/Actions Needed	PTI/GE Comments
gentpf	GENROU/IEEEVC		approved	WECC Model		
genrou	GENROU/IEEEVC		approved	Round rotor generator model, use for thermal generator models		
gensal	GENSAL/IEEEVC		approved	Salient pole generator model, Use for Hydro generator models		
gencc	GENROU/IEEEVC		approved	Cross Compound generator model		
genwri	not converted (1)			Vestas Wind turbine generator, 1 instance in 08HS3 base case	will be replaced with new wind models	We need details of this model This will be replaced by generic Type 2 WTG generator model.
gewtg	not used			GE Wind turbine generator	will be replaced with new wind models	We can convert this
motor1	CIMTR4		approved	Used for wind		
gencls	not used			Used to force a signal, or classical generator model		We have a GENCLS model. The PSLF model gencls does get converted to the PSS/E model GENCLS. [Forcing signal (playback) feature not needed in library datasets.]

PSS MODELS

GE PSLF	PTI PSS/E*	IEEE Standard	Status	Comments	Modifications/Actions Needed	PTI/GE Comments
wsccst	ST2CUT		approved	Dual input PSS		
pss2a	PSS2A	PSS2A, PSS3B	approved	Dual input PSS (2A is delta P-omega, 3A is Accelerating power (Unitrol))	extra lead/lag block	
ieeest	IEEEST	PSS1A	approved	Single input PSS, dual lead lag		
psssb	PSS2A	PSS2A, PSS3B	approved	pss2a + transient stabilizer		
[pss1a]		PSS1A				in next PSLF release
[pss2b]		PSS2B		Extra lead/lag (or rate) block added at end (up to 4 lead/lags total)		in next PSLF release
[pss3b]		PSS3B				in next PSLF release
[pss4b]		PSS4B		ABB multi-band		in next PSLF release
[psssh]				Siemens H infinity PSS		in next PSLF release

LOAD MODELS

GE PSLF	PTI PSS/E*	IEEE Standard	Status	Comments	Modifications/Actions Needed	PTI/GE Comments
alwscc	IEELAR		approved	Area load model		
blwscc	IEELBL		approved	Bus load model		
motorw	CIMWBL		approved	Induction Motor Model		

TURBINE/GOVERNOR MODELS

GE PSLF	PTI PSS/E*	IEEE Standard	Status	Comments	Modifications/Actions Needed	PTI/GE Comments
g2wscc	WSHYDD		approved			
gast	URGS3T		approved			
ggov1	GGOV1		approved			
gpwscc	WSHYGP		approved			
hyg3	WSHYGP		approved		Check WSHYGP conversion	
hygov	HYGOV		approved			
hygov4	IEEEG3		approved		Need new acceptable model in PTI	
ieeeg1	WSIEG1		approved			
ieeeg3	IEEEG3		approved			
lcfb1	ULCFB1		approved			
pidgov	PIDGOV		approved			

tgov1	TGOV1		approved			
ggov2	new		future	new in GE PSLF		We have the new GGOV2 model in a user written format. We will see if this can be given to users as a user model in the next point release. We hope to make it a standard model for the next major release.

OTHER MODELS

GE PSLF	PTI PSS/E*	IEEE Standard	Status	Comments	Modifications/Actions Needed	PTI/GE Comments
colatr	not converted (1)			Colstrip ATR relay		was developed for WECC. We don't have a PSS/E model for this, need details
dc4t	not converted (2)			old PDCI DC model		We have this model, but guess this old model will become obsolete Removed from PSLF.
dcmt	new		approved	new PDCI DC model		We have just developed two new models (north to south and south to north) for the PDCI. GE needs details for data conversion to PSLF.
epcdc	CDC6		approved	Intermountain DC model		
fmeta	not converted (1)			Frequency meter, whole system or bus		not converted for the same reason that vmeta is not converted (please see below)
gp1	not converted (4)			Generator Protection relay		We don't have a PSS/E model for this, need details
lsdt1	LDS3BL		approved	Underfrequency relay		
lsdt2	LVS3BL		approved	Undervoltage relay		
lsdt9	LDS3BL		approved	Underfrequency relay		
monit	not converted (1)			solution monitor		not converted for the same reason that vmeta is not converted (please see below)
ooslen	not converted (11)			3 zone out of step relay	low priority	We don't convert this. The reason is not because we don't have a model. PSS/E has a double circle or lens out-of step line relay model called 'CIROS1' (please note that like any other relay model, this also is a generic line-relay model not representing any particular manufacturer). The reason that the data is not converted is probably because the data requirements of the PSLF 'ooslen' model do not match the data requirements of the PSS/E 'CIROS1' model. However, this does not prevent the PSS/E users to create a DYR data record and include the CIROS1 model for every occurrence of the PSLF 'ooslen' model.
[scmov]				Series capacitor MOV and bypass model		in next PSLF release
stcon	not converted (2)			Static synchronous condensor		We don't convert this. This model, per our notes from the previous M&V mettings, was not to be used in WECC. This also is a generic model not representing any particular manufacturer. PSS/E also has two generic static condenser models - the CSTATT (use of this requires a generator model in load flow), and the CSTCNT (use of this requires a FACTS device model in load flow). We can not convert the PSLF STCON to PSS/E CSTATT or the CSTCNT models because the data requirements are different.
svcwsc	CSVGN5, CSVGN6		approved	Static Var Source model		
tlin1	not converted (114)			under frequency or under voltage line relay	Investigate better method for pump (Generator) tripping	We don't convert this, because PSS/E does not have the under frequency or under voltage line relay model. Our consulting group has a user written model and we can include it in PSS/E. We will add this in our list of task to do. As an interim solution we can check if we can make this available as a user written model before it becomes a PSS/E standard model. However, given the fact that this also is a generic model, the data requirements of the PSLF 'tlin1' may not match the data requirements of the PSS/E model, and hence we may not be able to convert from the PSLF to the correspinding PSS/E model. Nonetheless, a model can be made avialable for WECC PSS/E users.
vmeta	not converted (2)			Voltage meter, whole system or bus		We have this model, but don't (and can not convert) it. The reason the conversion is not possible is because the corresponding PSS/E model does not have to be entered into the PSS/E dynamics raw data file (the DYR file). In PSS/E, using the GUI we select CHSBNEW to place the subsystem (which could be on the basis of bus, area, owner or zone) voltages in the output channel.
vwscc	CSVGN5		approved	Static Var Source model		

WECC Field Test Report regarding
MOD-026 - Verification of Models and Data for Generator Excitation System Functions
MOD-027 - Verification of Generator Unit Frequency Response
PRC-019 - Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection

I - Background

WECC generator model data validation requirements were initially put in place following the July and August 1996 disturbances on the western interconnection. These disturbances provided a disturbing indication that the WECC dynamics models provided an overly optimistic view of system performance. At that time WECC initiated an extensive effort to initiate generator testing and data validation. Test guidelines were written, and testing and data requirements developed on a fast track and put in place during 1997. Several workshops were planned and implemented to inform generator owners regarding the new data validation requirements. Today approximately 80% of the generators required to validate their data (generators larger than 10 MW) in WECC have met those requirements on a voluntary basis.

Despite the initial validation efforts, WECC system modelers noted that the model still did not match the frequency response in the western system, so another effort was initiated to focus on frequency response modeling. As a result, new governor and load controller models were added to the major programs, and new model data verification methods were developed that focus on frequency response modeling. There was again a large effort to train generator owners in how to obtain the needed frequency response information and populate the newly developed models.

During the most recent few years, WECC modelers have updated the generator test and model validation requirements based upon the experiences with the initial requirements, and a new Generator test policy was approved in WECC during 2006. These new documents focus on model functional and validation requirements, while providing flexibility on how those requirements are met. For example, they provide for additional flexibility with regard to use of Disturbance Monitoring data to validate generator models.

The policy developed as a result of these efforts and associated documents are accessible to the public on the WECC web site at the following link:

http://www.wecc.biz/modules.php?op=modload&name=Downloads&file=index&req=viewdownload&cid=1

These documents were developed by the WECC Modeling and Validation Work Group and the WECC Controls Work Group, and have been approved through the WECC Committee structure and by the WECC Board of Directors during July of 2006.

Upon review of the WECC documents for this field test, the WECC Generator Test Policy requirements are found to meet the RRO requirements of MOD-026, MOD-027, and PRC-019 that are being field tested here. Additionally, approximately 80% of the generators in WECC have conducted initial testing under the existing WECC Generator test policy and its predecessor, and have thus met this field test requirement.

The WECC generator test policy was applied for several years and then was updated based upon the experiences of those that tested the generators under the initial requirement. Hence, the field test in WECC has been very thorough.

Recent validation efforts comparing disturbance monitor measurements to system model results indicate that current WECC model results track actual system response much better in more recent disturbances than before 1996. Continuing efforts are being made focused on load modeling to further improve system models.

II - Executive Summary of Field Test Results

The following current WECC documents meet the RRO requirements of the field test versions of MOD-026, MOD-027, and PRC-019. The WECC Generator Model Validation requirements and data requirements are gathered into one WECC policy and its accompanying attachments as follows:

WECC Generating Unit Model Validation Policy
This document succinctly states the WECC generator model validation and data submittal policies. It defines the responsibility of the Generator Owner, the Transmission Planner, and the RRO relative to testing and validating the generator model and processing model data. It defines which generators are required to be tested, and provides requirements regarding the timing under which validation and submittal of data for new or modified generator equipment must be performed. It requires an initial baseline test. It also requires a 5 year revalidation of generator data. It also provides a statement regarding the exemption policy. The Policy references the following documents for specific aspects of the requirement.

Generating Facility Data Requirements
This document details the data that are required for the generating facility. An important aspect is that it requires that target models for the data are found on a list of WECC Approved Models. This document requires certain information additional to the data targeted for the models in a dynamic stability program and

includes information such as nameplate information, type, and manufacturer for the various components. It includes a requirement for a one-line diagram, reactive capability curves, step-up transformer data, and a description of any load controller actions.

Generating Unit Baseline Test Requirements

This document provides guidance regarding how to comply with the policy baseline test requirement. Generator owners are required to test the generating unit and validate its model data. This document lists the items that must be verified through tests. However, it does not spell out how the test must be conducted, leaving that up to the expert tester. For example, under "Inertia" it says "A test that reasonably confirms the inertia constant of the turbine-generator." Then it provides an example of how the inertia constant can be confirmed. It also provides references to other documents that detail possible test methods, such as WECC's 1997 Generator Test requirement and other information that can be found on the WECC web site.

Generating Facility Model Validation Requirements

This documents details model validation requirements as required every 5 years. This is another innovation that arose from experience with WECC's 1997 Generator Test requirement and provides options for validating generator model data by comparison of model results to measurements from a performance monitor installed near the machine's terminals rather than requiring redoing the baseline tests every five years.

List of WECC-Approved Models

This is an important component of the WECC Policy, and was added to the WECC requirement as a direct result of experience with the 1997 WECC generator test policy. WECC found that data provided needed to specifically target models available in the commonly used dynamic stability programs. Since WECC

Members use the GE PSLF program and the PTI PSS/E program, the models used must be available in both programs. User defined models are problematic, and WECC is making efforts to correct perceived modeling deficiencies by making sure needed models are available to the industry (for example, there is an ongoing effort to develop standard wind models).

As mentioned in the background material, these documents meet the requirements of MOD-026, MOD-027, and PRC-019, and were approved by the WECC Board during July of 2006. Approximately 80% of the WECC generators have been tested under the WECC 1997 Generator Test Requirement, and lessons learned have been applied in the new 2006 WECC Generating Unit Model Validation Policy. The new policy spells out in more detail the responsibilities of the various parties, and provides more flexibility to experts to determine how to meet the requirements. In addition, the new policy has been applied directly during the validation/revalidation of data for several generators of all types.

As a result of the massive generator testing effort in WECC since 1996, including efforts to improve governor, wind, and load modeling, WECC models are significantly better today than during 1996. Improvements in WECC system models have been confirmed by comparing measurements from performance monitors to simulation results. There are significant ongoing efforts in wind generator modeling and load modeling to further improve system models.

It is very important that model results match system performance. Transfer capabilities are based upon results from system models, and if models are overly pessimistic, the system is not fully utilized, while using the results of system studies using overly optimistic models can be catastrophic. System disturbances are costly and dangerous. There have also been side benefits from the required generator testing through having independent experts review generator plant performance and operating procedures. For example, in some instances equipment problems have been discovered that could have resulted in costly generator outages had they not been detected. As a result of what was learned regarding plant frequency response, not only was the model improved but WECC was able to initiate discussions regarding possible new performance requirements.

WECC has had a generator test policy since 1997. The purpose of the updated 2006 policy is to provide clarification regarding responsibilities and requirements and to providing additional options for meeting the data needs (particularly of the revalidation requirement) rather than to add additional requirements. Thus, WECC has essentially been field testing the generator baseline test requirements since 1997. WECC and a majority of its Members are convinced that the generator testing requirements are important, and that the costs, although significant, are necessary.

WECC has established an implementation plan, which basically requires that those that have not yet met the WECC generator baseline test requirement (which has been a requirement since 1997) provide a schedule for when they plan to meet it. The implementation plan indicates that generators that have not met the baseline test requirement continue to be non-compliant until the tests are performed. The implementation plan also requests a schedule for completing the five-year revalidation requirement from those that met the baseline requirement. Those that have met the initial WECC requirement are rewarded in that they will continue to be considered compliant with the WECC generator test requirement until five years from December 31 2006, although some of the units were baseline tested as early as 1996. This helps maintain a distribution of revalidation dates throughout the five year period. There are limited organizations/individuals qualified to perform the validation testing, and the requirement must allow for them to manage their workload.

There are two suggestions for changes to the draft NERC Standards. WECC recommends that MOD-026 and MOD-027 be revised with regard to the generating unit exemption criteria in R1.2 to clarify that documentation of exempt units should describe the characteristics of the exempt units, and to clarify that it doesn't need to require a list of all of the exempt units. The requirements should also be revised by adding a requirement that there be a list of acceptable models and a procedure for updating the list of acceptable models. Mark-ups of the standards are attached.

III – Details/Appendices/Attachments

The following links to the area on the WECC web site where the WECC generator test documents may be found

.

http://www.wecc.biz/modules.php?op=modload&name=Downloads&file=index&req=viewdownload&cid=1

Additionally the WECC generator test policy is attached, along with referenced requirements documents.

Documents are attached that provide a red-line of the NERC MOD-026 and MOD-027 standards with suggested revisions.

A detailed explanation of how each of the field test standards is met by the WECC Generator test policy is also attached.

WECC Field Test Report regarding PRC-024 - Generator Performance During Frequency and Voltage Excursions

I - Background

WECC requirements regarding off-nominal frequency performance of generators are included in the document "*WECC Coordinated Off-Nominal Frequency Load Shedding and Restoration Requirements*."

For this field test, WECC reviewed the WECC requirements in the above document relative to the field test standard PRC024 and found that the requirements in the above referenced document meet the RRO frequency requirements of the NERC field test standard PRC-024.

The WECC off-nominal frequency plan was developed by a task force under the WECC TSS in 1997 and has been updated multiple times since then. In particular, the generator frequency requirements were updated based upon manufacturer input to better fit the frequency deviation capabilities of current equipment. The frequency requirements were developed under the WECC Technical Studies Subcommittee (TSS), and approved by TSS and the WECC Planning Coordination Committee. The WECC Board approved the most recent changes to the requirements during December 2003.

WECC approved a plan regarding voltage performance of generators titled "*WECC Low Voltage Ride Through Standard*" a few years ago, but after FERC and NERC revised some requirements, an effort was initiated to revise the WECC voltage requirements. WECC requirements regarding voltage performance of generators are still under development, and efforts are being made to coordinate the WECC requirements development efforts with ongoing FERC and NERC standards development efforts.

II - Executive Summary of Field Test Results

The following current WECC documents meet the RRO requirements of the field test version of PRC-024.

WECC *Coordinated Off-Nominal Frequency Load Shedding and Restoration Requirements*
This document provides for coordination of off-nominal frequency load shedding with allowable frequency/time delays for generators. The WECC off-nominal frequency plan provides minimum requirements. Each major region of WECC has chosen to have regional requirements that trip more load sooner than the minimum requirements plan. Generators are allowed exceptions to trip at higher frequencies/smaller time delays than allowed under the WECC plan only if they arrange for compensating load tripping.

WECC *Low Voltage Ride Through Standard*
This WECC Policy document will be replaced as a new standard is developed. This document identifies voltage levels and conditions under which a generator should remain connected to the system.

The *WECC Reliability Criteria* include the *NERC/WECC Planning Standards* and the *Minimum Operating Reliability Criteria*
These WECC documents include the voltage/time duration table W-1 referenced by the voltage requirements and also require Coordination of generator protection, including back-up protection, with transmission Protection Systems

July 12, 2006 Draft *WECC Voltage Ride-Through Standard*
This document is a draft and is only provided as a sample of what WECC envisions. Efforts will be made to match FERC and NERC requirements.

Further discussions may be needed to address exemptions and variances as specified in the NERC field test standard PRC-024. Otherwise, the listed current and draft WECC requirements meet the RRO requirements of the NERC field test standard PRC-024.

III – Details/Appendices/Attachments

A detailed explanation of how each of the field test standard requirements is met by the WECC policies is attached. The attached compares all four field test standards, PRC-024 is the last standard compared.

The WECC *Coordinated Off-Nominal Frequency Load Shedding and Restoration Requirements* can be obtained from the WECC web site by clicking on the following link: http://www.wecc.biz/documents/library/procedures/planning/WECC_ONF_Report_July_2005.pdf

The WECC *Low Voltage Ride Through Standard* is attached.

The *WECC Reliability Criteria* include the *NERC/WECC Planning Standards* and the *Minimum Operating Reliability Criteria* are available at the following link:

http://www.wecc.biz/documents/library/procedures/CriteriaMaster.pdf

The July 12, 2006 Draft *WECC Voltage Ride-Through Standard* is attached. This document is a draft and is only provided as a sample of what WECC envisions.

WECC Field Test of NERC draft Standards MOD-026, MOD-027, PRC-019, and PRC-024

Presented June 18, 2007

1996 Outages

- During July and August of 1996 System Disturbances Occurred
- Dynamic Simulations indicated the system would be stable
- Initiated a significant effort to improve the WECC System Models

Initiatives to Improve Models

- Generator Testing Program
- Load Model Improvements
  - Induction Motor Models
- Governor Model Improvements
- Extreme Disturbance Policy
  - NE/SE Separation Scheme
  - Reevaluate Underfreqency Load Shedding Programs

Field Testing

- Compared WECC Policies with the requirements of the field tested standards,
- Found that WECC Policies had already been developed, many as a result of the 1996 Disturbances that met most of the field test requirements

WECC Generator Testing

- Started in 1996
  - Reactive Test Requirement
  - Dynamic Data Validation Requirement
  - Certificates Issued to those meeting requirements
  - Approximately 80% (1340/1686) of the Generators Larger than 10 MW in WECC have been tested. Major Effort
  - Several have been retested (5 year requirement)
- New Policy Approved During 2006
  - Based on Experience with 1997 Policy

2006 Generator Test Policy

- Improvements
  - List of approved models –
    - Found in both major programs in use in WECC
    - User defined models and proprietary models are problematic
      - Must be able to share models freely to study the system
  - Clearly Assigned Responsibilities
    - Generator Owner Responsible for Tests
    - Transmission Planner Responsible for tracking completion of tests and reviewing results for connected generators

2006 Generator Test Policy

- Improvements (Continued)
  - Allow flexibility re procedures to provide validation
  - Performance based requirements,
  - Initial Baseline test and Data requirements
  - Option to perform data validation using performance validation equipment

2006 Generator Test Policy

- Components
  - *WECC Generating Unit Model Validation Policy*
    - This document succinctly states the WECC generator model validation and data submittal policies.
  - *Generating Facility Data Requirements*
    - This document details the data that are required for the generating facility.

2006 Generator Test Policy

- Components
  - *Generating Unit Baseline Test Requirements*
    - Guidance regarding how to comply with the policy baseline test requirement.
    - Generator owners are required to test the generating unit and validate its model data.
    - List of items that must be verified through tests.
    - Does not spell out how the test must be conducted, leaving that up to the expert tester.
      - Ie. “A test that reasonably confirms the inertia constant of the turbine-generator”
      - Also provides guidance regarding test options.

2006 Generator Test Policy

- Components
  – *Generating Facility Model Validation Requirements*
    - Details model validation requirements as required every 5 years.
    - Provides the option for validating generator model data by comparison of model results to measurements from a performance monitor

2006 Generator Test Policy

- Components
  - *List of WECC-Approved Models*
  - Needed ongoing model development efforts
    - Load Models
    - Wind Models

Governor Model Development

- Found that the model had about half the frequency dip of system disturbances
  - Needed some new improved models in the programs
  - Plant frequency control
  - Model unresponsive governors properly
- Verify governor model response with "good" SCADA data.
- Review multiple disturbances, variability

Off-nominal Frequency Policy

- Requirements include coordinated load and generator off-nominal requirements.

Recommendation for SAR

- Division of Six standards seems strange
  - Generator Testing Standard, cover verification of the entire generator model.
  - What about generator impedances, time constants, inertia, etc.
- Coordination of Relays (test?)

Recommendations re draft standards

- Clarify that documentation of exempt units should describe the characteristics of the exempt units,
- Clarify that it doesn’t need to require a list of all of the exempt units.
- There should be a list of acceptable models and a procedure for updating the list of acceptable models.

NERC
NORTH AMERICAN ELECTRIC
RELIABILITY CORPORATION

Maureen E. Long
Standards Process Manager

April 20, 2007

TO: REGISTERED BALLOT BODY

Ladies and Gentlemen:

Announcement: Comment Periods Open

The Standards Committee (SC) announces the following standards action:

SAR for Generator Verification (Project 2007-09) Posted for 30-day Comment Period April 20–May 21, 2007

The SAR for Project 2007-09 proposes completing the following four Phase III & IV standards that have been field tested but require additional modifications beyond the scope of their original SAR:

- PRC-019 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection
- PRC-024 — Generator Performance During Frequency and Voltage Excursions
- MOD-026 — Verification of Models and Data for Generator Excitation System Functions
- MOD-027 — Verification of Generator Unit Frequency Response

The SAR also involves revising the following two already-approved Phase III & IV standards:

- MOD-024 — Verification of Generator Gross and Net Real Power Capability
- MOD-025 — Verification of Generator Gross and Net Reactive Power Capability

The modifications will address issues raised by FERC and stakeholders about these standards, and will bring the standards into conformance with the ERO Sanctions Guidelines and the latest version of the Reliability Standards Development Procedure. Please use the comment form to provide comments on this SAR.

SAR for Permanent Changes to the Timing Table in the Coordinate Interchange Standards (Project 2007-14) Posted for 30-day Comment Period April 20–May 21, 2007

An Urgent Action SAR to modify the Timing Table in some of the Coordinate Interchange standards (INT-005, INT-006, and INT-008) was approved by its ballot pool on March 30, 2007. The Urgent Action SAR made modifications to the timing table so that the reliability assessment period for WECC was lengthened from 5 minutes to 10 minutes for e-tags submitted less than 1 hour and greater than 20 minutes prior to ramp start.

The new SAR for Permanent Changes to the Coordinate Interchange Table proposes to make the above changes permanent and also proposes to add the following to the timing table to bring the timing table into alignment with the categories (On-time, Late, After-the-Fact, and Pre-late) used in the latest E-Tag Specification with respect to receipt of an arranged interchange.

- Designation of request status based on start and submittal times
- Assess times for After-the-Fact requests
- WECC pre-schedule late (Pre-late) submittal definition

Please use the comment form to provide comments on this SAR.

Standards Development Process

The *Reliability Standards Development Procedure* contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate. If you have any questions, please contact me at 813-468-5998 or maureen.long@nerc.net.

Sincerely,

Maureen E. Long

Background Information

The Generator Verification SAR calls for finalizing the last four Phase III & IV standards (subsequent to field testing) and calls for revising two of the Phase III & IV standards that were approved by the NERC Board of Trustees but not by FERC. All six standards need to conform to the latest version of the ERO Sanction Guidelines and Reliability Standards Development Procedure and all need to address FERC concerns identified in FERC Order 693. The standards associated with this SAR are:

PRC-019 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection

PRC-024 — Generator Performance During Frequency and Voltage Excursions

MOD-024 — Verification of Generator Gross and Net Real Power Capability

MOD-025 — Verification of Generator Gross and Net Reactive Power Capability

MOD-026 —Verification of Models and Data for Generator Excitation System Functions

MOD-027 — Verification of Generator Unit Frequency Response

The SAR drafting team would like to receive comments on this SAR. Please review the SAR, answer the questions on the following pages, and e-mail the form to sarcomm@nerc.net with the subject "**Generator Verification**" by **May 21, 2007**.

You do not have to answer all questions.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. The field test from the Phase III & IV project included PRC-019, PRC-024, MOD-026, and MOD-027. The field testing has shown that requirements can be developed and incorporated into standards for the following:

   - Generator excitation system verification (MOD-026)
   - Generator frequency response verification (MOD-027)
   - Expectations for generators to remain connected during specified voltage and frequency excursions (PRC-024)
   - Coordination of generator voltage regulator controls and limit functions with generator capabilities and protective relays (PRC-019)

   Finalizing these standards will require significant changes that are outside the scope of the original Phase III & IV SARs, which is why the draft standards have been included in the scope of this new SAR. Do you agree that there is a reliability-related need to finalize these standards? If not, please explain in the comment area.

   ☐ Yes

   ☐ No

   Comments:

2. Two of the standards (MOD-024 and MOD-025) associated with this SAR had already been approved by the NERC Board of Trustees, but are "pending" with FERC because they include "fill-in-the-blank" requirements assigned to the Regional Reliability Organization. These standards must be revised to remove the fill-in-the-blank characteristics before they can become mandatory and enforceable. The intent of MOD-024 and MOD-025 is to ensure that accurate information on generator gross and net real and reactive power capability is available for the steady-state models used to assess bulk electric system reliability.

   To be enforceable, these standards need to be revised. Do you agree that there is a reliability-related need to revise these standards to support accurate modeling?

   ☐ Yes

   ☐ No

   Comments:

3. The scope of this project includes:

   - Modifying the six standards associated with this project so they conform to the latest version of NERC's Reliability Standards Development Procedure and the ERO Sanction Guidelines,

   - Replacing the fill-in-the-blank requirements assigned to the Regional Reliability Organization with requirements that can be applied on a continent-wide basis and are assigned to users, owners, or operators of the bulk power system, and

   - Addressing issues identified in FERC Order 693.

Do you agree with this scope? If not, please explain in the comment area.

☐ Yes

☐ No

Comments:

4. Page 6 of the SAR identifies a list of reliability functions that may be assigned responsibility for requirements in the set of standards addressed by this SAR. (At this point additional industry debate is needed on which function or functions will be assigned responsibility for the requirements currently assigned to the RRO — and that debate is expected to take place during standard drafting as the requirements are refined. Note that the standard drafting team can "reduce" but cannot "expand" this list of responsible reliability functions during standard drafting.) Do you agree with the list of proposed applicable functional entities? If you feel that the list should be modified, please explain in the comment area.

   ☐ Yes

   ☐ No

   Comments: Please transmit to the Standard Drafting Team the following specific suggested revisions to MOD-025:
   Key changes relate to FERC's requirement that regional "fill-in-the-blank" standards be rewritten as North American standards; these and other recommended changes are provided below:

   A. Introduction

   1. Title:Verification of Generator [ ] Reactive Power Capabilities

   3. Purpose: To ensure that [ ] steady-state models used for assessing Bulk Electric System reliability reflect realistic/usable generator reactive power capabilities.

   B. Requirements

R1. The North American Electric Reliability Corporation (NERC) shall establish and maintain procedures to address verification of generator gross and net Reactive Power capability. These procedures shall include the following:

R1.5. Information to be reported to Regional Reliability Organization (RRO):

R1.5.1. Verified maximum gross and net Reactive Power capability (both lagging and leading) at Seasonal Real Power generating capabilities as reported in accordance with Reliability Standard MOD-024 Requirement 1.5.1. and at Minimum Real Power output levels of generators. Net capabilities should be reported at the low- and high-voltage terminals of generator step-up (GSU) transformers.

R1.5.3. Verified Real and Reactive Power of auxiliary loads fed from: (a) generator bus, and (b) transmission system bus (listed separately).

R1.5.5. System bus voltages (as scheduled and as verified), generator bus voltage and generator hydrogen pressure.

R1.5.6. In-service transformer tap setting and impedance (including base quantities).

R1.6. Requirement that sanity checks (or analysis) be used to ensure consistency/accuracy of reactive power capabilities obtained via measurement.

R2. The RRO shall provide [ ] generator gross and net Reactive Power capability verification and reporting procedures, and any changes to those procedures, to ...

R3. The Generator Owner shall follow NERC's procedures for verifying and reporting to RRO generator gross and net Reactive Power capabilities per R1.

C. Measures

M2. The RRO shall have written evidence that [ ] procedures...

M3. The Generator Owner shall have written evidence it provided verified information of its generator gross and net Reactive Power capabilities, consistent with NERC's procedures.

D. Compliance

This section should be revised to recognize that the procedures for generator Reactive Power capability verification will be written by NERC as a continent-wide standard. AEP recommends that AEP's Circular Letter OP-G-CL-011 (Reactive Capability Testing of Generators), developed over nearly two decades of testing experience and advocacy within the former ECAR region, be used as a reference in drafting this standard.

Please use this form to submit comments on the SAR for Generator Verification. Comments must be submitted by **May 21, 2007**. You may submit the completed form by e-mail to sarcomm@nerc.net with the words "**Generator Verification**" in the subject line. If you have questions, please contact David Taylor at david.taylor@nerc.net or by telephone at 609-651-5089.

Background Information

The Generator Verification SAR calls for finalizing the last four Phase III & IV standards (subsequent to field testing) and calls for revising two of the Phase III & IV standards that were approved by the NERC Board of Trustees but not by FERC. All six standards need to conform to the latest version of the ERO Sanction Guidelines and Reliability Standards Development Procedure and all need to address FERC concerns identified in FERC Order 693. The standards associated with this SAR are:

PRC-019 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection

PRC-024 — Generator Performance During Frequency and Voltage Excursions

MOD-024 — Verification of Generator Gross and Net Real Power Capability

MOD-025 — Verification of Generator Gross and Net Reactive Power Capability

MOD-026 —Verification of Models and Data for Generator Excitation System Functions

MOD-027 — Verification of Generator Unit Frequency Response

The SAR drafting team would like to receive comments on this SAR. Please review the SAR, answer the questions on the following pages, and e-mail the form to sarcomm@nerc.net with the subject "**Generator Verification**" by **May 21, 2007**.

You do not have to answer all questions.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. The field test from the Phase III & IV project included PRC-019, PRC-024, MOD-026, and MOD-027. The field testing has shown that requirements can be developed and incorporated into standards for the following:

   - Generator excitation system verification (MOD-026)
   - Generator frequency response verification (MOD-027)
   - Expectations for generators to remain connected during specified voltage and frequency excursions (PRC-024)
   - Coordination of generator voltage regulator controls and limit functions with generator capabilities and protective relays (PRC-019)

   Finalizing these standards will require significant changes that are outside the scope of the original Phase III & IV SARs, which is why the draft standards have been included in the scope of this new SAR. Do you agree that there is a reliability-related need to finalize these standards? If not, please explain in the comment area.

   ☒ Yes

   ☐ No

   Comments:

2. Two of the standards (MOD-024 and MOD-025) associated with this SAR had already been approved by the NERC Board of Trustees, but are "pending" with FERC because they include "fill-in-the-blank" requirements assigned to the Regional Reliability Organization. These standards must be revised to remove the fill-in-the-blank characteristics before they can become mandatory and enforceable. The intent of MOD-024 and MOD-025 is to ensure that accurate information on generator gross and net real and reactive power capability is available for the steady-state models used to assess bulk electric system reliability.

   To be enforceable, these standards need to be revised. Do you agree that there is a reliability-related need to revise these standards to support accurate modeling?

   ☒ Yes

   ☐ No

   Comments: With regards to the scope of MOD-025, it should not be necessary to include a blanket requirement for verification of reactive power capability at multiple points for all generators. However, should a generator frequently have difficulty reaching its stated reactive power output, additional testing requirements for that generator would be indicated.

3. The scope of this project includes:

   - Modifying the six standards associated with this project so they conform to the latest version of NERC's Reliability Standards Development Procedure and the ERO Sanction Guidelines,

- Replacing the fill-in-the-blank requirements assigned to the Regional Reliability Organization with requirements that can be applied on a continent-wide basis and are assigned to users, owners, or operators of the bulk power system, and
- Addressing issues identified in FERC Order 693.

Do you agree with this scope? If not, please explain in the comment area.

☐ Yes

☐ No

Comments:

4. Page 6 of the SAR identifies a list of reliability functions that may be assigned responsibility for requirements in the set of standards addressed by this SAR. (At this point additional industry debate is needed on which function or functions will be assigned responsibility for the requirements currently assigned to the RRO — and that debate is expected to take place during standard drafting as the requirements are refined. Note that the standard drafting team can "reduce" but cannot "expand" this list of responsible reliability functions during standard drafting.) Do you agree with the list of proposed applicable functional entities? If you feel that the list should be modified, please explain in the comment area.

   ☐ Yes

   ☐ No

7. If you have any other comments on this SAR that you haven't already mentioned above, please provide them here:

   Comments: MOD-026-1 and MOD-027-1: The existing language in R1.2 for each of these standards states that manufacturer data is one of the methods which can be utilized for verification of models and data. However, typical data for these types of models is generally not adequate to sufficiently characterize the models for use in system simulations.

Please use this form to submit comments on the SAR for Generator Verification. Comments must be submitted by **May 21, 2007**. You may submit the completed form by e-mail to sarcomm@nerc.net with the words "**Generator Verification**" in the subject line. If you have questions, please contact David Taylor at david.taylor@nerc.net or by telephone at 609-651-5089.

Background Information

The Generator Verification SAR calls for finalizing the last four Phase III & IV standards (subsequent to field testing) and calls for revising two of the Phase III & IV standards that were approved by the NERC Board of Trustees but not by FERC. All six standards need to conform to the latest version of the ERO Sanction Guidelines and Reliability Standards Development Procedure and all need to address FERC concerns identified in FERC Order 693. The standards associated with this SAR are:

PRC-019 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection

PRC-024 — Generator Performance During Frequency and Voltage Excursions

MOD-024 — Verification of Generator Gross and Net Real Power Capability

MOD-025 — Verification of Generator Gross and Net Reactive Power Capability

MOD-026 —Verification of Models and Data for Generator Excitation System Functions

MOD-027 — Verification of Generator Unit Frequency Response

The SAR drafting team would like to receive comments on this SAR. Please review the SAR, answer the questions on the following pages, and e-mail the form to sarcomm@nerc.net with the subject "**Generator Verification**" by **May 21, 2007**.

You do not have to answer all questions.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. The field test from the Phase III & IV project included PRC-019, PRC-024, MOD-026, and MOD-027. The field testing has shown that requirements can be developed and incorporated into standards for the following:

   - Generator excitation system verification (MOD-026)
   - Generator frequency response verification (MOD-027)
   - Expectations for generators to remain connected during specified voltage and frequency excursions (PRC-024)
   - Coordination of generator voltage regulator controls and limit functions with generator capabilities and protective relays (PRC-019)

   Finalizing these standards will require significant changes that are outside the scope of the original Phase III & IV SARs, which is why the draft standards have been included in the scope of this new SAR. Do you agree that there is a reliability-related need to finalize these standards? If not, please explain in the comment area.

   ☐ Yes

   ☐ No

   Comments: At this point in time we cannot determine if there is a reliability related need to finalize these standards. The results of the field test by the 4 participating RROs will not be complete until late June 2007. The 4 RROs, in support of the NERC Field Test team, have spent significant resources in an attempt to implement procedures and subsequently carry out the draft Reliablity Standard requirements. Thus, in order to ensure proper consideration is given to the results of the field tests, the scope of the SAR should make it clear that the decision by the SDT to either refine / significantly revise / or delete these standards should be heavily weighted on the outcome of the field test. Recommend that the last sentence in the paragraph in the SAR on page SAR-3 under "Detailed Description" be modified to: "In addition, the SDT will consider and address all applicable FERC Orders, including Order 693, in addition to any modifications, deficiencies, and other items as found in the NERC Phase III-IV Planning Standard Field Tests, and in addition the following porposed changes for each of the six standards in this set of standards:"

2. Two of the standards (MOD-024 and MOD-025) associated with this SAR had already been approved by the NERC Board of Trustees, but are "pending" with FERC because they include "fill-in-the-blank" requirements assigned to the Regional Reliability Organization. These standards must be revised to remove the fill-in-the-blank characteristics before they can become mandatory and enforceable. The intent of MOD-024 and MOD-025 is to ensure that accurate information on generator gross and net real and reactive power capability is available for the steady-state models used to assess bulk electric system reliability.

   To be enforceable, these standards need to be revised. Do you agree that there is a reliability-related need to revise these standards to support accurate modeling?

   ☒ Yes

   ☐ No

Comments:

3. The scope of this project includes:

   - Modifying the six standards associated with this project so they conform to the latest version of NERC's Reliability Standards Development Procedure and the ERO Sanction Guidelines,
   - Replacing the fill-in-the-blank requirements assigned to the Regional Reliability Organization with requirements that can be applied on a continent-wide basis and are assigned to users, owners, or operators of the bulk power system, and
   - Addressing issues identified in FERC Order 693.

   Do you agree with this scope? If not, please explain in the comment area.

   ☒ Yes

   ☐ No

   Comments: The scope of MOD-025 has been expanded beyond what is stated above. The changes to the four field test standards should be based on the field test results.

4. Page 6 of the SAR identifies a list of reliability functions that may be assigned responsibility for requirements in the set of standards addressed by this SAR. (At this point additional industry debate is needed on which function or functions will be assigned responsibility for the requirements currently assigned to the RRO — and that debate is expected to take place during standard drafting as the requirements are refined. Note that the standard drafting team can "reduce" but cannot "expand" this list of responsible reliability functions during standard drafting.) 7. If you have any other comments on this SAR that you haven’t already mentioned above, please provide them here:

   Comments: The SAR includes language requiring the SDT to identify any generators that should be exempt from compliance. There are many standards both under this project and others (such as Project 2007-01) that need to consider applicability based on generator size and/or voltage. If these standards remain separate, this requirement will either force needless repetition of the same language in many standards, or there is a distinct possibility that differences will develop among the exemptions, making it very difficult for generator owners to know which of their generators are covered by which standards. I suggest there should be a global definition of minimum generator size to which all NERC Reliability Standards apply, much like the global definition of Bulk Electric System. To start the discussion let me suggest "generators with a net electrical output or 20 MW or greater, connected through a step-up transformer with a high voltage rating of 100 kV or higher."

   The wording in the third bullet point for MOD-024-1 and MOD-025-1 in the Detail Description should be changed from "Consider Requiring" to just "Require".

You do not have to answer all questions.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. The field test from the Phase III & IV project included PRC-019, PRC-024, MOD-026, and MOD-027. The field testing has shown that requirements can be developed and incorporated into standards for the following:

   - Generator excitation system verification (MOD-026)
   - Generator frequency response verification (MOD-027)
   - Expectations for generators to remain connected during specified voltage and frequency excursions (PRC-024)
   - Coordination of generator voltage regulator controls and limit functions with generator capabilities and protective relays (PRC-019)

   Finalizing these standards will require significant changes that are outside the scope of the original Phase III & IV SARs, which is why the draft standards have been included in the scope of this new SAR. Do you agree that there is a reliability-related need to finalize these standards? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: It is questionable whether there is a reliability related need for these standards. The field tests are not complete, but initial results show that PRC-024 and MOD-027 are difficult to perform, give questionable results, and may not be translated into better models or higher reliability. MOD-026 is also difficult to translate into better models or higher reliability.

2. Two of the standards (MOD-024 and MOD-025) associated with this SAR had already been approved by the NERC Board of Trustees, but are "pending" with FERC because they include "fill-in-the-blank" requirements assigned to the Regional Reliability Organization. These standards must be revised to remove the fill-in-the-blank characteristics before they can become mandatory and enforceable. The intent of MOD-024 and MOD-025 is to ensure that accurate information on generator gross and net real and reactive power capability is available for the steady-state models used to assess bulk electric system reliability.

   To be enforceable, these standards need to be revised. Do you agree that there is a reliability-related need to revise these standards to support accurate modeling?

   ☒ Yes

   ☐ No

   Comments: However, there is no need increase the scope and test multiple points for MOD-025 for leading and lagging. This will not improve reliability or accurate modeling.

3. The scope of this project includes:

- Modifying the six standards associated with this project so they conform to the latest version of NERC's Reliability Standards Development Procedure and the ERO Sanction Guidelines,
- Replacing the fill-in-the-blank requirements assigned to the Regional Reliability Organization with requirements that can be applied on a continent-wide basis and are assigned to users, owners, or operators of the bulk power system, and
- Addressing issues identified in FERC Order 693.

Do you agree with this scope? If not, please explain in the comment area.

☐ Yes

☒ No

Comments: The scope of MOD-025 has been expanded beyond what is stated above. The changes to the four field test standards should be based on the field test results up to and including their elimination if so recommended.

4. Page 6 of the SAR identifies a list of reliability functions that may be assigned responsibility for requirements in the set of standards addressed by this SAR. (At this point additional industry debate is needed on which function or functions will be assigned responsibility for the requirements currently assigned to the RRO — and that debate is expected to take place during standard drafting as the requirements are refined. Note that the standard drafting team can "reduce" but cannot "expand" this list of responsible reliability functions during standard drafting.)    Regional Variance:
   Comments:

6. If you are aware of any business practice that will be needed or that will need to be modified as a result of this project, please identify the business practice:

   Business Practice:
   Comments:

7. If you have any other comments on this SAR that you haven't already mentioned above, please provide them here:

   Comments: MOD-24 & 25 should not be increased beyond their current scope. Multiple test points cost time and money, and increase the potential of plant trips, but do not improve reliability. The rest of the standards should be judged based on the results of the field test and significantly modified or eliminated if the field test show that they are very difficult to perform, give questionable results or do not improve the reliability of the bulk power system.

Please use this form to submit comments on the SAR for Generator Verification. Comments must be submitted by **May 21, 2007**. You may submit the completed form by e-mail to sarcomm@nerc.net with the words "**Generator Verification**" in the subject line. MOD-024 — Verification of Generator Gross and Net Real Power Capability

MOD-025 — Verification of Generator Gross and Net Reactive Power Capability

MOD-026 —Verification of Models and Data for Generator Excitation System Functions

MOD-027 — Verification of Generator Unit Frequency Response

The SAR drafting team would like to receive comments on this SAR. Please review the SAR, answer the questions on the following pages, and e-mail the form to sarcomm@nerc.net with the subject "**Generator Verification**" by **May 21, 2007**.

You do not have to answer all questions.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. The field test from the Phase III & IV project included PRC-019, PRC-024, MOD-026, and MOD-027. The field testing has shown that requirements can be developed and incorporated into standards for the following:

   - Generator excitation system verification (MOD-026)
   - Generator frequency response verification (MOD-027)
   - Expectations for generators to remain connected during specified voltage and frequency excursions (PRC-024)
   - Coordination of generator voltage regulator controls and limit functions with generator capabilities and protective relays (PRC-019)

   Finalizing these standards will require significant changes that are outside the scope of the original Phase III & IV SARs, which is why the draft standards have been included in the scope of this new SAR. Do you agree that there is a reliability-related need to finalize these standards? If not, please explain in the comment area.

   ☒ Yes

   ☐ No

   Comments:

2. Two of the standards (MOD-024 and MOD-025) associated with this SAR had already been approved by the NERC Board of Trustees, but are "pending" with FERC because they include "fill-in-the-blank" requirements assigned to the Regional Reliability Organization. These standards must be revised to remove the fill-in-the-blank characteristics before they can become mandatory and enforceable. The intent of MOD-024 and MOD-025 is to ensure that accurate information on generator gross and net real and reactive power capability is available for the steady-state models used to assess bulk electric system reliability.

   To be enforceable, these standards need to be revised. Do you agree that there is a reliability-related need to revise these standards to support accurate modeling?

   ☒ Yes

   ☐ No

   Comments: The present legacy document ECAR Document 4 details the testing and is sufficient to cover the present accurary for a regional basis. The standards if spread to a national level will need to look at the difference between summer peaking regions and winter peaking. Presently the testing in RFC follows ECAR Document 4 which corrects the testing for average ambient conditions which is left up to the discretion of the testing personnel. The temperature conditions of the water inlet or ambient air needs to be defined.

3. The scope of this project includes:

- Modifying the six standards associated with this project so they conform to the latest version of NERC's Reliability Standards Development Procedure and the ERO Sanction Guidelines,
- Replacing the fill-in-the-blank requirements assigned to the Regional Reliability Organization with requirements that can be applied on a continent-wide basis and are assigned to users, owners, or operators of the bulk power system, and
- Addressing issues identified in FERC Order 693.

Do you agree with this scope? If not, please explain in the comment area.

☒ Yes

☐ No

Comments: The project should account for potential regional differences. See comment on question # 5 below.

4. Page 6 of the SAR identifies a list of reliability functions that may be assigned responsibility for requirements in the set of standards addressed by this SAR. (At this point additional industry debate is needed on which function or functions will be assigned responsibility for the requirements currently assigned to the RRO — and that debate is expected to take place during standard drafting as the requirements are refined. Note that the standard drafting team can "reduce" but cannot "expand" this list of responsible reliability functions during standard drafting.) Do you agree with the list of proposed applicable functional entities? If you feel that the list should be modified, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: It is recommended that the SAR be written to include the Generator Operator entity. If the drafting team determines only the GO is applicable and that the GOP is not needed it can be removed. As stated above, the SDTs can reduce scope but not expand. The Generator Operator may have involvement in PRC-024.

5. If you are aware of any regional variances that will be needed as a result of this project, please identify the Regional Variance:

   Regional Variance: Not aware of existing, but potential for regional differences exist.
   Comments: The fill-in-the-blank needs to take into account regional differences such as summer or winter peaking conditions. The standard needs to address the main factor in generation capacity which is inlet water temperatures on once through cooling units and ambient temperature and humidity on cooling towers and combustion turbines.

6. If you are aware of any business practice that will be needed or that will need to be modified as a result of this project, please identify the business practice:

   Business Practice:
   Comments: Aware of none.

7. If you have any other comments on this SAR that you haven't already mentioned above, please provide them here:

Comments: On page SAR-3 under PRC-024-1, the bullet "Add requirement for the Transmission Owner and Generator Owner to coordinate protection systems" should be revised or removed. If it is included, it should be revised to specifically state what protection schemes are being coordinated via this standard. Otherwise it should be removed because the coordination of the transmission and generation protection is covered in PRC-001-1 R3 and R4.

Please use this form to submit comments on the SAR for Generator Verification. Comments must be submitted by **May 21, 2007**. You may submit the completed form by e-mail to sarcomm@nerc.net with the words "**Generator Verification**" in the subject line. If you have questions, please contact David Taylor at david.taylor@nerc.net or by telephone at 609-651-5089.

Background Information

The Generator Verification SAR calls for finalizing the last four Phase III & IV standards (subsequent to field testing) and calls for revising two of the Phase III & IV standards that were approved by the NERC Board of Trustees but not by FERC. All six standards need to conform to the latest version of the ERO Sanction Guidelines and Reliability Standards Development Procedure and all need to address FERC concerns identified in FERC Order 693. The standards associated with this SAR are:

PRC-019 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection

PRC-024 — Generator Performance During Frequency and Voltage Excursions

MOD-024 — Verification of Generator Gross and Net Real Power Capability

MOD-025 — Verification of Generator Gross and Net Reactive Power Capability

MOD-026 —Verification of Models and Data for Generator Excitation System Functions

MOD-027 — Verification of Generator Unit Frequency Response

The SAR drafting team would like to receive comments on this SAR. Please review the SAR, answer the questions on the following pages, and e-mail the form to sarcomm@nerc.net with the subject "**Generator Verification**" by **May 21, 2007**.

You do not have to answer all questions.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. The field test from the Phase III & IV project included PRC-019, PRC-024, MOD-026, and MOD-027. The field testing has shown that requirements can be developed and incorporated into standards for the following:

   - Generator excitation system verification (MOD-026)
   - Generator frequency response verification (MOD-027)
   - Expectations for generators to remain connected during specified voltage and frequency excursions (PRC-024)
   - Coordination of generator voltage regulator controls and limit functions with generator capabilities and protective relays (PRC-019)

   Finalizing these standards will require significant changes that are outside the scope of the original Phase III & IV SARs, which is why the draft standards have been included in the scope of this new SAR. Do you agree that there is a reliability-related need to finalize these standards? If not, please explain in the comment area.

   ☒ Yes

   ☐ No

   Comments: It is our understanding and hope that the results of the recent field test will be considered during development of the Standards.

2. Two of the standards (MOD-024 and MOD-025) associated with this SAR had already been approved by the NERC Board of Trustees, but are "pending" with FERC because they include "fill-in-the-blank" requirements assigned to the Regional Reliability Organization. These standards must be revised to remove the fill-in-the-blank characteristics before they can become mandatory and enforceable. The intent of MOD-024 and MOD-025 is to ensure that accurate information on generator gross and net real and reactive power capability is available for the steady-state models used to assess bulk electric system reliability.

   To be enforceable, these standards need to be revised. Do you agree that there is a reliability-related need to revise these standards to support accurate modeling?

   ☒ Yes

   ☐ No

   Comments:

3. The scope of this project includes:

   - Modifying the six standards associated with this project so they conform to the latest version of NERC's Reliability Standards Development Procedure and the ERO Sanction Guidelines,
   - Replacing the fill-in-the-blank requirements assigned to the Regional Reliability Organization with requirements that can be applied on a continent-wide basis and are assigned to users, owners, or operators of the bulk power system, and

- Addressing issues identified in FERC Order 693.

Do you agree with this scope? If not, please explain in the comment area.

☒ Yes

☐ No

Comments:

4. Page 6 of the SAR identifies a list of reliability functions that may be assigned responsibility for requirements in the set of standards addressed by this SAR. (At this point additional industry debate is needed on which function or functions will be assigned responsibility for the requirements currently assigned to the RRO — and that debate is expected to take place during standard drafting as the requirements are refined. Note that the standard drafting team can "reduce" but cannot "expand" this list of responsible reliability functions during standard drafting.) Do you agree with the list of proposed applicable functional entities? If you feel that the list should be modified, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: Depending on the Requirements that are developed during the standard drafting phase, the Generator Operator may be an applicable entity.

5. If you are aware of any regional variances that will be needed as a result of this project, please identify the Regional Variance:

   Regional Variance: Possible
   Comments: For Québec Interconnection, there might be some specific value for frequency range applicable for PRC-024 and PRC-019

6. If you are aware of any business practice that will be needed or that will need to be modified as a result of this project, please identify the business practice:

   Business Practice: No
   Comments:

7. If you have any other comments on this SAR that you haven't already mentioned above, please provide them here:

   Comments: The industry should be provided the opportunity to comment on and provide suggestions for the periodicity and magnitude of the testing.

Please use this form to submit comments on the SAR for Generator Verification. Comments must be submitted by **May 21, 2007**. You may submit the completed form by e-mail to sarcomm@nerc.net with the words "**Generator Verification**" in the subject line. ☒ Yes

☒ No

Comments: The SDT should consider the term characteristics during the review of the standards. The following is an example of:

-PRC-019-1

R2.1.2 & R2.1.5 - How to define characteristics? A common interpretation could be to define characteristics as the "setpoints" for the controllers. However, this does not appear to be the case as in other requirements they request "setpoints" as is shown in R2.1.6. MOD-026-1 appears to address this but refers to the excitation system functions.

In other words, the terms "characteristics" and "setpoints/settings" are presented in the requirements without clearly clarifying the meaning of the terms. “Characteristic” could mean something like a Generator capability curve (or any operating curve for that matter or nomograms) where the operations are defined by a “bounded region of operation” as such and is kind of “analog” in nature. “Setpoint/Setting” on the other hand could be something like a Generator Under-frequency trip setting where there are “set-points” for tripping – kind of “digital” in nature. Is this what the SDT means by these terms. Please clarify.

As the standards are reviewed, there are specific questions that need to be addressed such as:

MOD-025-1

R1.5.3 - Is this individual loads, or is this an overall value for the total auxiliary loads running at full station output?

Also, What will define the need to revisit this when equipment changes occur?

In addition, the SDT should consider additional field tests for all the changes associated with the revised standard.

4. Page 6 of the SAR identifies a list of reliability functions that may be assigned responsibility for requirements in the set of standards addressed by this SAR. (At this point additional industry debate is needed on which function or functions will be assigned responsibility for the requirements currently assigned to the RRO — and that debate is expected to take place during standard drafting as the requirements are refined. Note that the standard drafting team can “reduce” but cannot “expand” this list of responsible reliability functions during standard drafting.) Do you agree with the list of proposed applicable functional entities? If you feel that the list should be modified, please explain in the comment area.

☒ Yes

☒ No

Comments: We agree that the list covers all the reliability functions that are listed in the existing standards. However, in view of the expected industry debate on this issue, it may be prudent to add Generator Operator to the list in the event that any of the six standards should be revised to hold Generator Operators responsible for any tasks.

☒ No

Comments: The SDT should consider the term characteristics during the review of the standards. Sections below are identified as locations for clarification.
-PRC-019-1
R2.1.2 & R2.1.5 - How to define characteristics? A common interpretation would be define characteristics as the "setpoints" for the controllers. However, this does not appear to be the case as in other requirements they request "setpoints" as is shown in R2.1.6. MOD-026-1 appears to address this but refers to the excitation system functions. What is meant by characterisitics, if the characteristics are not defined as the setpoint?

As the standards are reviewed, there are specific questions that need to be addressed such as:
MOD-025-1
R1.5.3 - Is this individual loads, or is this an overall value for the total auxiliary loads running at full station output?

Also, What will define the need to revisit this when equipment changes occur?

The SDT should also identify a date for compliance for each of the requirements and measures. Here are a few examples:

-MOD-024-1
M1 & M3 - Will need to prescribed a date for compliance

-MOD-026-1
M3 - Will need to prescribed a date for compliance

-MOD-027-1
M1 & M3 - Will need to prescribed a date for compliance

In addition the SDT should consider additional field tests for all the changes associated with the revised standard. Also careful consideration needs to be provided to the implementation plans.

4. Page 6 of the SAR identifies a list of reliability functions that may be assigned responsibility for requirements in the set of standards addressed by this SAR. (At this point additional industry debate is needed on which function or functions will be assigned responsibility for the requirements currently assigned to the RRO — and that debate is expected to take place during standard drafting as the requirements are refined. Note that the standard drafting team can “reduce” but cannot “expand” this list of responsible reliability functions during standard drafting.) Do you agree with the list of proposed applicable functional entities? If you feel that the list should be modified, please explain in the comment area.

☒ Yes

☒ No

Comments: The SDT should consider applicability to Generator Operators who will be required to actually perform the tests.

The SDT should also review the applicablity of this SAR to the Reliability Coordinator. It is unclear at this time what role the RC will have in requirements associated with this standard.

5. If you are aware of any regional variances that will be needed as a result of this project, please identify the Regional Variance:

   Regional Variance:
   Comments:

6. If you are aware of any business practice that will be needed or that will need to be modified as a result of this project, please identify the business practice:

   Business Practice:
   Comments:

7. If you have any other comments on this SAR that you haven't already mentioned above, please provide them here:

   Comments: There is a reliability need for this SAR, but the Industry must be allowed to comment on the periodicity of the tests. There should be justification for annual testing requirements, since some characteristics do not change appreciably over time.

Please use this form to submit comments on the SAR for Generator Verification. Comments must be submitted by **May 21, 2007**. You may submit the completed form by e-mail to sarcomm@nerc.net with the words "**Generator Verification**" in the subject line. 7. If you have any other comments on this SAR that you haven't already mentioned above, please provide them here:

   Comments: There is a reliability need for this SAR, but the Industry must be allowed to comment on the periodicity and magnitude of the tests. There should be justification for annual testing since characteristics do not change appreciably over time.

Please use this form to submit comments on the SAR for Generator Verification. Comments must be submitted by **May 21, 2007**. You may submit the completed form by e-mail to sarcomm@nerc.net with the words "**Generator Verification**" in the subject line. If you have questions, please contact David Taylor at david.taylor@nerc.net or by telephone at 609-651-5089.

Background Information

The Generator Verification SAR calls for finalizing the last four Phase III & IV standards (subsequent to field testing) and calls for revising two of the Phase III & IV standards that were approved by the NERC Board of Trustees but not by FERC. All six standards need to conform to the latest version of the ERO Sanction Guidelines and Reliability Standards Development Procedure and all need to address FERC concerns identified in FERC Order 693. The standards associated with this SAR are:

PRC-019 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection

PRC-024 — Generator Performance During Frequency and Voltage Excursions

MOD-024 — Verification of Generator Gross and Net Real Power Capability

MOD-025 — Verification of Generator Gross and Net Reactive Power Capability

MOD-026 —Verification of Models and Data for Generator Excitation System Functions

MOD-027 — Verification of Generator Unit Frequency Response

The SAR drafting team would like to receive comments on this SAR. Please review the SAR, answer the questions on the following pages, and e-mail the form to sarcomm@nerc.net with the subject "**Generator Verification**" by **May 21, 2007**.

You do not have to answer all questions.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. The field test from the Phase III & IV project included PRC-019, PRC-024, MOD-026, and MOD-027. The field testing has shown that requirements can be developed and incorporated into standards for the following:

   - Generator excitation system verification (MOD-026)
   - Generator frequency response verification (MOD-027)
   - Expectations for generators to remain connected during specified voltage and frequency excursions (PRC-024)
   - Coordination of generator voltage regulator controls and limit functions with generator capabilities and protective relays (PRC-019)

   Finalizing these standards will require significant changes that are outside the scope of the original Phase III & IV SARs, which is why the draft standards have been included in the scope of this new SAR. Do you agree that there is a reliability-related need to finalize these standards? If not, please explain in the comment area.

   ☒ Yes

   ☐ No

   Comments:

2. Two of the standards (MOD-024 and MOD-025) associated with this SAR had already been approved by the NERC Board of Trustees, but are "pending" with FERC because they include "fill-in-the-blank" requirements assigned to the Regional Reliability Organization. These standards must be revised to remove the fill-in-the-blank characteristics before they can become mandatory and enforceable. The intent of MOD-024 and MOD-025 is to ensure that accurate information on generator gross and net real and reactive power capability is available for the steady-state models used to assess bulk electric system reliability.

   To be enforceable, these standards need to be revised. Do you agree that there is a reliability-related need to revise these standards to support accurate modeling?

   ☒ Yes

   ☐ No

   Comments:

3. The scope of this project includes:

   - Modifying the six standards associated with this project so they conform to the latest version of NERC's Reliability Standards Development Procedure and the ERO Sanction Guidelines,
   - Replacing the fill-in-the-blank requirements assigned to the Regional Reliability Organization with requirements that can be applied on a continent-wide basis and are assigned to users, owners, or operators of the bulk power system, and
   - Addressing issues identified in FERC Order 693.

Do you agree with this scope? If not, please explain in the comment area.

☒ Yes

☐ No

Comments:

4. Page 6 of the SAR identifies a list of reliability functions that may be assigned responsibility for requirements in the set of standards addressed by this SAR. (At this point additional industry debate is needed on which function or functions will be assigned responsibility for the requirements currently assigned to the RRO — and that debate is expected to take place during standard drafting as the requirements are refined. Note that the standard drafting team can "reduce" but cannot "expand" this list of responsible reliability functions during standard drafting.) Do you agree with the list of proposed applicable functional entities? If you feel that the list should be modified, please explain in the comment area.

   ☒ Yes

   ☐ No

   Comments:

5. If you are aware of any regional variances that will be needed as a result of this project, please identify the Regional Variance:

   Regional Variance:
   Comments:

6. If you are aware of any business practice that will be needed or that will need to be modified as a result of this project, please identify the business practice:

   Business Practice:
   Comments:

7. If you have any other comments on this SAR that you haven't already mentioned above, please provide them here:

   Comments: Under Draft PRC-024-1 on the SAR form, the fourth bullet says "Add a requirement for the Transmission Owner and Generator Owner to coordinate protection systems". This is already required and measured under PRC-001-1, and should therefore not be added as a requirement in PRC-024-1.

Please use this form to submit comments on the SAR for Generator Verification. Comments must be submitted by **May 21, 2007**. You may submit the completed form by e-mail to sarcomm@nerc.net with the words "**Generator Verification**" in the subject line. If you have questions, please contact David Taylor at david.taylor@nerc.net or by telephone at 609-651-5089.

MOD-024 — Verification of Generator Gross and Net Real Power Capability

MOD-025 — Verification of Generator Gross and Net Reactive Power Capability

MOD-026 —Verification of Models and Data for Generator Excitation System Functions

MOD-027 — Verification of Generator Unit Frequency Response

The SAR drafting team would like to receive comments on this SAR. Please review the SAR, answer the questions on the following pages, and e-mail the form to sarcomm@nerc.net with the subject "**Generator Verification**" by **May 21, 2007**.

You do not have to answer all questions.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. The field test from the Phase III & IV project included PRC-019, PRC-024, MOD-026, and MOD-027. The field testing has shown that requirements can be developed and incorporated into standards for the following:

   - Generator excitation system verification (MOD-026)
   - Generator frequency response verification (MOD-027)
   - Expectations for generators to remain connected during specified voltage and frequency excursions (PRC-024)
   - Coordination of generator voltage regulator controls and limit functions with generator capabilities and protective relays (PRC-019)

   Finalizing these standards will require significant changes that are outside the scope of the original Phase III & IV SARs, which is why the draft standards have been included in the scope of this new SAR. Do you agree that there is a reliability-related need to finalize these standards? If not, please explain in the comment area.

   ☒ Yes

   ☐ No

   Comments: It is our understanding and hope that the results of the recent field test will be considered during development of the Standards.

2. Two of the standards (MOD-024 and MOD-025) associated with this SAR had already been approved by the NERC Board of Trustees, but are "pending" with FERC because they include "fill-in-the-blank" requirements assigned to the Regional Reliability Organization. These standards must be revised to remove the fill-in-the-blank characteristics before they can become mandatory and enforceable. The intent of MOD-024 and MOD-025 is to ensure that accurate information on generator gross and net real and reactive power capability is available for the steady-state models used to assess bulk electric system reliability.

   To be enforceable, these standards need to be revised. Do you agree that there is a reliability-related need to revise these standards to support accurate modeling?

   ☒ Yes

   ☐ No

   Comments:

3. The scope of this project includes:

   - Modifying the six standards associated with this project so they conform to the latest version of NERC's Reliability Standards Development Procedure and the ERO Sanction Guidelines,

   - Replacing the fill-in-the-blank requirements assigned to the Regional Reliability Organization with requirements that can be applied on a continent-wide basis and are assigned to users, owners, or operators of the bulk power system, and

- Addressing issues identified in FERC Order 693.

Do you agree with this scope? If not, please explain in the comment area.

☒ Yes

☐ No

Comments: The SDT should consider additional field tests for all the changes associated with the revised standard.

4. Page 6 of the SAR identifies a list of reliability functions that may be assigned responsibility for requirements in the set of standards addressed by this SAR. (At this point additional industry debate is needed on which function or functions will be assigned responsibility for the requirements currently assigned to the RRO — and that debate is expected to take place during standard drafting as the requirements are refined. Note that the standard drafting team can “reduce” but cannot “expand” this list of responsible reliability functions during standard drafting.) Do you agree with the list of proposed applicable functional entities? If you feel that the list should be modified, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: Depending on the Requirements that are developed during the standard drafting phase, the Generator Operator may be an applicable entity.

5. If you are aware of any regional variances that will be needed as a result of this project, please identify the Regional Variance:

   Regional Variance: No
   Comments: Within the Québec Interconnection, there might be some specific value for frequency range applicable for PRC-024 and PRC-019 and this should be allowed for in the standard drafting phase.

6. If you are aware of any business practice that will be needed or that will need to be modified as a result of this project, please identify the business practice:

   Business Practice: No
   Comments:

7. If you have any other comments on this SAR that you haven’t already mentioned above, please provide them here:

   Comments: The industry should be provided the opportunity to comment on and provide suggestions for the periodicity and magnitude of the testing.

Please use this form to submit comments on the SAR for Generator Verification. Comments must be submitted by **May 21, 2007**. You may submit the completed form by e-mail to sarcomm@nerc.net with the words "**Generator Verification**" in the subject line. Background Information

The Generator Verification SAR calls for finalizing the last four Phase III & IV standards (subsequent to field testing) and calls for revising two of the Phase III & IV standards that were approved by the NERC Board of Trustees but not by FERC. All six standards need to conform to the latest version of the ERO Sanction Guidelines and Reliability Standards Development Procedure and all need to address FERC concerns identified in FERC Order 693. The standards associated with this SAR are:

PRC-019 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection

PRC-024 — Generator Performance During Frequency and Voltage Excursions

MOD-024 — Verification of Generator Gross and Net Real Power Capability

MOD-025 — Verification of Generator Gross and Net Reactive Power Capability

MOD-026 —Verification of Models and Data for Generator Excitation System Functions

MOD-027 — Verification of Generator Unit Frequency Response

The SAR drafting team would like to receive comments on this SAR. Please review the SAR, answer the questions on the following pages, and e-mail the form to sarcomm@nerc.net with the subject "**Generator Verification**" by **May 21, 2007**.

You do not have to answer all questions.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. The field test from the Phase III & IV project included PRC-019, PRC-024, MOD-026, and MOD-027. The field testing has shown that requirements can be developed and incorporated into standards for the following:

   - Generator excitation system verification (MOD-026)
   - Generator frequency response verification (MOD-027)
   - Expectations for generators to remain connected during specified voltage and frequency excursions (PRC-024)
   - Coordination of generator voltage regulator controls and limit functions with generator capabilities and protective relays (PRC-019)

   Finalizing these standards will require significant changes that are outside the scope of the original Phase III & IV SARs, which is why the draft standards have been included in the scope of this new SAR. Do you agree that there is a reliability-related need to finalize these standards? If not, please explain in the comment area.

   ☐ Yes
   ☐ No

   Comments: At this point in time we cannot determine if there is a reliability related need to finalize these standards. The results of the field test by the 4 participating RROs will not be complete until late June 2007. The 4 RROs, in support of the NERC Field Test team, have spent significant resources in an attempt to implement procedures and subsequently carry out the draft Reliablity Standard requirements. Thus, in order to ensure proper consideration is given to the results of the field tests, the scope of the SAR should make it clear that the decision by the SDT to either refine / significantly revise / or delete these standards should be heavily weighted on the outcome of the field test. Recommend that the last sentence in the paragraph in the SAR on page SAR-3 under "Detailed Description" be modified to: "In addition, the SDT will consider and address all applicable FERC Orders, including Order 693, in addition to any modifications, deficiencies, and other items as found in the NERC Phase III-IV Planning Standard Field Tests, and in addition the following porposed changes for each of the six standards in this set of standards:"

2. Two of the standards (MOD-024 and MOD-025) associated with this SAR had already been approved by the NERC Board of Trustees, but are "pending" with FERC because they include "fill-in-the-blank" requirements assigned to the Regional Reliability Organization. These standards must be revised to remove the fill-in-the-blank characteristics before they can become mandatory and enforceable. The intent of MOD-024 and MOD-025 is to ensure that accurate information on generator gross and net real and reactive power capability is available for the steady-state models used to assess bulk electric system reliability.

   To be enforceable, these standards need to be revised. Do you agree that there is a reliability-related need to revise these standards to support accurate modeling?

   ☒ Yes
   ☐ No

Comments: However, the scope statement for MOD-025 includes increased scope: (scope creep to require expanded verification to include multiple operating points). The scope of this standard needs to be restricted to that of the current version!

3. The scope of this project includes:

   - Modifying the six standards associated with this project so they conform to the latest version of NERC's Reliability Standards Development Procedure and the ERO Sanction Guidelines,
   - Replacing the fill-in-the-blank requirements assigned to the Regional Reliability Organization with requirements that can be applied on a continent-wide basis and are assigned to users, owners, or operators of the bulk power system, and
   - Addressing issues identified in FERC Order 693.

   Do you agree with this scope? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: The scope of MOD-025 has been expanded beyond what is stated above. The changes to the four field test standards should be based on the field test results up to and including their elimination if so recommended.

4. Page 6 of the SAR identifies a list of reliability functions that may be assigned responsibility for requirements in the set of standards addressed by this SAR. (At this point additional industry debate is needed on which function or functions will be assigned responsibility for the requirements currently assigned to the RRO — and that debate is expected to take place during standard drafting as the requirements are refined. Note that the standard drafting team can "reduce" but cannot "expand" this list of responsible reliability functions during standard drafting.) Do you agree with the list of proposed applicable functional entities? If you feel that the list should be modified, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: The Generator Operator should be added to the list of possible applicable functional entities on page 6 of the SAR.

5. If you are aware of any regional variances that will be needed as a result of this project, please identify the Regional Variance:

   Regional Variance: none
   Comments:

6. If you are aware of any business practice that will be needed or that will need to be modified as a result of this project, please identify the business practice:

   Business Practice: none
   Comments:

7. If you have any other comments on this SAR that you haven't already mentioned above, please provide them here:

   Comments: The scope of MOD-024 and MOD-025 should not be expanded beyond the scope contained in the current version of these two standards. The results of the field test for the other 4 Draft Reliability Standards by the 4 participating RROs will not be complete until late June 2007. Thus, the scope of the SAR should make it clear that the decision by the SDT to either refine / significantly revise / or delete these standards should be heavily weighted on the outcome of the field test.

Please use this form to submit comments on the SAR for Generator Verification. Comments must be submitted by **May 21, 2007**. You may submit the completed form by e-mail to sarcomm@nerc.net with the words "**Generator Verification**" in the subject line. If you have questions, please contact David Taylor at david.taylor@nerc.net or by telephone at 609-651-5089.

Background Information

The Generator Verification SAR calls for finalizing the last four Phase III & IV standards (subsequent to field testing) and calls for revising two of the Phase III & IV standards that were approved by the NERC Board of Trustees but not by FERC. All six standards need to conform to the latest version of the ERO Sanction Guidelines and Reliability Standards Development Procedure and all need to address FERC concerns identified in FERC Order 693. The standards associated with this SAR are:

PRC-019 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection

PRC-024 — Generator Performance During Frequency and Voltage Excursions

MOD-024 — Verification of Generator Gross and Net Real Power Capability

MOD-025 — Verification of Generator Gross and Net Reactive Power Capability

MOD-026 —Verification of Models and Data for Generator Excitation System Functions

MOD-027 — Verification of Generator Unit Frequency Response

The SAR drafting team would like to receive comments on this SAR. Please review the SAR, answer the questions on the following pages, and e-mail the form to sarcomm@nerc.net with the subject "**Generator Verification**" by **May 21, 2007**.

You do not have to answer all questions.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. The field test from the Phase III & IV project included PRC-019, PRC-024, MOD-026, and MOD-027. The field testing has shown that requirements can be developed and incorporated into standards for the following:

   - Generator excitation system verification (MOD-026)
   - Generator frequency response verification (MOD-027)
   - Expectations for generators to remain connected during specified voltage and frequency excursions (PRC-024)
   - Coordination of generator voltage regulator controls and limit functions with generator capabilities and protective relays (PRC-019)

   Finalizing these standards will require significant changes that are outside the scope of the original Phase III & IV SARs, which is why the draft standards have been included in the scope of this new SAR. Do you agree that there is a reliability-related need to finalize these standards? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: We are in agreement with the comments made by the SERC Generator Standards Field Test Task Force to this question. To re-state their comments here, "At this point we cannot determine if there is a reliability related need to finalize these standards. The results of the field test by the 4 participating RROs will not be complete until late June 2007. The 4 RROs, in support of the NERC Field Test team, have spent significant resources in an attempt to implement procedures and subsequently carry out the draft Reliability Standard requirements. Thus, in order to ensure proper consideration is given to the results of the field tests, the scope of the SAR should make it clear that the decision by the SDT to either refine, significantly revise or delete these standards should be heavily weighted on the outcome of the field test. (We) Recommend that the last sentence in the paragraph in the SAR on page SAR-3 under "Detailed Description" be modified to: ""In addition, the SDT will consider and address all applicable FERC Orders, including Order 693, in addition to any modifications, deficiencies, and other items as found in the NERC Phase III-IV Planning Standard Field Tests, and in addition the following proposed changes for each of the six standards in this set of standards:"

2. Two of the standards (MOD-024 and MOD-025) associated with this SAR had already been approved by the NERC Board of Trustees, but are "pending" with FERC because they include "fill-in-the-blank" requirements assigned to the Regional Reliability Organization. These standards must be revised to remove the fill-in-the-blank characteristics before they can become mandatory and enforceable. The intent of MOD-024 and MOD-025 is to ensure that accurate information on generator gross and net real and reactive power capability is available for the steady-state models used to assess bulk electric system reliability.

   To be enforceable, these standards need to be revised. Do you agree that there is a reliability-related need to revise these standards to support accurate modeling?

☐ Yes

☒ No

Comments: The scope statement for both of these standards includes increases in their scope -- MOD-024 now reflects increased demonstration requirements and MOD-025 scope has crept to require expanded verification to include multiple operating points. The scope of these two standards should to be restricted to that of the current versions.

3. The scope of this project includes:

   - Modifying the six standards associated with this project so they conform to the latest version of NERC's Reliability Standards Development Procedure and the ERO Sanction Guidelines,
   - Replacing the fill-in-the-blank requirements assigned to the Regional Reliability Organization with requirements that can be applied on a continent-wide basis and are assigned to users, owners, or operators of the bulk power system, and
   - Addressing issues identified in FERC Order 693.

   Do you agree with this scope? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: We are essentially in agreement with the three bullet points included in this question (and project); however, we are not in agreement with the scope of the SAR, specifically as it relates to MOD-024 and MOD-025. The scope of MOD-024 and MOD-025 have both been expanded beyond what is stated in the bullet points of this question. As we point out in our response to Question #2, MOD-024 now reflects increased demonstration requirements and MOD-025 scope has expanded (crept) to require expanded verification to include multiple operating points. The changes to the other four standards (PRC-019, PRC-024, MOD-026 and MOD-027) should be based on the field test results up to, and including, their elimination, if so recommended.

4. Page 6 of the SAR identifies a list of reliability functions that may be assigned responsibility for requirements in the set of standards addressed by this SAR. (At this point additional industry debate is needed on which function or functions will be assigned responsibility for the requirements currently assigned to the RRO — and that debate is expected to take place during standard drafting as the requirements are refined. Note that the standard drafting team can "reduce" but cannot "expand" this list of responsible reliability functions during standard drafting.) Do you agree with the list of proposed applicable functional entities? If you feel that the list should be modified, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: The list of possible applicable functional entities found on page 6 of the SAR should include Generator Operators. It seems to us that generator testing involving real and reactive power quantites will not be possible without the inclusion of this functional entity.

5. If you are aware of any regional variances that will be needed as a result of this project, please identify the Regional Variance:

   Regional Variance: None.
   Comments:

6. If you are aware of any business practice that will be needed or that will need to be modified as a result of this project, please identify the business practice:

   Business Practice: None.
   Comments:

7. If you have any other comments on this SAR that you haven't already mentioned above, please provide them here:

   Comments: The scope of MOD-024 and MOD-025 should not be expanded beyond the scope contained in the current version of these two standards. As for the other four standards; PRC-019, PRC-024, MOD-026 and MOD-027, the timing of the subject SAR appears to be premature since the field testing is not complete.

Consideration of Comments on the First Posting of the SAR for Generator Verifications

The members of the SAR drafting team for Project 2007-09 Generator Verification thank all commenters who submitted comments on Draft 1 of the SAR. This SAR was posted for a 30-day public comment period from April 20 through May 21, 2007. The requester asked stakeholders to provide feedback on the SAR through a special SAR Comment Form. There were 16 sets of comments, including comments from 63 different individuals from more than 35 organizations representing 7 of the 10 Industry Segments as shown in the table on the following pages.

In response to the comments received, the SAR drafting team has revised the SAR for Project 2007-09 Generator Verification as follows:

- Added the Generator Operator and Reliability Coordinator as reliability functions that may have responsibilities in the proposed standards.
- Added language to clarify that the standard drafting team will consider the Phase III & IV field test results when developing the standards associated with this project.

In addition, the SAR drafting team received some comments recommending specific modifications to requirements that were outside the scope of responsibility of the SAR drafting team. These comments have been collected and added as Attachment 1 to the SAR for resolution during standard drafting.

Based on the comments received, the SAR drafting team recommends that the Standards Committee accept the revised SAR for Project 2007-09 Generation Verification for:

- New standards to be finalized as part of this project:
  - PRC-019 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection
  - PRC-024 — Generator Performance During Frequency and Voltage Excursions
  - MOD-026 — Verification of Models and Data for Generator Excitation System Functions
  - MOD-027 — Verification of Generator Unit Frequency Response
- Existing standards to be revised as part of this project:
  - MOD-024 — Verification of Generator Gross and Net Real Power Capability
  - MOD-025 — Verification of Generator Gross and Net Reactive Power Capability

In this "Consideration of Comments" document stakeholder comments have been organized so that it is easier to see the responses associated with each question. All comments received on the standards can be viewed in their original format at:

http://www.nerc.com/~filez/standards/Generator-Verification-Project-2007-09.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Director of Standards, Gerry Adamski, at 609-452-8060 or at gerry.adamski@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedure manual: http://www.nerc.com/standards/newstandardsprocess.html

The Industry Segments are:

1 — Transmission Owners
2 — RTOs, ISOs
3 — Load-serving Entities
4 — Transmission-dependent Utilities
5 — Electric Generators
6 — Electricity Brokers, Aggregators, and Marketers
7 — Large Electricity End Users
8 — Small Electricity End Users
9 — Federal, State, Provincial Regulatory or other Government Entities
10 – Regional Reliability Organizations, Regional Entities

1. Do you agree that there is a reliability-related need to finalize these standards (MOD-026, MOD-027, PRC-024, PRC-019)? 7
2. Do you agree that there is a reliability-related need to revise these standards (MOD-024 and MOD-025) to support accurate modeling?..11
3. Do you agree with this scope? 14
4. Do you agree with the list of proposed applicable functional entities?.........................19
5. If you are aware of any regional variances that will be needed as a result of this project, please identify the Regional Variance. 22
6. If you are aware of any business practice that will be needed or that will need to be modified as a result of this project, please identify the business practice. 24
7. If you have any other comments on this SAR that you haven't already mentioned above, please provide them here:...25

1. The field test from the Phase III & IV project included PRC-019, PRC-024, MOD-026, and MOD-027. The field testing has shown that requirements can be developed and incorporated into standards for the following:

   - Generator excitation system verification (MOD-026)
   - Generator frequency response verification (MOD-027)
   - Expectations for generators to remain connected during specified voltage and frequency excursions (PRC-024)
   - Coordination of generator voltage regulator controls and limit functions with generator capabilities and protective relays (PRC-019)

Finalizing these standards will require significant changes that are outside the scope of the original Phase III & IV SARs, which is why the draft standards have been included in the scope of this new SAR.

Do you agree that there is a reliability-related need to finalize these standards (MOD-026, MOD-027, PRC-024, PRC-019)? If not, please explain in the comment area.

Summary Consideration: Most commenters agreed that there is a reliability-related need to finalize the four Phase III & IV standards that were field tested.

Question #1			
Commenter	**Yes**	**No**	**Comment**
Ameren Services			At this point in time we cannot determine if there is a reliability related need to finalize these standards. The results of the field test by the 4 participating RROs will not be complete until late June 2007. The 4 RROs, in support of the NERC Field Test team, have spent significant resources in an attempt to implement procedures and subsequently carry out the draft Reliablity Standard requirements. Thus, in order to ensure proper consideration is given to the results of the field tests, the scope of the SAR should make it clear that the decision by the SDT to either refine / significantly revise / or delete these standards should be heavily weighted on the outcome of the field test. Recommend that the last sentence in the paragraph in the SAR on page SAR-3 under “Detailed Description” be modified to: “In addition, the SDT will consider and address all applicable FERC Orders, including Order 693, in addition to any modifications, deficiencies, and other items as found in the NERC Phase III-IV Planning Standard Field Tests, and in addition the following porposed changes for each of the six standards in this set of standards:”
Response: The NERC Phase III-IV Field Tests will be complete on June 19, before the subject SAR is completed and before the Generation Verification SDT is formed. The SAR DT is meeting at the same time that the field test reports are being given so that the DT will have first hand knowledge of the results. The intention of the SAR was to clearly direct the SDT to give			

Question #1			
Commenter	**Yes**	**No**	**Comment**
proper consideration to the results of the field tests. The SAR has been clarified accordingly.			
Entergy		☑	It is questionable whether there is a reliability related need for these standards. The field tests are not complete, but initial results show that PRC-024 and MOD-027 are difficult to perform, give questionable results, and may not be translated into better models or higher reliability. MOD-026 is also difficult to translate into better models or higher reliability.
Response: During the public posting for comment of the proposed draft Phase III-IV Standards, the industry did provide comments questioning the feasibility of performing the draft requirements, the industry did consistently affirm the reliability need. The purpose of the field test was to specifying confirm whether the requirements were feasible. In addition, since the NERC Phase III-IV Field Tests will be complete on June 19, before the subject SAR is completed and before the Generation Verification SDT is formed. The SAR DT is meeting at the same time that the field test reports are being given so that the DT will have first hand knowledge of the results. The intention of the SAR was to clearly direct the SDT to give proper consideration to the results of the field tests. The SAR has been clarified accordingly.			
SERC GSFT-TF			At this point in time we cannot determine if there is a reliability related need to finalize these standards. The results of the field test by the 4 participating RROs will not be complete until late June 2007. The 4 RROs, in support of the NERC Field Test team, have spent significant resources in an attempt to implement procedures and subsequently carry out the draft Reliablity Standard requirements. Thus, in order to ensure proper consideration is given to the results of the field tests, the scope of the SAR should make it clear that the decision by the SDT to either refine / significantly revise / or delete these standards should be heavily weighted on the outcome of the field test. Recommend that the last sentence in the paragraph in the SAR on page SAR-3 under “Detailed Description” be modified to: “In addition, the SDT will consider and address all applicable FERC Orders, including Order 693, in addition to any modifications, deficiencies, and other items as found in the NERC Phase III-IV Planning Standard Field Tests, and in addition the following porposed changes for each of the six standards in this set of standards:”
Response: The NERC Phase III-IV Field Tests will be complete on June 19, before the subject SAR is completed and before the Generation Verification SDT is formed. The SAR DT is meeting at the same time that the fiedld test reports are being given so that the DT will have first hand knowledge of the results. The intention of the SAR was to clearly direct the SDT to give proper consideration to the results of the field tests. The SAR has been clarified accordingly.			
SCT		☑	We are in agreement with the comments made by the SERC Generator Standards Field Test Task Force to this question. To re-state their comments here, “At this point we cannot determine if there is

Question #1			
Commenter	**Yes**	**No**	**Comment**
			a reliability related need to finalize these standards. The results of the field test by the 4 participating RROs will not be complete until late June 2007. The 4 RROs, in support of the NERC Field Test team, have spent significant resources in an attempt to implement procedures and subsequently carry out the draft Reliability Standard requirements. Thus, in order to ensure proper consideration is given to the results of the field tests, the scope of the SAR should make it clear that the decision by the SDT to refine, significantly revise or delete these standards should be heavily weighted on the outcome of the field test. (We) Recommend that the last sentence in the paragraph in the SAR on page SAR-3 under "Detailed Description" be modified to: ""In addition, the SDT will consider and address all applicable FERC Orders, including Order 693, in addition to any modifications, deficiencies, and other items as found in the NERC Phase III-IV Planning Standard Field Tests, and in addition the following proposed changes for each of the six standards in this set of standards:"
Response: The SAR Drafting Team agrees. The intention of the SAR was to clearly direct the SDT to give proper consideration to the results of the field tests. The SAR has been clarified accordingly.			
HQT NPCC CP9 RSWG	☑		It is our understanding and hope that the results of the recent field test will be considered during development of the Standards
Response: The SAR Drafting Team agrees. The intention of the SAR was to clearly direct the SDT to give proper consideration to the results of the field tests. The SAR has been clarified accordingly.

Question #1			
Commenter	**Yes**	**No**	**Comment**
PSC SC	☑		

2. Two of the standards (MOD-024 and MOD-025) associated with this SAR had already been approved by the NERC Board of Trustees, but are "pending" with FERC because they include "fill-in-the-blank" requirements assigned to the Regional Reliability Organization. These standards must be revised to remove the fill-in-the-blank characteristics before they can become mandatory and enforceable. The intent of MOD-024 and MOD-025 is to ensure that accurate information on generator gross and net real and reactive power capability is available for the steady-state models used to assess bulk electric system reliability. To be enforceable, these standards need to be revised.

Do you agree that there is a reliability-related need to revise these standards (MOD-024 and MOD-025) to support accurate modeling?

Summary Consideration: Most commenters agreed that there is a reliability-related need to revise MOD-024 and MOD-025.

Question #2			
Commenter	**Yes**	**No**	**Comment**
SCT		☑	The scope statement for both of these standards includes increases in their scope -- MOD-024 now reflects increased demonstration requirements and MOD-025 scope has crept to require expanded verification to include multiple operating points. The scope of these two standards should to be restricted to that of the current versions.
Response: In FERC Order 693, the ERO was directed to modify MOD-025-1 to "require verification of reactive power capability at multiple points….". The SDT will be expected , as outlined in "Guidance to Standards Drafting Team Relative to FERC Order Nos. 693 and 890" (April 13, 2006), to address verification of reactive power capability at multiple points or provide other viable alternatives that meet the same objective. In addition the FERC stated concerns about the lack of clarity in MOD-024.			
SERC GSFT-TF	☑		However, the scope statement for MOD-025 includes increased scope: (scope creep to require expanded verification to include multiple operating points). The scope of this standard needs to be restricted to that of the current version!
Response: In FERC Order 693, the ERO was directed to modify MOD-025-1 to "require verification of reactive power capability at multiple points….". The SDT will be expected , as outlined in "Guidance to Standards Drafting Team Relative to FERC Order Nos. 693 and 890" (April 13, 2006), to address verification of reactive power capability at multiple points or provide other viable alternatives that meet the same objective. Your suggestion will be forwarded to the SDT for their consideration.			
Ameren	☑		With regards to the scope of MOD-025, it should not be necessary to include a blanket requirement for verification of reactive power capability at multiple points for all generators. However, should a generator frequently have difficulty reaching its stated reactive power output, additional testing

Question #2			
Commenter	**Yes**	**No**	**Comment**
			requirements for that generator would be indicated.
Response: In FERC Order 693, the ERO was directed to modify MOD-025-1 to "require verification of reactive power capability at multiple points….". The SDT will be expected , as outlined in "Guidance to Standards Drafting Team Relative to FERC Order Nos. 693 and 890" (April 13, 2006), to address verification of reactive power capability at multiple points or provide other viable alternatives that meet the same objective. Your suggestion will be forwarded to the SDT for their consideration.			
Entergy	☑		However, there is no need increase the scope and test multiple points for MOD-025 for leading and lagging. This will not improve reliability or accurate modeling.
Response: In FERC Order 693, the ERO was directed to modify MOD-025-1 to "require verification of reactive power capability at multiple points….". The SDT will be expected , as outlined in "Guidance to Standards Drafting Team Relative to FERC Order Nos. 693 and 890" (April 13, 2006), to address verification of reactive power capability at multiple points or provide other viable alternatives that meet the same objective. Your suggestion will be forwarded to the SDT for their consideration.			
FirstEnergy	☑		The present legacy document ECAR Document 4 details the testing and is sufficient to cover the present accurary for a regional basis. The standards if spread to a national level will need to look at the difference between summer peaking regions and winter peaking. Presently the testing in RFC follows ECAR Document 4 which corrects the testing for average ambient conditions which is left up to the discretion of the testing personnel. The temperature conditions of the water inlet or ambient air needs to be defined.
Response: Thank you for your suggestions. Your specific concerns regarding summer and winter peaking regions and temperatures which impact capabilities will be forwarded to the Standard Drafting Team.

3. The scope of this project includes:
   - Modifying the six standards associated with this project so they conform to the latest version of NERC's Reliability Standards Development Procedure and the ERO Sanction Guidelines,
   - Replacing the fill-in-the-blank requirements assigned to the Regional Reliability Organization with requirements that can be applied on a continent-wide basis and are assigned to users, owners, or operators of the bulk power system, and
   - Addressing issues identified in FERC Order 693.

Do you agree with this scope?

If not, please explain in the comment area.

Summary Consideration: Most commenters indicated they do agree with the scope of this project. Some commenters suggested that the scope be modified to specifically include a notation that the standard drafting team will consider the results of the field tests, and the drafting team did modify the SAR to clarify that the project does include the following:
   - Considering and addressing issues identified during Phase III & IV field testing.

Some commenters suggested specific changes to the technical content of the requirements in the draft standards. The SAR DT modified the SAR to clarify that the standard drafting team must consider the comments submitted by stakeholders during the posting of the SAR, and the SAR DT appended these comments to the SAR.

Question #3			
Commenter	**Yes**	**No**	**Comment**
SCT		☑	We are essentially in agreement with the three bullet points included in this question (and project); however, we are not in agreement with the scope of the SAR, specifically as it relates to MOD-024 and MOD-025. The scope of MOD-024 and MOD-025 have both been expanded beyond what is stated in the bullet points of this question. As we point out in our response to Question #2, MOD-024 now reflects increased demonstration requirements and MOD-025 scope has expanded (crept) to require expanded verification to include multiple operating points. The changes to the other four standards (PRC-019, PRC-024, MOD-026 and MOD-027) should be based on the field test results up to, and including, their elimination, if so recommended.
Response: In FERC Order 693, the ERO was directed to modify MOD-024-1 and 025-1 including "require verification of reactive power capability at multiple points….". As such, the SDT is obligated to address, as outlined in "Guidance to Standards Drafting Team Relative to FERC Order Nos. 693 and 890" (April 13, 2006), the FERC directives or propose other viable alternatives that achieve that same objective. The SAR Drafting Team agrees. The intention of the SAR was to clearly direct the SDT to give proper consideration to the results of the field			

Question #3			
Commenter	**Yes**	**No**	**Comment**
tests. The SAR has been clarified accordingly.			
SERC GSFT-TF		☑	The scope of MOD-025 has been expanded beyond what is stated above. The changes to the four field test standards should be based on the field test results up to and including their elimination if so recommended.
Response: In FERC Order 693, the ERO was directed to modify MOD-025-1 to "require verification of reactive power capability at multiple points…." The SDT will be expected , as outlined in "Guidance to Standards Drafting Team Relative to FERC Order Nos. 693 and 890" (April 13, 2006), to address verification of reactive power capability at multiple points or provide other viable alternatives that meet the same objective. Your suggestion will be forwarded to the SDT for their consideration. The intention of the SAR was to clearly direct the SDT to give proper consideration to the results of the field tests. The SAR has been clarified accordingly.			
Entergy		☑	The scope of MOD-025 has been expanded beyond what is stated above. The changes to the four field test standards should be based on the field test results up to and including their elimination if so recommended.
Response: In FERC Order 693, the ERO was directed to modify MOD-025-1 to "require verification of reactive power capability at multiple points…." The SDT will be expected , as outlined in "Guidance to Standards Drafting Team Relative to FERC Order Nos. 693 and 890" (April 13, 2006), to address verification of reactive power capability at multiple points or provide other viable alternatives that meet the same objective. Your suggestion will be forwarded to the SDT for their consideration. The SAR Drafting Team agrees. The intention of the SAR was to clearly direct the SDT to give proper consideration to the results of the field tests. The SAR has been clarified accordingly.			
IESO	☑	☑	The SDT should consider the term characteristics during the review of the standards. The following is an example of: PRC-019-1 R2.1.2 & R2.1.5 - How to define characteristics? A common interpretation could be to define characteristics as the "setpoints" for the controllers. However, this does not appear to be the case as in other requirements they request "setpoints" as is shown in R2.1.6. MOD-026-1 appears to address this but refers to the excitation system functions. In other words, the terms "characteristics" and "setpoints/settings" are presented in the requirements without clearly clarifying the meaning of the terms. "Characteristic" could mean something like a Generator capability curve (or any operating curve for that matter or nomograms) where the operations are defined by a "bounded region of

Question #3			
Commenter	**Yes**	**No**	**Comment**
			operation" as such and is kind of "analog" in nature. "Setpoint/Setting" on the other hand could be something like a Generator Under-frequency trip setting where there are "set-points" for tripping – kind of "digital" in nature. Is this what the SDT means by these terms. Please clarify. As the standards are reviewed, there are specific questions that need to be addressed such as: MOD-025-1 R1.5.3 - Is this individual loads, or is this an overall value for the total auxiliary loads running at full station output? Also, What will define the need to revisit this when equipment changes occur? In addition, the SDT should consider additional field tests for all the changes associated with the revised standard.
Response: Thank you for your comments. They will all be forwarded to the SDT for their consideration. The task of the SDT is to clarify the current draft standards and remove RRO requirements. The commenter is encouraged to review and comment on the public postings by the future Generator Verification SDT. Regarding your comment concerning the field test results, the SAR Drafting Team agrees. The intention of the SAR was to clearly direct the SDT to give proper consideration to the results of the field tests. The SAR has been clarified accordingly.			
IRC-SRC ISO-NE	☑	☑	The SDT should consider the term characteristics during the review of the standards. Sections below are identified as locations for clarification. -PRC-019-1 R2.1.2 & R2.1.5 - How to define characteristics? A common interpretation would be define characteristics as the "setpoints" for the controllers. However, this does not appear to be the case as in other requirements they request "setpoints" as is shown in R2.1.6. MOD-026-1 appears to address this but refers to the excitation system functions. What is meant by characterisitics, if the characteristics are not defined as the setpoint? As the standards are reviewed, there are specific questions that need to be addressed such as: MOD-025-1 R1.5.3 - Is this individual loads, or is this an overall value for the total auxiliary loads running at full station output? Also, What will define the need to revisit this when equipment changes occur? The SDT should also identify a date for compliance for each of the requirements and measures. Here are a few examples: -MOD-024-1 M1 & M3 - Will need to prescribed a date for compliance -MOD-026-1 M3 - Will need to prescribed a date for compliance

Question #3			
Commenter	**Yes**	**No**	**Comment**
			-MOD-027-1 M1 & M3 - Will need to prescribed a date for compliance In addition the SDT should consider additional field tests for all the changes associated with the revised standard. Also careful consideration needs to be provided to the implementation plans.
Response: Thank you for your comments. They will all be forwarded to the SDT for their consideration. The task of the SDT is to clarify the current draft standards and remove RRO requirements. The commenter is encouraged to review and comment on the public postings by the future Generator Verification SDT. Regarding your comment concerning the field test results, the SAR Drafting Team agrees. The intention of the SAR was to clearly direct the SDT to give proper consideration to the results of the field tests. The SAR has been clarified accordingly.			
FirstEnergy	☑		The project should account for potential regional differences. See comment on question # 5 below
Response: Your comment will be forwarded to the SDT for their consideration. The SAR Drafting Team encourages the commenter to review the future posting of the draft Reliability Standards proposed by the future Generation Verification SDT, and make specific comments if necessary.			
Ameren Services	☑		The scope of MOD-025 has been expanded beyond what is stated above. The changes to the four field test standards should be based on the field test results.
Response: In FERC Order 693, the ERO was directed to modify MOD-025-1 to "require verification of reactive power capability at multiple points….". The SDT will be expected , as outlined in "Guidance to Standards Drafting Team Relative to FERC Order Nos. 693 and 890" (April 13, 2006), to address verification of reactive power capability at multiple points or provide other viable alternatives that meet the same objective. Your suggestion will be forwarded to the SDT for their consideration. The SAR Drafting Team agrees. The intention of the SAR was to clearly direct the SDT to give proper consideration to the results of the field tests. The SAR has been clarified accordingly.			
NPCC CP9 RSWG	☑		The SDT should consider additional field tests for all the changes associated with the revised standard.
Response:			

Question #3

4. Page 6 of the SAR identifies a list of reliability functions that may be assigned responsibility for requirements in the set of standards addressed by this SAR. (At this point additional industry debate is needed on which function or functions will be assigned responsibility for the requirements currently assigned to the RRO — and that debate is expected to take place during standard drafting as the requirements are refined. Note that the standard drafting team can "reduce" but cannot "expand" this list of responsible reliability functions during standard drafting.)

   Do you agree with the list of proposed applicable functional entities?

   If you feel that the list should be modified, please explain in the comment area.

Summary Consideration: Many commenters indicated that the Generator Operator should be added to the list of reliability functions with responsibilities in the revised standards and the drafting team modified the SAR to include the Generator Operator. In addition, one commenter suggested that the Reliability Coordinator may have additional requirements in the proposed standards, and the SAR DT adopted the suggestion to also add the Reliability Coordinator to the list of reliability functions that may have responsibilities in the proposed standards.

Question #4			
Commenter	**Yes**	**No**	**Comment**
ATC LLC.		☑	Generator Operator should be included.
Response: The SAR drafting team agrees and Generator Operator has been added to the list of responsible reliability functions.			
SCT		☑	The list of possible applicable functional entities found on page 6 of the SAR should include Generator Operators. It seems to us that generator testing involving real and reactive power quantites will not be possible without the inclusion of this functional entity.
Response: The SAR drafting team agrees and Generator Operator has been added to the list of responsible reliability functions.			
SERC GSFT-TF		☑	The Generator Operator should be added to the list of possible applicable functional entities on page 6 of the SAR.
Response: The SAR drafting team agrees and Generator Operator has been added to the list of responsible reliability functions.			
FirstEnergy		☑	It is recommended that the SAR be written to include the Generator Operator entity. If the drafting

Question #4			
Commenter	**Yes**	**No**	**Comment**
			team determines only the GO is applicable and that the GOP is not needed it can be removed. As stated above, the SDTs can reduce scope but not expand. The Generator Operator may have involvement in PRC-024.
Response: The SAR drafting team agrees and Generator Operator has been added to the list of responsible reliability functions.			
HQT		☑	Depending on the Requirements that are developed during the standard drafting phase, the Generator Operator may be an applicable entity.
Response: The SAR drafting team agrees and Generator Operator has been added to the list of responsible reliability functions.			
Entergy		☑	
IESO	☑	☑	We agree that the list covers all the reliability functions that are listed in the existing standards. However, in view of the expected industry debate on this issue, it may be prudent to add Generator Operator to the list in the event that any of the six standards should be revised to hold Generator Operators responsible for any tasks.
Response: The SAR drafting team agrees and Generator Operator has been added to the list of responsible reliability functions.			
IRC-SRC	☑	☑	The SDT should consider applicability to Generator Operators who will be required to actually perform the tests. The SDT should also review the applicability of this SAR to the Reliability Coordinator. It is unclear at this time what role the RC will have in requirements associated with this standard.
Response: The SAR drafting team agrees and Generator Operator has been added to the list of responsible reliability functions. The SAR drafting team also agrees that the SDT may determine it necessary for the Reliability Coordinator to be involved to the extent where verification activities are allowed or not for certain system conditions based on operational security analysis. Reliability Coordinator has been added to the list of responsible reliability functions.			
ISO-NE	☑	☑	ISO New England asked the SDT to consider applicability to Generator Operators who will be required to actually perform the tests.
Response:			

Question #4			
Commenter	**Yes**	**No**	**Comment**
The SAR drafting team agrees and Generator Operator will be added to the list of responsible reliability functions.			
NPCC CP9 RSWG		☑	Depending on the Requirements that are developed during the standard drafting phase, the Generator Operator may be an applicable entity.
Response: The SAR drafting team agrees and Generator Operator will be added to the list of responsible reliability functions.			
PHI		☑	Generator Operator should be added.
Response: The SAR drafting team agrees and Generator Operator will be added to the list of responsible reliability functions.			
Ameren Services	☑	☑	
MRO	☑		
PSC SC	☑		
AEP	☑		

5. If you are aware of any regional variances that will be needed as a result of this project, please identify the Regional Variance.

Summary Consideration: While some commenters identified the 'potential' for a regional variance, no commenters identified the need for any specific regional variances.

Question #5		
Commenter	**Regional Variance**	**Comment**
FirstEnergy		Not aware of existing, but potential for regional differences exist. The fill-in-the-blank needs to take into account regional differences such as summer or winter peaking conditions. The standard needs to address the main factor in generation capacity which is inlet water temperatures on once through cooling units and ambient temperature and humidity on cooling towers and combustion turbines.
Response: Your comment will be forwarded to the SDT for their consideration. The SAR Drafting Team encourages the commenter to review the future posting of the draft Reliability Standards proposed by the future Generation Verification SDT, and make specific comments if necessary.		
HQT	Possible	For Québec Interconnection, there might be some specific value for frequency range applicable for PRC-024 and PRC-019
Response: The SAR Drafting Team encourages the commenter to review the future posting of the draft Reliability Standards PRC-019 and PRC-024 proposed by the future Generation Verification SDT, and make specific comments if necessary. In removing the RRO requirement to establish requirements for frequency excursions, the SDT will need, as you indicate, to propose specific limits for excursions needed to develop a continent or interconnection wide requirement.		
NPCC CP9 RSWG	No	Within the Québec Interconnection, there might be some specific value for frequency range applicable for PRC-024 and PRC-019 and this should be allowed for in the standard drafting phase.
Response: The SAR Drafting Team encourages the commenter to review the future posting of the draft Reliability Standards PRC-019 and PRC-024 proposed by the future Generation Verification SDT, and make specific comments if necessary. In removing the RRO requirement to establish requirements for frequency excursions, the SDT will need, as you indicate, to propose specific limits for excursions needed to develop a continent or interconnection wide requirement.		

Question #5		
Commenter	**Regional Variance**	**Comment**
SCT	None	
Ameren Services	None	
SERC GSFT-TF	None	

6. If you are aware of any business practice that will be needed or that will need to be modified as a result of this project, please identify the business practice.

Summary Consideration: No commenter identified the need for a business practice to support the modified standards.

Question #6		
Commenter	**Business Practice**	**Comment**
FirstEnergy	-	Aware of none.
HQT	No	
NPCC CP9 RSWG	No	
SCT	None	
Ameren Services	None	
SERC GSFT-TF	None	

7. If you have any other comments on this SAR that you haven't already mentioned above, please provide them here:

Summary Consideration:

Question #7	
Commenter	**Comment**
AEP	Please transmit to the Standard Drafting Team the following specific suggested revisions to MOD-025: Key changes relate to FERC's requirement that regional "fill-in-the-blank" standards be rewritten as North American standards; these and other recommended changes are provided below: A. Introduction 1. Title: Verification of Generator [ ] Reactive Power Capabilities 3. Purpose: To ensure that [ ] steady-state models used for assessing Bulk Electric System reliability reflect realistic/usable generator reactive power capabilities. B. Requirements R1. The North American Electric Reliability Corporation (NERC) shall establish and maintain procedures to address verification of generator gross and net Reactive Power capability. These procedures shall include the following: R1.5. Information to be reported to Regional Reliability Organization (RRO): R1.5.1. Verified maximum gross and net Reactive Power capability (both lagging and leading) at Seasonal Real Power generating capabilities as reported in accordance with Reliability Standard MOD-024 Requirement 1.5.1. and at Minimum Real Power output levels of generators. Net capabilities should be reported at the low- and high-voltage terminals of generator step-up (GSU) transformers. R1.5.3. Verified Real and Reactive Power of auxiliary loads fed from: (a) generator bus and (b) transmission system bus (listed separately). R1.5.5. System bus voltages (as scheduled and as verified), generator bus voltage and generator hydrogen pressure. R1.5.6. In-service transformer taps setting and impedance (including base quantities). R1.6. Requirement that sanity checks (or analysis) be used to ensure consistency/accuracy of reactive power capabilities obtained via measurement. R2. The RRO shall provide [ ] generator gross and net Reactive Power capability verification and reporting procedures, and any changes to those procedures, to ... R3. The Generator Owner shall follow NERC's procedures for verifying and reporting to RRO generator gross and net Reactive Power capabilities per R1. C. Measures M2. The RRO shall have written evidence that [ ] procedures... M3. The Generator Owner shall have written evidence it provided verified information of its generator gross and net Reactive Power capabilities, consistent with NERC's procedures.

Question #7	
Commenter	**Comment**
	D. Compliance This section should be revised to recognize that the procedures for generator Reactive Power capability verification will be written by NERC as a continent-wide standard. AEP recommends that Ape's Circular Letter OP-G-CL-011 (Reactive Capability Testing of Generators), developed over nearly two decades of testing experience and advocacy within the former ECAR region, be used as a reference in drafting this standard.
Response: Thank you for your suggestions. Your specific recommendations will be made available to the Standard Drafting Team.	
Ameren	MOD-026-1 and MOD-027-1: The existing language in R1.2 for each of these standards states that manufacturer data is one of the methods which can be utilized for verification of models and data. However, typical data for these types of models is generally not adequate to sufficiently characterize the models for use in system simulations.
Response: As part of the process of modifying the existing MOD-024 and 025 standards to remove the "fill in the blank" requirements and replacing them with requirements that can be applied on a continent-wide basis, the SDT will be charged to carefully consider the validity of each method that can be utilized for verification of models and data.	
Ameren Services	The scope of MOD-024 and MOD-025 should not be expanded beyond the scope contained in the current version of these two standards. The results of the field test for the other 4 Draft Reliability Standards by the 4 participating RROs will not be complete until late June 2007. Thus, the scope of the SAR should make it clear that the decision by the SDT to either refine / significantly revise / or delete these standards should be heavily weighted on the outcome of the field test.
Response: In FERC Order 693, the ERO was directed to modify MOD-025-1 to "require verification of reactive power capability at multiple points….". The SDT will be expected , as outlined in "Guidance to Standards Drafting Team Relative to FERC Order Nos. 693 and 890" (April 13, 2006), to address verification of reactive power capability at multiple points or provide other viable alternatives that meet the same objective. In addition the FERC stated concerns about the lack of clarity in MOD-024. The NERC Phase III-IV Field Tests will be complete on June 19, before the subject SAR is completed and before the Generation Verification SDT is formed. The SAR DT is meeting at the same time that the field test reports are being given so that the DT will have first hand knowledge of the results. The intention of the SAR was to clearly direct the SDT to give proper consideration to the results of the field tests. The SAR has been clarified accordingly.	
ATC LLC.	The SAR includes language requiring the SDT to identify any generators that should be exempt from compliance.

Question #7	
Commenter	**Comment**
	There are many standards both under this project and others (such as Project 2007-01) that need to consider applicability based on generator size and/or voltage. If these standards remain separate, this requirement will either force needless repetition of the same language in many standards, or there is a distinct possibility that differences will develop among the exemptions, making it very difficult for generator owners to know which of their generators are covered by which standards. I suggest there should be a global definition of minimum generator size to which all NERC Reliability Standards apply, much like the global definition of Bulk Electric System. To start the discussion let me suggest "generators with a net electrical output or 20 MW or greater, connected through a step-up transformer with a high voltage rating of 100 kV or higher." The wording in the third bullet point for MOD-024-1 and MOD-025-1 in the Detail Description should be changed from "Consider Requiring" to just "Require".
Response: Part of the work performed by the SDT is to clearly state the applicable entities and any specific characteristics. This was commented on by FERC repeatedly. The SDT will have to develop the "applicability" that is consistent with other NERC standards as you indicate. This will need to be done in concert with the definition of the BES and the compliance registration guidelines. Your comment will be forwarded to the SDT. The SAR Drafting Team agrees with your second comment and has changed the SAR accordingly.	
Entergy	MOD-24 & 25 should not be increased beyond their current scope. Multiple test points cost time and money, and increase the potential of plant trips, but do not improve reliability. The rest of the standards should be judged based on the results of the field test and significantly modified or eliminated if the field test show that they are very difficult to perform, give questionable results or do not improve the reliability of the bulk power system.
Response: In FERC Order 693, the ERO was directed to modify MOD-025-1 to "require verification of reactive power capability at multiple points….". The SDT will be expected , as outlined in "Guidance to Standards Drafting Team Relative to FERC Order Nos. 693 and 890" (April 13, 2006), to address verification of reactive power capability at multiple points or provide other viable alternatives that meet the same objective. Your suggestion will be forwarded to the SDT for their consideration. The SAR Drafting Team agrees. The intention of the SAR was to clearly direct the SDT to give proper consideration to the results of the field tests. The SAR has been clarified accordingly.	
FirstEnergy	On page SAR-3 under PRC-024-1, the bullet "Add requirement for the Transmission Owner and Generator Owner to coordinate protection systems" should be revised or removed. If it is included, it should be revised to specifically state what protection schemes are being coordinated via this standard. Otherwise it should be removed because the coordination of the transmission and generation protection is covered in PRC-001-1 R3 and R4.

Question #7	
Commenter	**Comment**
Response: PRC-001-1 R3 requires "A Generator Operator or Transmission Operator shall coordinate NEW protective systems and CHANGES". R4 requires "Each Transmission Operator shall coordinate protection systems on MAJOR transmission lines and interconnections with NEIGHBORING Generator Operators …..." It is the task of the SDT to propose requirements as a result of this SAR that complement and/or supplement PRC-001-1. Based on the SDT considerations and/or comments received during public postings, the SDT may consider writing another SAR to address these issues in a revision of PRC-001.	
HQT NPCC CP9 RSWG	The industry should be provided the opportunity to comment on and provide suggestions for the periodicity and magnitude of the testing.
Response: Industry will have the opportunity to comment on all aspects of future drafts of the NERC Reliability Standards to be developed by the future Generator Verification SDT as required by the NERC Standard Development Procedure.	
IRC - SRC	There is a reliability need for this SAR, but the Industry must be allowed to comment on the periodicity of the tests. There should be justification for annual testing requirements, since some characteristics do not change appreciably over time.
Response: Thank you for your comments. They will all be forwarded to the SDT for their consideration. The task of the SDT is to clarify the current draft standards and remove RRO requirements. The commenter is encouraged to review and comment on the public postings by the future Generator Verification SDT.	
ISO-NE	There is a reliability need for this SAR, but the Industry must be allowed to comment on the periodicity and magnitude of the tests. There should be justification for annual testing since characteristics do not change appreciably over time.
Response:	
SCT	The scope of MOD-024 and MOD-025 should not be expanded beyond the scope contained in the current version of these two standards. As for the other four standards; PRC-019, PRC-024, MOD-026 and MOD-027, the timing of the subject SAR appears to be premature since the field testing is not complete.
Response: In FERC Order 693, the ERO was directed to modify MOD-025-1 to "require verification of reactive power capability at multiple points….". The SDT will be expected , as outlined in "Guidance to Standards Drafting Team Relative to FERC Order Nos. 693 and 890" (April 13, 2006), to address verification of reactive power capability at multiple points or provide other	

Question #7	
Commenter	**Comment**
viable alternatives that meet the same objective. The NERC Phase III-IV Field Tests will be complete on June 19, before the subject SAR is completed and before the Generation Verification SDT is formed. The SAR DT is meeting at the same time that the field test reports are being given so that the DT will have first hand knowledge of the results. The intention of the SAR was to clearly direct the SDT to give proper consideration to the results of the field tests. The SAR has been clarified accordingly.	
SERC GSFT-TF	The scope of MOD-024 and MOD-025 should not be expanded beyond the scope contained in the current version of these two standards. The results of the field test for the other 4 Draft Reliability Standards by the 4 participating RROs will not be complete until late June 2007. Thus, the scope of the SAR should make it clear that the decision by the SDT to either refine / significantly revise / or delete these standards should be heavily weighted on the outcome of the field test.
Response: In FERC Order 693, the ERO was directed to modify MOD-025-1 to "require verification of reactive power capability at multiple points….". The SDT will be expected , as outlined in "Guidance to Standards Drafting Team Relative to FERC Order Nos. 693 and 890" (April 13, 2006), to address verification of reactive power capability at multiple points or provide other viable alternatives that meet the same objective. Your suggestion will be forwarded to the SDT for their consideration. The intention of the SAR was to clearly direct the SDT to give proper consideration to the results of the field tests. The SAR has been clarified accordingly.	
XCEL	Under Draft PRC-024-1 on the SAR form, the fourth bullet says "Add a requirement for the Transmission Owner and Generator Owner to coordinate protection systems". This is already required and measured under PRC-001-1, and should therefore not be added as a requirement in PRC-024-1.
Response: PRC-001-1 R3 requires "A Generator Operator or Transmission Operator shall coordinate NEW protective systems and CHANGES". R4 requires "Each Transmission Operator shall coordinate protection systems on MAJOR transmission lines and interconnections with NEIGHBORING Generator Operators ….." It is the task of the SDT to propose requirements as a result of this SAR that complement and/or supplement PRC-001-1. Based on the SDT considerations and/or comments received during public postings, the SDT may consider writing another SAR to address these issues in a revision of PRC-001.	

Standard Authorization Request Form

Title of Proposed Standard	Generator Verification (Project 2007-09)
Request Date	April 3, 2007
Modified Date	June 14, 2007

SAR Requestor Information	**SAR Type** (*Check a box for each one that applies.*)	
Name: Bob Millard	☒	New Standards
Primary Contact: Bob Millard	☒	Revision to existing Standards:
Telephone: (708) 588-9886 Fax:	☐	Withdrawal of existing Standard
E-mail: bob.millard@rfirst.org	☐	Urgent Action

Purpose

The purpose of Project 2007-09 Generator Verification is:

- To ensure that generators will not trip off-line during specified voltage and frequency excursions or as a result of improper coordination between generator protective relays and generator voltage regulator controls and limit functions (such coordination will include the generating unit's capabilities).
- To ensure that generator models accurately reflect the generator's capabilities and operating characteristics.

New standards to be finalized as part of this project are:

PRC-019 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection

PRC-024 — Generator Performance During Frequency and Voltage Excursions

MOD-026 —Verification of Models and Data for Generator Excitation System Functions

MOD-027 — Verification of Generator Unit Frequency Response

Standards to be revised as part of this project are:

MOD-024 — Verification of Generator Gross and Net Real Power Capability

MOD-025 — Verification of Generator Gross and Net Reactive Power Capability

Industry Need

All six of the standards included in this project address generator verifications needed to support bulk power system reliability. All six of the standards included in this project were originally "Phase III & IV Planning Measures" that were translated into new or proposed standards as part of the Version 0 translation effort. Stakeholders have already agreed that there is a reliability-related need for each of these standards as part of the work performed in association with the Phase III & IV Modeling SAR. In addition, each of the standards included in this project has some "fill-in-the-blank" requirements assigned to the Regional Reliability Organization that need to be replaced with more specific "continent-wide" requirements before the standards are approved.

Specifically:

- MOD-024-1 and MOD-025-1 were approved by the NERC Board of Trustees but are "pending" with FERC because they include "fill-in-the-blank" requirements assigned to the Regional Reliability Organization (MOD-024-1 and MOD-025-1 require generator owners to verify the generator's gross and net real and reactive power capability using an RRO established procedure).

- PRC-019-1, PRC-024-1, MOD-026-1 and MOD-027-1 are draft standards that were developed under the Phase III & IV Modeling SAR that have not been presented to the NERC Board of Trustees yet. These four standards contain "fill-in-the-blank" requirements assigned to the Regional Reliability Organization (RRO) which were appropriate when the standards were initially drafted but are not appropriate under current requirements for approval of enforceable standards. Work on these standards to remove the "fill-in-the-blank" requirements under the Phase III & IV Modeling SAR is not authorized and therefore cannot be completed under the Phase III & IV Modeling SAR because the modifications needed to make the standards enforceable are outside the scope of the original Phase III & IV SARs. To properly complete these standards, a new SAR is needed and the prior SAR need to be terminated (termination of the Phase III & IV Modeling SAR will be performed outside the work of this SAR).
    - This set of standards includes verification of the generator's excitation system; verification of the generator's frequency response; verification that the generator can remain connected during specified voltage and frequency excursions; and verification that the generator's voltage regulator controls and limit functions have been coordinated with the generator's capabilities and protective relays.
    - The field test for this set of standards has shown that a standard can be written to support these verifications.

Brief Description

The scope of this project includes:

- modifying the six standards associated with this project so they conform to the latest version of NERC's Reliability Standards Development Procedure and the ERO Rules of Procedure,
- replacing the "fill-in-the-blank" requirements assigned to the Regional Reliability Organization with requirements that can be applied on a continent-wide basis and are assigned to users, owners or operators of the bulk power system,
- considering and addressing issues identified in FERC orders, including the modifications to MOD-024-1 and MOD-025-1 as proposed in FERC Order 693, and
- considering and addressing issues identified during Phase III & IV field testing.

Detailed Description

The standards drafting team (SDT) will bring the six standards into conformance with the latest version of NERC's Reliability Standards Development Procedure and the ERO Rules of Procedure. In addition, the SDT will consider and address all applicable FERC Orders including but not limited to FERC Order 693, the field test results from the Phase III & IV field testing, issues raised by the industry during the posting of the SAR for Project 2007-09 Generator Verification identified in Attachment 1, and the following proposed changes for each of the six standards in this set of standards:

Draft PRC-019-1

- Revise the purpose statement to include the reliability-related benefit of the standard
- Provide more details to the applicability section of the standard to identify any generators that should be exempt from compliance with the requirements in the standard
- Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of 'continent-wide' criteria for verification that generator voltage regulator controls and limit functions are coordinated with the generator's capabilities and protective relays
- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the Regional Reliability Organization
- Add a 'violation risk factor' and a 'time horizon' for each requirement
- Update all the compliance sections of the standard, including:
    - Update the compliance monitoring section to clarify that the regional entity will be the compliance monitor for the generator owner
    - Replace the 'levels of non-compliance' with 'violation severity levels'

Draft PRC-024-1

- Provide more details to the applicability section of the standard to identify any generators that should be exempt from compliance with the requirements in the standard
- Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of 'continent-wide' criteria for verification that generators will remain connected during specified system frequency and voltage excursions
- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the Regional Reliability Organization
- Add a requirement for the Transmission Owner and Generator Owner to coordinate protection systems
- Add a 'violation risk factor' and a 'time horizon' for each requirement
- Update all the compliance sections of the standard, including:
    - Update the compliance monitoring section to clarify that the regional entity will be the compliance monitor for the generator owner
    - Replace the 'levels of non-compliance' with 'violation severity levels'

MOD-024-1:

- Provide more details to the applicability section of the standard to identify any generators that should be exempt from compliance with the requirements in the standard
- Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of 'continent-wide' criteria for verification of models and data associated with verification of generator gross and net real power capability
    - Consider requiring the generator owner to document the test conditions and

    - the relationships between test conditions and generator output
- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the Regional Reliability Organization
- Add a 'time horizon' for each requirement
- Update all the compliance sections of the standard, including:
    - Update the compliance monitoring section to clarify that the regional entity will be the compliance monitor for the generator owner
    - Replace the 'levels of non-compliance' with 'violation severity levels'

MOD-025-1:
- Provide more details to the applicability section of the standard to identify any generators that should be exempt from compliance with the requirements in the standard
- Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of 'continent-wide' criteria for verification of models and data associated with verification of generator gross and net Reactive Power capability
    - Consider requiring verification of reactive power capability at multiple points over a unit's operating range
- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the Regional Reliability Organization
- Add a 'time horizon' for each requirement
- Update all the compliance sections of the standard, including:
    - Update the compliance monitoring section to clarify that the regional entity will be the compliance monitor for the generator owner
    - Replace the 'levels of non-compliance' with 'violation severity levels'

Draft MOD-026-1
- Provide more details to the applicability section of the standard to identify any generators that should be exempt from compliance with the requirements in the standard
- Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of 'continent-wide' criteria for verification of models and data associated with generator excitation system functions
- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the Regional Reliability Organization
- Add a 'violation risk factor' and a 'time horizon' for each requirement
- Update all the compliance sections of the standard, including:
    - Update the compliance monitoring section to clarify that the regional entity will be the compliance monitor for the generator owner
    - Replace the 'levels of non-compliance' with 'violation severity levels'

Draft MOD-027-1
- Revise the purpose statement to include the reliability-related benefit of the standard
- Provide more details to the applicability section of the standard to identify any generators that should be exempt from compliance with the requirements in the standard
- Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of 'continent-wide' criteria for verification of models and data associated with generator unit frequency response

- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the Regional Reliability Organization
- Add a 'violation risk factor' and a 'time horizon' for each requirement
- Update all the compliance sections of the standard, including:
    - Update the compliance monitoring section to clarify that the regional entity will be the compliance monitor for the generator owner
    - Replace the 'levels of non-compliance' with 'violation severity levels'

Reliability Functions

The Standard Drafting Team will Consider Applicability to All Functional Entities *(Check box for each one that may apply.)*		
☒	Reliability Coordinator	Responsible for the real-time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator's wide area view.
☐	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within a Balancing Authority Area and supports Interconnection frequency in real time.
☐	Interchange Coordinator	Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced interchange schedules between Balancing Authority Areas.
☒	Planning Coordinator	Assesses the longer-term reliability of its Planning Coordinator Area.
☐	Resource Planner	Develops a >one year plan for the resource adequacy of its specific loads within a Planning Coordinator area.
☒	Transmission Planner	Develops a >one year plan for the reliability of the interconnected Bulk Electric System within its portion of the Planning Coordinator area.
☐	Transmission Service Provider	Administers the transmission tariff and provides transmission services under applicable transmission service agreements (e.g., the pro forma tariff).
☒	Transmission Owner	Owns and maintains transmission facilities.
☒	Transmission Operator	Ensures the real-time operating reliability of the transmission assets within a Transmission Operator Area.
☐	Distribution Provider	Delivers electrical energy to the End-use customer.
☒	Generator Owner	Owns and maintains generation facilities.
☒	Generator Operator	Operates generation unit(s) to provide real and reactive power.
☐	Purchasing-Selling Entity	Purchases or sells energy, capacity, and necessary reliability-related services as required.
☐	Market Operator	Interface point for reliability functions with commercial functions.
☐	Load-Serving Entity	Secures energy and transmission service (and related reliability-related services) to serve the End-use Customer.

Reliability and Market Interface Principles

Applicable Reliability Principles *(Check box for all that apply.)*	
☒	1. Interconnected bulk electric systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
☒	2. The frequency and voltage of interconnected bulk electric systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
☒	3. Information necessary for the planning and operation of interconnected bulk electric systems shall be made available to those entities responsible for planning and operating the systems reliably.
☐	4. Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed, coordinated, maintained and implemented.
☐	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk electric systems.
☐	6. Personnel responsible for planning and operating interconnected bulk electric systems shall be trained, qualified, and have the responsibility and authority to implement actions.
☐	7. The security of the interconnected bulk electric systems shall be assessed, monitored and maintained on a wide area basis.
☐	8. Bulk power systems shall be protected from malicious physical or cyber attacks.

Does the proposed Standard comply with all of the following Market Interface Principles? *(Select 'yes' or 'no' from the drop-down box.)*
1. A Reliability Standard shall not give any market participant an unfair competitive advantage.Yes
2. A Reliability Standard shall neither mandate nor prohibit any specific market structure. Yes
3. A Reliability Standard shall not preclude market solutions to achieving compliance with that Standard. Yes
4. A Reliability Standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards. Yes

Attachment 1

Issues Raised by Industry During 1st Posting of SAR for Project 2007-09 Generator Verification Which are Outside the Responsibility of the SAR Drafting Team

Question 2 of the Comment Form: *Two of the standards (MOD-024 and MOD-025) associated with this SAR had already been approved by the NERC Board of Trustees, but are "pending" with FERC because they include "fill-in-the-blank" requirements assigned to the Regional Reliability Organization. These standards must be revised to remove the fill-in-the-blank characteristics before they can become mandatory and enforceable. The intent of MOD-024 and MOD-025 is to ensure that accurate information on generator gross and net real and reactive power capability is available for the steady-state models used to assess bulk electric system reliability. To be enforceable, these standards need to be revised. Do you agree that there is a reliability-related need to revise these standards to support accurate modeling?*

Ameren commented:

With regards to the scope of MOD-025, it should not be necessary to include a blanket requirement for verification of reactive power capability at multiple points for all generators. However, should a generator frequently have difficulty reaching its stated reactive power output, additional testing requirements for that generator would be indicated.

FirstEnergy commented:

The present legacy document ECAR Document 4 details the testing and is sufficient to cover the present accurary for a regional basis. The standards if spread to a national level will need to look at the difference between summer peaking regions and winter peaking. Presently the testing in RFC follows ECAR Document 4 which corrects the testing for average ambient conditions which is left up to the discretion of the testing personnel. The temperature conditions of the water inlet or ambient air needs to be defined.

Question 3 of the Comment Form: *The scope of this project includes:*

- *Modifying the six standards associated with this project so they conform to the latest version of NERC's Reliability Standards Development Procedure and the ERO Sanction Guidelines,*
- *Replacing the fill-in-the-blank requirements assigned to the Regional Reliability Organization with requirements that can be applied on a continent-wide basis and are assigned to users, owners, or operators of the bulk power system, and*
- *Addressing issues identified in FERC Order 693.*

Do you agree with this scope? If not, please explain in the comment area.

IESO commented:

The SDT should consider the term characteristics during the review of the standards. The following is an example of: PRC-019-1
R2.1.2 & R2.1.5 - How to define characteristics? A common interpretation could be to define characteristics as the "setpoints" for the controllers. However, this does not appear to be the case as in other requirements they request "setpoints" as is shown in R2.1.6. MOD-026-1 appears to address this but refers to the excitation system functions.

In other words, the terms "characteristics" and "setpoints/settings" are presented in the requirements without clearly clarifying the meaning of the terms. “Characteristic” could mean something like a Generator capability curve (or any operating curve for that matter or nomograms) where the operations are defined by a “bounded region of operation” as such and is kind of “analog” in nature. “Setpoint/Setting” on the other hand could be something like a Generator Under-frequency trip setting where there are “set-points” for tripping – kind of “digital” in nature. Is this what the SDT means by these terms. Please clarify. As the standards are reviewed, there are specific questions that need to be addressed such as: MOD-025-1
R1.5.3 - Is this individual loads, or is this an overall value for the total auxiliary loads running at full station output?
Also, What will define the need to revisit this when equipment changes occur? In addition, the SDT should consider additional field tests for all the changes associated with the revised standard.

IRC-SRC and ISO-NE commented:

The SDT should consider the term characteristics during the review of the standards. Sections below are identified as locations for clarification.
-PRC-019-1
R2.1.2 & R2.1.5 - How to define characteristics? A common interpretation would be define characteristics as the "setpoints" for the controllers. However, this does not appear to be the case as in other requirements they request "setpoints" as is shown in R2.1.6. MOD-026-1 appears to address this but refers to the excitation system functions. What is meant by characterisitics, if the characteristics are not defined as the setpoint? As the standards are reviewed, there are specific questions that need to be addressed such as:
MOD-025-1
R1.5.3 - Is this individual loads, or is this an overall value for the total auxiliary loads running at full station output?

Also, What will define the need to revisit this when equipment changes occur?
The SDT should also identify a date for compliance for each of the requirements and measures. Here are a few examples:
-MOD-024-1
M1 & M3 - Will need to prescribed a date for compliance
-MOD-026-1
M3 - Will need to prescribed a date for compliance
-MOD-027-1
M1 & M3 - Will need to prescribed a date for compliance

FirstEnergy commented:

The project should account for potential regional differences. See comment on question # 5 below.

Question 5 of the Comment Form: *If you are aware of any regional variances that will be needed as a result of this project, please identify the Regional Variance:*

FirstEnergy commented:

Not aware of existing, but potential for regional differences exist. The fill-in-the-blank needs to take into account regional differences such as summer or winter peaking conditions. The standard needs to address the main factor in generation capacity which is inlet water temperatures on once through cooling units and ambient temperature and humidity on cooling towers and combustion turbines.

Question 7 of the Comment Form: *If you have any other comments on this SAR that you haven’t already mentioned above, please provide them here:*

AEP commented:

Please transmit to the Standard Drafting Team the following specific suggested revisions to MOD-025:

Key changes relate to FERC's requirement that regional "fill-in-the-blank" standards be rewritten as North American standards; these and other recommended changes are provided below:

A. Introduction

1. Title: Verification of Generator [ ] Reactive Power Capabilities

3. Purpose: To ensure that [ ] steady-state models used for assessing Bulk Electric System reliability reflect realistic/usable generator reactive power capabilities.

B. Requirements

R1. The North American Electric Reliability Corporation (NERC) shall establish and maintain procedures to address verification of generator gross and net Reactive Power capability. These procedures shall include the following:

R1.5. Information to be reported to Regional Reliability Organization (RRO):

R1.5.1. Verified maximum gross and net Reactive Power capability (both lagging and leading) at Seasonal Real Power generating capabilities as reported in accordance with Reliability Standard MOD-024 Requirement 1.5.1. and at Minimum Real Power output levels of generators. Net capabilities should be reported at the low- and high-voltage terminals of generator step-up (GSU) transformers.

R1.5.3. Verified Real and Reactive Power of auxiliary loads fed from: (a) generator bus and (b) transmission system bus (listed separately).

R1.5.5. System bus voltages (as scheduled and as verified), generator bus voltage and generator hydrogen pressure.

R1.5.6. In-service transformer taps setting and impedance (including base quantities).

R1.6. Requirement that sanity checks (or analysis) be used to ensure consistency/accuracy of reactive power capabilities obtained via measurement.

R2. The RRO shall provide [ ] generator gross and net Reactive Power capability verification and reporting procedures, and any changes to those procedures, to ...

R3. The Generator Owner shall follow NERC's procedures for verifying and reporting to RRO generator gross and net Reactive Power capabilities per R1.

C. Measures

M2. The RRO shall have written evidence that [ ] procedures...

M3. The Generator Owner shall have written evidence it provided verified information of its generator gross and net Reactive Power capabilities, consistent with NERC's procedures.

D. Compliance

This section should be revised to recognize that the procedures for generator Reactive Power capability verification will be written by NERC as a continent-wide standard. AEP recommends that Ape’s Circular Letter OP-G-CL-011 (Reactive Capability Testing of Generators), developed over nearly two decades of testing experience and advocacy within the former ECAR region, be used as a reference in drafting this standard.

ATC LLC commented:

The SAR includes language requiring the SDT to identify any generators that should be exempt from compliance. There are many standards both under this project and others (such as Project 2007-01) that need to consider applicability based on generator size and/or voltage. If these standards remain separate, this requirement will either force

needless repetition of the same language in many standards, or there is a distinct possibility that differences will develop among the exemptions, making it very difficult for generator owners to know which of their generators are covered by which standards. I suggest there should be a global definition of minimum generator size to which all NERC Reliability Standards apply, much like the global definition of Bulk Electric System. To start the discussion let me suggest "generators with a net electrical output or 20 MW or greater, connected through a step-up transformer with a high voltage rating of 100 kV or higher."
The wording in the third bullet point for MOD-024-1 and MOD-025-1 in the Detail Description should be changed from "Consider Requiring" to just "Require".

Standard Authorization Request Form

Title of Proposed Standard	Generator Verification (Project 2007-09)
Request Date	April 3, 2007
Modified Date	June 14, 2007

SAR Requestor Information	**SAR Type** (*Check a box for each one that applies.*)	
Name: Bob Millard	☒	New Standards
Primary Contact: Bob Millard	☒	Revision to existing Standards:
Telephone: (708) 588-9886 Fax:	☐	Withdrawal of existing Standard
E-mail: bob.millard@rfirst.org	☐	Urgent Action

116-390 Village Boulevard, Princeton, New Jersey 08540-5721
Phone: 609.452.8060 ▪ Fax: 609.452.9550 ▪ www.nerc.com

Purpose

The purpose of Project 2007-09 Generator Verification is:

- To ensure that generators will not trip off-line during specified voltage and frequency excursions or as a result of improper coordination between generator protective relays and generator voltage regulator controls and limit functions (such coordination will include the generating unit's capabilities).
- To ensure that generator models accurately reflect the generator's capabilities and operating characteristics.

New standards to be finalized as part of this project are:

PRC-019 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection

PRC-024 — Generator Performance During Frequency and Voltage Excursions

MOD-026 —Verification of Models and Data for Generator Excitation System Functions

MOD-027 — Verification of Generator Unit Frequency Response

Standards to be revised as part of this project are:

MOD-024 — Verification of Generator Gross and Net Real Power Capability

MOD-025 — Verification of Generator Gross and Net Reactive Power Capability

Industry Need

All six of the standards included in this project address generator verifications needed to support bulk power system reliability. All six of the standards included in this project were originally "Phase III & IV Planning Measures" that were translated into new or proposed standards as part of the Version 0 translation effort. Stakeholders have already agreed that there is a reliability-related need for each of these standards as part of the work performed in association with the Phase III & IV Modeling SAR. In addition, each of the standards included in this project has some "fill-in-the-blank" requirements assigned to the Regional Reliability Organization that need to be replaced with more specific "continent-wide" requirements before the standards are approved.

Specifically:

- MOD-024-1 and MOD-025-1 were approved by the NERC Board of Trustees but are "pending" with FERC because they include "fill-in-the-blank" requirements assigned to the Regional Reliability Organization (MOD-024-1 and MOD-025-1 require generator owners to verify the generator's gross and net real and reactive power capability using an RRO established procedure).

- PRC-019-1, PRC-024-1, MOD-026-1 and MOD-027-1 are draft standards that were developed under the Phase III & IV Modeling SAR that have not been presented to the NERC Board of Trustees yet. These four standards contain "fill-in-the-blank" requirements assigned to the Regional Reliability Organization (RRO) which were appropriate when the standards were initially drafted but are not appropriate under current requirements for approval of enforceable standards. Work on these standards to remove the "fill-in-the-blank" requirements under the Phase III & IV Modeling SAR is not authorized and therefore cannot be completed under the Phase III & IV Modeling SAR because the modifications needed to make the standards enforceable are outside the scope of the original Phase III & IV SARs. To properly complete these standards, a new SAR is needed and the prior SAR need to be terminated (termination of the Phase III & IV Modeling SAR will be performed outside the work of this SAR).
    - This set of standards includes verification of the generator's excitation system; verification of the generator's frequency response; verification that the generator can remain connected during specified voltage and frequency excursions; and verification that the generator's voltage regulator controls and limit functions have been coordinated with the generator's capabilities and protective relays.
    - The field test for this set of standards has shown that a standard can be written to support these verifications.

Brief Description

The scope of this project includes:

- modifying the six standards associated with this project so they conform to the latest version of NERC's Reliability Standards Development Procedure and the ERO Rules of Procedure,
- replacing the "fill-in-the-blank" requirements assigned to the Regional Reliability Organization with requirements that can be applied on a continent-wide basis and are assigned to users, owners or operators of the bulk power system, ~~and~~
- considering and addressing issues identified in FERC orders, including the modifications to MOD-024-1 and MOD-025-1 as proposed in FERC Order 693, and~~.~~
- considering and addressing issues identified during Phase III & IV field testing.

Detailed Description
The standards drafting team (SDT) will bring the six standards into conformance with the latest version of NERC's Reliability Standards Development Procedure and the ERO Rules of Procedure. In addition, the S~~T~~DT will consider and address all applicable FERC Orders~~,~~ including but not limited to FERC Order 693, the field test results from the Phase III & IV field testing, issues raised by the industry during the posting of the SAR for Project 2007-09 Generator Verification identified in Attachment 1, and the following proposed changes for each of the six standards in this set of standards:

Draft PRC-019-1
- Revise the purpose statement to include the reliability-related benefit of the standard
- Provide more details to the applicability section of the standard to identify any generators~~ owners~~ that should be exempt from compliance with the requirements in the standard
- Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of 'continent-wide' criteria for verification that generator voltage regulator controls and limit functions are coordinated with the generator's capabilities and protective relays
- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the Regional Reliability Organization
- Add a 'violation risk factor' and a 'time horizon' for each requirement
- Update all the compliance sections of the standard, including:
    - Update the compliance monitoring section to clarify that the regional entity will be the compliance monitor for the generator owner
    - Replace the 'levels of non-compliance' with 'violation severity levels'

Draft PRC-024-1
- Provide more details to the applicability section of the standard to identify any generators that should be exempt from compliance with the requirements in the standard
- Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of 'continent-wide' criteria for verification that generators will remain connected during specified system frequency and voltage excursions
- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the Regional Reliability Organization
- Add a requirement for the Transmission Owner and Generator Owner to coordinate protection systems
- Add a 'violation risk factor' and a 'time horizon' for each requirement
- Update all the compliance sections of the standard, including:
    - Update the compliance monitoring section to clarify that the regional entity will be the compliance monitor for the generator owner
    - Replace the 'levels of non-compliance' with 'violation severity levels'

MOD-024-1:
- Provide more details to the applicability section of the standard to identify any generators that should be exempt from compliance with the requirements in the standard
- Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of 'continent-wide' criteria for verification of models and data associated with verification of generator gross and net real power capability
    - Consider requiring the generator owner to document the test conditions and

    - the relationships between test conditions and generator output
- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the Regional Reliability Organization
- Add a 'time horizon' for each requirement
- Update all the compliance sections of the standard, including:
    - Update the compliance monitoring section to clarify that the regional entity will be the compliance monitor for the generator owner
    - Replace the 'levels of non-compliance' with 'violation severity levels'

MOD-025-1:
- Provide more details to the applicability section of the standard to identify any generators that should be exempt from compliance with the requirements in the standard
- Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of 'continent-wide' criteria for verification of models and data associated with verification of generator gross and net Reactive Power capability
    - Consider requiring verification of reactive power capability at multiple points over a unit's operating range
- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the Regional Reliability Organization
- Add a 'time horizon' for each requirement
- Update all the compliance sections of the standard, including:
    - Update the compliance monitoring section to clarify that the regional entity will be the compliance monitor for the generator owner
    - Replace the 'levels of non-compliance' with 'violation severity levels'

Draft MOD-026-1
- Provide more details to the applicability section of the standard to identify any generators that should be exempt from compliance with the requirements in the standard
- Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of 'continent-wide' criteria for verification of models and data associated with generator excitation system functions
- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the Regional Reliability Organization
- Add a 'violation risk factor' and a 'time horizon' for each requirement
- Update all the compliance sections of the standard, including:
    - Update the compliance monitoring section to clarify that the regional entity will be the compliance monitor for the generator owner
    - Replace the 'levels of non-compliance' with 'violation severity levels'

Draft MOD-027-1
- Revise the purpose statement to include the reliability-related benefit of the standard
- Provide more details to the applicability section of the standard to identify any generators that should be exempt from compliance with the requirements in the standard
- Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of 'continent-wide' criteria for verification of models and data associated with generator unit frequency response

- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the Regional Reliability Organization
- Add a 'violation risk factor' and a 'time horizon' for each requirement
- Update all the compliance sections of the standard, including:
    - Update the compliance monitoring section to clarify that the regional entity will be the compliance monitor for the generator owner
    - Replace the 'levels of non-compliance' with 'violation severity levels'

Reliability Functions

The Standard Drafting Team will Consider Applicability to All Functional Entities *(Check box for each one that may apply.)*		
☒	Reliability Coordinator	Responsible for the real-time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator's wide area view.
☐	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within a Balancing Authority Area and supports Interconnection frequency in real time.
☐	Interchange Coordinator	Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced interchange schedules between Balancing Authority Areas.
☒	Planning Coordinator	Assesses the longer-term reliability of its Planning Coordinator Area.
☐	Resource Planner	Develops a >one year plan for the resource adequacy of its specific loads within a Planning Coordinator area.
☒	Transmission Planner	Develops a >one year plan for the reliability of the interconnected Bulk Electric System within its portion of the Planning Coordinator area.
☐	Transmission Service Provider	Administers the transmission tariff and provides transmission services under applicable transmission service agreements (e.g., the pro forma tariff).
☒	Transmission Owner	Owns and maintains transmission facilities.
☒	Transmission Operator	Ensures the real-time operating reliability of the transmission assets within a Transmission Operator Area.
☐	Distribution Provider	Delivers electrical energy to the End-use customer.
☒	Generator Owner	Owns and maintains generation facilities.
☒~~☐~~	Generator Operator	Operates generation unit(s) to provide real and reactive power.
☐	Purchasing-Selling Entity	Purchases or sells energy, capacity, and necessary reliability-related services as required.
☐	Market Operator	Interface point for reliability functions with commercial functions.
☐	Load-Serving Entity	Secures energy and transmission service (and related reliability-related services) to serve the End-use Customer.

Reliability and Market Interface Principles

Applicable Reliability Principles *(Check box for all that apply.)*	
☒	1. Interconnected bulk electric systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
☒	2. The frequency and voltage of interconnected bulk electric systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
☒	3. Information necessary for the planning and operation of interconnected bulk electric systems shall be made available to those entities responsible for planning and operating the systems reliably.
☐	4. Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed, coordinated, maintained and implemented.
☐	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk electric systems.
☐	6. Personnel responsible for planning and operating interconnected bulk electric systems shall be trained, qualified, and have the responsibility and authority to implement actions.
☐	7. The security of the interconnected bulk electric systems shall be assessed, monitored and maintained on a wide area basis.

Does the proposed Standard comply with all of the following Market Interface Principles? *(Select 'yes' or 'no' from the drop-down box.)*
1. A Reliability Standard shall not give any market participant an unfair competitive advantage.Yes
2. A Reliability Standard shall neither mandate nor prohibit any specific market structure. Yes
3. A Reliability Standard shall not preclude market solutions to achieving compliance with that Standard. Yes
4. A Reliability Standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards. Yes

Attachment 1

Issues Raised by Industry During 1st Posting of SAR for Project 2007-09 Generator Verification Which are Outside the Responsibility of the SAR Drafting Team

Question 2 of the Comment Form: *Two of the standards (MOD-024 and MOD-025) associated with this SAR had already been approved by the NERC Board of Trustees, but are "pending" with FERC because they include "fill-in-the-blank" requirements assigned to the Regional Reliability Organization. These standards must be revised to remove the fill-in-the-blank characteristics before they can become mandatory and enforceable. The intent of MOD-024 and MOD-025 is to ensure that accurate information on generator gross and net real and reactive power capability is available for the steady-state models used to assess bulk electric system reliability. To be enforceable, these standards need to be revised. Do you agree that there is a reliability-related need to revise these standards to support accurate modeling?*

Ameren commented:

With regards to the scope of MOD-025, it should not be necessary to include a blanket requirement for verification of reactive power capability at multiple points for all generators. However, should a generator frequently have difficulty reaching its stated reactive power output, additional testing requirements for that generator would be indicated.

FirstEnergy commented:

The present legacy document ECAR Document 4 details the testing and is sufficient to cover the present accurary for a regional basis. The standards if spread to a national level will need to look at the difference between summer peaking regions and winter peaking. Presently the testing in RFC follows ECAR Document 4 which corrects the testing for average ambient conditions which is left up to the discretion of the testing personnel. The temperature conditions of the water inlet or ambient air needs to be defined.

Question 3 of the Comment Form: *The scope of this project includes:*

- *Modifying the six standards associated with this project so they conform to the latest version of NERC's Reliability Standards Development Procedure and the ERO Sanction Guidelines,*
- *Replacing the fill-in-the-blank requirements assigned to the Regional Reliability Organization with requirements that can be applied on a continent-wide basis and are assigned to users, owners, or operators of the bulk power system, and*
- *Addressing issues identified in FERC Order 693.*

Do you agree with this scope? If not, please explain in the comment area.

IESO commented:

The SDT should consider the term characteristics during the review of the standards. The following is an example of: PRC-019-1
R2.1.2 & R2.1.5 - How to define characteristics? A common interpretation could be to define characteristics as the "setpoints" for the controllers. However, this does not appear to be the case as in other requirements they request "setpoints" as is shown in R2.1.6. MOD-026-1 appears to address this but refers to the excitation system functions.

In other words, the terms "characteristics" and "setpoints/settings" are presented in the requirements without clearly clarifying the meaning of the terms. “Characteristic” could mean something like a Generator capability curve (or any operating curve for that matter or nomograms) where the operations are defined by a “bounded region of operation” as such and is kind of “analog” in nature. “Setpoint/Setting” on the other hand could be something like a Generator Under-frequency trip setting where there are “set-points” for tripping – kind of “digital” in nature. Is this what the SDT means by these terms. Please clarify. As the standards are reviewed, there are specific questions that need to be addressed such as: MOD-025-1
R1.5.3 - Is this individual loads, or is this an overall value for the total auxiliary loads running at full station output?
Also, What will define the need to revisit this when equipment changes occur? In addition, the SDT should consider additional field tests for all the changes associated with the revised standard.

IRC-SRC and ISO-NE commented:

The SDT should consider the term characteristics during the review of the standards. Sections below are identified as locations for clarification.
-PRC-019-1
R2.1.2 & R2.1.5 - How to define characteristics? A common interpretation would be define characteristics as the "setpoints" for the controllers. However, this does not appear to be the case as in other requirements they request "setpoints" as is shown in R2.1.6. MOD-026-1 appears to address this but refers to the excitation system functions. What is meant by characterisitics, if the characteristics are not defined as the setpoint? As the standards are reviewed, there are specific questions that need to be addressed such as:
MOD-025-1
R1.5.3 - Is this individual loads, or is this an overall value for the total auxiliary loads running at full station output?

Also, What will define the need to revisit this when equipment changes occur?
The SDT should also identify a date for compliance for each of the requirements and measures. Here are a few examples:
-MOD-024-1
M1 & M3 - Will need to prescribed a date for compliance
-MOD-026-1
M3 - Will need to prescribed a date for compliance
-MOD-027-1
M1 & M3 - Will need to prescribed a date for compliance

FirstEnergy commented:

The project should account for potential regional differences. See comment on question # 5 below.

Question 5 of the Comment Form: *If you are aware of any regional variances that will be needed as a result of this project, please identify the Regional Variance:*

FirstEnergy commented:

Not aware of existing, but potential for regional differences exist. The fill-in-the-blank needs to take into account regional differences such as summer or winter peaking conditions. The standard needs to address the main factor in generation capacity which is inlet water temperatures on once through cooling units and ambient temperature and humidity on cooling towers and combustion turbines.

Question 7 of the Comment Form: *If you have any other comments on this SAR that you haven’t already mentioned above, please provide them here:*

AEP commented:

Please transmit to the Standard Drafting Team the following specific suggested revisions to MOD-025:

Key changes relate to FERC's requirement that regional "fill-in-the-blank" standards be rewritten as North American standards; these and other recommended changes are provided below:

A. Introduction

1. Title: Verification of Generator [ ] Reactive Power Capabilities

3. Purpose: To ensure that [ ] steady-state models used for assessing Bulk Electric System reliability reflect realistic/usable generator reactive power capabilities.

B. Requirements

R1. The North American Electric Reliability Corporation (NERC) shall establish and maintain procedures to address verification of generator gross and net Reactive Power capability. These procedures shall include the following:

R1.5. Information to be reported to Regional Reliability Organization (RRO):

R1.5.1. Verified maximum gross and net Reactive Power capability (both lagging and leading) at Seasonal Real Power generating capabilities as reported in accordance with Reliability Standard MOD-024 Requirement 1.5.1. and at Minimum Real Power output levels of generators. Net capabilities should be reported at the low- and high-voltage terminals of generator step-up (GSU) transformers.

R1.5.3. Verified Real and Reactive Power of auxiliary loads fed from: (a) generator bus and (b) transmission system bus (listed separately).

R1.5.5. System bus voltages (as scheduled and as verified), generator bus voltage and generator hydrogen pressure.

R1.5.6. In-service transformer taps setting and impedance (including base quantities).

R1.6. Requirement that sanity checks (or analysis) be used to ensure consistency/accuracy of reactive power capabilities obtained via measurement.

R2. The RRO shall provide [ ] generator gross and net Reactive Power capability verification and reporting procedures, and any changes to those procedures, to ...

R3. The Generator Owner shall follow NERC's procedures for verifying and reporting to RRO generator gross and net Reactive Power capabilities per R1.

C. Measures

M2. The RRO shall have written evidence that [ ] procedures...

M3. The Generator Owner shall have written evidence it provided verified information of its generator gross and net Reactive Power capabilities, consistent with NERC's procedures.

D. Compliance

This section should be revised to recognize that the procedures for generator Reactive Power capability verification will be written by NERC as a continent-wide standard. AEP recommends that Ape's Circular Letter OP-G-CL-011 (Reactive Capability Testing of Generators), developed over nearly two decades of testing experience and advocacy within the former ECAR region, be used as a reference in drafting this standard.

ATC LLC commented:

The SAR includes language requiring the SDT to identify any generators that should be exempt from compliance. There are many standards both under this project and others (such as Project 2007-01) that need to consider applicability based on generator size and/or voltage. If these standards remain separate, this requirement will either force needless repetition of the same language in many standards, or there is a distinct possibility that differences will develop among the exemptions, making it very difficult for generator owners to know which of their generators are covered by which standards. I suggest there should be a global definition of minimum generator size to which all NERC Reliability Standards apply, much like the global definition of Bulk Electric System. To start the discussion let me suggest "generators with a net electrical output or 20 MW or greater, connected through a step-up transformer with a high voltage rating of 100 kV or higher."

The wording in the third bullet point for MOD-024-1 and MOD-025-1 in the Detail Description should be changed from "Consider Requiring" to just "Require".

NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Maureen E. Long
Standards Process Manager

July 17, 2007

TO: REGISTERED BALLOT BODY

Ladies and Gentlemen:

Announcement: Nomination Periods Open for Five New Drafting Teams

The Standards Committee announces the following standards actions:

Project 2007-04 — Certifying System Operators SAR Drafting Team (July 17–30, 2007)

The Standards Committee is seeking industry experts to serve on the Certifying System Operators SAR Drafting Team. The drafting team will work on the modification of the following standard:

PER-003 — Operating Personnel Credentials

If you are interested in serving on this SAR drafting team, please complete this nomination form and return it to sarcomm@nerc.net by July 30, 2007 with "SO Certification SAR DT" in the subject line. For questions, please contact Linda Clarke at 610-310-7210 or linclrke@msn.com.

Project 2007-05 — Balancing Authority Controls SAR Drafting Team (July 17–30, 2007)

The Standards Committee is seeking industry experts to serve on the Balancing Authority Controls SAR Drafting Team. The drafting team will work on modifications to the following standards:

- BAL-002 — Disturbance Control Performance
- BAL-004 — Time Error Correction
- BAL-005 — Automatic Generation Control
- BAL-006 — Inadvertent Interchange

If you are interested in serving on this SAR drafting team, please complete this nomination form and return it to sarcomm@nerc.net by July 30, 2007 with "BA Controls SAR DT" in the subject line. For questions, please contact Linda Clarke at 610-310-7210 or linclrke@msn.com.

Project 2007-09 — Generator Verification Standard Drafting Team (July 17–30, 2007)

The Standards Committee is seeking industry experts to serve on the Generator Verification Standard Drafting Team. If you are interested in serving on this team, please complete this nomination form and return it to sarcomm@nerc.net with "Gen Verification SDT" in the subject line by July 30, 2007. For questions, please contact David Taylor at 609-651-5089 or david.taylor@nerc.net.

The drafting team will work on finalizing the following Phase III & IV standards:

- PRC-019 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection
- PRC-024 — Generator Performance during Frequency and Voltage Excursions
- MOD-026 — Verification of Models and Data for Generator Excitation System Functions
- MOD-027 — Verification of Generator Unit Frequency Response

The drafting team will also work on revising two existing standards that were not approved by the FERC because of their "fill-in-the-blank" elements:

- MOD-024 — Verification of Generator Gross and Net Real Power Capability
- MOD-025 — Verification of Generator Gross and Net Reactive Power Capability

Project 2007-12 — Frequency Response Standard Drafting Team (July 17–30, 2007)
The Standards Committee is seeking industry experts to serve on the Frequency Response Standard Drafting Team. The drafting team will work to develop a standard that requires entities to provide data so that Frequency Response in each of the Interconnections can be modeled, and the reasons for the decline in Frequency Response can be identified.

If you are interested in serving on this standard drafting team, please complete this nomination form and return it to sarcomm@nerc.net by July 30, 2007 with "FR SDT" in the subject line. For questions, please contact Linda Clarke at 610-310-7210 or linclrke@msn.com.

Project 2007-23 — Violation Severity Levels Drafting Team (July 17–30, 2007)
The Standards Committee is seeking industry experts to serve on the Violation Severity Levels SAR Drafting Team. The drafting team will work to achieve consensus on a set of criteria for assigning Violation Severity Levels, and will work (with other existing drafting teams) to replace "Levels of Non-compliance" with "Violation Severity Levels" in the 83 standards approved by the FERC. FERC directed NERC to replace "Levels of Non-compliance" with "Violation Severity Levels' so that the ERO's Sanctions Guidelines can be used as intended.

If you are interested in serving on this standard drafting team, please complete this nomination form and return it to sarcomm@nerc.net by July 30, 2007 with "VSL DT" in the subject line. For questions please contact Al Calafiore at 678-524-1188 or al.calafiore@nerc.net or Stephen Crutchfield at 609-651-9455 or stephen.crutchfield@nerc.net.

Standards Development Process
The *Reliability Standards Development Procedure* contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate. If you have any questions, please contact me at 813-468-5998 or maureen.long@nerc.net.

Sincerely,

Maureen E. Long

Nomination Form for Generator Verification Standard Drafting Team (Project 2007-09)

Please return this form to sarcomm@nerc.net by **July 30, 2007** with the words "**Gen Verification SDT**" in the subject line. If you have questions please contact Dave Taylor at david.taylor@nerc.net or by telephone at 609-651-5089.

Name:

Organization:

Address:

Office Telephone:

E-mail:

Please briefly describe your experience and qualifications to serve on the Generator Verification Standard Drafting Team. Prefer experience in developing generator models, in verifying generator capabilities, or in coordinating generator protection with transmission protection. Previous experience working on or applying NERC or IEEE standards is beneficial, but not a requirement.

I represent the following NERC Reliability Region(s) (check all that apply):		**I represent the following Industry Segment(s) (check all that apply):**
☐ ERCOT	☐	1 — Transmission Owners
☐ FRCC	☐	2 — RTOs, ISOs
☐ MRO	☐	3 — Load-serving Entities
☐ NPCC	☐	4 — Transmission-dependent Utilities
☐ RFC	☐	5 — Electric Generators
☐ SERC	☐	6 — Electricity Brokers, Aggregators, and Marketers
☐ SPP	☐	7 — Large Electricity End Users
☐ WECC	☐	8 — Small Electricity End Users
☐ NA – Not Applicable	☐	9 — Federal, State, and Provincial Regulatory or other Government Entities
	☐	10 – Regional Reliability Organizations and Regional Entities

Which of the following Function(s)[1] do you have expertise or responsibilities:

☐ Balancing Authority	☐ Planning Coordinator
☐ Compliance Monitor	☐ Transmission Operator
☐ Distribution Provider	☐ Transmission Owner
☐ Generator Operator	☐ Transmission Planner
☐ Generator Owner	☐ Transmission Service Provider
☐ Interchange Authority	☐ Purchasing-selling Entity
☐ Load-serving Entity	☐ Resource Planner
☐ Market Operator	☐ Reliability Coordinator

Provide the names and contact information for two references who could attest to your technical qualifications and your ability to work well in a group.

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

SAR authorized by Standards Committee for development as a reliability standard July 12, 2007.

Standard Drafting Team appointed by Standards Committee September 11, 2007.

Proposed Action Plan and Description of Current Draft:

This is the first draft of the proposed standard and includes requirements with violation risk factors, time horizons and measures; additional compliance elements will be added later. This first posting of the standard is for a 45-day comment period from February 17 through April 2, 2009.

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Post response to comments and second version of standard.	May 4, 2009
2. Post response to comments and request authorization to ballot the revised standard.	To be determined
3. Conduct initial ballot.	To be determined
4. Post response to comments.	To be determined
5. Conduct recirculation ballot.	To be determined
6. BOT adoption.	To be determined
7. File with regulatory authorities.	To be determined

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

None.

A. Introduction

1. **Title:** **Generator Frequency and Voltage Protective Relay Settings**

2. **Number:** PRC-024-1

3. **Purpose:** Ensure that generator frequency and voltage protective relays[1] are set to support transmission system stability during voltage and frequency excursions.

4. **Applicability**

   4.1. Functional entities:

   4.1.1 Generator Owners

   4.2. Facilities:

   4.2.1 Each generating unit (with installed voltage or frequency protective relays) greater than 20 MVA connected to the Bulk Electric System (BES).

   4.2.2 Each unit (with installed voltage or frequency protective relays) at generating plants/facilities consisting of multiple units with total generation > 75 MVA (gross aggregate nameplate rating) at the point of interconnection to the BES.

5. **Effective Dates:** The standard is effective the first day of the first calendar quarter after applicable regulatory approvals (or the standard otherwise becomes effective the first day of the first calendar quarter after NERC BOT adoption in those jurisdictions where regulatory approval is not required).

   Each Generator Owner's unit with installed voltage or frequency protective relays shall be compliant with the standard based on the following phased implementation schedule:

   5.1. No less than 33% of a Generator Owner's units shall be fully compliant with the standard within 1 year of the effective date of the standard.

   5.2. No less than 66% of a Generator Owner's units shall be fully compliant with the standard within 2 years of the effective date of the standard

   5.3. No less than 100% of a Generator Owner's units shall be fully compliant with the standard within 3 years of the effective date of the standard

A. Requirements

R1. Each Generator Owner shall set its installed generator frequency protective relaying not to trip during the following frequency-related operating conditions unless the Generator Owner has documented and reported the unit's limitation in accordance with Requirement R5: *(Violation Risk Factors: High - Units ≥500 MVA; Medium - Units >100 MVA and <500 MVA; Lower - Units ≤100 MVA) (Time Horizon – Operations Planning)*

R1.1. When operating within a frequency range of 59.5 Hz to 60.5 Hz, inclusive.

R1.2. During the off-normal frequency excursions specified in PRC-024-1 Attachment 1.

R1.3. Instantaneous underfrequency relay trip setting shall be set no higher than 57.8 Hz.

R1.4. Instantaneous overfrequency relay trip settings shall be set no lower than 62.2 Hz.

---

[1] Includes voltage and frequency protective functions for discrete relays, multi-function protective devices, voltage regulators, etc.

R2. Each Generator Owner shall set its installed generator over and under voltage (including volts per hertz relays evaluated at nominal frequency) protective relays not to trip during the steady-state and voltage-related operating conditions as follows unless the Generator Owner has documented and reported the unit's limitation in accordance with Requirement R5 of this standard: *(Violation Risk Factors: High - Units ≥500 MVA; Medium - Units >100 MVA and <500 MVA; Lower - Units ≤100 MVA) (Time Horizons – Operations Planning)*

R2.1. When operating within 95% to 105% of rated generator terminal voltage.

R2.2. During the transient voltage excursions measured at the point of interconnection to the BES as specified in PRC-024-1 Attachment 2. The following generator protective relaying settings are acceptable:

R2.2.1. For three-phase transmission system zone one faults with Normal Clearing, relaying may be set based on actual fault clearing times, but not greater than nine cycles.

R2.2.2. Relaying may be set to meet a shorter voltage ride through duration curve as specified by the Transmission Planner based on the location specific voltage recovery characteristics.

R2.2.3. Relaying may be set to trip a generator after fault initiation if this action is intended as part of a Special Protection System (SPS) or Remedial Action Scheme (RAS).

R2.2.4. Relaying may be set to trip a generator if clearing a system fault necessitates disconnecting the generator.

R3. Each Generator Owner shall provide to the Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners (that monitor or model the associated unit) its generator protection trip settings as specified by Requirement R1 and Requirement R2 within 30 calendar days of any change to those trip settings. *(Violation Risk Factor – Lower) (Time Horizon – Operations Planning)*

R4. Each Generator Owner shall provide to the Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners (that monitor or model the associated unit), its generator protection trip settings as specified by Requirement R1 and Requirement R2 within 30 calendar days of a written request for the data. *(Violation Risk Factor – Lower) (Time Horizon – Operations Planning)*

R5. If an existing generator unit[2] cannot meet either Requirement R1 or Requirement R2 due to equipment limitations, such as manufacturer warranty requirements or limitations that endanger the equipment according to published manufacturer instructions, (Protection System excluded), the Generator Owner is granted an exception for that unit from meeting the portion of Requirement R1 or R2 for that limitation once it provides documentation of the equipment limitation(s) to the Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners that monitor or model the associated unit, within 30 days of identifying the equipment limitation. *(Violation Risk Factors: Medium - Units >100 MVA; Lower - Units ≤100 MVA) (Time Horizon – Operations Planning)*

[2] Including generators under construction, generators with an executed interconnection agreement or Power Purchase Agreement, or generators with an executed equipment purchase contract and scheduled delivery within 2 years of the effective date of the standard.

The exception for the equipment limitation shall expire coincident with either of the following conditions:

- The equipment causing the limitation is replaced with equipment that removes the technical limitation.
- The equipment causing the limitation is modified or upgraded resulting in an increase of generator nameplate capacity rating greater than 10%.

R6. The Generator Owner shall provide a written response within 90 calendar days of receipt of written comments from a Reliability Coordinator, Planning Coordinator, Transmission Operator or Transmission Planner (that monitors or models the associated unit) regarding the equipment limitation. The response shall indicate whether a change will be made to the equipment limitation or if no change will be made to the equipment limitation, the reason why. *(Violation Risk Factor – Lower) (Time Horizon – Operations Planning)*

B. Measures

M1. Each Generator Owner shall have evidence such as setting sheets, calibration sheets, or other documentation, that generator frequency protective relays have been set in accordance with Requirement R1.

M2. Each Generator Owner shall have evidence such as setting sheets, voltage-time curves, calibration sheets, coordination plots or dynamic simulation studies, that generator voltage protective relays have been set in accordance with Requirement R2.

M3. Each Generator Owner shall have evidence such as dated e-mails, mail receipts or other documentation that generator protective relay settings changes have been communicated to the entities listed in Requirement R3.

M4. Each Generator Owner shall have evidence such as dated e-mails, mail receipts, request received or other documentation that generator protective relay settings have been communicated to the entities listed in Requirement R4.

M5. Each Generator Owner of existing generators that are unable to comply with Requirements R1 or R2 due to equipment limitations (Protection System excluded) shall have evidence such as warranty agreements, insurance agreements, manufacturers documented limitations, engineering analysis or other documentation that explains the equipment limitation of the unit(s).

M6. Each Generator Owner shall have evidence such as dated copy, e-mail receipts or other evidence that it provided a written response to a commenting entity within 90 calendar days of receipt of comments.

Time	Voltage
0.20	1.200
0.50	1.175
1.00	1.150
4.00	1.100

LVRT DURATION	
Time	Voltage
0.15	0.000
0.30	0.450
2.00	0.650
3.00	0.750
4.00	0.900

Voltage Ride-Through Curve Clarifications

1. The per unit voltage base for this curve is the nominal operating voltage as measured at the point of interconnection to the BES.
2. As long as the cumulative voltage duration at the point of interconnection with the BES is within the voltage boundaries of the curve, the generator voltage protective relaying will not trip the generator.
3. The curve depicted in this Attachment 2 assumes system frequency of 60 Hertz and all of the units connected to the same transformer are on line.

Unofficial Comment Form for the First Draft of PRC-024-1 — Generator Frequency and Voltage Protective Relay Settings (Project 2007-09)

Please **DO NOT** use this form. Please use the **electronic comment form** located at the link below to submit comments on the proposed first draft of the Generator Verification standard PRC-024-1 — Generator Frequency and Voltage Protective Relay Settings. Comments must be submitted by **April 2, 2009.** If you have questions please contact Harry Tom at harry.tom@nerc.net or by telephone at (860) 550-4157.

http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html

Background Information:

This comment form pertains to PRC-024-1 — Generator Frequency and Voltage Protective Relay Settings. The Generator Verification Standard Drafting Team (Project 2007-09) is comprised of six standards, one of which is PRC-024-1. These standards were originally "Phase III & IV Planning Measures" that were translated into new or a proposed standard as part of the Phase III & IV Standard Drafting Team effort. Collectively they set forth requirements to:

- Ensure generator and generator ancillary equipment are accurately modeled.
- Generator Protective Relay systems are appropriately set to "ride through" voltage and frequency excursions and to coordinate with load shed programs.
- Establish a regular process of verifying actual generator performance capability through periodic testing.

Draft standards that were field tested in 2006–2007 and are to be finalized as part of this project are:

PRC-019 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection

PRC-024 — Generator Frequency and Voltage Protective Relay Settings

MOD-026 — Verification of Models and Data for Generator Excitation System Functions

MOD-027 — Verification of Generator Unit Frequency Response

Standards to be revised as part of this project are:

MOD-024 — Verification of Generator Gross and Net Real Power Capability

MOD-025 — Verification of Generator Gross and Net Reactive Power Capability

PRC-024-1 — Generator Frequency and Voltage Protective Relay Settings was developed with consideration to key issues stated in the SAR:

- Provide more details to the applicability section of the standard to identify any generators that should be exempt from compliance with the requirements in the standard

- Replace the requirements assigned to the Regional Reliability Organization with a set of requirements that has more specificity and includes a set of ‘continent-wide’ criteria for verification that generators will remain connected during specified system frequency and voltage excursions
- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the Regional Reliability Organization
- Add a requirement for the Transmission Owner and Generator Owner to coordinate protection systems
- Add a ‘violation risk factor’ and a ‘time horizon’ for each requirement
- Update all the compliance sections of the standard, including:
    - Update the compliance monitoring section to clarify that the regional entity will be the compliance monitor for the generator owner
    - Replace the ‘levels of non-compliance’ with ‘violation severity levels’

The SDT first considered the purpose of the standard as defined in the SAR, the verifiable and measurable quantities in PRC-024-1 to ensure that the generators would stay connected are the relay settings in the generator protective relay schemes. The SDT has therefore proposed that standard PRC-024-1 be based on generator relay setting and coordination requirements, such as the time durations associated with various levels of voltage or frequency excursions.

For frequency excursions, this would include turbine under frequency protection relays. It was assumed by the SDT that excitation controls and limiters are set such that generator protective relays that are implemented to protect against excessive rotor field and stator over currents would not trip the unit as a result of the proposed frequency excursion.

For voltage excursions, only generator under or over voltage protective relays and volts per hertz relays would need to be evaluated to meet the draft requirements. Steady state evaluations only are expected. As such, dynamic simulations are not necessary to meet the requirements of the draft standard. The assessment of other generator protective relays that would require dynamic simulation to assess if they could ride through the proposed voltage excursion, such as generator backup over current or impedance, loss of field, are not within the scope of this draft standard.

In addition, the requirements are focused on the time immediately after a fault but before upsets to the auxiliary equipment could potentially cause the generator to trip.

The SDT next considered the “applicability”. Although the Generator Operator is the entity that can obtain the verified values of the relay settings, the Generator Owner is responsible for such settings.

In developing the proposed requirements, the SDT has reviewed the requirements of Regional Entities associated with potential voltage and frequency excursions, as well as simulated system responses to faults cleared with zone 1 and zone 2 distance relays. Understanding that some existing older generators were designed and constructed based on the then existing standards and may not be able to conform to the proposed new requirements, the SDT proposed that such limitations of existing generators be communicated to the Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners that monitor or model the associated unit so that they be accounted for in the simulations of system responses. However, the generator will be required to conform to the standard if limitations are removed, for example, through equipment upgrades.

The following questions will assist the SDT in finalizing the development of PRC-024-1 Generator Frequency and Voltage Protective Relay Settings. For questions where you agree with the SDT, please state that you agree and if available, please provide supporting documentation. If you disagree with the SDT, please explain why you disagree and provide data to support your position. To improve this first draft of PRC-024-1 Generator Frequency and Voltage Protective Relay Settings, the SDT would appreciate responses to as many of these questions as you can answer.

1. The PRC-024-1 Standard is applicable to the Generator Owner as opposed to Generator Operator, do you agree? If not, please explain in the comment area.

☐ Yes

☐ No

Comments:

2. The SDT has established the Requirements in this Standard only for the setting of voltage and frequency generator protective relays. Do you agree? If not, please explain in the comment area.

☐ Yes

☐ No

Comments:

3. PRC-024-1 specifies the limits for generator protective system settings as defined in PRC-024-1 - Attachment 1 and PRC-024-1 - Attachment 2. Are there generating units in your fleet that are not capable of meeting the thresholds in these attachments due to turbine/generator equipment design limitations?

☐ Yes

☐ No

Comments:

If yes, please estimate the percentage and total MW capacity of your units that cannot meet the requirement.

Estimated percentage of units that can't meet thresholds due to design limitations:

Estimated total MW capacity of units that cannot meet the requirement:

4. The curve in PRC-024-1 - Attachment 2 was based upon analysis performed of simulated system disturbances. System voltage traces representative of several hundred disturbances were co-plotted on a voltage versus time graph. The voltage duration curve in this attachment is derived from these voltage traces. A margin was then applied to the voltage duration curve to account for unanticipated system conditions. The 9 cycle fault clearing time required by the FERC 661-A Order is incorporated into this curve. Given this background on the development of PRC-024-1 - Attachment 2, do you agree with the parameters of the curve? If not, please explain in the comment area.

☐ Yes

☐ No

Comments:

5. Coordination between UFLS programs and generator frequency tripping is especially a concern in islanded situations. Is the connection voltage of ≥100kV, the size threshold for generator units 20 MVA and greater and 75 MVA for multiple units at a single site, sufficient to address this concern? If not, please explain in the comment area.

☐ Yes

☐ No

Comments:

6. The SDT proposed a set of VRFs based on size delineation of units. Do you agree with this approach? Do you agree with the MVA levels? If you disagree with either the approach or the MVA levels, please explain in the comment area.

☐ Yes I agree with the approach

☐ No I disagree with the approach

Comments:

Do you agree with the MVA levels?

☐ Yes

☐ No

Comments:

7. If you are aware of any regional variances that would be required as a result of this standard please identify the regional variance here.

Regional Variance:

8. If you aware of any conflicts between the proposed standard and any regulatory function, rule order, tariff, rate schedule, legislative requirement or agreement, please identify the conflict here.

Conflict:

9. Are there other improvements that the SDT should consider for this revision of PRC-024-1 that you haven't already identified in response to other questions? If yes, please provide in the comment area.

☐ Yes

☐ No

Field Tested Version of PRC-024 Mapped to Proposed PRC-024-1, Generator Frequency and Voltage Protective Relay Settings

Field Tested Version of PRC-024	Comment	Proposed PRC-024-1
2. Number: PRC-024-0	Proposed standard will only cover PRC-024-0 content and will not be merged with any other standard	**2. Number:** PRC-024-1
1. Title: Generator Performance During Frequency and Voltage Excursions	Protective System has been added to reflect the scope of the related requirements in the proposed Standard	**1. Title:** Generator Frequency and Voltage Protective Relay Settings
3. Purpose: To ensure that generators remain connected to the electrical grid during voltage and frequency excursions and are not normally tripped manually or by preset protection schemes during frequency and voltage excursions.	The Purpose has been modified to specifically focus on the coordination of protection schemes.	**3. Purpose:** Ensure that generator frequency and voltage protective relays[1] are set to support transmission system stability during voltage and frequency excursions. [1] Includes voltage and frequency protective functions for discrete relays, multi-function protective devices, voltage regulators, etc.
4. Applicability: **4.1.** Regional Reliability Organizations. **4.2.** Generation Owners. **4.3.** Transmission Owners	Regional Reliability Organization and Transmission Owner applicability is eliminated. The Standard further specifies which facilities must comply.	**4. Applicability** **4.1.** Functional entities: **4.1.1** Generator Owners **4.2.** Facilities: **4.2.1** Each generating unit (with installed voltage or frequency protective relays) greater than 20 MVA connected to the Bulk Electric System, **4.2.2** Each unit (with installed voltage or frequency protective relays) at generating plants/facilities consisting of

Field Tested Version of PRC-024	Comment	Proposed PRC-024-1
		multiple units with total generation > 75 MVA (gross aggregate nameplate rating) at the point of interconnection to the Bulk Electric System
R1. The Regional Reliability Organization shall establish requirements for generators to remain connected during system frequency and voltage excursions expressed as a function of:	Regional applicability is eliminated and direct entity responsibility is defined	Requirements R1, & R2 define the verification and data reporting previously addressed by regional procedures. These requirements are detailed in the following mapping.
R1.1. Time duration in seconds or cycles **R1.2.** Amplitude or magnitude of the excursion **R1.3.** Relationship between time and amplitude or magnitude	The details of the frequency excursions are defined in **R1.1, R1.2, R1.3, R1.4,** and **Attachment 1-PRC-024-1**. The details of the voltage excursions are defined in **R2.1, R2.2, R2.2.1, R2.2.2, R2.2.3, R2.2.4,** and **Attachment 2-PRC-024-1**.	**R1**. Each Generator Owner shall set its installed generator frequency protective relaying not to trip during the following frequency-related operating conditions unless the Generator Owner has documented and reported the unit's limitation in accordance with Requirement R5: (Violation Risk Factors: High - Units ≥500 MVA; Medium - Units >100 MVA and <500 MVA; Lower - Units ≤100 MVA) (Time Horizon – Operations Planning) **R1.1.** When operating within a frequency range of 59.5 Hz to 60.5 Hz, inclusive. **R1.2**. During the off-normal frequency excursions specified in PRC-024-1 Attachment 1. **R1.3**. Instantaneous underfrequency relay trip setting shall be set no higher than 57.8 Hz. **R1.4.** Instantaneous overfrequency relay trip settings shall be set no lower than 62.2 Hz. **R2.** Each Generator Owner shall set its installed generator over and under voltage (including volts per hertz relays evaluated at nominal frequency) protective relays not to trip during the steady-state and voltage-related operating conditions as follows unless the Generator Owner has documented and reported the unit's limitation in accordance with Requirement R5: (Violation Risk Factors: High - Units ≥500 MVA; Medium - Units >100 MVA and <500 MVA; Lower - Units ≤100 MVA)

Field Tested Version of PRC-024	Comment	Proposed PRC-024-1
		(Time Horizons – Operations Planning) **R2.1.** When operating within 95% to 105% of rated generator terminal voltage. **R2.2.** During the transient voltage excursions measured at the point of interconnection to the BES as specified in PRC-024-1 Attachment 2. The following generator protective relaying settings are acceptable: **R2.2.1** For three-phase transmission system zone one faults with Normal Clearing, relaying may be set based on actual fault clearing times, but not greater than nine cycles. **R2.2.2.** Relaying may be set to meet a shorter voltage ride through duration curve as specified by the Transmission Planner based on the location specific voltage recovery characteristics. **R2.2.3.** Relaying may be set to trip a generator after fault initiation if this action is intended as part of a Special Protection Scheme (SPS) or Remedial Action Scheme (RAS). **R2.2.4.** Relaying may be set to trip a generator if clearing a system fault necessitates disconnecting the generator.
R2. The Regional Reliability Organization shall establish and maintain requirements for generators to remain connected during frequency and voltage excursions. These requirements shall include:	Regional applicability is eliminated and direct entity responsibility is defined. Requirements **R1.2, R1.3,** and **R1.4** define the requirements for generator off-nominal frequency protective relay settings so that generating units remain connected during frequency excursions. Requirements **R2.2, R2.21, R2.2.2, R2.2.3** and **R2.2.4** define the requirements for	**R1.2**. During the off-normal frequency excursions specified in PRC-024-1 Attachment 1. **R1.3**. Instantaneous underfrequency relay trip setting shall be set no higher than 57.8 Hz. **R1.4.** Instantaneous overfrequency relay trip settings shall be set no lower than 62.2 Hz. **R2.2.** During the transient voltage excursions measured at the point of interconnection to the BES as specified in PRC-024-1 Attachment 2. The following generator protective relaying settings are acceptable: **R2.2.1** For three-phase transmission system zone one faults with Normal Clearing, relaying may be set based on actual fault clearing times, but not greater than nine cycles. **R2.2.2.** Relaying may be set to meet a shorter voltage ride through duration curve as specified by the Transmission Planner based on the location specific voltage recovery characteristics.

Field Tested Version of PRC-024	Comment	Proposed PRC-024-1
	generator under and over voltage protective relay settings so that generating units remain connected during voltage excursions.	**R2.2.3.** Relaying may be set to trip a generator after fault initiation if this action is intended as part of a Special Protection Scheme (SPS) or Remedial Action Scheme (RAS). **R2.2.4.** Relaying may be set to trip a generator if clearing a system fault necessitates disconnecting the generator.
R2.1. Coordination between the generator under frequency protection and the regional Under Frequency Load Shedding (UFLS) program.	During the drafting of this Standard, the Generator Verification Standard Drafting Team (GV SDT) maintained contact with the Under Frequency Load Shedding Standard Drafting Team (UFLS SDT) to ensure that the requirements of this Standard coordinated with the requirements being developed by the UFLS SDT. Requirements **R1, R1.1, R1.2, R1.3, R1.4, and Attachment 1-PRC-024-1** coordinate with the UFLS SDT effort.	**R1**. Each Generator Owner shall set installed generator frequency protective relaying not to trip during the following frequency-related operating conditions unless the Generator Owner has documented and reported the unit's limitation in accordance with Requirement R5: (Violation Risk Factors: High - Units ≥500 MVA; Medium - Units >100 MVA and <500 MVA; Lower - Units ≤100 MVA) (Time Horizon – Operations Planning) **R1.1.** When operating within a frequency range of 59.5 Hz to 60.5 Hz, inclusive. **R1.2**. During the off-normal frequency excursions specified in PRC-024-1 Attachment 1. **R1.3**. Instantaneous underfrequency relay trip setting shall be set no higher than 57.8 Hz. **R1.4.** Instantaneous overfrequency relay trip settings shall be set no lower than 62.2 Hz.
R2.2. Coordination of generator protection, including back-up protection, with transmission Protection Systems.	The GV SDT created requirements for generator over and under voltage protective relay settings based on a voltage excursion defined by FERC Order 693 and low voltage excursion studies performed in WECC and SERC. Requirements **R2, R2.1, R2.2,**	**R2.** Each Generator Owner shall set installed generator over and under voltage (including volts per hertz relays evaluated at nominal frequency) protective relays not to trip during the steady-state and voltage-related operating conditions as follows unless the Generator Owner has documented and reported the unit's limitation in accordance with Requirement R5: (Violation Risk Factors: High - Units ≥500 MVA; Medium - Units >100 MVA and <500 MVA; Lower - Units ≤100 MVA) (Time Horizons – Operations Planning) **R2.1.** When operating within 95% to 105% of rated generator terminal voltage. **R2.2.** During the transient voltage excursions measured at the point of

Field Tested Version of PRC-024	Comment	Proposed PRC-024-1
	R2.2.1, R2.2.2, R2.2.3, R2.2.4, and Attachment 2-PRC-024-2 define these requirements. The GV SDT feels that coordination between the generator protection system and transmission protection system beyond that defined in this Standard is covered under **PRC-001 R3.**	interconnection to the BES as specified in PRC-024-1 Attachment 2. The following generator protective relaying settings are acceptable: **R2.2.1** For three-phase transmission system zone one faults with Normal Clearing, relaying may be set based on actual fault clearing times, but not greater than nine cycles. **R2.2.2.** Relaying may be set to meet a shorter voltage ride through duration curve as specified by the Transmission Planner based on the location specific voltage recovery characteristics. **R2.2.3.** Relaying may be set to trip a generator after fault initiation if this action is intended as part of a Special Protection Scheme (SPS) or Remedial Action Scheme (RAS). **R2.2.4.** Relaying may be set to trip a generator if clearing a system fault necessitates disconnecting the generator.
	New	**R3.** Each Generator Owner shall provide to the Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners (that monitor or model the associated unit) its generator protection trip settings as specified by Requirement R1 and Requirement R2 within 30 calendar days of any change to those trip settings. *(Violation Risk Factor – Lower) (Time Horizon – Operations Planning)* **R4.** Each Generator Owner shall provide to the Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners (that monitor or model the associated unit) its generator protection trip settings as specified by Requirement R1 and Requirement R2 within 30 calendar days of a written request for the data. *(Violation Risk Factor – Lower) (Time Horizon – Operations Planning)*
R3. The Regional Reliability Organization shall establish and maintain criteria for exemptions to any of the regional requirements established in accordance with R1 and R2.	Regional Reliability Organization applicability is eliminated and direct entity responsibility is defined	**R5**. If an existing generator unit[2] cannot meet either Requirement R1 or Requirement R2 due to equipment limitations, such as manufacturer warranty requirements or limitations that endangers the equipment according to published manufacturer instructions, (Protection System excluded), the Generator Owner is granted an exception for that unit from meeting the portion of Requirement R1 or R2 for that limitation

Field Tested Version of PRC-024	Comment	Proposed PRC-024-1
	R5 defines the criteria for exceptions from the frequency and voltage requirements and the process to use for reporting this to the Reliability Coordinators, Planning Coordinators, Transmission Operators, and Transmission Planners. **R6** defines the process for the Generator Owner to respond to comments on the notification of exception.	once it provides documentation of the equipment limitation(s) to the Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners that monitor or model the associated unit, within 30 days of identifying the equipment limitation. *(Violation Risk Factors: Medium - Units >100 MVA; Lower - Units ≤100 MVA) (Time Horizon – Operations Planning)* The exception for the equipment limitation shall expire coincident with either of the following conditions: • The equipment causing the limitation is replaced with equipment that removes the technical limitation. • The equipment causing the limitation is modified or upgraded resulting in an increase of nameplate capacity rating greater than 10%. [2] Including generators under construction, generators with an executed interconnection agreement or Power Purchase Agreement, or generators with an executed equipment purchase contract and scheduled delivery within 2 years of the effective date of the standard. **R6**. The Generator Owner shall provide a written response within 90 calendar days of receipt of written comments from a Reliability Coordinator, Planning Coordinator, Transmission Operator or Transmission Planner (that monitors or models the associated unit) regarding the equipment limitation. The response shall indicate whether a change will be made to the equipment limitation or if no change will be made to the equipment limitation, the reason why. *(Violation Risk Factor – Lower) (Time Horizon – Operations Planning)*
R4. The Regional Reliability Organization shall establish and maintain a procedure for handling variances (i.e., different criteria or methods) from the Regional Reliability Organization's requirements established in R1 and R2, including steps for requesting and approving such variances.	Regional Reliability Organization applicability is eliminated and direct entity responsibility is defined. For the low voltage portion of the **Attachment 2-PRC-024-1**, **R2.2.2** allows the Transmission	**R2.2.2.** Relaying may be set to meet a shorter voltage ride through duration curve as specified by the Transmission Planner based on the location specific voltage recovery characteristics.

Field Tested Version of PRC-024	Comment	Proposed PRC-024-1
	Planner to modify the shape of the curve based on location-specific breaker clearing time and voltage recovery characteristics.	
R5. The Regional Reliability Organization shall provide documentation of its excursion requirements, exemptions, and variance procedure to the Transmission Owners and Generator Owners within its Region within 30 calendar days of approval.	Regional Reliability Organization applicability is eliminated. Since the excursion requirements, exemptions and variance procedures are defined in the Standard, there are no requirements for communication to applicable entities.	This is not addressed by any requirement of the proposed Standard because it is no longer applicable.
R6. The Regional Reliability Organization shall, at least every five years, review and, as necessary, update its requirements, exemption criteria, and variance procedure.	Regional Reliability Organization applicability is eliminated. Since the excursion requirements, exemptions and variance procedures are defined in the Standard, the method for making modifications involves implementing the NERC SAR process.	This is not addressed by any requirement of the proposed Standard because it is no longer applicable.
R7. Generator Owners and Transmission Owners shall comply with the regional requirements for coordination of generator protection defined in R2 and any approved variances	Transmission Owner applicability is eliminated. The requirement for a Generator Owner to comply with the requirements in this Standard is implicit in being an applicable entity.	This is addressed by the Applicability section of the proposed Standard.

Standards Announcement

Comment Periods Open
February 17 – April 2, 2009

Now available at: http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html

Two Proposed Standards for Project 2007-09 — Generator Verification

The Generator Verification Standard Drafting Team (Project 2007-09) has posted drafts of two proposed standards for 45-day comment periods. Mapping documents that compare these standards with field-tested versions are also posted. The comment periods are now **open until 8 p.m. EDT on April 2, 2009**. Please use the electronic forms (see links below) to submit comments. If you experience any difficulties in using the electronic forms, please contact Lauren Koller at 609-524-7047. Off-line, unofficial copies of the comment forms are posted on the project page: http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html

PRC-024-1 — Generator Performance During Frequency and Voltage Excursions

Electronic comment form:
https://www.nerc.net/nercsurvey/Survey.aspx?s=aaa41c53fb80462e8783344cd70f6ce0

Note: the drafting team will hold a WebEx to explain the concepts in proposed standard PRC-024-1 on February 26 from 2 p.m. to 4 p.m. EST. More information about the WebEx will be sent in a separate announcement.

MOD-026-1 — Verification of Models and Data for Generator Excitation System Functions

Electronic comment form:

Background

Project 2007-09 includes six standards to address generator verifications needed to support bulk power system reliability – four proposed standards and revisions to two existing standards. The purpose of the project is:

- To ensure that generators will not trip off-line during specified voltage and frequency excursions or as a result of improper coordination between generator protective relays and generator voltage regulator controls and limit functions (such coordination will include the generating unit's capabilities).
- To ensure that generator models accurately reflect the generator's capabilities and operating characteristics.

More information is available on the project Web page:
http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html

Standards Development Process

The Reliability Standards Development Procedure contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

No
I believe it should be applicable to both.
Yes
No
please see my further comments on this.
No
Yes I agree with the approach
Yes
Yes
0. (Overall) This is a good document that has good background study and contains a lot of expertise; 1. (Voltage definition inconsistency)In the LVRT curves, it talks about the voltage at

the point of interconnection. However, in R2.1 it uses voltage at the generator terminals. I think there is a little inconsistency between these two. It would be good to just use one of them, preferably the former one. The reason is that different generator plants might have different impedance between the generator terminals and the points of interconnection, so defining the voltage at the terminals poses a little unfairness. Another part of the reason is that for transmission protection purpose, it should ends at the point of interconnection. 2. (Voltage range inconsistency)The voltage range is 0.9-1.1pu in the VRT curve, but it says 0.95-1.05 in R2.1. It would be good to make it consistent. 3. (Date point missing) In the table supporting the VRT curves, the 0.95 and 1.05pu data are missing. 4. (Priority) WECC and MRO have different VRT curves. Which one will override which one at the end? Will the NERC PRC-024 take priority than the Regional Entities? 5. Was reactive power support during faults considered in the draft group? Will it be required in the future? Thanks

Consumers Energy Company
Yes
Yes
No
Consumers Energy doesn't have generating units that cannot meet the thresholds. However, we would like to offer the following comments: The Standards Drafting Team should be congratulated for the excellent curves in Attachment 1. A review of our fleet which contains units of several vintages, manufactured by General Electric, Westinghouse, Siemens, and Allis-Chalmers, shows that turbine-generators from all of these manufacturers comply with these curves. To assist Generator Owners and Compliance Auditors, the SDT should furnish mathematical formulae for the "slanted lines" in the curves. Should a Generator Owner elect to set an underfrequency relay at 120 seconds and 59.1 Hz, there might be uncertainty or disagreement about compliance, depending upon how the interpolation of the graph is viewed. Interpolation from a semi-log plot is often not easy. This uncertainty can and should be eliminated by including the two formulae in Attachment 1.
Yes
Yes
We believe this is sufficient to address the concern if this picks up the wind farms that are a growing part of generating capacity.
Yes I agree with the approach

Generator Owner is responsible for the maintenance of the facility. Relay settings are a Generator Owner function.
No
I disagree in principle that NERC is dictating how generator protective relays are set. These relays are set to protect the generation equipment and ensure long term reliability of the unit. Dictating settings which enhances ride through capability ensure short term reliability and can hurt long term reliability. If this if force upon us, I agree with only addressing the voltage and frequency generator protective relays.
No
Yes

I do not know enough about this to comment either way
Yes

NERC System Protection and Control Subcommittee (SPCS)
John Ciufo - SPCS
Hydro One
Yes
No
PRC-024 should only apply to non-synchronous machines. The SPCS believes that coordination of synchronous generator voltage and frequency protective relays with transmission relays should not be addressed in PRC-024. An effort is underway to address coordination of generator voltage and frequency protective relay settings with transmission protection systems either by modifications to PRC-001 or the development of a new SAR to address coordination requirements. SPCS is preparing a Technical Reference paper on such coordination that is expected to be completed in June, 2009. Generator voltage and frequency protective relays are included in that that paper. The purpose as stated in the SAR is "To ensure that generators will not trip off-line during specified voltage and frequency excursions." The Standard will not accomplish its stated purpose by limiting requirements to generator protective relays alone. In fact it may actually have the exact opposite consequence. Undervoltage relays are not usually set on most synchronous generators. When undervoltage relays are applied, IEEE C37.102 recommends alarm rather than trip. The more likely cause for the loss of a generator due to a dip in voltage is from the loss of equipment on the auxiliary bus. This was the cause sited for a well documented event on March 27, 1994 losing all generating units at Cinergy's Gibson Station. Other events since 1994 were also due to tripping of generators due to loss of auxiliary busses caused by voltage dips from system faults. In fact, the Standard may result in the unintended consequence of reducing reliability. Many generator owners may take the recommendation as an implied directive to set previously unused generator undervoltage relay elements to the minimums stated in the Standard. That would cause more generator trips for system faults rather than fewer trips. Similarly, many generators that currently do not have undervoltage relay settings would trip at various other inherent voltage levels during a voltage excursion. With all of them set at or about 0.90 per unit, they would all trip at the same point, causing a catastrophic loss of generation. There are significant machine protection issues which are not addressed, such as the Volts/Hertz relay which protects the machine from an over-fluxing thermal hazard. Loss of generation consequential to problems on auxiliaries is a significant problem, which is not addressed in this Standard.
No
FERC 661-A is a wind generator facility ride-through performance criterion, not a synchronous generator relay setting requirement. They cannot be compared as being equivalent. A synchronous generator undervoltage capability will be quite different from an entire wind facility undervoltage ride-through capability. The 9 cycle zero voltage interval is inadequate. The 9 cycle setting would cover for most normally cleared faults but generators must also remain on line through faults with delayed clearing due to breaker failure as required in the NERC TPL Standards. The time interval for such clearing is more typically 12 to 15 cycles. This time delay can increase to 0.5 seconds if high speed protection is out of service, for example a single relay communication channel, at the time of a fault and the fault is then cleared in zone 2 time. SPCS believes that R.R.1 is worded in a confusing way. It implies that you had to trip in 9 cycles or less â€“ rather than not trip for a minimum of 9 cycles- albeit we want to wait longer than that. SPCS respectfully questions whether it is conceptually possible to properly state these criteria as a single curve. It is more appropriate to have separate requirements for wind generation and other generators. Additionally, they should differ related to points of interconnections (a contractual arrangement), and refer to the high-side of the GSU for all other generation. This would lend consistency and avoid unnecessary confusion. There are a number of important

issues that arise with current approach, including: ï‚§ In general, generator protection should not trip generators on UV, but should alarm, as stated in IEEE C37.102. Please also see latest C50.12 and C50.13. UV is generally a thermal consideration and an alarm is more appropriate to call operator attention to a malfunction. ï‚§ The existence of a curve such as this in a NERC Standard will lead to generator owners enabling UV relays to trip and setting them per the curve, which is a serious danger to system reliability. ï‚§ For some specific situations such as unmanned hydro units, tripping on time-UV may be considered. ï‚§ The idea of a ride-through curve originated with wind farms, and is not generally conceptually appropriate for other generators. For example, this approach is not conceptually appropriate for cylindrical rotor synchronous machines. ï‚§ The Voltages presented are at the point of interconnection and are not directly translatable to machine relay voltage settings. ï‚§ Machine Volts/Hertz curves are a significant issue and are not addressed. ï‚§ The UV performance of plant auxiliaries is a significant issue, and is not addressed. ï‚§ The standard should be very clear to discourage plant owners from setting under- and over- voltage relays if they don't already have them, or need them for very specific situations. SPCS also is concerned because it appears the SDT has considered only the positive sequence voltage in developing the curves in Attachment 2. Overvoltage relays measure individual phase-to-ground or phase-to-phase quantities and SPCS expect that generator owners will apply these curves based on the quantities measured by the relays in developing relay settings. As such, the curves must be based on the quantities that are measured by protective relays and the quantities must be clearly stated. To highlight our concern, consider that for a line-to-ground fault at the point of interconnection on an effectively grounded system the unfaulted phases may have fundamental frequency voltages of 125% or more for the duration of the fault. Under such conditions generators with overvoltage relays set per the curve may trip at 120% voltage prior to clearing the fault from the transmission system. Under these conditions tripping is not required for generator protection and may have a detrimental impact on system reliability, yet it is permissible per the proposed curve. There is guidance in the industry and C37.102 to provide dielectric (insulation) protection for extremely high voltages, however 120 % voltage is overprotecting the generator. For Generator protection, the first line of defense is generator surge arrestors but some units may also use a high set overvoltage protection as well. This voltage is a much higher level then 120% shown in the curve (i.e. 150% of rated voltage). Voltage relays applied to the system side of the generator step-up transformer should be configured and set in such a way that they do trip the generator for higher voltages on unfaulted phases for phase-to- ground faults. As you may know generator windings are sometimes tested with high potential: New machines can be tested as high as twice (200%) rated line-to-line voltage plus 1000 Volts (Commissioning High Pot) for one minute. Older Machines that are in service for significant time can be tested at 125% to 150% of rated line-to-line voltage (Maintenance High Pot) for one minute. There are some industry differences of opinion on this topic of course but 120% instantaneously is too low. Voltage settings are based on type of insulation material (Class F is in common present days) and its thickness. A curve would need to be developed that takes insulation thickness into account. USBR's practice is to use manufacture designed 105% continuous. Then, 59 is set a 110% of 105% (continuous use) for time coordination (TOV) and 130% of 105% of phase-to-ground voltage for instantaneous (IOV).
No
The interconnection Voltage is not relevant, only the amount of generation potentially lost to the system.
The FRCC UFLS has a requirement for generators to remain on line for 1 second with frequency down to 57.5 Hz. Regional differences are developing as the Regions perform studies to current UFLS strategies while considering the coordination requirements of generator underfrequency tripping. To date, NPCC and FRCC may be the only regions that have completed their studies. It is recommended that PRC- 024-1 wait on going forward in the standards process until the regions conclude their studies and develop their requirements based on their particular portions of the interconnected power system.
Yes
PRC-024 should only apply to non-synchronous machines. Coordination of synchronous generator voltage and frequency protective relay settings with transmission protection systems should be addressed along with all other coordination in PRC-001 â€“ Protection coordination. SPCS is preparing a Technical Reference paper on such coordination that is expected to be completed in June, 2009. Generator voltage and frequency protective relays are included in that that paper. The Attachment 2 voltage ride through curve was developed, to SPCSâ€™ understanding, by compiling a number of system events delineating those events whereby the tripping of generators would exacerbate the event. It does not appear that the SDT analyzed data from the August 14, 2003 Northeast Blackout. Actual data from the event in Michigan, before the system cascaded and broke apart revealed 345 kV system voltages of less than 0.9 per unit. Some

generators in Michigan tripped by undervoltage relays set at 0.9 per unit that significantly accelerated the cascade. Even those generators along the western fringe of the soon-to-be separated power system were of event more concern; data indicated these large units were experiencing 345-kV voltages of less than 0.9 per unit. Those generators did not trip because they did not have undervoltage relaying set to trip. Had these units tripped on undervoltage relaying, the event would have extended much further to the west of the actual impacted area. The Standard requires generator relays to be set based on a voltage at the interconnection point to the BES. However the relays are typically connected to a voltage source at the generator, not the BES interconnection. The translation from generator terminal voltage to a point of interconnection voltage is not a direct relationship. It will vary depending upon the assumption made for generator real and reactive output, or the distance to the â€œpoint of interconnection.â€ The Standard gives no direction regarding these assumptions. The voltage to be sensed must be the generator terminal voltage. IEEE C50.13 describes the standards to which the modern generators were built. This standard recommends reducing unit output after ascertaining the presence of an undervoltage alarm. This standard does not recommend unit tripping. Totally different relay settings will be obtained with different generator output assumptions. This lack of consistency will make it impossible to determine if compliance to the Standard is achieved. SPCS also have concerns with the overfrequency curve in Attachment 1 in light of the August 14, 2003 Northeast Cascade and Blackout. During the sequence of events an island formed consisting of portions of western New York and eastern Ontario with a significant generation-load mismatch. The surplus generation in the island resulted in an overfrequency condition to which several large generating units responded to arrest the overfrequency at 63 Hz. Had those units been set to trip on the proposed curve on August 14, the units would have tripped prematurely potentially leading to a collapse of the island. While the overfrequency curve may be acceptable as a floor for setting the overfrequency relays, there should also be a requirement to coordinate the overfrequency tripping with the unit controls and unit capability to maximize the ability of machines to control overfrequency while operating within their capability. Undervoltage alarms as experienced by hydro, fossil, combustion, and nuclear units are an indicator of possible thermal issues within the generator. Other alarms from RTDs and hydrogen pressure are better indicators. Manufacturers recommend operator action up to and including reduction in unit output rather than a unit trip. Tripping units on undervoltage is not recommended by the IEEE C37.102 standard on generator protection. Rather C37.102 also recommends alarm. Each type of unit, hydro, fossil, nuclear, combustion, and renewable generator have different thermal issues relating to system undervoltage. A single curve over-simplifies the issue to the point that system reliability is degraded. If any curve is included, it should be focused only on wind turbines as they have voltage ride through controls. Attachment 2 requires voltage evaluation at the system voltage level. Concerning Attachment 1, SPCS believes this is mainly present to insure that generator tripping will not interfere with UFLS programs. There should be a statement that settings should not interfere with UFLS program in effect. Also on Attachment 1, this is now labeled "Off Nominal Frequency Capability Curve." SPCS suggests that the word "capability" in this label is potentially misleading. This is not a machine capability curve. There should be a statement that protective device settings should be based on machine damage considerations and should be arrived at in consultation with the machine manufacturer. The curve presents limits to those settings which are designed to prevent interference with UFLS programs. The SDT has not described how the curve was compiled. Technical committees within the IEEE went to great lengths to describe the turbine blading off-frequency limitation curves. Every manufacturer submitted their curve and a family of curves was created that showed distinct curves for each manufacturer. The NERC 1978 document, "Underfrequency and Undervoltage Relay Applications Large Turbine Generators included a collection of individual manufacturer which when plotted together provided a prospective on the widely varying limits of the various turbines. There is a danger of misinterpretation to use one curve. In PRC-024-1 there was no description stating how the curve was developed. If a machine is not at risk and if a UFLS simulation shows that the bottom frequency will occur outside of the "one size fits all curve" then there should be a provision to use the manufacturer's curve rather than shed more load just to fit the attachment 1 curve. A.R1 and A.R2 wording could be taken to require that such relaying should be enabled and set. The phrase "Installed â€¦ relaying not to trip during â€¦" could be taken to mean that such relaying is assumed to be, or should be, installed. Also, in the case of generator multifunction protective devised, such relaying is always installed but it is not appropriate in many cases that it be enabled and set. Note this consideration applies to both frequency and Voltage. In general, this Standard should take care to point out that any protection application should be based on actual specific machine protective considerations which should be arrived at in consultation with the machine manufacturer. Concerning A.R1.2 and Attachment 1, the language refers to a â€œno trip zone" between curves, and obviously there is a permissible trip zone outside the curves. Questions will arise on permissibility of settings which are actually on the curves. SPCS would suggest that setting directly on the curves should be permitted. For example, if 1.0 seconds at 57.8 Hz is directly on the curve, failure to deal with this question will result in pointless and counterproductive settings such as 1.0 seconds at 57.79 Hz. SPCS suggests "Setting directly on the curves is permitted, and settings outside the curves are permitted." Concerning A.R2, this Standard addresses setting of Voltage relays based on Voltage

at the point of interconnection, which is not directly translatable to Voltage at the generator terminals. The generator real and reactive power output will affect the relationship, and this is not dealt with in this Standard. Simply setting the generator protection relay at 0.90 per unit may, in fact, be an incorrect setting to achieve the desired performance. Settings must include allowances for all equipment tolerances: voltage transformer errors, relay tolerances, and testing instrumentation errors. The actual setting needed to account for such variances may require that the relay be actually set to trip at 0.84 or 0.86, or some other seemingly conflicting value, in order to achieve the goal of not tripping at 0.90 per unit.

All generators identified in a transmission owner's restoration plan warrant a high VRF. Additionally, generators â‰¥ 500 MVA warrant a high, generators > 100 MVA but < 500 MVA warrant a medium and generators â‰¤ 100 MVA warranty a low VRF

Yes

We are not aware of any. However, we are aware that a number of regions have draft UFLS standards that apply to generators despite the fact NERC Reliability Standards PRC-007, PRC-008 and PRC-009 do not contain either GO or GOP in the applicability section. These regional drafts contain provisions that require non-conforming generators to acquire 'load shed' service. We have repeatedly cited our inability to find any entity that would offer such service as well as technical difficulties in developing a UFLS predicted upon such a service. Despite our comments, the latest drafts continue to require non-conforming generators to acquire 'load shed' service.

Yes. We are aware of agreements between some generators and their respective transmission owners that contain frequency coordination requirements that differ from those in Table 1, and that, in some cases, the transmission facility(ies) that connects the generator to the BES has underfrequency tripping that would operate prior to the levels shown in Table 1, thus negating any modification that a generator might make to conform. We suggest that this standard also exempt these GOs from meeting R1 and R2 and that R5 be modified to allow for such exception.

Yes

We would like to commend the SDT for recognizing that there may be technical reasons that prevent a generator from meeting requirements 1 and 2 and allowing an exemption when technical basis is provided (R5). There is a paragraph on the second page which states that " For voltage excursions, only generator under or over voltage protective relays and volts per hertz relays would need to be evaluated to meet the draft requirements. Steady state evaluations only are expected " We have the following questions: (1) Do the relays mentioned in the statement above include auxiliary system under voltage relays? It appears the voltage relay part of the standard is limited to only relays that directly trip the generator and not relays that trip auxiliaries. Is that the intent? What if the relay was attached to an auxiliary bus, but tripped the generator? (2) How is that only steady state evaluations are enough? How do you study voltage recovery characteristics without dynamic simulations? If the standard is intended to apply to volts per hertz relays, suggest: 1. Revising footnote 1 to specifically include volts per hertz relays. 2. Revise Steps 4.2.1 and 4.2.2 to specifically include volts per hertz relays. 3. That the standard should incorporate specific guidance for facilities using volts per hertz logics and include a graph showing the voltage and frequency excursions in terms of volts per hertz.

No

Both bullets should be checked above (form will not accept). The responses received were divided, and below are the comments received for your consideration. The Generator Operators, and not the Generator Owners, are typically responsible for establishing relay setpoints, calibrations, and maintenance. The Generator Owner is the Functional Model entity that has direct control over the generating unit protection settings.

No

Both bullets should be checked above (form will not accept). The proposed standard addresses all issues identified in the Standard Authorization Request. Coordination of generator and transmission system protection is addressed in PRC-001. As presently constituted this Standard will likey result in the inappropriate enabling and setting of frequency and voltage relays with the settings which are permitted, thus reducing system reliability, which is contrary to its stated

purpose. This is supported in the comments provided below. There are significant machine protection issues which are not addressed, such as Volts per Hertz. Loss of generation consequential to problems on auxiliary systems, problems which arise due to low voltage or low frequency, or a combination of both, is a significant problem, and is not addressed in this Standard.
Yes
A relatively small percentage of units do not meet this requirement but it is not known which of these cases are due to actual machine design limitations.
A relatively small percentage of units do not meet this requirement but it is not known which of these cases are due to actual machine design limitations.
No
Both bullets should be checked above (form will not accept). The curves should be revised based on generator capabilities and design requirements rather than the expected system response for simulated disturbances. Although the simulation results and tools used to develop the curves have not been provided it appears that the proposed curves are based on transient stability simulations. The transient stability program includes only the positive sequence component of system voltage and neglects phenomena that do not result in significant shaft torques. By contrast, protective relays measure individual phase or phase-to-phase quantities or in some cases specific sequence quantities. As proposed the curves may be interpreted differently in relay applications to the detriment of bulk electric system reliability and customer service. Since the curves will be used to set protective relays they should be based on the quantities that are measured by protective relays and the quantities should be clearly stated. We have provided examples of how the curves could be misinterpreted or misapplied if the curves are not constructed in terms of measured relay quantities and settings specific to the point of measurement: â€¢ Based on the proposed curve an overvoltage relay can be set at 120% with no intentional time delay. If this relay measures phase-to-ground voltage at the Point of Interconnection (POI) then for a close-in line-to-ground fault the unfaulted phases may have fundamental frequency voltages of 125% or more for the duration of the fault (effectively grounded system), resulting in undesired generator tripping prior to clearing the fault from the transmission system. â€¢ Protection against overvoltages that are shorter in duration than the operating time of circuit breaker is provided by surge arresters on the high-voltage terminals of the transformer and by surge protectors on the terminals of the generator. The curve implies that for a voltage of more than 120% that the generator can trip instantaneously (without intentional time delay). We suggest that instantaneous trips at any voltage level are neither required nor effective for generator protection. The overvoltage curve should approach zero time asymptotically or alternatively 250% for 20ms, 135% for 300ms, 120% for 20 seconds, 110% continuously. Alternatively the curve should be based on generator capability rather than FERC 661A which is applicable to wind generators with very limited capability. â€¢ In the undervoltage region the 9 cycle zero voltage has been carried over from FERC 661-A which is to facilitate wind integration. The 9 cycle zero voltage ride-thru, although less than prior utility designs, may be sufficient. We again recommend that SDT translate the intended positive sequence values to phase quantities measured by the relay to avoid misapplication. A single-line-to-ground fault will result in a positive sequence voltage of approximately 0.5-0.7pu but the voltages on individual phases or between phases may be quite different. The curve appears adequate from a positive sequence perspective but may not be interpreted as intended. â€¢ In the undervoltage region we recommend that 85% be applied from 3 seconds to 15 seconds to ensure that generators stay connected longer than load and to permit time for automatic reactive element switching. There is no reason to trip this fast in this region Based on the proposed curves we are concerned that the SDT has considered only the system response to typical design contingencies and only the positive sequence voltage from transient stability simulations. Although we have suggested alternate values the final values will depend on how the curve is defined, the form of measurement and relay application. As proposed we believe the curves leave too much for misinterpretation and misapplication. We respectfully question whether it is conceptually possible to properly state this criteria as a single curve. There are a number of important issues that arise with this approach, including the following: > In general generators should not trip on UV, but should alarm. Please see latest C50.12 and C50.13. UV is generally a thermal consideration and an alarm is appropriate to call operator attention to a malfunction. > The existence of a curve such as this in a NERC Standard will lead to generators enabling UV and setting per some part of the curve, which could be a serious hazard to system reliability. > For some specific situations such as unmanned hydro units, tripping on time-UV is appropriate. > The idea of a ride-through curve originated with wind farms, and is not generally conceptually appropriate. For example, this approach is not conceptually appropriate for cylindrical rotor synchronous machines. > The minimum voltage for 9 cycles does not allow enough time to allow for breaker failure protection operation. 13 -15 cycles would be appropriate. > The voltages presented are at the point of interconnection and are not directly translatable to machine relay Voltage settings. > Machine Volts per Hertz curves are a significant issue and are not addressed. > The UV performance of plant auxiliaries is a significant issue, and is not addressed. > We suggest that ANSI/IEEE Standards C37.102, C50.12, and C50.13 should be used and listed as references to

this Standard.
No
Both bullets should bec checked above (form will not accept). Reliability of underfrequency load shedding (UFLS) programs is dependent on assurance that the UFLS program will shed load prior to generation tripping in islanded conditions. The frequency response to generator tripping is primarily a function of the amount of generation tripped and is substantially independent of the location of the generator interconnection. Therefore, the standard should not specify a threshold on interconnection voltage. We are concerned that the generator unit capacity thresholds are set too high. Given the tolerances in UFLS program design, the unit capacity thresholds should be established to ensure that 99 percent of the generation in a system complies with the requirements of this standard. The SDT should identify unit capacity thresholds on this basis, similar to how thresholds were developed in MOD-026. The interconnection voltage is not relevant, only the amount of generation potentially lost to the system. Some sub-regions, employing a UFLS Program, are dependent on Generator Owners/Operators meeting the specifications for generator Underfrequency setpoints in order to maintain a viable UFLS Program. For sub-regions where a large percentage of the total generation fleet is comprised of individual units < 20 MVA and connected to buses < 100 kV, the contribution of these units to the overall success of the sub-regions UFLS Program are more pronounced. It is suggested that the threshold should be established by refering to the requirements of the Region or as established by the Reliability Coordinator (sub-region). As an alternative, it is suggested that all generating units operating in a Reliability Coordinators' or RTO/ISO's market system, regardless of size, shall follow this Standard based on their materiality to the reliability of the bulk power system.
No I disagree with the approach
Both bullets should be checked above (form will not accept).
No
Both bullets should be checked above (form will not accept). Given the potential impact on survivability of an island, and the need to lower the unit capacity thresholds for which this standard is applicable, as recommended in the comment to Question 5, it is suggested that the folowing Violation Risk Factor thresholds be applied: High > 100 MVA Medium > 20 MVA and < 100 MVA Lower < 20 MVA Given the potential impact on survivability of an island, and the recommendation in our response to Question 5 to lower the unit capacity thresholds for which this standard is applicable, we recommend the following Violation Risk Factor thresholds: High >100 MVA Medium > 20 MVA and â‰¤ 100 MVA Lower â‰¤ 20 MVA
We are aware that a number of regions have draft UFLS standards that apply to generators despite the fact NERC Reliability Standards PRC-007, PRC-008 and PRC-009 do not contain either GO or GOP in the applicability section. These regional drafts contain provisions that require non-conforming generators to acquire 'load shed' service. We have repeatedly cited our inability to find any entity that would offer such service as well as technical difficulties in developing a UFLS predicated upon such a service. Despite our comments, the latest drafts continue to require non-conforming generators to acquire 'load shed' service. The Quebec Interconnection, within the Eastern Interconnection, would need different settings from the ones listed in Attachment 1 to coordinate with its UFLS program.
Yes. We are aware of agreements between some generators and their respective transmission owners that contain frequency coordination requirements that differ from those in Table 1, and that, in some cases, the transmission facility(ies) that connects the generator to the BES has underfrequency tripping that would operate prior to the levels shown in Table 1, thus negating any modification that a generator might make to conform. We suggest that this standard also exempt these GOs from meeting R1 and R2 and that R5 be modified to allow for such exception.
Yes
Referencing R5 and R6 of the Standard: The Reliability Coordinator should be give veto power over exceptions to the requirements herein. Should the Generator Owner/Operator not be able to, or be unwilling to, make changes to setpoints to come into compliance with this Standard, the Reliability Coordinator should be given the authority to invoke required mitigation, such as requiring the Generator Owner/Operator to contract for compensatory load shedding up to the total amount of MW of each generating unit that fails to comply with the required setpoints. In addition, The "Off-Nominal Frequency Capability Curve" in Attachment 1 does not coordinate with the underfrequency load shedding (UFLS) program design parameters proposed by the NERC Underfrequency Load Shedding Standard Drafting Team for Project 2007-01. The misccoordination occurs in the time range approximatley between 5 and 10 seconds. This miscoordination can be eliminated by extending the horizontal line at 57.8 Hz to 5 seconds and revising the diagonal line to have endpoints at 57.8 Hz/5s and 59.5 Hz/1800s. This modification will provide coordination with the UFLS program design parameters while still maintaining coordination with turbine-generator capability. Due to the time scale on the graph in Attachment 2, the curves do not indicate the time at which the transient overvoltage and undervoltage requirements end, at which point the continuous voltage requirements would be applicable. Here are several other points that have come up regarding other parts of PRC-024-1 that were not

covered above: > Concerning Attachment 1, we believe this is mainly present to infer that generator tripping will not interfere with UFLS programs. There should be a statement that settings should not interfere with UFLS program in effect. Also on Attachment 1, this is now labeled "Off Nominal Frequency Capability Curve." We wish to suggest that the word "capability" in this label is potentially misleading. This is not a machine capability curve. There should be a statement that protective device settings should be based on machine damage considerations and should be arrived at in consultation with the machine manufacturer. The curve presents limits to those settings which are designed to prevent interference with UFLS programs, and the curve should be so labeled. > A.R1 and A.R2 wording could be taken to require that such relaying should be enabled and set. The phrase "Installed â€¦ relaying not to trip during â€¦" could be taken to mean that such relaying is assumed to be, or should be, installed. Also, in the case of generator multifunction protective devised, such relaying is always installed but it is not appropriate in many cases that it be enabled and set. Note this consideration applies to both frequency and voltage. In general, this Standard should take care to point out that any protection application should be based on actual specific machine protective considerations which should be arrived at in consultation with the machine manufacturer. > Concerning A.R1.2 and Attachment 1, the language refers to a 'no trip zone" between curves, and obviously there is a permissible trip zone outside the curves. Questions will arise on permissibility of settings which are actually on the curves. We would suggest that setting directly on the curves should be permitted. For example, if 1.0 s. at 57.8 Hz is directly on the curve, failure to deal with this question will result in pointless and counterproductive settings such as 1.0 s. at 57.79 Hz. We suggest "Setting directly on the curves are permitted, and settings outside the curves are permitted." > Concerning A.R2, this Standard addresses setting of voltage relays based on voltage at the point of interconnection, which is not directly translatable to voltage at the generator terminals. The generator real and reactive power output will affect the relationship, and this is not dealt with in this Standard. We would like to commend the SDT for recognizing that there may be technical reasons that prevent a generator from meeting requirements 1 and 2 and allowing an exemption when technical basis is provided (R5). There is a paragraph on the second page which states that " For voltage excursions, only generator under or over voltage protective relays and volts per hertz relays would need to be evaluated to meet the draft requirements. Steady state evaluations only are expected " We have the following questions: (1) Do the relays mentioned in the statement above include auxiliary system undervoltage relays? It appears the voltage relay part of the standard is limited to only relays that directly trip the generator and not relays that trip auxiliaries. Is that the intent? What if the relay was attached to an auxiliary bus, but tripped the generator? (2) How is that only steady state evaluations are enough? How do you study voltage recovery characteristics without dynamic simulations?

I have some problems with the intent of this standard in general, but a standard of this nature would have to apply to the generator owner.
No
Generation under frequency protection is an area I have spend much time on over the last 20 years, and I admit that I hold some strong opinions, but these opinions were arrived at after much study, disturbance analysis, and from being directly involved in actual design of three regional underfrequency load shedding (UFLS) programs. It appears that the generator off-nominal frequency protection limits shown in attachment 1 represent someone's judgment call of what is a reasonable loss of life per event, what the expected minimum frequency might be when load shedding occurs, and so forth. Such judgment calls are subjective, and there is room for interpretation. I feel that generation underfrequency/overfrequency settings of this nature have to be developed on a regional basis as part of a regional underfrequency load shedding program. I am uncomfortable with this showing up in a draft NERC standard without any supporting technical documentation or justification. I agree that unit capabilities have to be considered, but perhaps more important, we have to consider the realities of what we can achieve with UFLS and give ourselves enough generator tripping delay time and relay margin to make the program work. Tradeoff's are involved, and this type of underfrequency analysis is inherently an estimation, so some time delay margin is needed to ensure coordination with load shedding. If generation trips too soon, the island imbalance will increase and it may not be possible to prevent total collapse of the island. Keep in mind that the real off-nominal frequency loss of life exposure is when black start programs try to pick up the pieces after load shedding fails, and premature tripping of generation is what causes load shedding to fail. In addition, hydro systems can operate at much lower frequencies than steam units, and this criteria is not appropriate for hydro systems. In my opinion, UFLS is supposed to be a safety net to cover the unforeseen, and it needs to be designed with that in mind. Ideally, we want it to be as robust as possible. Relay coordination is going to be more robust when based on worst-case performance and not on best case. This helps deal with real world complications imposed by things we have not anticipated or foreseen, or due to "as implemented" programs always being a little different than the ideal stated in the design phase. My most recent involvement with UFLS and generator off-nominal frequency protection coordination came about through the MRO Underfrequency Load Shedding Task Force effort that developed a new coordinated UFLS program for the MRO footprint. I served as chair of this taskforce and did much of the analysis. I do not want PRC-024-1 to establish standards that conflict with the MRO program. Doing so would sacrifice the effectiveness of the load shedding program we came up with. There are a couple of other areas where conflicts occur. This is in regards to how to deal with programs that need to shed more

than the minimum amount of load, and in regards to the overfrequency implications. I will discuss the issues in sequence. Although the MRO UFLS Taskforce expects that under "typical conditions" that minimum frequency will be above 58 Hz, (for loss of generation/import of up to 30% of system load in the island), our worst case simulations indicate we could briefly dip below that, and we used our worst case results to set generation protection times and delays. In addition, our "equivalent inertia" modeling approach ignores machine to machine oscillations which might cause frequency at different locations to differ by .2 Hz or so as the system rings down. For this reason, we chose 57.6 Hz as the point where instant tripping is allowed. This is below our worst-case minimum frequency of 57.77 Hz (for a very low inertia, low damping, no governor scenario that is perhaps overly pessimistic). This can also be justified by considering that our design criteria set a target of average system frequency >= 58 Hz, which has to be adjusted by about - .2 Hz for machine to machine oscillations seen in the real system and not in our model, plus about .2 Hz margin to ensure good relay coordination). In order to come up with the MRO generation protection settings we monitored time spent in frequency bands spaced .1 Hz apart and we consider the performance over the full range of coverage (0 to 30 % loss of generation) and considered a wide range of assumptions concerning system based inertia (H system base = MW-sec stored in rotating mass divided by P gen) and damping in addition to a possible range of governor actions. We optimized the program to minimize time spent below 60 Hz while addressing all the other constraints we had to deal with. Once we knew the expected worst case times in each .1 Hz band below 60 Hz for the optimized program, we came up with the stair step type of generation time delay settings that gave a reasonable fit to the expected worst-case time versus frequency information (plus some margin) with the fewest frequency bands. The MRO UFLS effort tried to anticipate as much complication as possible, but we could not cover all of the inherent uncertainty involved. No one could. The main source of uncertainty we could not deal with is how potential overvoltageâ€™s may increase load and decrease the effectiveness of the load shedding program. This gave us additional justification for using a "no net governor response" scenario for evaluating coordination between load shedding and generator protection (this voltage uncertainty is not the only reason for using a no governor assumption: basically units that are base loaded cannot respond to underfrequency, power/load controllers may override governor action, combustion turbine thermal limits will quickly override their governor action with power dropping off faster than the frequency decline, wind generation may drop off and would not have a governor anyway, and so forth; the bottom line is that we do not know what level of net governor type of action we can count on, and what little we get may be offset by increases in voltage). To fully understand what we did you will have to refer to the MRO UFLS report on the MRO website. The short version is that we ran 1000's of cases to arrive at our conclusions. What we came up with for generator underfrequency protection minimum time delays is what we need to ensure the load shedding has time to play out to restore frequency and to give some margin to ensure relay coordination. If we tighten up the generation protection time delays and raise the frequency setting for the instant trip point, then there is a narrower range of conditions for which the UFLS program would be expected to work as intended. Our safety net becomes less robust, we make things less secure. On the other hand, the MRO load shedding program is designed to be the first line of protection for the generators as it is designed to force frequency recovery even in the absence of governor action by having small blocks of load shed on delay to kick us back towards 60 Hz when recovery is too slow. Although there is a chance that frequency may be slow to recover as a worst case, most of the time it will recover much faster than the times we used for generation tripping coordination. The expected time spent below 60 Hz sort of takes on the form of a probability density function. This type of information gives a better idea of what units may be exposed to. Therefore, our approach was to coordinate generation off-nominal frequency protection to match the worst case, and then do everything possible to minimize underfrequency exposure to generators when designing the load shedding program. The recommendations of the MRO UFLS report should take precedence over what is being proposed in this document. In MRO, we recognize that the Canadian portion of MRO needs to shed more than 30% of connected load. The MRO UFLS report indicates that any program that needs to shed more than 30% of load will need to relax the MRO generator off nominal frequency time delay settings for generation and accept longer delays and lower minimum frequencies. This is an engineering reality. The Off-Nominal Frequency Capability Curve on Attachment 1 does not give this kind of flexibility. Alternately, some improvement on minimum frequency can be realized by designing a program that oversheds but then the program will be prone to overspeed problems. Programs can also start shedding at higher frequencies to improve the minimum frequency but then that creates other coordination problems with neighboring programs. This standard writing process should not replace engineering judgment. Utilities need flexibility so they can make the necessary compromises after all things are considered. Making adjustments to generation protection is most likely the best approach to ensure coordination with these larger load shedding programs. The diagram from PRC-024-1 may suggest to some folks that over frequency tripping is going to be needed or perhaps even encouraged. I do not know what the intent is, so I will just express my concerns up front. I have serious reservations about applying dedicated relays, of the type used for underfrequency protection, to trip units on overspeed. Extreme caution is needed. That is a good way to ensure total collapse of a power grid. Seriously, this could be catastrophic. Consider that plants already have internal overspeed controls. These are needed to deal with full load rejection. These controls are in addition to the normal governor, and are much more drastic. These emergency overspeed controls are not modeled in stability cases, but they exist, and will take drastic action to slow down units if frequency gets high so I feel confident that the units self protect and take care of themselves. I believe that overspeed protection should be left to these inherent controls, and that we should not put in additional relays to trip generation on overspeed unless this is done carefully and solely for the purpose of restoring load and generation within an island. Plant internal overspeed controls have to limit speed following full load rejection, but they will also react to partial load rejections that we get by islanding. If a plant loses all lines to it (i.e. full load rejection), then go ahead and allow these inherent controls to trip the unit on overspeed or do what ever is needed. NERC does not need a standard for that. The emergency overspeed controls that protect for full load rejection can also activate on an islanding condition where we have too much generation in an island. On steam units these controls kick in between 61 to 62 Hz (it varies with each unit so I have to generalize), so system frequency is unlikely to get much higher than 61.4 Hz to 62 Hz (most that I have seen activate around 61.2 to 61.4 Hz) no matter how large the initial imbalance. Once these controls activate frequency is no longer a measure of the imbalance between load and generation. The action taken to prevent overspeed involves things like closing all the steam valves on thermal units, so it is safe to say we cannot stay in this high frequency condition for too long before random unit trips start to occur due to any number of internal plant problems. Often times one plant dies first and rebalances things for other units. The random nature of what happens next complicates any planned unit tripping actions to correct the imbalance. If dedicated unit tripping on overspeed is to be done, it can only be done on a few selected units and only as a way to hammer the imbalance back to a smaller size that we can deal with. The worst of all worlds would be to apply overspeed tripping to all units like we do for underfrequency. That would ensure any island with an initial excess of generation is going to go black after we dump all the generation. If generation is tripped to correct overspeed in an island, it has to be done in small increments (about 1 to 1.5 % of remaining load) and trip times have to be staggered. This is something that has to be studied on a case-by-case basis. In summary, we do not believe that it is appropriate to be creating a standard like this to specify settings for underfrequency/overfrequency protection for all generation. The technical basis of these limits are not given, and these setting may not coordinate with existing or proposed underfrequency load shedding programs. Aggressive load shedding programs are quite likely to need to accept more time below 60 Hz to coordinate with underfrequency relaying and expected system frequency recovery times. Protection settings of this nature should be developed in conjunction with underfrequency load shedding programs so that appropriate trade offs can be considered. Such coordination is most effective at the regional or subregional basis where a specific load shedding program can be evaluated in detail. We must give sufficient time for load shedding to act even if it means we need to accept some additional potential loss of life to generation for some hypothetical underfrequency event.

No

It is unclear what limits apply to wind generation, but we believe our conventional generation can easily accommodate the settings defined by Attachment 1, even though we feel that such off-nominal protection settings should not be established in this standard and that such coordination should occur at the regional level were UFLS program details are worked out. I would like to offer some observations based on real life experience. Our experience is that some folks have a good technical understanding of generation capabilities and others do not. In many instances, folks do not know what actual capabilities are, and if the proposed settings conflict with existing settings then they will initially report that they cannot accommodate the recommendations (the status quo carries a lot of weight even when no one can find the original justification for existing settings). Generally, all the parties have to get together and work through things to create a higher level of awareness of the issues so we can eliminate misconceptions. The new non-utility generation owners do not have the same load serving obligations as traditional utilities and this gives them different incentives for how they want to set generation protection. In many instances, they want to trip too early, to the detriment of the grid.

No

This may be appropriate but I have not seen the supporting technical report so I cannot say that I agree.

No

This is likely to be something that has to be applied on a case by case basis, with consideration given to how many units we have that would not be covered by some sort of coordinated UFLS/generation protection settings. There is some latitude to make exceptions, but in the future, we may have many more units that fit this category, and then this becomes a big issue. Units which trip too soon will just impact the load shedding program unless a corresponding amount of load is shed at essentially the same time and more or less at that same location.

No I disagree with the approach

This may be appropriate but I have not seen the supporting technical report so I cannot say that

I agree. This is likely to be something that has to be applied on a case-by-case basis, with consideration given to how many units would be excluded in some geographic area. There is some latitude to make exceptions, but in the future, we may have many more units that fit this category, and then this exclusion becomes a big issue.
No
see above comment
See the detailed answer provided to question 2. It covers the need for regional variance.
The proposed generation off-nominal frequency criteria conflicts with the MRO UFLS program, and will not work for programs that need to shed more than 30% of system load. Technically this is not a conflict with regulatory functions, rule order, tariff, rate schedule, legislative requirement or agreement; but it is a conflict with our efforts to design an appropriate load shedding program for the MRO region.

The Generator Operators, and not the Generator Owners, are typically responsible for establishing relay setpoints, calibrations, and maintenance. The Generator Owner is the Functional Model entity that has direct control over the generating unit protection settings.
No
The proposed standard addresses all issues identified in the Standard Authorization Request. Coordination of generator and transmission system protection is addressed in PRC-001. As presently constituted this Standard will likey result in the inappropriate enabling and setting of frequency and voltage relays with the settings which are permitted, thus reducing system reliability, which is contrary to its stated purpose. This is supported in the comments provided below. There are significant machine protection issues which are not addressed, such as Volts per Hertz. Loss of generation consequential to problems on auxiliary systems, problems which arise due to low voltage or low frequency, or a combination of both, is a significant problem, and is not addressed in this Standard.
Yes
A number of our units do not meet this requirement but it is not known which of these cases are, due to actual machine design limitations.
No
The curves should be revised based on generator capabilities and design requirements rather than the expected system response for simulated disturbances. Although the simulation results and tools used to develop the curves have not been provided it appears that the proposed curves are based on transient stability simulations. The transient stability program includes only the positive sequence component of system voltage and neglects phenomena that do not result in significant shaft torques. By contrast, protective relays measure individual phase or phase-to-phase quantities or in some cases specific sequence quantities. As proposed the curves may be

interpreted differently in relay applications to the detriment of bulk electric system reliability and customer service. Since the curves will be used to set protective relays they should be based on the quantities that are measured by protective relays and the quantities should be clearly stated. We have provided examples of how the curves could be misinterpreted or misapplied if the curves are not constructed in terms of measured relay quantities and settings specific to the point of measurement: â€¢ Based on the proposed curve an overvoltage relay can be set at 120% with no intentional time delay. If this relay measures phase-to-ground voltage at the Point of Interconnection (POI) then for a close-in line-to-ground fault the unfaulted phases may have fundamental frequency voltages of 125% or more for the duration of the fault (effectively grounded system), resulting in undesired generator tripping prior to clearing the fault from the transmission system. â€¢ Protection against overvoltages that are shorter in duration than the operating time of circuit breaker is provided by surge arresters on the high-voltage terminals of the transformer and by surge protectors on the terminals of the generator. The curve implies that for a voltage of more than 120% that the generator can trip instantaneously (without intentional time delay). We suggest that instantaneous trips at any voltage level are neither required nor effective for generator protection. The overvoltage curve should approach zero time asymptotically or alternatively 250% for 20ms, 135% for 300ms, 120% for 20 seconds, 110% continuously. Alternatively the curve should be based on generator capability rather than FERC 661A which is applicable to wind generators with very limited capability. â€¢ In the undervoltage region the 9 cycle zero voltage has been carried over from FERC 661-A which is to facilitate wind integration. The 9 cycle zero voltage ride-thru, although less than prior utility designs, may be sufficient. We again recommend that SDT translate the intended positive sequence values to phase quantities measured by the relay to avoid misapplication. A single-line-to-ground fault will result in a positive sequence voltage of approximately 0.5-0.7pu but the voltages on individual phases or between phases may be quite different. The curve appears adequate from a positive sequence perspective but may not be interpreted as intended. â€¢ In the undervoltage region we recommend that 85% be applied from 3 seconds to 15 seconds to ensure that generators stay connected longer than load and to permit time for automatic reactive element switching. There is no reason to trip this fast in this region Based on the proposed curves we are concerned that the SDT has considered only the system response to typical design contingencies and only the positive sequence voltage from transient stability simulations. Although we have suggested alternate values the final values will depend on how the curve is defined, the form of measurement and relay application. As proposed we believe the curves leave too much for misinterpretation and misapplication. We respectfully question whether it is conceptually possible to properly state this criteria as a single curve. There are a number of important issues that arise with this approach, including the following: * In general generators should not trip on UV, but should alarm. Please see latest C50.12 and C50.13. UV is generally a thermal consideration and an alarm is appropriate to call operator attention to a malfunction. * The existence of a curve such as this in a NERC Standard will lead to generators enabling UV and setting per some part of the curve, which could be a serious hazard to system reliability. * For some specific situations such as unmanned hydro units, tripping on time-UV is appropriate. * The idea of a ride-through curve originated with wind farms, and is not generally conceptually appropriate. For example, this approach is not conceptually appropriate for cylindrical rotor synchronous machines. * The minimum voltage for 9 cycles does not allow enough time to allow for breaker failure protection operation. 13 -15 cycles would be appropriate. * The voltages presented are at the point of interconnection and are not directly translatable to machine relay Voltage settings. * Machine Volts per Hertz curves are a significant issue and are not addressed. * The UV performance of plant auxiliaries is a significant issue, and is not addressed. * We suggest that ANSI/IEEE Standards C37.102, C50.12, and C50.13 should be used and listed as references to this Standard.

No

Reliability of underfrequency load shedding (UFLS) programs is dependent on assurance that the UFLS program will shed load prior to generation tripping in islanded conditions. The frequency response to generator tripping is primarily a function of the amount of generation tripped and is substantially independent of the location of the generator interconnection. Therefore, the standard should not specify a threshold on interconnection voltage. We are concerned that the generator unit capacity thresholds are set too high. Given the tolerances in UFLS program design, the unit capacity thresholds should be established to ensure that 99 percent of the generation in a system complies with the requirements of this standard. The SDT should identify unit capacity thresholds on this basis, similar to how thresholds were developed in MOD-026.

No I disagree with the approach

No

We are not aware of any. However, we are aware that a number of regions have draft UFLS standards that apply to generators despite the fact NERC Reliability Standards PRC-007, PRC-008 and PRC-009 do not contain either GO or GOP in the applicability section. These regional drafts contain provisions that require non-conforming generators to acquire 'load shed' service.

We have repeatedly cited our inability to find any entity that would offer such service as well as technical difficulties in developing a UFLS predicted upon such a service. Despite our comments, the latest drafts continue to require non-conforming generators to acquire 'load shed' service.
Yes. We are aware of agreements between some generators and their respective transmission owners that contain frequency coordination requirements that differ from those in Table 1, and that, in some cases, the transmission facility(ies) that connects the generator to the BES has underfrequency tripping that would operate prior to the levels shown in Table 1, thus negating any modification that a generator might make to conform. We suggest that this standard also exempt these GOs from meeting R1 and R2 and that R5 be modified to allow for such exception.
Yes
The 4 kV protection that includes underfrequency and under volthge relays trip the generator in some of our plants. The SDT needs to clarify whether this standard applies to such protection.

Progress Energy, Inc.
Yes
Since the generator operator does not own the equipment addressed by the standard, he cannot change the settings without the owner's approval. The standard potentially requires changing the frequency and voltage relay trip settings. Since the generator owner owns the equipment, they also own the settings and should be the one held accountable for meeting the requirements of this standard.
No
The purpose of the standard, to ensure that generators ride through the proposed system transients, will not be accomplished by only looking at generator protective relays. PE is concerend that these same profiles for frequency and voltage (Attachment 1 and 2) could later become applicable to all plant equipment. The generating plants are not designed to ride thru/stay connected for these proposed profiles.
Yes
100% of Progress Energy nuclear units will not stay connected per the proposed Attachment 1 and 2 due to auxliary equipment protection. 70-80% of the combustion turbine units would trip during the frequency excursions proposed by NERC. To make sure that generation "ride through" is coordinated with conditions that could damage all types of generation facilities, Progress Energy recommends that the SDT consult with turbine manfacturers to develop the frequency profile. Frequency limitations are typically driven by turbine manfacture design. We also need to the mindful of the total cummulative off-frquency excursions limits laid down by the turbine manufacturers. For example, most large steam turbine vendors prohibit turbine operation below 58 hz in order to prevent the probable occurrence of turbine blade resonance (turbine blade failure). Our nuclear plant operators will immediately manually trip the turbines at 58 hz to prevent equipment damage. For combustion turbines under frequency limitations exist below 59 Hz while the maximum operating duration at 59.5 Hz is limited to 60 seconds. Of our five nuclear plants, all five would not be capable of riding through either the proposed frequency or voltage transitents due to manual turbine and automatic reactor protection settings. These settings are not generator protective relays but they will result in a complete loss of generation. Two Progress Energy nuclear plants will trip on reactor coolant pump undervoltage below 80% pu at 0.75 seconds and one will trip on underfrequency below 58.2 hz at 0.2 seconds.
Approximately 3,500 MW of nuclear generation for SERC and 900 MW for FRCC. Approximately 3500 MW CT generation in SERC and 5000 MW CT generation in FRCC.
No
PE is concerend that the proposed profile for voltage (Attachment 2) could later become applicable to all plant equipment. The generating plants are not designed to ride thru/stay connected for this proposed profile. 100% of our nuclear units will trip if subjected to the proposed voltage transient test. The trips would be due to reactor coolant pump undervoltage, reactor coolant pump power monitoring protection, and reactor protection system power supply undervoltage exceeding their respective time delays during the voltage excursion. Each nuclear plant has slightly different trips based on the reactor design and vintage.
Yes
All generator units with the given thresholds are registered in the NERC compliance registry. We consider that such units should adhere to the requirements in the standard. Each system reacts differently to the loss of different sizes of generators. This standard, which is applicable to every entity, should cover all such situations. Hence, the given thresholds, though restrictive, are adequate.
No I disagree with the approach
It is the aggregate impact of all an entity's units that matters. There should be only one VRF - HIGH. Consider the example where a plant consists of numerous medium (100-200 MVA) units with a common relay setting error. WECC have relatively small units, but potentially large impact when the whole plant is affected.
No
There should not be levels.
No. FRCC has suspended work on a regional version of PRC-024. The regional version will have to reviewed and compared to the NERC standard once developed.
Yes, if the standard is extended to other plant equipment NRC nuclear plant licenses will be in conflict.
Yes
1. Recommend deleting proposed R2.2.2. If not deleted the language needs to be clarified as follows: "meet a shorter voltage ride through" should be changed to "meet a less stringent voltage ride through". 2. In R3, change "within 30 calendar days of any change" to "at least 30 calendar days prior to any change". The changes should be provided before they are made in the field. 3. In M4, change "entities listed in Requirement 4" to "entities listed in Requirement 4 that provide a written request" 4. The purpose and the applicability of the standard needs to be

revised to clearly specify that the scope of PRC-024-1 only applies to main generator protective relaying and excludes protective functions associated with plant auxilary equipment.

Since the generator operator does not own the equipment addressed by the standard, he cannot change the settings without the generator owner's approval. The standard potentially requires changing the frequency and voltage relay trip settings. Since the generator owner owns the equipment, they also own the settings and should be the one held accountable for meeting the requirements of this standard.
No
Settings for generator backup impedance and voltage restrained overcurrent relays need to be covered too. Their inclusion will provide complete coverage of the generator. There have been instances where these relays have operated in the past. We understand that this will drive the need for dynamic simluations because steady state simulations will not suffice.
Yes
However, the wording used in section R2.2.1 is confusing. The words should be changed to "For three-phase transmission system zone 1 faults with Normal Clearing, generator relaying shall be set longer than the expected fault clearing time, but not greater than nine cycles."
Yes
All generating units with the given thresholds are registered in the NERC compliance registry. We believe that these units should adhere to the requirements in the Standard. Each system reacts differently to the loss of different sizes of generators. This Standard, which is applicable to every registered entity, should cover these situations. Hence, the given thresholds, though restrictive, are adequate.
No I disagree with the approach
It is the aggregate impact of all an entity's units that matters. There should be only one VRF - HIGH. Consider the example where a plant consists of numerous medium sized (100-200 MVA) units with a common relay setting error. Even though the individual units are relatively small, there is a potentially large impact when the whole plant is considered.
No
There should not be levels
Yes
1. We recommend deleting the proposed section R2.2.2. If not deleted, change: "meet a shorter voltage ride through" to "meet a less stringent voltage ride through". 2. In R3, change "within 30 calendar days of any change" to "at least 30 calendar days prior to any change". The changes should be provided before they are made in the field. 3. Significant generator capacity may be connected at distribution voltages and set with sensitive anti-islanding frequency/voltage setpoints. These generators need to report their setpoint data to the owner of any UFLS/UVLS systems that may be affected by the generator performance. This can be a significant amount of generation relative to the size of the UFLS/UVLS program. Consideration should also be given as to whether the requirements should apply to generators where the site aggregate is >20MVA.
Yes I agree with the approach
Yes
R2.2.1 seems to imply that a generator must set an undervoltage trip with a time delay of no more than 9 cycles. This seems to conflict with the intent of PRC-024. Is the intent perhaps to require the TO to clear Zone 1 faults in no more than 9 cycles? Or is the intent to allow the GO to set the time delay as low as 9 cycles and no less? I suggest the latter. R3, R4, and R5 - This information should be provided to the owner of any UFLS or UVLS as well.

If the standard is in place, it belongs to the Generator Owner. The SAR seemed to be written for transmission, but this standard seems to be evolving to a geneator setting standard. Does the SAR need to be revised? Although GO has the access to the equipment settings/records, GOP may not, GOP is the entity to operate the units. GO must communicate settings to the GOP. Since the generator operator does not own the equipment addressed by the standard, he cannot change the settings without the generator owner's approval. The standard potentially requires changing the frequency and voltage relay trip settings. Since the generator owner owns the equipment, they also own the settings and should be the one held accountable for meeting the requirements of this standard.
No
What the standard addresses is probably what is practical, but the ultimate goal of the SAR is not practical to implement. We question whether the goal of this standard can be truly addressed from a practical standpoint. The scope of the protective equipment covered in the current draft excludes excitation system protection including over excitation, station service under voltage protection, certain nuclear facility protection schemes, boiler controls, turbine controls, each of which may not ride through the frequency and voltage swings. We feel as though the limited approach of specifying F and V relay settings on the generator may be futile in improving the ability to ride through â€“ yet on the other hand the inclusion of all of the impacted plant subsystem components would be practically and financially unmanageable. In other words, will any appreciable improvement in system reliability result from the implementation of this standard looking at F and V gen settings only. Settings for generator backup impedance and voltage restrained overcurrent relays may need to be covered too. Their inclusion will provide complete coverage of the generator. There have been instances where these relays have operated in the past. We understand that this will drive the need for dynamic simluations because steady state simulations will not suffice.
Yes
Some are, some are not. Some we can prove, some we don't know and can't find out. With no experts to evaluate turbine under/over frequency in our company and turbine manufacturers either out of business or unwilling to provide turbine limits, is there any possible exception allowed for settings inside the no trip zone? Also, for existing turbines, we believe that the turbine blade conditions would have to be evaluated to make a judgement on how to shift the withstand. How can we be sure that we are not stressing our turbine if we set our devices outside of the curve in the standard? Can question 3 be addressed quantitatively? Instead of "100% on voltage", it should be "0%". Auxiliary systems are not included in the standards scope

as drafted. 100% on voltage (can't prove - auxilliary system) Unknown on frequency
40,000MW voltage, Unknown frequency
No
Controversy of Voltage cumulative nature, not showing the 95%-100% generator terminal voltage, difference between the curve being on the tranmission side of the GSU and the generator relay being on the generator side of the GSU. The generator terminal voltage shown at 95%-105% listed in R2.1. We are concerned that future auditors will interpret this limit as being the coordination limit. The voltage curve of Attachment 2 is stated for system voltage; however as mentioned in the conference call, the volts per hertz protection was specifically referenced and used to support setting criteria. We have a problem with this approach since the V/HZ relay is looking at the generator voltage and the curve is shown for the system voltage. How do we demonstrate coordination since the two are on different basis which cannot accurately be resolved via steady state techniques? The wording used in section R2.2.1 is confusing. The words should be changed to "For three-phase transmission system zone 1 faults with Normal Clearing, generator relaying shall be set longer than the expected fault clearing time, but does not have to be set for greater than nine cycles."
No
The unit size and plant size seem to be conservatively small. From a practical standpoint, our focus in this standard should be on the largest units, those that are most cricital in the reliability. A more reasonable limit would be 100MVA generator units and 200 MVA for multiple units at a single site.
Yes I agree with the approach
No
The VRF levels should range from low to high based on size of unit. Low risk 100-200MVA. Medium risk 200-500 MVA. High risk >500MVA.
No.
Nuclear Plant Requirements may conflict.
Yes
1. We recommend deleting the proposed section R2.2.2. If not deleted, change "meet a shorter voltage ride through" to "meet a less stringent voltage ride through". 2. In R3, change "within 30 calendar days of any change" to "at least 30 calendar days prior to any change". The changes should be provided before they are made in the field. 3. In M4, change "entities listed in Requirement 4" to "entities listed in Requirement 4 that provide a written request" 4. How did the SDT translate the transient voltage excursion plot to the cumulative voltage curve? 5. The voltage ride through curve was said to be cumulative â€“ this should be specified on the curve. 6. How can we prove that our static voltage curve coordinates with this cumulative curve? 7. Implementation schedule â€“ we believe that the unit size should be considered, and that the most critical units should be worked on first. Completing 33% each year is too ambitious for those members that have > 300 units. 8. What regions are working on voltage ride through and Underfrequency (ufls and undefrequency tripping of generators)? 9. Should the PRC-024 SDT wait until the regions have completed their work? 10. Generator engineers do not see a relevence for a voltage ride-through for any generator other than wind.

In many cases the exciter voltage regulator includes generator protective functions (for example, Basler DECS 300, DECS 400) such as Volts/Hertz, undervoltage, overvoltage, underfrequency that will also trip the Unit. These functions are usually set slightly above the trip settings of the equivalent generator protective relaying, but to not include them in this requirement would effectively nullify the stability effort sought by this requirement.
Yes
There are a number of generating units that currently have relay settings outside the proposed underfrequency and overfrequency relay settings. It is not known at this time if it is possible to adjust the settings within the proposed relay settings. 50%
1900 MW
No
R2 specifies that the generator may not operate on V/Hz evaluated at nominal frequency. Some generators have specific requirements to trip on V/Hz at 110%. This is in conflict with the upper

boundry point of Attachment 2 for times greater than 1 second. We recommend to change this requirement so that it does not apply to V/Hz settings. It is not practical to set generator protective relays fed from generator potential transformers to meet the voltage requirement at the point of interconnect to the BES. We recommend that the voltage chart requirement be applicable to the voltage measured by the generator protective relays, not the voltage at the point of interconnect to the BES.
Yes
Yes I agree with the approach
No
What is the basis for the MVA levels proposed by the standard here?
Not aware of any regional differences.
Not aware of any conflicts.
Yes
Please consider including the Balancing Authority as an entitiy for the Geneator Owner to provide settings information in requirements R3 & R4 since the BA is an entity that has a direct relationship with the operational status of generating stations. R5: Do not agree with the bulleted item where increasing the capabilility of a generator by 10% is a reason for exemption expiration. As an example, turbine or boiler enhancements can result in greater effeciencies and resulting in an increase of generator capability with no change to the generator or its protection capabilities whatsoever. Recommend removal of this bulleted item. R5: The generator exciter voltage regulator contains protective relay settings such as Volts/Hertz, undervoltage, overvoltage, underfrequency that will also trip the Unit. Is the exciter voltage regulator considered to be part of the generator protective relay system? If so, would a limitation of the exciter voltage regulator be allowed as an exception to the standard or, since the protective system is excluded, would R5 mandate that the excitor voltage regulator be replaced to remove the exception? This issue should be clarified in R5.

Yes
The Generator Owner is the Functional Model entity that has direct control over the generating unit protection settings.
No
The proposed standard addresses all issues identified in the Standard Authorization Request. Coordination of generator and transmission system protection is addressed in PRC-001. As presently constituted this Standard will likey result in the inappropriate enabling and setting of frequency and voltage relays with the settings which are permitted, thus reducing system reliability, which is contrary to its stated purpose. This is supported in the comments provided below. There are significant machine protection issues which are not addressed, such as Volts per Hertz. Loss of generation consequential to problems on auxiliary systems, problems which arise due to low voltage or low frequency, or a combination of both, is a significant problem, and is not addressed in this Standard.
Yes
A relatively small percentage of units do not meet this requirement but it is not known which of these cases are due to actual machine design limitations.
A relatively small percentage of units do not meet this requirement but it is not known which of these cases are due to actual machine design limitations.
No
The curves should be revised based on generator capabilities and design requirements rather than the expected system response for simulated disturbances. Although the simulation results and tools used to develop the curves have not been provided it appears that the proposed curves are based on transient stability simulations. The transient stability program includes only the positive sequence component of system voltage and neglects phenomena that do not result in significant shaft torques. By contrast, protective relays measure individual phase or phase-to-phase quantities or in some cases specific sequence quantities. As proposed the curves may be interpreted differently in relay applications to the detriment of bulk electric system reliability and customer service. Since the curves will be used to set protective relays they should be based on the quantities that are measured by protective relays and the quantities should be clearly stated. We have provided examples of how the curves could be misinterpreted or misapplied if the curves are not constructed in terms of measured relay quantities and settings specific to the point of measurement: â€¢ Based on the proposed curve an overvoltage relay can be set at 120% with no intentional time delay. If this relay measures phase-to-ground voltage at the Point

of Interconnection (POI) then for a close-in line-to-ground fault the unfaulted phases may have fundamental frequency voltages of 125% or more for the duration of the fault (effectively grounded system), resulting in undesired generator tripping prior to clearing the fault from the transmission system. â€¢ Protection against overvoltages that are shorter in duration than the operating time of circuit breaker is provided by surge arresters on the high-voltage terminals of the transformer and by surge protectors on the terminals of the generator. The curve implies that for a voltage of more than 120% that the generator can trip instantaneously (without intentional time delay). We suggest that instantaneous trips at any voltage level are neither required nor effective for generator protection. The overvoltage curve should approach zero time asymptotically or alternatively 250% for 20ms, 135% for 300ms, 120% for 20 seconds, 110% continuously. Alternatively the curve should be based on generator capability rather than FERC 661A which is applicable to wind generators with very limited capability. â€¢ In the undervoltage region the 9 cycle zero voltage has been carried over from FERC 661-A which is to facilitate wind integration. The 9 cycle zero voltage ride-thru, although less than prior utility designs, may be sufficient. We again recommend that SDT translate the intended positive sequence values to phase quantities measured by the relay to avoid misapplication. A single-line-to-ground fault will result in a positive sequence voltage of approximately 0.5-0.7pu but the voltages on individual phases or between phases may be quite different. The curve appears adequate from a positive sequence perspective but may not be interpreted as intended. â€¢ In the undervoltage region we recommend that 85% be applied from 3 seconds to 15 seconds to ensure that generators stay connected longer than load and to permit time for automatic reactive element switching. There is no reason to trip this fast in this region Based on the proposed curves we are concerned that the SDT has considered only the system response to typical design contingencies and only the positive sequence voltage from transient stability simulations. Although we have suggested alternate values the final values will depend on how the curve is defined, the form of measurement and relay application. As proposed we believe the curves leave too much for misinterpretation and misapplication. We respectfully question whether it is conceptually possible to properly state this criteria as a single curve. There are a number of important issues that arise with this approach, including the following: > In general generators should not trip on UV, but should alarm. Please see latest C50.12 and C50.13. UV is generally a thermal consideration and an alarm is appropriate to call operator attention to a malfunction. > The existence of a curve such as this in a NERC Standard will lead to generators enabling UV and setting per some part of the curve, which could be a serious hazard to system reliability. > For some specific situations such as unmanned hydro units, tripping on time-UV is appropriate. > The idea of a ride-through curve originated with wind farms, and is not generally conceptually appropriate. For example, this approach is not conceptually appropriate for cylindrical rotor synchronous machines. > The minimum voltage for 9 cycles does not allow enough time to allow for breaker failure protection operation. 13 -15 cycles would be appropriate. > The voltages presented are at the point of interconnection and are not directly translatable to machine relay Voltage settings. > Machine Volts per Hertz curves are a significant issue and are not addressed. > The UV performance of plant auxiliaries is a significant issue, and is not addressed. > We suggest that ANSI/IEEE Standards C37.102, C50.12, and C50.13 should be used and listed as references to this Standard.
No
Reliability of underfrequency load shedding (UFLS) programs is dependent on assurance that the UFLS program will shed load prior to generation tripping in islanded conditions. The frequency response to generator tripping is primarily a function of the amount of generation tripped and is substantially independent of the location of the generator interconnection. Therefore, the standard should not specify a threshold on interconnection voltage. We are concerned that the generator unit capacity thresholds are set too high. Given the tolerances in UFLS program design, the unit capacity thresholds should be established to ensure that 99 percent of the generation in a system complies with the requirements of this standard. The SDT should identify unit capacity thresholds on this basis, similar to how thresholds were developed in MOD-026. The interconnection voltage is not relevant, only the amount of generation potentially lost to the system. Some sub-regions, employing a UFLS Program, are dependent on Generator Owners/Operators meeting the specifications for generator Underfrequency setpoints in order to maintain a viable UFLS Program. For sub-regions where a large percentage of the total generation fleet is comprised of individual units < 20 MVA and connected to buses < 100 kV, the contribution of these units to the overall success of the sub-regions UFLS Program are more pronounced. It is suggested that the threshold should be established by refering to the requirements of the Region or as established by the Reliability Coordinator (sub-region). As an alternative, it is suggested that all generating units operating in a Reliability Coordinators' or RTO/ISO's market system, regardless of size, shall follow this Standard based on their materiality to the reliability of the bulk power system.
No I disagree with the approach
Given the potential impact on survivability of an island, and the need to lower the unit capacity thresholds for which this standard is applicable, as recommended in the comment to Question 5, it is suggested that the folowing Violation Risk Factor thresholds be applied: High > 100 MVA

Medium > 20 MVA and < 100 MVA Lower < 20 MVA Given the potential impact on survivability of an island, and the recommendation in our response to Question 5 to lower the unit capacity thresholds for which this standard is applicable, we recommend the following Violation Risk Factor thresholds: High >100 MVA Medium > 20 MVA and â‰¤ 100 MVA Lower â‰¤ 20 MVA
No
Given the potential impact on survivability of an island, and the need to lower the unit capacity thresholds for which this standard is applicable, as recommended in the comment to Question 5, it is suggested that the folowing Violation Risk Factor thresholds be applied: High > 100 MVA Medium > 20 MVA and < 100 MVA Lower < 20 MVA Given the potential impact on survivability of an island, and the recommendation in our response to Question 5 to lower the unit capacity thresholds for which this standard is applicable, we recommend the following Violation Risk Factor thresholds: High >100 MVA Medium > 20 MVA and â‰¤ 100 MVA Lower â‰¤ 20 MVA
Yes, the Québec Interconnection, within the Eastern Interconnection, would need different settings than the ones depicted in the Attachment 1 to coordinate with its UFLS program. We are also aware that a number of regions have draft UFLS standards that apply to generators despite the fact NERC Reliability Standards PRC-007, PRC-008 and PRC-009 do not contain either GO or GOP in the applicability section. These regional drafts contain provisions that require non-conforming generators to acquire 'load shed' service. We have repeatedly cited our inability to find any entity that would offer such service as well as technical difficulties in developing a UFLS predicted upon such a service. Despite our comments, the latest drafts continue to require non-conforming generators to acquire 'load shed' service.
Yes. We are aware of agreements between some generators and their respective transmission owners that contain frequency coordination requirements that differ from those in Table 1, and that, in some cases, the transmission facility(ies) that connects the generator to the BES has underfrequency tripping that would operate prior to the levels shown in Table 1, thus negating any modification that a generator might make to conform. We suggest that this standard also exempt these GOs from meeting R1 and R2 and that R5 be modified to allow for such exception.
Yes
Referencing R5 and R6 of the Standard: The Reliability Coordinator should be give veto power over exceptions to the requirements herein. Should the Generator Owner/Operator not be able to, or be unwilling to, make changes to setpoints to come into compliance with this Standard, the Reliability Coordinator should be given the authority to invoke required mitigation, such as requiring the Generator Owner/Operator to contract for compensatory load shedding up to the total amount of MW of each generating unit that fails to comply with the required setpoints. In addition, The "Off-Nominal Frequency Capability Curve" in Attachment 1 does not coordinate with the underfrequency load shedding (UFLS) program design parameters proposed by the NERC Underfrequency Load Shedding Standard Drafting Team for Project 2007-01. The misccoordination occurs in the time range approximatley between 5 and 10 seconds. This miscoordination can be eliminated by extending the horizontal line at 57.8 Hz to 5 seconds and revising the diagonal line to have endpoints at 57.8 Hz/5s and 59.5 Hz/1800s. This modification will provide coordination with the UFLS program design parameters while still maintaining coordination with turbine-generator capability. Due to the time scale on the graph in Attachment 2, the curves do not indicate the time at which the transient overvoltage and undervoltage requirements end, at which point the continuous voltage requirements would be applicable. Here are several other points that have come up regarding other parts of PRC-024-1 that were not covered above: > Concerning Attachment 1, we believe this is mainly present to infer that generator tripping will not interfere with UFLS programs. There should be a statement that settings should not interfere with UFLS program in effect. Also on Attachment 1, this is now labeled "Off Nominal Frequency Capability Curve." We wish to suggest that the word "capability" in this label is potentially misleading. This is not a machine capability curve. There should be a statement that protective device settings should be based on machine damage considerations and should be arrived at in consultation with the machine manufacturer. The curve presents limits to those settings which are designed to prevent interference with UFLS programs, and the curve should be so labeled. > A.R1 and A.R2 wording could be taken to require that such relaying should be enabled and set. The phrase "Installed â€¦ relaying not to trip during â€¦" could be taken to mean that such relaying is assumed to be, or should be, installed. Also, in the case of generator multifunction protective devised, such relaying is always installed but it is not appropriate in many cases that it be enabled and set. Note this consideration applies to both frequency and voltage. In general, this Standard should take care to point out that any protection application should be based on actual specific machine protective considerations which should be arrived at in consultation with the machine manufacturer. > Concerning A.R1.2 and Attachment 1, the language refers to a 'no trip zone" between curves, and obviously there is a permissible trip zone outside the curves. Questions will arise on permissibility of settings which are actually on the curves. We would suggest that setting directly on the curves should be permitted. For example, if 1.0 s. at 57.8 Hz is directly on the curve, failure to deal with this question will result in pointless and counterproductive settings such as 1.0 s. at 57.79 Hz. We suggest "Setting directly on the curves are permitted, and settings outside the curves are permitted." > Concerning A.R2, this Standard addresses setting of voltage relays based on

voltage at the point of interconnection, which is not directly translatable to voltage at the generator terminals. The generator real and reactive power output will affect the relationship, and this is not dealt with in this Standard. We would like to commend the SDT for recognizing that there may be technical reasons that prevent a generator from meeting requirements 1 and 2 and allowing an exemption when technical basis is provided (R5). There is a paragraph on the second page which states that " For voltage excursions, only generator under or over voltage protective relays and volts per hertz relays would need to be evaluated to meet the draft requirements. Steady state evaluations only are expected " We have the following questions: (1) Do the relays mentioned in the statement above include auxiliary system undervoltage relays? It appears the voltage relay part of the standard is limited to only relays that directly trip the generator and not relays that trip auxiliaries. Is that the intent? What if the relay was attached to an auxiliary bus, but tripped the generator? (2) How is that only steady state evaluations are enough? How do you study voltage recovery characteristics without dynamic simulations?

Yes
Where would be the appropriate voltage measurement point? (Generator bus or POI)
Yes
Yes I agree with the approach
Yes
If a region has performed a detailed system study of the Under Frequency protection systems in their region and developed protective settings based off the characteristics developed in the study, the region should be allowed to deviate from the Generator Protection curve in Attachment 1.
No known conflict at this time.
Yes
It would be good to have the option of measuring the voltage at the Generator bus or POI. With the understanding that the voltage must be maintained of the POI.
Individual
Mark Thompson
AESO
Yes
In addition to the SRC ISO/RTO comments the AESO would like to add: As we understand it, the intent of this standard is to ensure that the generators ride through certain levels of frequency and voltage excursions, yet it only addresses the generator protection. We feel it must also address the protection and capabilities of the auxilliaries, unit transformers, lines, etc. If any of these trip off due to the same excursions that the generator is required to ride through, then the generator will be down and the standard will not have achieved its goal.

The applicability of the curve is limited to the protective relays addressed by the standard. This curve is not meaningful if the plants were going to trip due to other causes. See our response to Question #9.
Yes
No I disagree with the approach
It is the aggregate impact of all an entity's units that matters. There should be only one VRF - HIGH.
No
It is the aggregate impact of all an entity's units that matters. There should be only one VRF - HIGH.
None
None
Yes
The issue typically addressed by international grid codes is an over-all plant performance standard and plant dynamic studies are perfomed to evaluate the impact on in-plant systems. Standards applicable to only generator protection might give a false sense that a plant could

survive the transients and the reliability of the BES would be just as adversely impacted if large plants were to trip for causes other than a main generator relay. The basis and reliability benefit for voltage ride through transients should be clarified. Generator UF relays must coordinate with grid UFLS relaying. Some areas may apply UVLS and logic dictates that the coordination of that protection with a generator ride through criteria should be specified. Recommend that the scope of "equipment" that can be granted an exception be limited in some way or explicitly qualified. Otherwise, plant performance can be dictated by less-consequential auxiliary equipment (e.g. variable speed drives with UV settings per manufacturer standard instructions). Because R5 grants exception automatically in response to the GO providing documentation of any limitation. R5 bullet 2 - recommend changing "generator nameplate capacity rating" to "generator gross Real Power capability". The existing words are too general and including 'nameplate' is confusing.

Yes
However, it should clearer in the requirements how mechanical and electrical overspeed protection is coordinated with the UF relay settings. Also, we would appreciate the SDT's view on why the frequency requirement are not being written into the existing PRC-006 (UFLS) standard.
No
A possible concern would be the effect on auxiliary system equipment and reliability at voltages below 90%.
Yes
Yes
Yes I agree with the approach
A suggestion for SDT's consideration is that VRFs could be based on percentage of units not in compliance. A utility may have several large units (high VRF) and many small (low VRF) not in compliance.
Yes
This standard may need to be coordinated with current efforts to revise standard PRC-006-1, and with the Regional standards being developed for UFLS, such as RFC's PRC-006-RFC-01.
Yes
1. FE's consensus is that the PRC-024 allowable under-frequency vs. time tripping curve is too tight. By too tight, we mean that the LP turbine buckets and blades are much more tolerant of off freq operation than the proposed tables. Comparing them to the old ECAR curves and allowable tripping times shows they are more stringent. Given how seldom these events occur, (never happened yet in the Eastern Interconnect) expending more of this capacity appears justified. 2. Section A5 Implementation schedule - it may not give sufficient time to implement these requirements. We suggest an additional year as follows: no less than 33% within 2 years of effective date no less than 66% within 3 years of effective date no less than 100% within 4 years of effective date 3. R1.2 Should say off-nominal not off-normal. 4. R2.1 Suggest changing the word "measured" to "experienced". 5. In R5, we suggest changing the first bullet to read: "The equipment causing the limitation is modified, upgraded or replaced with equipment that removes the technical limitation.", and then delete the second bullet. 6. Requirements 3, 4 and 6 specify that the Generator Owner shall provide information to RCs, PCs, TOPs, and TPs that monitor or model the associated unit; however, there is no requirement for these entities to identify

themselves to the Generator Owner. How will the Generator Owner know they have identified all of the entities that need the information? 7. In R5, the Generator Owner is granted an exception from requirements R1 or R2 simply by providing documentation of a equipment limitations. There is no independent view of the appropriateness of this exception. The drafting team should consider requiring independent verification of the equipment limitation prior to the granting of an exception to the requirements of the standard. 8. Sec. D References - Is this intended to be part of the standard? If so, it would be helpful if it was linked to the white paper so that we can review it. 9. In Requirements R3 through R6, the SDT may want to consider adding the Transmission Owner as nother entity who may need this information. 10. R2.2.1 may need to be re-worded as it requires that protection trip in no greater than 9 cycles. We are not aware of a disadvantage to the system if the tripping takes longer than 9 cycles.

Armin Klusman
CenterPoint Energy
No
a) CenterPoint Energy does not agree with limiting the application of this standard to the few relays that the SDT has chosen to address (only generator under or over voltage protective relays and volts per hertz relays). In effect, the SDT is allowing possible tripping of generation during off nominal frequency and voltage excursions from several other types of relays and control systems. This may not provide adequate reliability, as loss of significant generation can occur for voltage sags. b) The SDT has not included generator backup over current, impedance, and loss of field relays within the scope of this draft standard. CenterPoint Energy believes these additional relays should also be addressed. CenterPoint Energy believes it is illogical to have a transmission relay loadability standard (PRC-023 â€˜Transmission Relay Loadabilityâ€™) based on current and impedance ride-through while exempting generators from comparable requirements. Such an exemption defeats the purpose of the transmission relay loadability requirements by allowing a system event to escalate due to failure of generator relays to ride-through the same types of events envisioned by PRC-023 requirements. One key purpose for PRC-023 is to â€œnot interfere with system operatorsâ€™ ability to take remedial action to protect system reliability.â€ c) In addition to including other types of generator relays, the relaying and control for plant auxiliary systems should also be addressed for operation during off nominal frequency and voltage excursions. Again, it is illogical to have a transmission relay loadability requirements based on current and impedance ride-through while exempting a generation plant from comparable requirements. CenterPoint Energy realizes that generating plants have many internal control systems on auxiliary equipment that could be impacted during low voltage events, but exempting such systems from this standard defeats its purpose. CenterPoint Energy also recognizes that failures or incorrect operation of equipment installed for voltage ride-through capability on auxiliary equipment controls, such as UPS devices, will occur. Therefore, CenterPoint Energy recommends the SDT specifically address plant auxiliary equipment ride through. CenterPoint Energy suggests that the requirements be similar to those in NERC standard PRC-004 â€˜Analysis and Mitigation of Transmission and Generation Protection System Misoperationsâ€™. That is, if the plant incorrectly trips during a voltage sag due to

auxiliary systems problems, the problem will be investigated and, where necessary, a system-wide corrective action plan will be developed and completed.
No
a) Attachment 2 of PRC-024-2 is truncated at 4 seconds and does not define the duration of the 0.9 pu voltage level. CenterPoint Energy recommends the total duration of the 0.9 pu voltage level be established at a MINIMUM of 10 seconds. The basis for 10 seconds is for coordination with undervoltage load shedding (UVLS) systems. b) Attachment 2 has a step function profile. CenterPoint Energy has reviewed these proposed steps for voltage recovery to 0.9 pu and concurs with most proposed steps. However, CenterPoint Energy studies indicate an insufficient coordination margin at the proposed 0.30 seconds at 0.65 pu voltage point. Noting the CenterPoint Energy transmission grid is a compact and stout system, CenterPoint Energy believes it is highly unlikely many transmission systems can recover to a 0.65 voltage level in 18 cycles (0.30 seconds). To address this, CenterPoint Energy recommends reducing the number of steps. For this, as well as including a 0.9 pu voltage level ride-through for a minimum of 10 seconds, CenterPoint Energy recommends the data points (Time / Voltage) in the â€œLVRT DURATIONâ€ table be as follows: 0.15 / 0.000, 2.00 / 0.450, 3.00 / 0.750, and 10.00 / 0.900.
Yes
a) CenterPoint Energy is concerned with what appears to be a lack of consistency and coordination between standards efforts. Considering PRC-023, CenterPoint Energy believes it is illogical to have transmission relay loadability requirements based on 0.85 pu system voltage for an extended period (such as, 15 minutes) to allow system operators to take remedial actions, while exempting generators from comparable requirements. For another example, it appears this proposed standard is not consistent with that being proposed for under-frequency load shedding systems that can help prevent cascading outages. b) Requirements, such as R2.2.1 and R2.2.2, are essentially fill-in-the-blank, location-specific criteria that are unnecessary and could have unintended consequences. Location-specific criteria can change over time with additions and modifications of the transmission system. Entities will have no incentives to voluntarily exceed the minimum required criteria, even though their plant has a greater ride-though capability. R2.2.1 further allows relaying to â€œbe set on actual fault clearing timesâ€, instead of the 9 cycles indicated in Attachment 2. In addition, R2.2.2 allows the use of location-specific criteria, but only if such criteria are less stringent. CenterPoint Energy believes NERC reliability standards should not include fill-in-the-blank, location-specific criteria. CenterPoint Energy recommends modifying R2.2.1 to reference Attachment 2 and to clarify the ride-through criteria is zero voltage for 0.15 seconds (9 cycles). CenterPoint Energy recommends deleting R2.2.2. c) R5 allows generating plants to meet less stringent criteria if generator manufacturer literature indicates limitations, which would further erode system support from generation resources. It does not appear there is any process to substantiate the legitimacy of such limitations. CenterPoint Energy recommends deleting R5 and associated references.

Independent Electricity System Operator
Yes
We agree. This is consistent with our view expressed for MOD-026 for which we suggest the Generator Owner, not the Generator Operator, be held responsible for generating unit equipment/device settings and data verification.
Yes
We agree that it is a good start. However, other settings such as those mentioned in the Background Information Section (generator backup over current or impedance, loss of field, etc.) also give rise to tripping of the generator. Consideration should be given to expanding the scope of the SAR to include these settings. The lack of a standard for generator out-of-step protection resulted in adverse effects on the Michigan-Ontario ties during the 2003 blackout.
We are unable to comment on how many generating units in the fleet that are not capable of meeting the threshold in the Attachments since we are not a Generator Owner. However, we are unclear on the basis of the 57.8 Hz setting stipulated in R1.3 as it is not consistent with the proposed UFLS characteristics (posted in July of 2008) in which it indicates that frequency should be arrested at no less than 58.0 Hz. Further, the basis for the very restrictive over-frequency curve proposed in attachment #1 is not obvious. The over-frequency standard proposed in PRC-024 was exceeded during the blackout of 2003 for Ontario generation that was connected radially

into New York. No adverse effects attributed to this over frequency event have been reported to the IESO.
No
Simulation results only add value when sufficient validation has been performed to provide confidence that good decision can be made on the basis of these simulations. Simulations by themselves are not enough. Were the simulations used in this exercise validated against actual performance? To cater for protection differences within jurisdictions, it would be better to label the jogs in the voltage characteristic with the corresponding physical meaning (e.g. maximum normal fault clearing, maximum delayed fault clearing) rather than assign specific times. Within Ontario, it is unclear whether the voltage curves are sufficient to accommodate present practice for delayed fault clearing. It is unclear in the curves whether the POI voltage is the positive sequence voltage or phase voltage. The meaning of per unit should also be clarified. For example, Ontario uses a 220kV voltage basis for a system operated as high as 250kV. Does 1.2PU mean 264 kV or 300kV? The over-voltage settings should be re-expressed to ensure the short duration over-voltages that follow lightning strikes and capacitor switching do not result in generator tripping.
No
In an islanded situation, each generator's status is critical to ensuring frequency decline is successfully arrested based on the assumption that all on-line generators would not trip within specific frequency bounds unless prior approval has been sought and granted to allow tripping. Not holding the smaller generators subject to the requirements associated with generator frequency tripping exposes the island to a great uncertainty on the amount of generation that can be relied upon to arrest frequency excursion.
No I disagree with the approach
Size dependent VRFs do not reflect the potential reliability risk associated with more than one Medium size generating unit (>100 MVA and <500 MVA) failing to comply with the standard. Two of such units at, say, 400 MVA each, that trip unnecessarily will have a greater collective impact on the island frequency than the tripping of a 500 MVA unit.
No
Please see above comments. We suggest that the same VRFs apply to all units that meet the Applicability criteria.
None
None
Yes
a. R5: The wording "â€¦the Generator Owner is granted an exception for that unit from meeting the portion of Requirement R1 or R2 for that limitation once it provides documentation of the equipment limitation(s) to the Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners that monitor or model the associated unit, within 30 days of identifying the equipment limitation." is not written in a way to hold an entity responsible for any action. We suggest to reword it such that it places a responsibilility to the Generator to seek approval for an exception, as follows: "â€¦the Generator Owner shall obtain approval for an exception for that unit from meeting the portion of Requirement R1 or R2 for that limitation through the submission of documentation of the equipment limitation(s) to the Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners that monitor or model the associated unit within 30 days of identifying the equipment limitation." The requirement for getting non-conforming protection approved should be so stipulated to put the onus for mitigating actions on the Generator Owners. For example, in the case of non-conforming underfrequency settings, the requesting Generator Owner should be required to demonstrate that mitigating (i.e. arrangements for additional compensating load shedding) measures have been arranged with the Balancing Authority in their submission. Equipment settings that infringe upon the curves may be implemented only after approval is granted by the appropriate entities. Along with this proposed change, there is also a need for the entities receiving the approval request to respond to the request. Another requirement is needed to complete this process. b. The latter part of R5 should be reworded to hold an entity responsible for the needed actions associated with expiring the exception such that the requirement is measurable and enforceable. c. R6: It is unclear to us what purpose this requirement serves. If R5 is to be revised as we suggest (see above), then the "limitation" in question will be presented with technical justification in the request for approval. The receiving entities (RC, PC, TOP and TP) will have a chance to accept or reject the request with due consideration of the technical argument. This is part of the approval request process, hence we do not see the need for R6 if R5 is to be reworded. If a remand process needs to be stipulated, then inclusion in R5 a requirement for the receiving entity(ies) to respond to the request - either approving or disproving the with a rationale, would suffice.

Yes
None
Yes
Please clearly state that such relays do not have to be added or elements enabled, GO makes the decision what protection to include. R1 and M1, and R2 and M2 should allow for proof that the frequency and/or voltage relays are omitted or set to alarm only, not trip. Please clearly define 'point of interconnection' used in 4.2.2; typically this is where the generating source connects to the switchyard or networked transmission system but these relays are typically at the generator terminals on the low side of the generator step-up transformer.
Yes
We have not yet performed a detailed review wrt proposed limits, but expect there will be some that are not capable of meeting these stated thresholds. It can be hard to get capability data and warranties have expired, for older units or those purchased from other owners. The PRC-024-1 curves should not become a de facto requirement. If decades of operating experience have proven satisfactory from both a BES and generator equipment life persperctive, this should be accepted as evidence as well. Generic guidance, such as past ANSI/IEEE standards, recommended practices, and guides should be allowed for older units exception evidence as well. Clearly state that field testing is not required.
No
FERC 661-A applies to wind generator Voltage Ride Though (VRT) for a three phase fault. We disagree with PRC-024-1 now expanding it to all generators. R2.2.1 wording is confusing: it implies that the UV trip setting must be less than 9 cycles which conflicts with the LVRT curve and its interpretation for lessor voltage dips.
Yes
Again from our perspective, the main objective is allow UFLS/UVLS to do their job to arrest frequency/voltage decline and retain generation on-line so as not to exacerabate the extreme disturbance. Of course, generation equipment limits must be respected. This standard should not encourage GO to augment protection or become more conservative than warranted, possibly refuting the main objective. We formerly belonged to the now defunct MAIN region. Previous MAIN requirements for generators were: Generator UF Setting (Hz) Minimum Time Delay (Sec) > 59.5 Hz Automatic tripping not permitted < 59.5 to > 59.2 Hz 2700 seconds < 59.2 to > 58.5 Hz 120 seconds < 58.5 to > 58.0 Hz 15 seconds < 58.0 Hz Ownerâ€™s Discretion We have applied these to generation that has connected in the last decade unless the GO had manufacturer recommendations to the contrary.
No I disagree with the approach
Are they based on the individual unit or the aggregate at the Point of Interconnection? Average annual production (MWh) is a better indicator of their threat to the BES during UF or UV events. Larger units should not be penalized just because they are large. If large and generating many MWh then they're big and likely to be on-line for an event.
No
See above
It seems that geography (e.g. peninsulas, coastal areas) and load sparcity, and dense load served by distant generation have been significant factors in blackout events. As such, regional differences do exist.
Nuclear Plant Requirements may conflict. Footnote 2 refers to the agreements for which the GO is not responsible. Also, grandfathered generation of more vertically integrated entities and/or in certain states may not have such formal agreements.
Yes
This standard could be ineffective if someoneâ€™s auxiliary power protection trips out on low voltage or frequency and brings the unit down before the generator protection. Those settings on the aux buses are there to protect the equipment from failure since most of the downstream loads such as motors and electronics wonâ€™t ride through an excursion as well as large T/G sets. We suggest that ANSI/IEEE Standards C37.102, C50.12, and C50.13 should be used and listed as references to this Standard. Reporting mechanism in R3 and R4 raises some commercial concerns. We prefer a secure repository of reporting to the RRO. Then only those who do have valid reasons for studies or monitoring could be granted access to the information. Footnote 1 expands 'protective relays' definition to include voltage regulator, etc. Instead state that only direct trip elements (functions) in the voltage regulator and exciter are included, if that's the intent. It should be made very clear.
Individual
John Cummings
PPL Energy Plus

Yes

PPL is concerned with the following concepts in the standard: 1) The standard applies equally to asynchronous and synchronous machines, salient pole and round rotor machines, photovoltaic, and other resources and as such the standard does not appear to recognize that these technologies respond differently to voltage and frequency excursions. 2) Better clarity of generator owner and transmission owner roles regarding changing existing fault clearing times is needed in the proposed standard. 3) R2.2 requires further clarity regarding relay settings. 4) R3 and R4 look the same. 5) The reference paper under Section D needs a thorough review by the industry.

Individual

Robert Jenkins

First Solar

Yes

No

The application of the standard to arrays of solar inverters is unclear. While the primary breaker can be set to comply with the standards, when the system voltage is driven to zero during the fault, the inverters will lose their phase lock and begin to shut down.

Yes

The response, and therefore compliance with this proposed Standard, are not clear. The standard does not seem to contemplate static power generators that would be part of renewable energy systems like solar PV. As part of the requirement there should be specificity on a number of points. For example as written it does not clearly define what the generator does during the out of frequency/voltage conditions. Presumably the inverters would not be required to drive current into the fault and thereby increase fault duties. Furthermore, once the fault is cleared, it does not define the speed/rate at which power is ramped up from the generator. This rate could be hard to achieve with a static converter. Finally, the standard does not define the rate of change of frequency or voltage. Typically devices are more sensitive to high rate changes. All of these items need more detail and specificity to determine how new forms of generation can meet these requirements.

No

See response to the previous question. While this may envelope the probable range of voltages that may occur on the system, it does not sufficiently describe the response of the generating plant to these disturbances. To simply say that the protective relays should not trip lacks sufficient detail to apply to inverter based PV projects.

The requirements are inconsistent with UL 1741 and IEEE 1547 as applied to existing solar PV inverter design. Compliance withn the proposed Standard would require an industry re-design and recognition from the Interconnecting Transmission Owner that projects would not meet these other standards. Additionally the Standard should provide for a phase in period for inverter based PV facilities so that such redesign can be accommodated.

Individual

Jay Seitz

US Bureau of Reclamation

Yes

We agree since PRC-004-1, Protection System Misoperation Analysis and Correction and PRC-005-1, Protection System Maintenance, are applicable to the Generator Owner (and Transmission

Owner); however, PRC-001-1 Protection System Coordination is applicable to the Generator Operator (and Transmission Operator). We believe all of the above should be coordinated and applicable to the Owner. The Standard also has a role for a Transmission entity (in this case the Transmission Planner) to specify clearing times; however no applicability or requirement is provided in the standard. We believe the role for a Transmission entity should be clarified in the Standard and applicability and requirement(s) added.
No
Now that the draft standard has been posted, it appears to be a more structured and limited version of existing Standard PRC-001-1 - System Protection Coordination. PRC-001-1 requires the Generator entity to coordinate protection settings with the Transmission entity. The stated Purpose of PRC-024-1 "Ensure that generator frequency and voltage protective relays are set to support transmission system stability during voltage and frequency excursions" should be attainable through PRC-001-1. If PRC-001-1 is not adequate it should be modified rather than adding an additional standard only addressing generator frequency and voltage settings. As such we do not believe there is a clear, reliability based justification for this standard as currently drafted.
No
No
The SDT background material above states that the 9 cycle time is required by FERC Order 661-A. FERC Order 661-A applies to wind generators. We believe there is no convincing reliability based rationale to expand the scope of the FERC Order via this standard to include synchronous machines, noting that Genrators are already required (PRC-001-1) to coordinate settings with the host Transmission Operator.
Yes
The threshold should be consistent with the NERC Reliability Compliance Registry Criteria.
No I disagree with the approach
If this approach is appropriate for this standard, it seems this approach should be used for all Standards applicable to generators.
Yes
Requirements R3 and R4 place a coordinating role on the Generator Owner to provide trip settings to four entities, the Reliability Coordinator, Planning Coordinator, Transmission Operator, and Transmission Planner. We believe it is more appropriate for the Generator Owner to coordinate settings with a single Transmission entity since the purpose of the Standard is " ... to support transmission system stability during voltage and frequency excursions." and for the Transmission entity to further coordinate if necessary. The Transmission entity is in a better position to know what additional entities, if any should be involved. For the data points provided in the Attachment 2, HVRT DURATION and LVRT DURATION, we recommend both time and voltage units of measure be provided.

Yes
We agree. This is consistent with our view expressed for MOD-026 for which we suggest the Generator Owner, not the Generator Operator, be held responsible for generating unit equipment/device settings and data verification.
Yes
We agree that it is a good start.
No
We are unable to comment on how many generating units in the fleet that are not capable of meeting the threshold in the Attachments since we are not a Generator Owner. However, we are unclear on the basis of the 57.8 Hz setting stipulated in R1.3 as it is not consistent with the proposed UFLS characteristics (posted in July of 2008) in which it indicates that frequency should be arrested at no less than 58.0 Hz. We also think the question is a bit misleading and may not result in providing the SDT any grounded suggestions or concurrence on the appropriate frequency levels that the SDT may already have in mind. The question as written suggests that the SDT is trying to canvass the industry through this commenting process. This is a way to obtain feedback, but it does not provide the rationale of the proposed levels. We suggest that the SDT research the limitations of the machines that are connected to the BPS (perhaps by a survey or a NERC data request) to better support the proposed frequency limit, then ask for concurrence or alternative suggestions.
Yes
From a system operator's perspective, we think these parameters are appropriate to prevent unnecessary tripping of the generators, which may otherwise give rise to unreliability, while minimizing their expose to prolonged period of under and overvoltages.
No
There should not be any exemption of the coordination on frequency trip setting. In an islanded situation, each generator's status is critical to ensuring that frequency decline is successfully arrested based on the assumption that all on-line generators would not trip within specific frequency bounds unless prior approval has been sought and granted to allow tripping. Not holding the smaller generators subject to the requirements associated with generator frequency tripping exposes the island to a great uncertainty on the amount of generation that can be relied upon to arrest frequency excursion.
No I disagree with the approach
Size dependent VRFs do not reflect the potential reliability risk associated with more than one Medium size generating unit (>100 MVA and <500 MVA) failing to comply with the standard. Two of such units at, say, 400 MVA each, that trip unnecessarily will have a greater collective impact on the island frequency than the tripping of a 500 MVA unit.
No
Please see above comments. We suggest that the same VRFs apply to all units that meet the Applicability criteria.
None
None
Yes
a. R5: The wording "â€¦the Generator Owner is granted an exception for that unit from meeting the portion of Requirement R1 or R2 for that limitation once it provides documentation of the equipment limitation(s) to the Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners that monitor or model the associated unit, within 30 days of identifying the equipment limitation." is not written in a way to hold an entity responsible for any action. We suggest to reword it such that it places a responsibility to the Generator to seek approval for an exception, as follows: "the Generator Owner shall obtain approval for an exception for that unit from meeting the portion of Requirement R1 or R2 for that limitation through the submission of documentation of the equipment limitation(s) to the Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners that monitor or model the associated unit within 30 days of identifying the equipment limitation.

Along with this proposed change, there is also a need for the entities receiving the approval request to respond to the request. Another requirement is needed to complete this process. b. The latter part of R5 should be reworded to hold an entity responsible for the needed actions associated with expiring the exception such that the requirement is measurable and enforceable. c. R6: It is unclear to us what purpose this requirement serves. If R5 is to be revised as we suggest (see above), then the "limitation" in question will be presented with technical justification in the request for approval. The receiving entities (RC, PC, TOP and TP) will have a chance to accept or reject the request with due consideration of the technical argument. This is part of the approval request process, hence we do not see the need for R6 if R5 is to be reworded. If a remand process needs to be stipulated, then inclusion in R5 a requirement for the receiving entity(ies) to respond to the request - either approving or disproving the with a rationale, would suffice.

Consideration of Comments on Draft Standard PRC-024-1 for the Generator Verification Standard Drafting Team — Project 2007-09

The Generator Verification Standard Drafting Team thanks all commenters who submitted comments on the proposed revision to the PRC-024-1 — Generator Frequency and Voltage Protective Relay Settings standard. This standard was posted for a 45-day public comment period from February 17-April 2, 2009. Stakeholders were asked to provide feedback on the standard through a special electronic comment form. There were 43 sets of comments, including comments from more than 100 different people from over 60 companies representing 9 of the 10 Industry Segments as shown in the table on the following pages.

For this report, the comments have been organized by question number so it is easier to see where there is consensus. The comments submitted can be reviewed in their original format on the following Web page:

http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html

The drafting team considered stakeholder comments and made the following changes based on those comments:

Purpose:
The drafting team revised the purpose to clarify that new generators must be capable of riding through voltage and frequency excursions and expected unit performance during frequency and voltage excursions must be communicated to entities that monitor or model the associated generator.

Applicability:
The drafting team has determined that only the Generator Owner has responsibilities required by this NERC Standard. The "facility applicability" language that duplicated the language from the Compliance Registry Criteria is not necessary to include in the applicability section of the standard, and was removed.

The team added a footnote to both Requirements R1 and R2 to clarify that the requirements in the standard do not require any entity to have frequency or voltage protective relaying installed or activated on its units.

Requirement R1:

- Modified the sequence of the wording in the requirement
- Replaced the range of VRFs based on MVA to a single VRF for consistency with other standards
- Added the following as an additional criterion under which the generating unit may not trip:
    - When the transmission system frequency rate of change is less than 2.5 Hz/second with a total change of up to 1.0 Hz.

Requirement R2:

- Modified the language to clarify that the intent is to address trippings associated with events external to the generator
- Added more specificity to each of the criterion under which the generator unit may not trip
- Replaced the range of VRFs based on MVA to a single VRF for consistency with other standards

Requirement R3 and Requirement R4 (now R7 in the revised standard)

- Merged these requirements and moved the requirement so that it is the last requirement in the standard so that the sequence of requirements has more of a chronological order

Requirement R5 (now R3 in the revised standard)

- Modified the sequence of wording in the requirement and simplified the language for greater clarity on the required documentation of equipment limitations..

Requirement R6 (now R4 in the revised standard)

- Modified the sequence of wording in the requirement and simplified the language for greater clarity.

New Requirement R5

- Requires Generator Owners to provide requesting entities with specific documentation to support an estimate of a unit's performance during Frequency/Voltage Excursions for modeling and study accuracy.

- This requirement addresses the inability of some existing units to ride-through the voltage and frequency excursions identified in Attachment 1 and 2. The purpose of this Requirement is to provide the Transmission Planner the ability to more accurately model generating plant performance during system voltage and frequency excursions.

New Requirement R6:

- Requires Generator Owners to have new generating units designed, built, and maintained so that they don't trip and do remain within specified parameters during frequency and voltage excursions associated with events external to the unit.

Attachments 1 and 2:

- The SDT developed the off nominal frequency curve (Attachment 1) in coordination with the NERC UFLS Standard Drafting Team. The 57.8 Hz setting for generator underfrequency and 58 Hz for UFLS is to ensure that the UFLS will have a chance to arrest the system frequency decline before reaching the minimum permissible frequency for generators. The intent of the curves is to ensure that the generators do not trip when the frequency is within the area bounded by the high and low frequency curves. When the frequency excursion reaches outside the high or low curve, the generator is allowed to trip.
- The SDT developed the off nominal frequency capabilities based on turbine manufacturers' capabilities in conjunction with the ability to set relays between the frequency curve and the manufacturers' curves.
- Updated Attachment 2 to add more clarity on the calculations for the 'voltage ride through curve.

The team made conforming changes to the measures and added compliance elements to the standard. If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herbert Schrayshuen, at 315 439 1390 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

Index to Questions, Comments, and Responses

1. The PRC-024-1 Standard is applicable to the Generator Owner as opposed to Generator Operator, do you agree? If not, please explain in the comment area. 11

2. The SDT has established the Requirements in this Standard only for the setting of voltage and frequency generator protective relays. Do you agree? If not, please explain in the comment area. 17

3. PRC-024-1 specifies the limits for generator protective system settings as defined in PRC-024-1 - Attachment 1 and PRC-024-1 - Attachment 2. Are there generating units in your fleet that are not capable of meeting the thresholds in these attachments due to turbine/generator equipment design limitations? 29

4. The curve in PRC-024-1 — Attachment 2 was based upon analysis performed of simulated system disturbances. System voltage traces representative of several hundred disturbances were co-plotted on a voltage versus time graph. The voltage duration curve in this attachment is derived from these voltage traces. A margin was then applied to the voltage duration curve to account for unanticipated system conditions. The 9 cycle fault clearing time required by the FERC 661-A Order is incorporated into this curve. Given this background on the development of PRC-024-1 — Attachment 2, do you agree with the parameters of the curve? If not, please explain in the comment area. 40

5. Coordination between UFLS programs and generator frequency tripping is especially a concern in islanded situations. Is the connection voltage of >100kV, the size threshold for generator units 20 MVA and greater and 75 MVA for multiple units at a single site, sufficient to address this concern? If not, please explain in the comment area. 70

6. The SDT proposed a set of VRFs based on size delineation of units. Do you agree with this approach? Do you agree with the MVA levels? If you disagree with either the approach or the MVA levels, please explain in the comment area. 78

7. If you are aware of any regional variances that would be required as a result of this standard please identify the regional variance here. 89

8. If you aware of any conflicts between the proposed standard and any regulatory function, rule order, tariff, rate schedule, legislative requirement or agreement, please identify the conflict here. 94

9. Are there other improvements that the SDT should consider for this revision of PRC-024-1 that you haven't already identified in response to other questions? If yes, please provide in the comment area. 98

1. **The PRC-024-1 Standard is applicable to the Generator Owner as opposed to Generator Operator, do you agree? If not, please explain in the comment area.**

Summary Consideration:

A majority of responders commented that the relay settings are the responsibility of the GO with several respondents indicating that this Standard ought to apply to both the GO and the GOP.

The minority included comments as follows:

- The relay settings are the responsibility of the GOP
- Since the GOP does not own the generator, he cannot change the settings w/o GO approval
- The GO has the maintenance responsibility
- The GOP has the maintenance responsibility
- There will be complications for generators with multiple owners
- TP should be added to specify clearing times

The latest version of the Functional Model provides some clarity on the division of duties between the Generator Owner and Generator Operator. The Generator Owner has the responsibility for making decisions about the design and maintenance of generating facilities, including the generator protection systems: "Generator Owner Task 2: Design and authorize maintenance of generation plant protective relaying systems, protective relaying systems on the transmission lines connecting the generation plant to the transmission system, and Special Protection Systems."

The drafting team has determined that the Generator Owner has the responsibilities required by this NERC Standard. The Generator Owner requirements include following specified limits on protective relay settings, providing notification of changes to protective relay settings, documenting equipment limitations, and responding to comments from the RC, PC, TO, or TP on this subject.

Organization	Yes or No	Question 1 Comment
Northeast Power Coordinating Council	No	Both bullets should be checked above (form will not accept).The responses received were divided, and below are the comments received for your consideration. The Generator Operators, and not the Generator Owners, are typically responsible for establishing relay setpoints, calibrations, and maintenance. The Generator Owner is the Functional Model entity that has direct control over the generating unit protection settings.

Organization	Yes or No	Question 1 Comment
Response: Thank you for your response. The drafting team has determined that the Generator Owner is the appropriate party to fulfill the responsibilities required by this NERC Standard since the required actions are related to the design and maintenance of the protection systems. Please see the summary considerations above.		
Constellation Power Generation & Constellation Nuclear	No	The Generator Operators, and not the Generator Owners, are typically responsible for establishing relay setpoints, calibrations, and maintenance. The Generator Owner is the Functional Model entity that has direct control over the generating unit protection settings.
Response: Thank you for your response. The drafting team has determined that the Generator Owner is the appropriate party to fulfill the responsibilities required by this NERC Standard since the required actions are related to the design and maintenance of the protection systems. Please see the summary considerations above.		
Converteam Naval Systems Inc.	No	I believe it should be applicable to both.
Response: Thank you for your response. The drafting team has determined that the Generator Owner is the appropriate party to fulfill the responsibilities required by this NERC Standard since the required actions are related to the design and maintenance of the protection systems. Please see the summary considerations above.		
Gainesville Regional Utilities	No	In a number of smaller utilities, they are the same and do not need to be addressed separately
Response: Thank you for your response. The drafting team has determined that the Generator Owner is the appropriate party to fulfill the responsibilities required by this NERC Standard since the required actions are related to the design and maintenance of the protection systems.		
Veolia Environmental Services	No	The generator operator is the entity charged with maintaining the facility. Therefore, the GOP has all the necessary records and procedures.
Response: Thank you for your response. The drafting team has determined that the Generator Owner is the appropriate party to fulfill the responsibilities required by this NERC Standard since the required actions are related to the design and maintenance of the protection systems. Please see the summary considerations above.		
Old Dominion Electric Cooperative	No	I agree that the GO is the primary function for this requirement, but given the multitude of Go/GOP configurations out there, I think the GOP function should also be included in the applicability section of this standard.
Response: Thank you for your response. The drafting team has determined that the Generator Owner is the appropriate party to fulfill the		

Organization	Yes or No	Question 1 Comment
responsibilities required by this NERC Standard since the required actions are related to the design and maintenance of the protection systems. Please see the summary considerations above.		
Southern California Edison Company	No	The Generator Operator should be the functional entity to whom the standard applies because Generator Operators tend to change the settings without warning or permission.
Response: Thank you for your response. The drafting team has determined that the Generator Owner is the appropriate party to fulfill the responsibilities required by this NERC Standard since the required actions are related to the design and maintenance of the protection systems. Please see the summary considerations above.		
Xcel Energy	No	We feel the GO would only be applicable for R6 and for when a new unit is being built. Once a unit is online, it is the GOP that would be performing all the actions to ensure compliance with R1-R5 of this standard. We also foresee compliance issues with jointly-owned units, if applicability were to remain only with the GO.
Response: Thank you for your response. The drafting team has determined that the Generator Owner is the appropriate party to fulfill the responsibilities required by this NERC Standard since the required actions are related to the design and maintenance of the protection systems. Please see the summary considerations above.		
Entergy Fossil Operations	Yes	Generator Owner is responsible for the maintenance of the facility. Relay settings are a Generator Owner function.
Response: Thank you for your response. The SDT agrees with your comments.		
SERC Dynamics Review Subcommittee (DRS)	Yes	Since the generator operator does not own the equipment addressed by the standard, he cannot change the settings without the generator owner's approval. The standard potentially requires changing the frequency and voltage relay trip settings. Since the generator owner owns the equipment, they also own the settings and should be the one held accountable for meeting the requirements of this standard.
Response: Thank you for your response. The SDT agrees with your comments.		
IRC Standards Review Committee	Yes	We agree. This is consistent with our view expressed for MOD-026 for which we suggest the Generator Owner, not the Generator Operator, be held responsible for generating unit equipment/device settings and data verification.
Response: Thank you for your response. The SDT agrees with your comments.		

Organization	Yes or No	Question 1 Comment
Southern Company	Yes	If the standard is in place, it belongs to the Generator Owner. The SAR seemed to be written for transmission, but this standard seems to be evolving to a generator setting standard. Does the SAR need to be revised? Although GO has the access to the equipment settings/records, GOP may not, GOP is the entity to operate the units. GO must communicate settings to the GOP. Since the generator operator does not own the equipment addressed by the standard, he cannot change the settings without the generator owner's approval. The standard potentially requires changing the frequency and voltage relay trip settings. Since the generator owner owns the equipment, they also own the settings and should be the one held accountable for meeting the requirements of this standard.
Response: Thank you for your response. The SDT agrees with your comments. The proposed requirements are within the scope of the SAR.		
Basin Electric Power Cooperative	Yes	I have some problems with the intent of this standard in general, but a standard of this nature would have to apply to the generator owner.
Response: Thank you for your response. The SDT agrees with your comment.		
Progress Energy, Inc.	Yes	Since the generator operator does not own the equipment addressed by the standard, he cannot change the settings without the owner's approval. The standard potentially requires changing the frequency and voltage relay trip settings. Since the generator owner owns the equipment, they also own the settings and should be the one held accountable for meeting the requirements of this standard.
Response: Thank you for your response. The SDT agrees with your comment.		
Hydro-Québec TransEnergie (HQT)	Yes	The Generator Owner is the Functional Model entity that has direct control over the generating unit protection settings.
Response: Thank you for your response. The SDT agrees with your comment.		
Independent Electricity System Operator	Yes	We agree. This is consistent with our view expressed for MOD-026 for which we suggest the Generator Owner, not the Generator Operator, be held responsible for generating unit equipment/device settings and data verification.
Response: Thank you for your response. The SDT agrees with your comment.		
US Bureau of Reclamation	Yes	We agree since PRC-004-1, Protection System Misoperation Analysis and Correction and PRC-005-1, Protection System Maintenance, are applicable to the Generator Owner (and Transmission Owner); however, PRC-001-1 Protection System

Organization	Yes or No	Question 1 Comment
		Coordination is applicable to the Generator Operator (and Transmission Operator). We believe all of the above should be coordinated and applicable to the Owner. The Standard also has a role for a Transmission entity (in this case the Transmission Planner) to specify clearing times; however no applicability or requirement is provided in the standard. We believe the role for a Transmission entity should be clarified in the Standard and applicability and requirement(s) added.
Response: Thank you for your response. The SDT agrees that the GO is the responsible party for PRC-024-1. Substantial rewriting of this Standard has occurred since the first posting, yet the TP has not yet been included in the applicability.

2. **The SDT has established the Requirements in this Standard only for the setting of voltage and frequency generator protective relays. Do you agree? If not, please explain in the comment area.**

Summary Consideration:

Minority comments were wide-ranging and covered the following issues:

- Some respondents expressed that the Standard needs more technical justification.
- Generator protection relays are designed to protect generation equipment. NERC has no business dictating how Generator Owners or Operators protect their equipment. Reducing generator protection ultimately reduces power system reliability.
- Generator loss of life should be considered.
- This Standard should only apply to non-synchronous generators. PRC-001 or a new SAR will take care of synchronous generators. This Standard will encourage setting of relays that are not already set and reduce reliability.
- Setting all generator voltage trip points at the same point will result in catastrophic loss of generation.
- Other relays and devices should be included including Volts/Hertz, generator backup impedance, voltage restrained over-current, and exciter voltage regulator protective functions.
- Footnote 1 is too broad and the Standard should not address voltage regulators.
- Some locations do not need to include generators that are smaller than 100 MVA.
- Include formulas as well as the curves.
- Worst case conditions should be considered with extra margins allowed for oscillations. Generator frequency trip settings should be longer with UFLS normally reducing the frequency recovery time.

On the larger issue of performance, a significant number of respondents pointed that the SAR was clear in its scope and that the SDT should address generator plant performance and not merely propose a relay setting standard. In other words, the Standard should apply to all components of the generation plant. As originally written the Standard defeats the purpose of PRC-023 on transmission loadability.

A small dissenting minority expressed that the SAR's goal of having generators ride through voltage and frequency disturbances is not practical and that "generators" are not designed to ride through these events.

The GV SDT has determined that this NERC Standard should require new generators to ride through voltage and frequency excursions. The revised Standard does not dictate how generators should be protected. The revised Standard specifies the limits for events that new generators are required to ride through. These limits were developed based on manufacturers' information on machine capabilities as well as on power system reliability requirements. The Standard is a protective relay setting Standard for existing generators. Further, the GV SDT has included a provision for existing generators that cannot meet the limits specified in R1 and R2.

Organization	Yes or No	Question 2 Comment
Entergy Fossil Operations	No	I disagree in principle that NERC is dictating how generator protective relays are set. These relays are set to protect the generation equipment and ensure long term reliability of the unit. Dictating settings which enhances ride through capability ensure short term reliability and can hurt long term reliability. If this if force upon us, I agree with only addressing the voltage and frequency generator protective relays.
Response: Based on industry input, the Standard has been modified to require new generators to ride through voltage and frequency excursions. The Standard does not dictate how generators should be protected. The Standard specifies the limits for events that new generators are required to ride through. These limits were developed based on manufacturers' information on machine capabilities as well as on power system reliability requirements. The Standard is a protective relay setting Standard for existing generators. Further, the SDT has included a provision for existing generators that cannot meet the limits specified in R1 and R2.		
NERC System Protection and Control Subcommittee (SPCS)	No	PRC-024 should only apply to non-synchronous machines. The SPCS believes that coordination of synchronous generator voltage and frequency protective relays with transmission relays should not be addressed in PRC-024. An effort is underway to address coordination of generator voltage and frequency protective relay settings with transmission protection systems either by modifications to PRC-001 or the development of a new SAR to address coordination requirements. SPCS is preparing a Technical Reference paper on such coordination that is expected to be completed in June, 2009. Generator voltage and frequency protective relays are included in that that paper. The purpose as stated in the SAR is "To ensure that generators will not trip off-line during specified voltage and frequency excursions." The Standard will not accomplish its stated purpose by limiting requirements to generator protective relays alone. In fact it may actually have the exact opposite consequence. Undervoltage relays are not usually set on most synchronous generators. When undervoltage relays are applied, IEEE C37.102 recommends alarm rather than trip. The more likely cause for the loss of a generator due to a dip in voltage is from the loss of equipment on the auxiliary bus. This was the cause sited for a well documented event on March 27, 1994 losing all generating units at Cinergy's Gibson Station. Other events since 1994 were also due to tripping of generators due to loss of auxiliary busses caused by voltage dips from system faults. In fact, the Standard may result in the unintended consequence of reducing reliability. Many generator owners may take the recommendation as an implied directive to set previously unused generator undervoltage relay elements to the minimums stated in the Standard. That would cause more generator trips for system faults rather than fewer trips. Similarly, many generators that currently do not have undervoltage relay settings would trip at various other inherent voltage levels during a voltage excursion. With all of them set at or about 0.90 per unit, they would all trip at the same point, causing a catastrophic loss of generation. There are significant machine protection issues which are not addressed, such as the Volts/Hertz relay which protects the machine from an over-fluxing thermal hazard. Loss of generation consequential to problems on auxiliaries is a significant problem, which is not addressed in this Standard.

Organization	Yes or No	Question 2 Comment
Response: The SDT agrees with you that the previous version of the draft Standard "will not accomplish its stated purpose by limiting requirements to generator protective relays alone." The Standard has been modified to require new generators to ride through voltage and frequency excursions. The standard is technology neutral and applies to all generators. The SDT followed the SAR in applying the Standard to all new generators and by coordinating with the underfrequency load shedding Standard development.		
Northeast Power Coordinating Council	No	Both bullets should be checked above (form will not accept).The proposed standard addresses all issues identified in the Standard Authorization Request. Coordination of generator and transmission system protection is addressed in PRC-001.As presently constituted this Standard will likely result in the inappropriate enabling and setting of frequency and voltage relays with the settings which are permitted, thus reducing system reliability, which is contrary to its stated purpose. This is supported in the comments provided below. There are significant machine protection issues which are not addressed, such as Volts per Hertz. Loss of generation consequential to problems on auxiliary systems, problems which arise due to low voltage or low frequency, or a combination of both, is a significant problem, and is not addressed in this Standard.
Response: The SDT has modified the standard to address those relays that have frequency or voltage inputs that would directly trip the unit. The SDT has clarified that generators are not required to install or set the relays to trip. The Standard has been modified to address loss of generation consequent to problems on auxiliary systems, problems which arise due to low voltage or low frequency, or a combination of both.		
SERC Dynamics Review Subcommittee (DRS)	No	Settings for generator backup impedance and voltage restrained overcurrent relays need to be covered too. Their inclusion will provide complete coverage of the generator. There have been instances where these relays have operated in the past. We understand that this will drive the need for dynamic simulations because steady state simulations will not suffice.
Response: The SDT has modified the Standard to address those relays that have frequency or voltage inputs that would directly trip the unit.		
Kansas City Power & Light	No	In many cases the exciter voltage regulator includes generator protective functions (for example, Basler DECS 300, DECS 400) such as Volts/Hertz, undervoltage, overvoltage, underfrequency that will also trip the Unit. These functions are usually set slightly above the trip settings of the equivalent generator protective relaying, but to not include them in this requirement would effectively nullify the stability effort sought by this requirement.
Response: The SDT has modified the Standard to address those relays that have frequency or voltage inputs that would directly trip the unit.		
Constellation Power Generation & Constellation Nuclear	No	The proposed standard addresses all issues identified in the Standard Authorization Request. Coordination of generator and transmission system protection is addressed in PRC-00. As presently constituted this Standard will likely result in the inappropriate enabling and setting of frequency and voltage relays with the settings which are permitted, thus reducing system reliability, which is contrary to its stated purpose. This is supported in the comments provided below. There are significant machine protection issues which are not addressed, such as Volts per Hertz. Loss of generation consequential to problems

Organization	Yes or No	Question 2 Comment
		on auxiliary systems, problems which arise due to low voltage or low frequency, or a combination of both, is a significant problem, and is not addressed in this Standard.
Response: The SDT has modified the Standard to address those relays that have frequency or voltage inputs that would directly trip the unit. The SDT has clarified that generators are not required to install or set the protective relays. The Standard has been modified to address loss of generation consequent to problems on auxiliary systems, problems which arise due to low voltage or low frequency, or a combination of both.		
Southern Company	No	What the standard addresses is probably what is practical, but the ultimate goal of the SAR is not practical to implement. We question whether the goal of this standard can be truly addressed from a practical standpoint. The scope of the protective equipment covered in the current draft excludes excitation system protection including over excitation, station service under voltage protection, certain nuclear facility protection schemes, boiler controls, turbine controls, each of which may not ride through the frequency and voltage swings. We feel as though the limited approach of specifying F and V relay settings on the generator may be futile in improving the ability to ride through yet on the other hand the inclusion of all of the impacted plant subsystem components would be practically and financially unmanageable. In other words, will any appreciable improvement in system reliability result from the implementation of this standard looking at F and V gen settings only. Settings for generator backup impedance and voltage restrained overcurrent relays may need to be covered too. Their inclusion will provide complete coverage of the generator. There have been instances where these relays have operated in the past. We understand that this will drive the need for dynamic simulations because steady state simulations will not suffice.
Response: Based on industry input, the Standard has been modified to require new generators to ride through voltage and frequency excursions and believes this is practical. An exemption is provided for existing generators that are unable to meet the ride through requirement. The SDT has modified the Standard to address those relays that have frequency or voltage inputs that would directly trip the unit.		
Gainesville Regional Utilities	No	In some areas there is no reason to include generators less than 100 MVA
Response: The SDT believes the Standard should apply to all units that meet the criteria of the compliance registry.		
Basin Electric Power Cooperative	No	Generation under frequency protection is an area I have spend much time on over the last 20 years, and I admit that I hold some strong opinions, but these opinions were arrived at after much study, disturbance analysis, and from being directly involved in actual design of three regional underfrequency load shedding (UFLS) programs. It appears that the generator off-nominal frequency protection limits shown in attachment 1 represent someone's judgment call of what is a reasonable loss of life per event, what the expected minimum frequency might be when load shedding occurs, and so forth. Such judgment calls are subjective, and there is room for interpretation. I feel that generation underfrequency/overfrequency settings of this nature have to be developed on a regional basis as part of a regional underfrequency load shedding program. I am uncomfortable with this showing up in a draft NERC standard without any

Organization	Yes or No	Question 2 Comment
		supporting technical documentation or justification. I agree that unit capabilities have to be considered, but perhaps more important, we have to consider the realities of what we can achieve with UFLS and give ourselves enough generator tripping delay time and relay margin to make the program work. Tradeoff's are involved, and this type of underfrequency analysis is inherently an estimation, so some time delay margin is needed to ensure coordination with load shedding. If generation trips too soon, the island imbalance will increase and it may not be possible to prevent total collapse of the island. Keep in mind that the real off-nominal frequency loss of life exposure is when black start programs try to pick up the pieces after load shedding fails, and premature tripping of generation is what causes load shedding to fail. In addition, hydro systems can operate at much lower frequencies than steam units, and this criteria is not appropriate for hydro systems. In my opinion, UFLS is supposed to be a safety net to cover the unforeseen, and it needs to be designed with that in mind. Ideally, we want it to be as robust as possible. Relay coordination is going to be more robust when based on worst-case performance and not on best case. This helps deal with real world complications imposed by things we have not anticipated or foreseen, or due to "as implemented" programs always being a little different than the ideal stated in the design phase. My most recent involvement with UFLS and generator off-nominal frequency protection coordination came about through the MRO Underfrequency Load Shedding Task Force effort that developed a new coordinated UFLS program for the MRO footprint. I served as chair of this taskforce and did much of the analysis. I do not want PRC-024-1 to establish standards that conflict with the MRO program. Doing so would sacrifice the effectiveness of the load shedding program we came up with. There are a couple of other areas where conflicts occur. This is in regards to how to deal with programs that need to shed more than the minimum amount of load, and in regards to the overfrequency implications. I will discuss the issues in sequence. Although the MRO UFLS Taskforce expects that under "typical conditions" that minimum frequency will be above 58 Hz, (for loss of generation/import of up to 30% of system load in the island), our worst case simulations indicate we could briefly dip below that, and we used our worst case results to set generation protection times and delays. In addition, our "equivalent inertia" modeling approach ignores machine to machine oscillations which might cause frequency at different locations to differ by .2 Hz or so as the system rings down. For this reason, we chose 57.6 Hz as the point where instant tripping is allowed. This is below our worst-case minimum frequency of 57.77 Hz (for a very low inertia, low damping, no governor scenario that is perhaps overly pessimistic). This can also be justified by considering that our design criteria set a target of average system frequency >= 58 Hz, which has to be adjusted by about - .2 Hz for machine to machine oscillations seen in the real system and not in our model, plus about .2 Hz margin to ensure good relay coordination). In order to come up with the MRO generation protection settings we monitored time spent in frequency bands spaced .1 Hz apart and we consider the performance over the full range of coverage (0 to 30 % loss of generation) and considered a wide range of assumptions concerning system based inertia (H system base = MW-sec stored in rotating mass divided by P gen) and damping in addition to a possible range of governor actions. We optimized the program to minimize time spent below 60 Hz while addressing all the other constraints we had to deal with. Once we knew the expected worst case times in each .1 Hz band below 60 Hz for the optimized program, we came up with the stair step type of generation time delay settings that gave a reasonable fit to the expected worst-case time versus frequency information (plus some margin) with the fewest frequency bands. The MRO UFLS effort tried to anticipate as much complication as possible, but we could not cover all of the inherent uncertainty involved. No one could. The main source of uncertainty we could not deal with is how potential overvoltage's may increase load and decrease the effectiveness of the load shedding program. This gave us additional justification for using a "no net governor

Organization	Yes or No	Question 2 Comment
		response" scenario for evaluating coordination between load shedding and generator protection (this voltage uncertainty is not the only reason for using a no governor assumption: basically units that are base loaded cannot respond to underfrequency, power/load controllers may override governor action, combustion turbine thermal limits will quickly override their governor action with power dropping off faster than the frequency decline, wind generation may drop off and would not have a governor anyway, and so forth; the bottom line is that we do not know what level of net governor type of action we can count on, and what little we get may be offset by increases in voltage). To fully understand what we did you will have to refer to the MRO UFLS report on the MRO website. The short version is that we ran 1000's of cases to arrive at our conclusions. What we came up with for generator underfrequency protection minimum time delays is what we need to ensure the load shedding has time to play out to restore frequency and to give some margin to ensure relay coordination. If we tighten up the generation protection time delays and raise the frequency setting for the instant trip point, then there is a narrower range of conditions for which the UFLS program would be expected to work as intended. Our safety net becomes less robust, we make things less secure. On the other hand, the MRO load shedding program is designed to be the first line of protection for the generators as it is designed to force frequency recovery even in the absence of governor action by having small blocks of load shed on delay to kick us back towards 60 Hz when recovery is too slow. Although there is a chance that frequency may be slow to recover as a worst case, most of the time it will recover much faster than the times we used for generation tripping coordination. The expected time spent below 60 Hz sort of takes on the form of a probability density function. This type of information gives a better idea of what units may be exposed to. Therefore, our approach was to coordinate generation off-nominal frequency protection to match the worst case, and then do everything possible to minimize underfrequency exposure to generators when designing the load shedding program. The recommendations of the MRO UFLS report should take precedence over what is being proposed in this document. In MRO, we recognize that the Canadian portion of MRO needs to shed more than 30% of connected load. The MRO UFLS report indicates that any program that needs to shed more than 30% of load will need to relax the MRO generator off nominal frequency time delay settings for generation and accept longer delays and lower minimum frequencies. This is an engineering reality. The Off-Nominal Frequency Capability Curve on Attachment 1 does not give this kind of flexibility. Alternately, some improvement on minimum frequency can be realized by designing a program that oversheds but then the program will be prone to overspeed problems. Programs can also start shedding at higher frequencies to improve the minimum frequency but then that creates other coordination problems with neighboring programs. This standard writing process should not replace engineering judgment. Utilities need flexibility so they can make the necessary compromises after all things are considered. Making adjustments to generation protection is most likely the best approach to ensure coordination with these larger load shedding programs.The diagram from PRC-024-1 may suggest to some folks that over frequency tripping is going to be needed or perhaps even encouraged. I do not know what the intent is, so I will just express my concerns up front. I have serious reservations about applying dedicated relays, of the type used for underfrequency protection, to trip units on overspeed. Extreme caution is needed. That is a good way to ensure total collapse of a power grid. Seriously, this could be catastrophic. Consider that plants already have internal overspeed controls. These are needed to deal with full load rejection. These controls are in addition to the normal governor, and are much more drastic. These emergency overspeed controls are not modeled in stability cases, but they exist, and will take drastic action to slow down units if frequency gets high so I feel confident that the units self protect and take care of themselves. I believe that overspeed protection should be left to these inherent controls, and that we should not put in additional relays to trip generation

Organization	Yes or No	Question 2 Comment
		on overspeed unless this is done carefully and solely for the purpose of restoring load and generation within an island.Plant internal overspeed controls have to limit speed following full load rejection, but they will also react to partial load rejections that we get by islanding. If a plant loses all lines to it (i.e. full load rejection), then go ahead and allow these inherent controls to trip the unit on overspeed or do what ever is needed. NERC does not need a standard for that. The emergency overspeed controls that protect for full load rejection can also activate on an islanding condition where we have too much generation in an island. On steam units these controls kick in between 61 to 62 Hz (it varies with each unit so I have to generalize), so system frequency is unlikely to get much higher than 61.4 Hz to 62 Hz (most that I have seen activate around 61.2 to 61.4 Hz) no matter how large the initial imbalance. Once these controls activate frequency is no longer a measure of the imbalance between load and generation. The action taken to prevent overspeed involves things like closing all the steam valves on thermal units, so it is safe to say we cannot stay in this high frequency condition for too long before random unit trips start to occur due to any number of internal plant problems. Often times one plant dies first and rebalances things for other units. The random nature of what happens next complicates any planned unit tripping actions to correct the imbalance. If dedicated unit tripping on overspeed is to be done, it can only be done on a few selected units and only as a way to hammer the imbalance back to a smaller size that we can deal with. The worst of all worlds would be to apply overspeed tripping to all units like we do for underfrequency. That would ensure any island with an initial excess of generation is going to go black after we dump all the generation. If generation is tripped to correct overspeed in an island, it has to be done in small increments (about 1 to 1.5 % of remaining load) and trip times have to be staggered. This is something that has to be studied on a case-by-case basis.In summary, we do not believe that it is appropriate to be creating a standard like this to specify settings for underfrequency/overfrequency protection for all generation. The technical basis of these limits are not given, and these setting may not coordinate with existing or proposed underfrequency load shedding programs. Aggressive load shedding programs are quite likely to need to accept more time below 60 Hz to coordinate with underfrequency relaying and expected system frequency recovery times. Protection settings of this nature should be developed in conjunction with underfrequency load shedding programs so that appropriate trade offs can be considered. Such coordination is most effective at the regional or subregional basis where a specific load shedding program can be evaluated in detail. We must give sufficient time for load shedding to act even if it means we need to accept some additional potential loss of life to generation for some hypothetical underfrequency event.
Response: The SDT developed the off-nominal frequency capabilities based on turbine manufacturers' capabilities in conjunction with the ability to set relays between the frequency curve and the manufacturers' curves. In addition, the SDT developed the off-nominal frequency curve in coordination with the NERC UFLS Standard Drafting team. The Standard is technology neutral and applies to all generators.		
First Solar	No	The application of the standard to arrays of solar inverters is unclear. While the primary breaker can be set to comply with the standards, when the system voltage is driven to zero during the fault, the inverters will lose their phase lock and begin to shut down.
Response: The Standard includes a provision to document an equipment limitation that would prohibit compliance with Requirements R1 and R2 for		

Organization	Yes or No	Question 2 Comment
existing generators.		
US Bureau of Reclamation	No	Now that the draft standard has been posted, it appears to be a more structured and limited version of existing Standard PRC-001-1 – System Protection Coordination. PRC-001-1 requires the Generator entity to coordinate protection settings with the Transmission entity. The stated Purpose of PRC-024-1 “Ensure that generator frequency and voltage protective relays are set to support transmission system stability during voltage and frequency excursions” should be attainable through PRC-001-1. If PRC-001-1 is not adequate it should be modified rather than adding an additional standard only addressing generator frequency and voltage settings. As such we do not believe there is a clear, reliability based justification for this standard as currently drafted.
Response: Based on industry input, the Standard has been modified to require new generators to ride through voltage and frequency excursions.		
Progress Energy, Inc.	No	The purpose of the standard, to ensure that generators ride through the proposed system transients, will not be accomplished by only looking at generator protective relays. PE is concerned that these same profiles for frequency and voltage (Attachment 1 and 2) could later become applicable to all plant equipment. The generating plants are not designed to ride thru/stay connected for these proposed profiles.
Response: Based on industry input, the Standard has been modified to require new generators to ride through voltage and frequency excursions.		
Hydro-Québec TransEnergie (HQT)	No	The proposed standard addresses all issues identified in the Standard Authorization Request. Coordination of generator and transmission system protection is addressed in PRC-00. As presently constituted this Standard will likely result in the inappropriate enabling and setting of frequency and voltage relays with the settings which are permitted, thus reducing system reliability, which is contrary to its stated purpose. This is supported in the comments provided below. There are significant machine protection issues which are not addressed, such as Volts per Hertz. Loss of generation consequential to problems on auxiliary systems, problems which arise due to low voltage or low frequency, or a combination of both, is a significant problem, and is not addressed in this Standard.
Response: The SDT has modified the Standard to address those relays that have frequency or voltage inputs that would directly trip the unit. The SDT has clarified that generators are not required to install or set the protective relays. The Standard has been modified to address loss of generation consequent to problems on auxiliary systems, problems which arise due to low voltage or low frequency, or a combination of both.		
Duke Energy	No	Footnote 1 is unclear and too broad. As stated, it includes voltage regulators – which is beyond the scope of this standard. Take voltage regulator out, or specify the volts per hertz protection function only.
Response: The SDT has modified the footnote.		

Organization	Yes or No	Question 2 Comment
New York Independent System Operator	No	As presently constituted this Standard could result in the inappropriate enabling and setting of frequency and Voltage relays with the settings which are permitted, thus reducing system reliability, which is contrary to its stated purpose. This is supported in the comments provided below. It would have been much more important to require that Voltage and frequency relays be applied only when they are required for machine protection, which this Standard does not do. There are significant machine protection issues which are not addressed, such as Volts per Hertz. Loss of generation consequential to problems on auxiliary systems, problems which arise due to low Voltage or low frequency, or a combination of both, is a significant problem, and is not addressed in this Standard.
Response: The SDT has modified the Standard to address those relays that have frequency or voltage inputs that would directly trip the unit. The SDT has clarified that generators are not required to install or set the protective relays. The Standard has been modified to address loss of generation consequent to problems on auxiliary systems, problems which arise due to low voltage or low frequency, or a combination of both.		
CenterPoint Energy	No	a) CenterPoint Energy does not agree with limiting the application of this standard to the few relays that the SDT has chosen to address (only generator under or over voltage protective relays and volts per hertz relays). In effect, the SDT is allowing possible tripping of generation during off nominal frequency and voltage excursions from several other types of relays and control systems. This may not provide adequate reliability, as loss of significant generation can occur for voltage sags. B) The SDT has not included generator backup over current, impedance, and loss of field relays within the scope of this draft standard. CenterPoint Energy believes these additional relays should also be addressed. CenterPoint Energy believes it is illogical to have a transmission relay loadability standard (PRC-023 Transmission Relay Loadability) based on current and impedance ride-through while exempting generators from comparable requirements. Such an exemption defeats the purpose of the transmission relay loadability requirements by allowing a system event to escalate due to failure of generator relays to ride-through the same types of events envisioned by PRC-023 requirements. One key purpose for PRC-023 is to not interfere with system operators' ability to take remedial action to protect system reliability. C) In addition to including other types of generator relays, the relaying and control for plant auxiliary systems should also be addressed for operation during off nominal frequency and voltage excursions. Again, it is illogical to have a transmission relay loadability requirements based on current and impedance ride-through while exempting a generation plant from comparable requirements. CenterPoint Energy realizes that generating plants have many internal control systems on auxiliary equipment that could be impacted during low voltage events, but exempting such systems from this standard defeats its purpose. CenterPoint Energy also recognizes that failures or incorrect operation of equipment installed for voltage ride-through capability on auxiliary equipment controls, such as UPS devices, will occur. Therefore, CenterPoint Energy recommends the SDT specifically address plant auxiliary equipment ride through. CenterPoint Energy suggests that the requirements be similar to those in NERC standard PRC-004 Analysis and Mitigation of Transmission and Generation Protection System Misoperations. That is, if the plant incorrectly trips during a voltage sag due to auxiliary systems problems, the problem will be investigated and, where necessary, a system-wide

Organization	Yes or No	Question 2 Comment
		corrective action plan will be developed and completed.
Response: Based on industry input, the Standard has been modified to require new generators to ride through voltage and frequency excursions.		
American Wind Energy Association	Yes	A relay setting standard is fine, although the wind industry would also be able to comply with the standard if it were a performance standard.
Response: Based on industry input, the Standard has been modified to require new generators to ride through voltage and frequency excursions.		
AWEA	Yes	PRC-024 should be a performance standard but since that is unlikely to pass I can live with a relay setting standard
Response: Based on industry input, the Standard has been modified to require new generators to ride through voltage and frequency excursions.		
FirstEnergy	Yes	However, it should clearer in the requirements how mechanical and electrical overspeed protection is coordinated with the UF relay settings. Also, we would appreciate the SDT's view on why the frequency requirement are not being written into the existing PRC-006 (UFLS) standard.
Response: Based on industry input, the Standard has been modified to require new generators to ride through voltage and frequency excursions thus covering all aspects of the generating plant. The SDT has coordinated the development of the UF relay curve with UFLS SDT.		
IRC Standards Review Committee	Yes	We agree that it is a good start.
Response: Based on industry input, the Standard has been modified to require new generators to ride through voltage and frequency excursions.		
Indiana Municipal Power Agency	Yes	A performance standard would be virtually impossible to perform and verify for all the equipment at a plant. The relay approach may not meet the SAR objective for generators to remain on line through voltage and frequency excursions, but this approach is the only practical way that allows standard requirements to be written and enforced.
Response: Based on industry input, the Standard has been modified to require new generators to ride through voltage and frequency excursions.		
American Electric Power	Yes	It is appropriate to limit the scope of this standard to setting of voltage and frequency generator protective relays, but it should be noted that other factors may cause generators to trip as a consequence of voltage or frequency excursions besides voltage or frequency sensing relays. An example is tripping due to complications involving over-excitation protection. Are other factors addressed elsewhere?

Organization	Yes or No	Question 2 Comment
Response: Based on industry input, the Standard has been modified to require new generators to ride through voltage and frequency excursions.		
Independent Electricity System Operator	Yes	We agree that it is a good start. However, other settings such as those mentioned in the Background Information Section (generator backup over current or impedance, loss of field, etc.) also give rise to tripping of the generator. Consideration should be given to expanding the scope of the SAR to include these settings. The lack of a standard for generator out-of-step protection resulted in adverse effects on the Michigan-Ontario ties during the 2003 blackout.
Response: The SDT has modified the Standard to address those relays that have frequency or voltage inputs that would directly trip the unit, while staying within the scope of the approved SAR.		
Ameren	Yes	Please clearly state that such relays do not have to be added or elements enabled, GO makes the decision what protection to include. R1 and M1, and R2 and M2 should allow for proof that the frequency and/or voltage relays are omitted or set to alarm only, not trip.Please clearly define 'point of interconnection' used in 4.2.2; typically this is where the generating source connects to the switchyard or networked transmission system but these relays are typically at the generator terminals on the low side of the generator step-up transformer.
Response: The SDT has clarified that generators are not required to install or set the protective relays.		
MRO NERC Standards Review Subcommittee	Yes

3. PRC-024-1 specifies the limits for generator protective system settings as defined in PRC-024-1 - Attachment 1 and PRC-024-1 - Attachment 2. Are there generating units in your fleet that are not capable of meeting the thresholds in these attachments due to turbine/generator equipment design limitations?

If yes, please estimate the percentage and total MW capacity of your units that cannot meet the requirement.

Estimated total MW capacity of units that cannot meet the requirement:

Summary Consideration:

There was no consensus on this issue.

The issues associated with the majority of the comments received:

1. A wide range (from 0% to 100%) of existing generators may not be able to meet the Standard's requirements based on existing turbine/generator equipment design limitations, auxiliary bus low voltage ride-thru incapability, or manual turbine and automatic reactor protection settings (15 comments)
2. It is not certain, without more study, if equipment limitations will require relay settings in the "no trip" zone (8 comments)
3. It is unclear what limits apply to variable generation (3 comments)
4. The "no trip" curves need clarification (2 comments)

The GV SDT considerations for issues associated with the majority of the comments received are:

1. Requirement R4 has been written to address the inability of existing units to ride-through the voltage and frequency excursions of Attachment 1 and 2. The purpose of this Requirement is to provide the Transmission Planner the ability to more accurately model generating plant performance during system voltage and frequency excursions.
2. The Generator Owner has an opportunity to obtain an exception for those existing units that cannot meet Requirements R1 or R2 in accordance with Requirement R3. R3 has been revised to provide greater clarity on the required documentation of equipment limitation.
3. As written, the BES registry criterea delineates which generating units are in the scope of the standard. The SDT is interested in voltage and frequency rate-of-change concerns and welcomes more technical information on this issue in comments to the next posting.

4. R1, R2, and R3, as well as Attachments 1 and 2, have been revised to provide greater clarity. The table in Attachment 1 showing frequency-time relationship is intended to provide further clarification to the Off Nominal Frequency Capability Curve.

Some other comment issues are:

1. The Jul 2008 UFLS suggested setting state to arrest frequency no lower than 58Hz. Why is Attachment 1 below this value? (2 comments) (Attachment 1 has 57.8 Hz as the no trip threshold.)
2. The basis for the UF curve should be provided (1 comment). (Off nominal OF events have occurred which have exceeded the curve in Attachment 1 with no detrimental effects reported.)
3. Decades of operating experience should be acceptible proof of ride-thru capability (1 comment)
4. Rate of changes in voltage and frequency should be specified on the ride-thru capability requirements (1 comment)

The GV SDT considerations for the other comment issues are:

1. The SDT developed the off nominal frequency curve in coordination with the NERC UFLS Standard Drafting Team. The 57.8 Hz setting for generator underfrequency and 58 Hz for UFLS is to ensure that the UFLS will have a chance to arrest the system frequency decline before reaching the minimum permissible frequency for generators. The intent of the curves is to ensure that the generators do not trip when the frequency is within the area bounded by the high and low frequency curves. When the frequency excursion reaches outside the high or low curve, the generator is allowed to trip.
2. The SDT developed the off nominal frequency capabilities based on turbine manufacturers' capabilities in conjunction with the ability to set relays between the frequency curve and the manufacturers' curves.
3. The Generator Owner has an opportunity to obtain exception for those existing units that cannot meet Requirements R1 or R2 in accordance with Requirement R3. R3 has been revised to provide greater clarity on the required documentation of equipment limitation.
4. The SDT is interested in voltage and frequency rate-of-change concerns and welcomes more technical information on this issue in comments to the next posting.

Northeast Utilities		Information not available at this time.	Information not available at this time.

Organization	Yes or No	Question 3 Estimated percentage of units that can't meet thresholds due to design limitations:	Question 3 Estimated total MW capacity of units that cannot meet the requirement:
Response: Thank you for your comments.			
Independent Electricity System Operator		We are unable to comment on how many generating units in the fleet that are not capable of meeting the threshold in the Attachments since we are not a Generator Owner. However, we are unclear on the basis of the 57.8 Hz setting stipulated in R1.3 as it is not consistent with the proposed UFLS characteristics (posted in July of 2008) in which it indicates that frequency should be arrested at no less than 58.0 Hz. Further, the basis for the very restrictive over-frequency curve proposed in attachment #1 is not obvious. The over-frequency standard proposed in PRC-024 was exceeded during the blackout of 2003 for Ontario generation that was connected radically into New York. No adverse effects attributed to this over frequency event have been reported to the IESO.	
Response: The SDT developed the off nominal frequency capabilities based on turbine manufacturers' capabilities in conjunction with the ability to set relays between the frequency curve and the manufacturers' curves. In addition, the SDT developed the off nominal frequency curve in coordination with the NERC UFLS Standard Drafting Team. The 57.8 Hz setting for generator underfrequency and 58 Hz for UFLS is to ensure that the UFLS will have a chance to arrest the system frequency decline before reaching the minimum permissible frequency for generators. The intent of the curves is to ensure that the generators do not trip when the frequency is within the area bounded by the high and low frequency curves. When the frequency excursion reaches outside the high or low curve, the generator is allowed to trip.			
MRO NERC Standards Review Subcommittee	No	The MRO does not own any generation.	
Response: Thank you for your comments.			
FirstEnergy	No	A possible concern would be the effect on auxiliary system equipment and reliability at voltages below 90%.	
Response: Thank you for your comments.			

Organization	Yes or No	Question 3 Estimated percentage of units that can't meet thresholds due to design limitations:	Question 3 Estimated total MW capacity of units that cannot meet the requirement:
IRC Standards Review Committee	No	We are unable to comment on how many generating units in the fleet that are not capable of meeting the threshold in the Attachments since we are not a Generator Owner. However, we are unclear on the basis of the 57.8 Hz setting stipulated in R1.3 as it is not consistent with the proposed UFLS characteristics (posted in July of 2008) in which it indicates that frequency should be arrested at no less than 58.0 Hz.We also think the question is a bit misleading and may not result in providing the SDT any grounded suggestions or concurrence on the appropriate frequency levels that the SDT may already have in mind. The question as written suggests that the SDT is trying to canvass the industry through this commenting process. This is a way to obtain feedback, but it does not provide the rationale of the proposed levels. We suggest that the SDT research the limitations of the machines that are connected to the BPS (perhaps by a survey or a NERC data request) to better support the proposed frequency limit, then ask for concurrence or alternative suggestions.	
Response: Thank you for your comments. The SDT developed the off nominal frequency capabilities based on turbine manufacturers' capabilities in conjunction with the ability to set relays between the frequency curve and the manufacturers' curves. In addition, the SDT developed the off nominal frequency curve in coordination with the NERC UFLS Standard Drafting team. The 57.8 Hz setting for generator underfrequency and 58 Hz for UFLS is to ensure that the UFLS will have a chance to arrest the system frequency decline before reaching the minimum permissible frequency for generators.			
Consumers Energy Company	No	Consumers Energy doesn't have generating units that cannot meet the thresholds. However, we would like to offer the following comments:The Standards Drafting Team should be congratulated for the excellent curves in Attachment 1. A review of our fleet which contains units of several vintages, manufactured by General Electric, Westinghouse, Siemens, and Allis-Chalmers, shows that turbine-generators from all of these manufacturers comply with these curves. To assist Generator Owners and Compliance Auditors, the SDT should furnish mathematical formulae for the "slanted lines" in the curves. Should a	

Organization	Yes or No	Question 3 Estimated percentage of units that can't meet thresholds due to design limitations:	Question 3 Estimated total MW capacity of units that cannot meet the requirement:
		Generator Owner elect to set an underfrequency relay at 120 seconds and 59.1 Hz, there might be uncertainty or disagreement about compliance, depending upon how the interpolation of the graph is viewed. Interpolation from a semi-log plot is often not easy. This uncertainty can and should be eliminated by including the two formulae in Attachment 1.	
Response: Thank you for your comments. The table in Attachment 1 showing frequency-time relationship is intended to provide further clarification to the Off Nominal Frequency Capability Curve.			
Old Dominion Electric Cooperative	No	I am not 100% sure this is the case, but I am fairly confident all our units do meet these thresholds.	
Response: Thank you for your comments.			
Basin Electric Power Cooperative	No	It is unclear what limits apply to wind generation, but we believe our conventional generation can easily accommodate the settings defined by Attachment 1, even though we feel that such off-nominal protection settings should not be established in this standard and that such coordination should occur at the regional level were UFLS program details are worked out. I would like to offer some observations based on real life experience. Our experience is that some folks have a good technical understanding of generation capabilities and others do not. In many instances, folks do not know what actual capabilities are, and if the proposed settings conflict with existing settings then they will initially report that they cannot accommodate the recommendations (the status quo carries a lot of weight even when no one can find the original justification for existing settings). Generally, all the parties have to get together and work through things to create a higher level of awareness of the issues so we can eliminate misconceptions. The new non-utility generation owners do not have the same load serving obligations as traditional utilities and this gives them different incentives for	

Organization	Yes or No	Question 3 Estimated percentage of units that can't meet thresholds due to design limitations:	Question 3 Estimated total MW capacity of units that cannot meet the requirement:
		how they want to set generation protection. In many instances, they want to trip too early, to the detriment of the grid.

Progress Energy, Inc.	Yes	100% of Progress Energy nuclear units will not stay connected per the proposed Attachment 1 and 2 due to auxliary equipment protection.70-80% of the combustion turbine units would trip during the frequency excursions proposed by NERC.To make sure that generation "ride through" is coordinated with conditions that could damage all types of generation facilities, Progress Energy recommends that the SDT consult with turbine manfacturers to develop the frequency profile. Frequency limitations are typically driven by turbine manfacture design. We also need to the mindful of the total cummulative off-frquency excursions limits laid down by the turbine manufacturers.For example, most large steam turbine vendors prohibit turbine operation below 58 hz in order to prevent the probable occurrence of turbine blade resonance (turbine blade failure). Our nuclear plant operators will immediately manually trip the turbines at 58 hz to prevent equipment damage. For combustion turbines under frequency limitations exist below 59 Hz while the maximum operating duration at 59.5 Hz is limited to 60 seconds. Of our five nuclear plants, all five would not be capable of riding through either the proposed frequency or voltage transitents due to manual turbine and automatic reactor protection settings. These settings are not generator protective relays but they will result in a complete loss of generation. Two Progress Energy nuclear plants will trip on reactor coolant pump undervoltage below 80% pu at 0.75 seconds and one will trip on underfrequency below 58.2 hz at 0.2 seconds.	Approximately 3,500 MW of nuclear generation for SERC and 900 MW for FRCC. Approximately 3500 MW CT generation in SERC and 5000 MW CT generation in FRCC.
Response: Thank you for your comments. The SDT developed the off nominal frequency capabilities based on turbine manufacturers' capabilities in conjunction with the ability to set relays between the frequency curve and the manufacturers' curves. In addition, the SDT developed the off nominal frequency curve in coordination with the NERC UFLS Standard Drafting Team.

Response: Thank you for your comments.			
Hydro-Québec TransEnergie (HQT)	Yes	A relatively small percentage of units do not meet this requirement but it is not known which of these cases are due to actual machine design limitations.	A relatively small percentage of units do not meet this requirement but it is not known which of these cases are due to actual machine design limitations.
Response: Thank you for your comments.			
Northeast Power Coordinating Council	Yes	A relatively small percentage of units do not meet this requirement but it is not known which of these cases are due to actual machine design limitations.	A relatively small percentage of units do not meet this requirement but it is not known which of these cases are due to actual machine design limitations.
Response: Thank you for your comments.			
Kansas City Power & Light	Yes	There are a number of generating units that currently have relay settings outside the proposed underfrequency and overfrequency relay settings. It is not known at this time if it is possible to adjust the settings within the proposed relay settings.50%	1900 MW
Response: Thank you for your comments.			
Duke Energy	Yes	15% of system capacity	Approximately 4000 MW
Response: Thank you for your comments.			
New York Independent System Operator	Yes	A relatively small percentage of units do not meet this requirement but it is not known which of these cases are due to actual machine design limitations.	A relatively small percentage of units do not meet this requirement but it is not known which of these cases are due to actual machine design limitations.

Organization	Yes or No	Question 3 Estimated percentage of units that can't meet thresholds due to design limitations:	Question 3 Estimated total MW capacity of units that cannot meet the requirement:
Response: Thank you for your comments.			
Constellation Power Generation & Constellation Nuclear	Yes	A number of our units do not meet this requirement but it is not known which of these cases are, due to actual machine design limitations.	
Response: Thank you for your comments.			
Ameren	Yes	We have not yet performed a detailed review wrt proposed limits, but expect there will be some that are not capable of meeting these stated thresholds. It can be hard to get capability data and warranties have expired, for older units or those purchased from other owners. The PRC-024-1 curves should not become a de facto requirement. If decades of operating experience have proven satisfactory from both a BES and generator equipment life persperctive, this should be accepted as evidence as well. Generic guidance, such as past ANSI/IEEE standards, recommended practices, and guides should be allowed for older units exception evidence as well. Clearly state that field testing is not required.	
Response: Thank you for your comments. The Generator Owner has an opportunity to obtain an exception for those existing units that cannot meet Requirements R1 or R2 in accordance with Requirement R3. R3 has been revised to provide greater clarity on the required documentation of equipment limitation.			
Southern California Edison Company	Yes	Uncertain, as curves and tables in attachments need additional clarification.	Uncertain, as curves and tables in attachments need additional clarification.
Response: Thank you for your comments. R1, R2, and R3, as well as Attachments 1 and 2, have been revised to provide greater clarity.			
Southern Company	Yes	Some are, some are not. Some we can prove, some we don't know and can't find out. With no experts to evaluate turbine under/over frequency in our company and turbine manufacturers	40,000MW voltage, Unknown frequency

Organization	Yes or No	Question 3 Estimated percentage of units that can't meet thresholds due to design limitations:	Question 3 Estimated total MW capacity of units that cannot meet the requirement:
		either out of business or unwilling to provide turbine limits, is there any possible exception allowed for settings inside the no trip zone? Also, for existing turbines, we believe that the turbine blade conditions would have to be evaluated to make a judgement on how to shift the withstand. How can we be sure that we are not stressing our turbine if we set our devices outside of the curve in the standard? Can question 3 be addressed quantitatively? Instead of "100% on voltage", it should be "0%".Auxiliary systems are not included in the standards scope as drafted.100% on voltage (can't prove - auxilliary system) Unknown on frequency	
Response: Thank you for your comments. The Generator Owner has an opportunity to obtain exception for those existing units that cannot meet Requirements R1 or R2 in accordance with Requirement R3.			
First Solar	Yes	The response, and therefore compliance with this proposed Standard, are not clear. The standard does not seem to contemplate static power generators that would be part of renewable energy systems like solar PV. As part of the requirement there should be specificity on a number of points. For example as written it does not clearly define what the generator does during the out of frequency/voltage conditions. Presumably the inverters would not be required to drive current into the fault and thereby increase fault duties. Furthermore, once the fault is cleared, it does not define the speed/rate at which power is ramped up from the generator. This rate could be hard to achieve with a static converter. Finally, the standard does not define the rate of change of frequency or voltage. Typically devices are more sensitive to high rate changes. All of these items need more detail and specificity to determine how new forms of generation can meet these requirements.	
Response: The SDT thanks you for your comments. The standard does apply to variable energy resource facilities such as solar PV. The standard does not set requirements for generator output during a fault. Conventional synchronous generators will supply fault current so that protective relaying can			

Organization	Yes or No	Question 3 Estimated percentage of units that can't meet thresholds due to design limitations:	Question 3 Estimated total MW capacity of units that cannot meet the requirement:
detect the fault expeditiously. A performance requirement (R6) has been added for new generation (designed, built, and connected to the grid) after the Standard becomes effective, but does not specify a post-fault output for a facility. The SDT has added a limit to the rate of change of frequency that the Generator Owner is expected to ride through.			

4. The curve in PRC-024-1 — Attachment 2 was based upon analysis performed of simulated system disturbances. System voltage traces representative of several hundred disturbances were co-plotted on a voltage versus time graph. The voltage duration curve in this attachment is derived from these voltage traces. A margin was then applied to the voltage duration curve to account for unanticipated system conditions. The 9 cycle fault clearing time required by the FERC 661-A Order is incorporated into this curve. Given this background on the development of PRC-024-1 — Attachment 2, do you agree with the parameters of the curve? If not, please explain in the comment area.

Summary Consideration:

- A majority of respondents indicated support that simulations should be verified.
- Some commenters questioned the general applicability:
  - o Wind generator performance requirements should not be imposed on synchronous generator relay settings
  - o Curves should be based on generator capabilities, not on expected system performance
  - o Generators should not trip on under voltage but should only alarm
  - o Concern that the curves could be extended to other plant equipment
- Still other commenters questioned specific values:
  - o Delayed clearing may require 30 cycles at zero voltage, 9 cycles is inadequate
  - o The curve should go to at least 10 seconds at 0.9pu, not 4. Also 2 seconds at 0.45pu, and 3 seconds at 0.75pu
  - o Phase to ground faults will result in higher voltages on the un-faulted phases
  - o It is not clear if the curves are for phase to neutral voltages, phase to phase voltages, or positive sequence voltages
- Another minority comment was that relays are at the machine terminals not at the POI so the curves should be applied at the generator terminals

The GV SDT has determined that the curves in Attachment 2 are reasonable. Only minor modifications were contemplated, such as the addition of new text in the notes section.

Organization	Yes or No	Question 4 Comment
NERC System Protection and	No	FERC 661-A is a wind generator facility ride-through performance criterion, not a synchronous generator relay setting requirement. They cannot be compared as being equivalent. A synchronous generator undervoltage capability will be quite

Organization	Yes or No	Question 4 Comment
Control Subcommittee (SPCS)		different from an entire wind facility undervoltage ride-through capability. The 9 cycle zero voltage interval is inadequate. The 9 cycle setting would cover for most normally cleared faults but generators must also remain on line through faults with delayed clearing due to breaker failure as required in the NERC TPL Standards. The time interval for such clearing is more typically 12 to 15 cycles. This time delay can increase to 0.5 seconds if high speed protection is out of service, for example a single relay communication channel, at the time of a fault and the fault is then cleared in zone 2 time. SPCS believes that R.R.1 is worded in a confusing way. It implies that you had to trip in 9 cycles or less - rather than not trip for a minimum of 9 cycles- albeit we want to wait longer than that. SPCS respectfully questions whether it is conceptually possible to properly state these criteria as a single curve. It is more appropriate to have separate requirements for wind generation and other generators. Additionally, they should differ related to points of interconnections (a contractual arrangement), and refer to the high-side of the GSU for all other generation. This would lend consistency and avoid unnecessary confusion. There are a number of important issues that arise with current approach, including: In general, generator protection should not trip generators on UV, but should alarm, as stated in IEEE C37.102. Please also see latest C50.12 and C50.13. UV is generally a thermal consideration and an alarm is more appropriate to call operator attention to a malfunction. The existence of a curve such as this in a NERC Standard will lead to generator owners enabling UV relays to trip and setting them per the curve, which is a serious danger to system reliability. For some specific situations such as unmanned hydro units, tripping on time-UV may be considered. The idea of a ride-through curve originated with wind farms, and is not generally conceptually appropriate for other generators. For example, this approach is not conceptually appropriate for cylindrical rotor synchronous machines. The Voltages presented are at the point of interconnection and are not directly translatable to machine relay voltage settings. Machine Volts/Hertz curves are a significant issue and are not addressed. The UV performance of plant auxiliaries is a significant issue, and is not addressed. The standard should be very clear to discourage plant owners from setting under- and over- voltage relays if they don't already have them, or need them for very specific situations. SPCS also is concerned because it appears the SDT has considered only the positive sequence voltage in developing the curves in Attachment 2. Overvoltage relays measure individual phase-to-ground or phase-to-phase quantities and SPCS expect that generator owners will apply these curves based on the quantities measured by the relays in developing relay settings. As such, the curves must be based on the quantities that are measured by protective relays and the quantities must be clearly stated. To highlight our concern, consider that for a line-to-ground fault at the point of interconnection on an effectively grounded system the unfaulted phases may have fundamental frequency voltages of 125% or more for the duration of the fault. Under such conditions generators with overvoltage relays set per the curve may trip at 120% voltage prior to clearing the fault from the transmission system. Under these conditions tripping is not required for generator protection and may have a detrimental impact on system reliability, yet it is permissible per the proposed curve. There is guidance in the industry and C37.102 to provide dielectric (insulation) protection for extremely high voltages, however 120 % voltage is overprotecting the generator. For Generator protection, the first line of defense is generator surge arrestors but some units may also use a high set overvoltage protection as well. This voltage is a much higher level then 120% shown in the curve (i.e. 150% of rated voltage). Voltage relays applied to the system side of the generator step-up transformer should be configured and set in such a way that they do trip the generator for higher voltages on unfaulted phases for phase-to- ground faults. As you may know generator windings are sometimes tested with high potential: New machines can be tested as high as twice (200%) rated line-to-line voltage plus 1000 Volts (Commissioning

Organization	Yes or No	Question 4 Comment
		High Pot) for one minute. Older Machines that are in service for significant time can be tested at 125% to 150% of rated line-to-line voltage (Maintenance High Pot) for one minute. There are some industry differences of opinion on this topic of course but 120% instantaneously is too low.Voltage settings are based on type of insulation material (Class F is in common present days) and its thickness. A curve would need to be developed that takes insulation thickness into account. USBR's practice is to use manufacture designed 105% continuous. Then, 59 is set a 110% of 105% (continuous use) for time coordination (TOV) and 130% of 105% of phase-to-ground voltage for instantaneous (IOV).
Response: Thank you for your detailed response to this question. Based on industry input a Requirement has been added to require generators designed and built after the Standard goes into effect to ride through voltage and frequency excursions. The Standard is technology neutral and applies to all generators. The SDT has clarified that generators are not required to install or set the relays to trip. The Standard has been modified to address loss of generation consequent to problems on auxiliary systems, problems which arise due to low voltage or low frequency, or a combination of both. The intent of the Standard is to provide a definition of the no trip boundary for generator relay operation (existing plants) or generating facility performance (new plants). If the generator can remain on line during this boundary, no relay changes or modifications are required. The boundary defines generator relay settings for normally cleared three-phase fault on the transmission system and does not address transmission relay failures that would result in delayed clearing. Delayed clearing with the POI voltage at zero presents serious out-of-step issues for generators. The SDT recognizes the IEEE C37.102 requirement that generator protection should not trip on undervoltage, but should alarm. The proposed PRC-24-1 Standard does not require tripping, but rather defines a boundary when generators that are equipped with high and low voltage relays should not trip generators. Attachment 2 was developed based on a positive sequence model. As such, only balanced voltages should be considered when addressing relay settings.		
Northeast Power Coordinating Council	No	Both bullets should be checked above (form will not accept).The curves should be revised based on generator capabilities and design requirements rather than the expected system response for simulated disturbances. Although the simulation results and tools used to develop the curves have not been provided it appears that the proposed curves are based on transient stability simulations. The transient stability program includes only the positive sequence component of system voltage and neglects phenomena that do not result in significant shaft torques. By contrast, protective relays measure individual phase or phase-to-phase quantities or in some cases specific sequence quantities. As proposed the curves may be interpreted differently in relay applications to the detriment of bulk electric system reliability and customer service. Since the curves will be used to set protective relays they should be based on the quantities that are measured by protective relays and the quantities should be clearly stated. We have provided examples of how the curves could be misinterpreted or misapplied if the curves are not constructed in terms of measured relay quantities and settings specific to the point of measurement: Based on the proposed curve an overvoltage relay can be set at 120% with no intentional time delay. If this relay measures phase-to-ground voltage at the Point of Interconnection (POI) then for a close-in line-to-ground fault the unfaulted phases may have fundamental frequency voltages of 125% or more for the duration of the fault (effectively grounded system), resulting in undesired generator tripping prior to clearing the fault from the transmission system. Protection against overvoltages that are shorter in duration than the operating time of circuit breaker is provided by surge arresters on the high-voltage terminals of the transformer and by surge protectors on the terminals of the generator. The curve implies that for a voltage of more than 120% that the generator can trip instantaneously (without intentional time

Organization	Yes or No	Question 4 Comment
		delay). We suggest that instantaneous trips at any voltage level are neither required nor effective for generator protection. The overvoltage curve should approach zero time asymptotically or alternatively 250% for 20ms, 135% for 300ms, 120% for 20 seconds, 110% continuously. Alternatively the curve should be based on generator capability rather than FERC 661A which is applicable to wind generators with very limited capability. In the undervoltage region the 9 cycle zero voltage has been carried over from FERC 661-A which is to facilitate wind integration. The 9 cycle zero voltage ride-thru, although less than prior utility designs, may be sufficient. We again recommend that SDT translate the intended positive sequence values to phase quantities measured by the relay to avoid misapplication. A single-line-to-ground fault will result in a positive sequence voltage of approximately 0.5-0.7pu but the voltages on individual phases or between phases may be quite different. The curve appears adequate from a positive sequence perspective but may not be interpreted as intended. In the undervoltage region we recommend that 85% be applied from 3 seconds to 15 seconds to ensure that generators stay connected longer than load and to permit time for automatic reactive element switching. There is no reason to trip this fast in this regionBased on the proposed curves we are concerned that the SDT has considered only the system response to typical design contingencies and only the positive sequence voltage from transient stability simulations. Although we have suggested alternate values the final values will depend on how the curve is defined, the form of measurement and relay application. As proposed we believe the curves leave too much for misinterpretation and misapplication.We respectfully question whether it is conceptually possible to properly state this criteria as a single curve. There are a number of important issues that arise with this approach, including the following:> In general generators should not trip on UV, but should alarm. Please see latest C50.12 and C50.13. UV is generally a thermal consideration and an alarm is appropriate to call operator attention to a malfunction.> The existence of a curve such as this in a NERC Standard will lead to generators enabling UV and setting per some part of the curve, which could be a serious hazard to system reliability.> For some specific situations such as unmanned hydro units, tripping on time-UV is appropriate.> The idea of a ride-through curve originated with wind farms, and is not generally conceptually appropriate. For example, this approach is not conceptually appropriate for cylindrical rotor synchronous machines.> The minimum voltage for 9 cycles does not allow enough time to allow for breaker failure protection operation. 13 -15 cycles would be appropriate.> The voltages presented are at the point of interconnection and are not directly translatable to machine relay Voltage settings.> Machine Volts per Hertz curves are a significant issue and are not addressed.> The UV performance of plant auxiliaries is a significant issue, and is not addressed.> We suggest that ANSI/IEEE Standards C37.102, C50.12, and C50.13 should be used and listed as references to this Standard.

Response: Thank you for your detailed response to the question. Development of the voltage ride-through curve started by reviewing the needs of the transmission system and then comparing them to known technical papers and standards. The positive sequence models of the power system that were utilized in the performance analysis did include detailed machine representation accepted by IEEE which calculated shaft torques and other machine parameters. The SDT recognizes the IEEE C37.102 requirement that generator protection should not trip on undervoltage, but should alarm. The proposed PRC-24-1 Standard does not require tripping, but rather defines a boundary when generators that are equipped with high and low voltage relays should not trip generators. The SDT has clarified that generators are not required to install or set the relays to trip. Attachment 2 was developed based on a positive sequence model. As such, only balanced voltages should be considered when addressing relay settings. The boundary defines generator relay settings for normally cleared three-phase fault on the transmission system and does not address transmission relay failure that would

Organization	Yes or No	Question 4 Comment
result in delayed clearing.		
Kansas City Power & Light	No	R2 specifies that the generator may not operate on V/Hz evaluated at nominal frequency. Some generators have specific requirements to trip on V/Hz at 110%. This is in conflict with the upper boundry point of Attachment 2 for times greater than 1 second. We recommend to change this requirement so that it does not apply to V/Hz settings. It is not practical to set generator protective relays fed from generator potential transformers to meet the voltage requirement at the point of interconnect to the BES. We recommend that the voltage chart requirement be applicable to the voltage measured by the generator protective relays, not the voltage at the point of interconnect to the BES.
Response: Thank you for providing a response to this question. Attachment 2 defines voltage durations at the generating facility substation (POI). For a POI voltage of 1.1pu the voltage at the generator terminals will be lower due to voltage regulation and the impedance of the step-up transformer. The Standard is concerned with generator response to excursions on the transmission system, so the voltage profile in Attachment 2 must be defined at the transmission voltage (POI) level. The equivalent profile at the generator terminals depends on the characteristics of the equipment at each facility, so the Generator Owner would have to determine how it affects his specific equipment.		
Constellation Power Generation & Constellation Nuclear	No	The curves should be revised based on generator capabilities and design requirements rather than the expected system response for simulated disturbances. Although the simulation results and tools used to develop the curves have not been provided it appears that the proposed curves are based on transient stability simulations. The transient stability program includes only the positive sequence component of system voltage and neglects phenomena that do not result in significant shaft torques. By contrast, protective relays measure individual phase or phase-to-phase quantities or in some cases specific sequence quantities. As proposed the curves may be interpreted differently in relay applications to the detriment of bulk electric system reliability and customer service. Since the curves will be used to set protective relays they should be based on the quantities that are measured by protective relays and the quantities should be clearly stated. We have provided examples of how the curves could be misinterpreted or misapplied if the curves are not constructed in terms of measured relay quantities and settings specific to the point of measurement: Based on the proposed curve an overvoltage relay can be set at 120% with no intentional time delay. If this relay measures phase-to-ground voltage at the Point of Interconnection (POI) then for a close-in line-to-ground fault the unfaulted phases may have fundamental frequency voltages of 125% or more for the duration of the fault (effectively grounded system), resulting in undesired generator tripping prior to clearing the fault from the transmission system. Protection against overvoltages that are shorter in duration than the operating time of circuit breaker is provided by surge arresters on the high-voltage terminals of the transformer and by surge protectors on the terminals of the generator. The curve implies that for a voltage of more than 120% that the generator can trip instantaneously (without intentional time delay). We suggest that instantaneous trips at any voltage level are neither required nor effective for generator protection. The overvoltage curve should approach zero time asymptotically or alternatively 250% for 20ms, 135% for 300ms, 120% for 20 seconds, 110% continuously. Alternatively the curve should be based on generator capability rather than FERC 661A which is applicable to wind generators with very limited capability. In the undervoltage region the 9 cycle zero voltage has been carried over from FERC 661-A which is to facilitate wind integration. Response: Thank you for your detailed response to the question. Development of the voltage ride-through curve started by reviewing the needs of the transmission system and then comparing them to known technical papers and standards. The positive sequence models of the power system that were utilized in the performance analysis did include detailed machine representation accepted by IEEE which calculated shaft torques and other machine parameters. The SDT recognizes the IEEE C37.102 requirement that generator protection should not trip on undervoltage, but should alarm. The proposed PRC-24-1 Standard does not require tripping, but rather defines a boundary when generators that are equipped with high and low voltage relays should not trip generators. The SDT has clarified that generators are not required to install or set the relays to trip. Attachment 2 was developed based on a positive sequence model. As such, only balanced voltages should be considered when addressing relay settings. The boundary defines generator relay settings for normally cleared three-phase fault on the transmission system and does not address transmission relay failure that would result in delayed clearing. The Standard is concerned with generator response to excursions on the transmission system, so the voltage profile in Attachment 2 is defined at the transmission voltage (or POI) level. The equivalent profile at the generator terminals depends on the characteristics of the equipment at each facility, so the Generator Owner would have to determine how it affects his equipment and evaluate accordingly. Machine Volts per Hertz capabilities were reviewed by the SDT. The upper boundary of the voltage duration curve in Attachment 2 is designed to accommodate those limits.

Organization	Yes or No	Question 4 Comment
Southern Company	No	Controversy of Voltage cumulative nature, not showing the 95%-100% generator terminal voltage, difference between the curve being on the tranmission side of the GSU and the generator relay being on the generator side of the GSU. The generator terminal voltage shown at 95%-105% listed in R2.1. We are concerned that future auditors will interpret this limit as being the coordination limit. The voltage curve of Attachment 2 is stated for system voltage; however as mentioned in the conference call, the volts per hertz protection was specifically referenced and used to support setting criteria. We have a problem with this approach since the V/HZ relay is looking at the generator voltage and the curve is shown for the system voltage. How do we demonstrate coordination since the two are on different basis which cannot accurately be resolved via steady state techniques?The wording used in section R2.2.1 is confusing. The words should be changed to "For three-phase transmission system zone 1 faults with Normal Clearing, generator relaying shall be set longer than the expected fault clearing time, but does not have to be set for greater than nine cycles."
Response: Thank you for your detailed response to the question. The Attachment 2 voltage ride-through diagram is referenced to the point of interconnection to the BES; therefore, addressing the generator terminal voltage on this diagram would add confusion. Attachment 2 was developed based on a positive sequence model. As such, only balanced voltages should be considered when addressing relay settings. The reference document addressed interactions between the synchronous generator Volts/Hertz curves and the Attachment 2 curve. The Attachment 2 curve is intended to fit within the Volts/Hertz curve requirements. The voltage profile at the generator terminals depends on the characteristics of the equipment at each facility and can be determined either by load flow for steady state conditions or dynamically. The Generator Owner would have to determine how it affects his equipment and evaluate accordingly. The SDT has clarified the R2.1 (now R2.1.1. in the revised standard) Standard language.		
Converteam Naval Systems Inc.	No	please see my further comments on this.
Response: Thank you for your comment.		
Gainesville Regional Utilities	No	I am concerned that Generator Operators even understand what is written above
Response: Thank you for providing a response to this question. The Standard is intended to be written such that generator operators will understand the requirements. We welcome any recommendations would help to clarify the document.		
Southern California Edison Company	No	Additional information is need for clarity on the curve and table in the attachment.
Response: Thank you or providing a response to the question. We welcome any recommendations that would help to clarify the document.		

Organization	Yes or No	Question 4 Comment
Basin Electric Power Cooperative	No	This may be appropriate but I have not seen the supporting technical report so I cannot say that I agree.
Response: Thank you or providing a response to the question. Supporting documents are available on the NERC website.		
Progress Energy, Inc.	No	PE is concerend that the proposed profile for voltage (Attachment 2) could later become applicable to all plant equipment. The generating plants are not designed to ride thru/stay connected for this proposed profile. 100% of our nuclear units will trip if subjected to the proposed voltage transient test. The trips would be due to reactor coolant pump undervoltage, reactor coolant pump power monitoring protection, and reactor protection system power supply undervoltage exceeding their respective time delays during the voltage excursion. Each nuclear plant has slightly different trips based on the reactor design and vintage.
Response: Thank you or providing a response to the question. For existing generators, the proposed PRC-24-1 Standard defines requirements for the setting of generator protective relays. The Standard does not require a redesign of the auxiliary systems for existing generators. For generating facilities that are designed and built after this Standard goes into effect, a new performance requirement has been added.		
Hydro-Québec TransEnergie (HQT)	No	The curves should be revised based on generator capabilities and design requirements rather than the expected system response for simulated disturbances. Although the simulation results and tools used to develop the curves have not been provided it appears that the proposed curves are based on transient stability simulations. The transient stability program includes only the positive sequence component of system voltage and neglects phenomena that do not result in significant shaft torques. By contrast, protective relays measure individual phase or phase-to-phase quantities or in some cases specific sequence quantities. As proposed the curves may be interpreted differently in relay applications to the detriment of bulk electric system reliability and customer service. Since the curves will be used to set protective relays they should be based on the quantities that are measured by protective relays and the quantities should be clearly stated. We have provided examples of how the curves could be misinterpreted or misapplied if the curves are not constructed in terms of measured relay quantities and settings specific to the point of measurement: Based on the proposed curve an overvoltage relay can be set at 120% with no intentional time delay. Although we have suggested alternate values the final values will depend on how the curve is defined, the form of measurement and relay application. As proposed we believe the curves leave too much for misinterpretation and misapplication.We respectfully question whether it is conceptually possible to properly state this criteria as a single curve. There are a number of important issues that arise with this approach, including the following:> In general generators should not trip on UV, but should alarm. Please see latest C50.12 and C50.13. UV is generally a thermal consideration and an alarm is appropriate to call operator attention to a malfunction.> The existence of a curve such as this in a NERC Standard will lead to generators enabling UV and setting per some part of the curve, which could be a serious hazard to system reliability.> For some specific situations such as unmanned hydro units, tripping on time-UV is appropriate.> The idea of a ride-through curve originated with wind farms, and is not generally conceptually appropriate. For example, this approach is not conceptually appropriate for cylindrical rotor synchronous machines.> The minimum voltage for 9 cycles does not allow enough time to allow for breaker failure protection operation. 13 -15 cycles would be appropriate.> The voltages presented are at the point of interconnection and are not directly translatable to machine relay Voltage settings.> Machine Volts per Hertz curves are a significant issue and are not addressed.> The UV performance of plant auxiliaries is a significant issue, and is not addressed.> We suggest that ANSI/IEEE Standards C37.102, C50.12, and C50.13 should be used and listed as references to this Standard.

Response: Thank you for your detailed response to the question. Development of the voltage ride-through curve started by reviewing the needs of the transmission system and then comparing them to known technical papers and standards. The positive sequence models of the power system that were utilized in the performance analysis did include detailed machine representation accepted by IEEE which calculated shaft torques and other machine parameters. The SDT recognizes the IEEE C37.102 requirement that generator protection should not trip on undervoltage, but should alarm. The proposed PRC-24-1 Standard does not require tripping, but rather defines a boundary when generators that are equipped with high and low voltage relays should not trip generators. The SDT has clarified that generators are not required to install or set the relays to trip. Attachment 2 was developed based on a positive sequence model. As such, only balanced voltages should be considered when addressing relay settings. The boundary defines generator relay settings for normally cleared three-phase fault on the transmission system and does not address transmission relay failure that would result in delayed clearing. The Attachment 2 curve is intended to fit within the Volts/Hertz curve requirements. The voltage profile at the generator terminals depends on the characteristics of the equipment at each facility and can be determined either by load flow for steady state conditions or dynamically. The Generator Owner would have to determine how it affects his equipment and evaluate accordingly.

Organization	Yes or No	Question 4 Comment
New York Independent System Operator	No	We respectfully question whether it is conceptually possible to properly state this criteria as a single curve. There are a number of important issues that arise with this approach, including the following:> In general generators should not trip on UV, but should alarm. Please see latest C50.12 and C50.13. UV is generally a thermal consideration and an alarm is appropriate to call operator attention to a situation or malfunction which results in low voltage.> The existence of a curve such as this in a NERC Standard will lead to some generator owners enabling UV and setting per some part of the curve, which could be a serious hazard to system reliability.> For some specific situations such as unmanned hydro units, tripping on time-UV is appropriate.> The idea of a ride-through curve originated with wind farms, and is not generally conceptually appropriate. For example, this approach is not conceptually appropriate for cylindrical rotor synchronous machines.> The minimum Voltage for 9 cycles does not allow enough time for breaker failure protection operation. 13 -15 cycles would be appropriate.> The Voltages presented are at the point of interconnection and are not directly translatable to machine relay Voltage settings.> Machine Volts per Hertz curves are a significant issue and are not addressed.> The UV performance of plant auxiliaries is a significant issue, and is not addressed.> We suggest that ANSI/IEEE Standards C37.102, C50 12, and C50.13 should be used and listed as references to this Standard.
Response: Thank you for your detailed response to this question. The SDT has clarified that generators are not required to install or set the relays to trip. The intent of the Standard is to provide a definition of the no trip boundary for generator relays. If the generator can remain on line during this boundary, no relay changes or modifications are required. The boundary defines generator relay settings for normally cleared three-phase fault on the transmission system and does not address transmission relay failures that would result in delayed clearing. The SDT recognizes the IEEE C37.102 requirement that generator protection should not trip on undervoltage, but should alarm. The proposed PRC-24-1 Standard does not require tripping, but rather defines a boundary when generators that are equipped with high and low voltage relays should not trip generators. Based on industry input, the Standard has been modified to require new generators to ride through voltage and frequency excursions, addressing plant auxiliaries concerns. Machine Volts per Hertz capabilities were reviewed by the SDT. The upper boundary of the voltage duration curve in Attachment 2 is designed to accommodate those limits.		
CenterPoint Energy	No	a) Attachment 2 of PRC-024-2 is truncated at 4 seconds and does not define the duration of the 0.9 pu voltage level. CenterPoint Energy recommends the total duration of the 0.9 pu voltage level be established at a MINIMUM of 10 seconds. The basis for 10 seconds is for coordination with undervoltage load shedding (UVLS) systems. b) Attachment 2 has a step function profile. CenterPoint Energy has reviewed these proposed steps for voltage recovery to 0.9 pu and concurs with most proposed steps. However, CenterPoint Energy studies indicate an insufficient coordination margin at the proposed 0.30 seconds at 0.65 pu voltage point. Noting the CenterPoint Energy transmission grid is a compact and stout system, CenterPoint Energy believes it is highly unlikely many transmission systems can recover to a 0.65 voltage level in 18 cycles (0.30 seconds). To address this, CenterPoint Energy recommends reducing the number of steps. For this, as well as including a 0.9 pu voltage level ride-through for a minimum of 10 seconds, CenterPoint Energy recommends the data points (Time / Voltage) in the LVRT DURATION table be as follows: 0.15 / 0.000, 2.00 / 0.450, 3.00 / 0.750, and 10.00 / 0.900.
Response: Thank you for your detailed response to this question. Attachment 2 has been extended to 600 seconds. The profile of the voltage duration		

Organization	Yes or No	Question 4 Comment
curve is based on studies done in the Eastern and Western Interconnections. If you have studies that document longer recovery times, please share them with the SDT.		
Independent Electricity System Operator	No	Simulation results only add value when sufficient validation has been performed to provide confidence that good decision can be made on the basis of these simulations. Simulations by themselves are not enough. Were the simulations used in this exercise validated against actual performance? To cater for protection differences within jurisdictions, it would be better to label the jogs in the voltage characteristic with the corresponding physical meaning (e.g. maximum normal fault clearing, maximum delayed fault clearing) rather than assign specific times. Within Ontario, it is unclear whether the voltage curves are sufficient to accommodate present practice for delayed fault clearing. It is unclear in the curves whether the POI voltage is the positive sequence voltage or phase voltage. The meaning of per unit should also be clarified. For example, Ontario uses a 220kV voltage basis for a system operated as high as 250kV. Does 1.2PU mean 264 kV or 300kV? The over-voltage settings should be re-expressed to ensure the short duration over-voltages that follow lightning strikes and capacitor switching do not result in generator tripping.
Response: Thank you for your detailed response to this question. Validation against actual system performance is important. The simulations that were initially performed as part of this analysis had their genesis within WECC. On an ongoing basis, the Modeling & Validation Work Group validates system model performance against actual system events. The voltage ride-through curve provided in Attachment 2 of PRC-24-1 addresses specific performance that would be required over a wide range of system events and locations. The positive sequence models of the power system that were utilized in the performance analysis did include detailed machine representation accepted by IEEE which calculated shaft torques and other machine parameters. Clarification 1 currently indicates: "The per unit voltage base for this curve is the scheduled operating voltage as measured at the point of interconnection to the Bulk Electric System."		
Ameren	No	FERC 661-A applies to wind generator Voltage Ride Though (VRT) for a three phase fault. We disagree with PRC-024-1 now expanding it to all generators.R2.2.1 wording is confusing: it implies that the UV trip setting must be less than 9 cycles which conflicts with the LVRT curve and its interpretation for lessor voltage dips.
Response: Thank you for your detailed response to this question. The SDT has developed a technology neutral Standard that applies to all generators. Based on industry input, the Standard has been modified to require new generators to ride through voltage and frequency excursions. The SDT has clarified that generators are not required to install or set the relays to trip. The SDT revised R2.1.1 as follows: " For three-phase transmission system zone 1 faults with Normal Clearing, set voltage relays based on actual fault clearing times, not to exceed 9 cycles."		
First Solar	No	See response to the previous question. While this may envelope the probable range of voltages that may occur on the system, it does not sufficiently describe the response of the generating plant to these disturbances. To simply say that the protective relays should not trip lacks sufficient detail to apply to inverter based PV projects.
Response: Thank you for your response to this question. The SDT has developed a technology neutral Standard that applies to all generators. Based on industry input, the Standard has been modified to require new generators to ride through voltage and frequency excursions. The SDT has clarified		

Organization	Yes or No	Question 4 Comment
that generators are not required to install or set the relays to trip.		
US Bureau of Reclamation	No	The SDT background material above states that the 9 cycle time is required by FERC Order 661-A. FERC Order 661-A applies to wind generators. We believe there is no convincing reliability based rationale to expand the scope of the FERC Order via this standard to include synchronous machines, noting that Genrators are already required (PRC-001-1) to coordinate settings with the host Transmission Operator.
Response: Thank you for your response to this question. The SDT has developed a technology neutral Standard that applies to all generators. Based on industry input, the Standard has been modified to require new generators to ride through voltage and frequency excursions. The SDT has clarified that generators are not required to install or set the relays to trip.		
American Transmission Company	No	It would be beneficial to have the option of measuring the voltage at the generator bus or point of interconnection (POI), with the understanding that the proper voltage must be maintained at the POI.
Response: Thank you for your comment. The SDT specifically chose the point of interconnection because that is where the faults occur that this Standard is intended to address. The SDT has provided additional assumptions for the calculation of relay settings on the basis of the voltage as measured at the POI.		
Luminant Power	No	
E.ON U.S.	No	
AWEA	No	
American Wind Energy Association	No	
Veolia Environmental Services	No	
Lakeland Electric	No	
Manitoba Hydro	No	

<table>

</table>

Organization	Yes or No	Question 4 Comment
Duke Energy	Yes	The applicability of the curve is limited to the protective relays addressed by the standard. This curve is not meaningful if the plants were going to trip due to other causes. See our response to Question #9.
Response: Thanks you for your response to the questions. Based on industry input, the Standard has been modified to require new generators to ride through voltage and frequency excursions.		
PJM Interconnection	Yes	In R2.2.1, replace -greater- with -faster- or -slower-, whichever is correct. In R2.2.3 replace -intended- with -required-. In R4, replace -written- with -documented-. In R5, add an -s- to -System- in the parentheses. In R3, R4 and R5 - Concerned with the GO responsibility to send to their RC, PC, TO and TP. Would rather see the GO responsibility be to just to respond to any RC, PC, TO and TP requests.
Response: Thank you for your comments. The SDT has modified the Standard to address the language concerns relative to R2.2.1 (now 2.1.1 in the revised standard) and R2.2.3 (now 2.1.3). The SDT prefers the choice of written as opposed to documented in R4. In R3 and R5 all the named entities must receive the information. In R4 we agree that only the requesting entity must receive the information.		
Dominion	Yes	We would like to commend the SDT for recognizing that there may be technical reasons that prevent a generator from meeting requirements 1 and 2 and allowing an exemption when technical basis is provided (R5). There is a paragraph on the second page which states that " For voltage excursions, only generator under or over voltage protective relays and volts per hertz relays would need to be evaluated to meet the draft requirements. Steady state evaluations only are expected "We have the following questions: (1) Do the relays mentioned in the statement above include auxiliary system under voltage relays? It appears the voltage relay part of the standard is limited to only relays that directly trip the generator and not relays that trip auxiliaries. Is that the intent? What if the relay was attached to an auxiliary bus, but tripped the generator (2) How is that only steady state evaluations are enough? How do you study voltage recovery characteristics without dynamic simulations? If the standard is intended to apply to volts per hertz relays, suggest:1. Revising footnote 1 to specifically include volts per hertz relays.2. Revise Steps 4.2.1 and 4.2.2 to specifically include volts per hertz relays.3. That the standard should incorporate specific guidance for facilities using volts per hertz logics and include a graph showing the voltage and frequency excursions in terms of volts per hertz.
Response: Based on industry input, the Standard has been modified to require new generators to ride through voltage and frequency excursions, addressing the auxiliary systems concern. With respect to steady state evaluations versus dynamic simulations, the Standard does not preclude the application of either. The SDT agrees and has added volts per hertz relays among the listed items in footnote 1.		
Northeast Power Coordinating Council	Yes	Referencing R5 and R6 of the Standard: The Reliability Coordinator should be give veto power over exceptions to the requirements herein. Should the Generator Owner/Operator not be able to, or be unwilling to, make changes to setpoints to come into compliance with this Standard, the Reliability Coordinator should be given the authority to invoke required mitigation, such as requiring the Generator Owner/Operator to contract for compensatory load shedding up to the total

Organization	Yes or No	Question 4 Comment
		amount of MW of each generating unit that fails to comply with the required setpoints. In addition, The "Off-Nominal Frequency Capability Curve" in Attachment 1 does not coordinate with the underfrequency load shedding (UFLS) program design parameters proposed by the NERC Underfrequency Load Shedding Standard Drafting Team for Project 2007-01. The misccoordination occurs in the time range approximately between 5 and 10 seconds. This miscoordination can be eliminated by extending the horizontal line at 57.8 Hz to 5 seconds and revising the diagonal line to have endpoints at 57.8 Hz/5s and 59.5 Hz/1800s. This modification will provide coordination with the UFLS program design parameters while still maintaining coordination with turbine-generator capability.Due to the time scale on the graph in Attachment 2, the curves do not indicate the time at which the transient overvoltage and undervoltage requirements end, at which point the continuous voltage requirements would be applicable. Here are several other points that have come up regarding other parts of PRC-024-1 that were not covered above:> Concerning Attachment 1, we believe this is mainly present to infer that generator tripping will not interfere with UFLS programs. There should be a statement that settings should not interfere with UFLS program in effect. Also on Attachment 1, this is now labeled "Off Nominal Frequency Capability Curve." We wish to suggest that the word "capability" in this label is potentially misleading. This is not a machine capability curve. There should be a statement that protective device settings should be based on machine damage considerations and should be arrived at in consultation with the machine manufacturer. The curve presents limits to those settings which are designed to prevent interference with UFLS programs, and the curve should be so labeled. > A.R1 and A.R2 wording could be taken to require that such relaying should be enabled and set. The phrase "Installed relaying not to trip during" could be taken to mean that such relaying is assumed to be, or should be, installed. Also, in the case of generator multifunction protective devised, such relaying is always installed but it is not appropriate in many cases that it be enabled and set. Note this consideration applies to both frequency and voltage. In general, this Standard should take care to point out that any protection application should be based on actual specific machine protective considerations which should be arrived at in consultation with the machine manufacturer.> Concerning A.R1.2 and Attachment 1, the language refers to a 'no trip zone" between curves, and obviously there is a permissible trip zone outside the curves. Questions will arise on permissibility of settings which are actually on the curves. We would suggest that setting directly on the curves should be permitted. For example, if 1.0 s. at 57.8 Hz is directly on the curve, failure to deal with this question will result in pointless and counterproductive settings such as 1.0 s. at 57.79 Hz. We suggest "Setting directly on the curves are permitted, and settings outside the curves are permitted."> Concerning A.R2, this Standard addresses setting of voltage relays based on voltage at the point of interconnection, which is not directly translatable to voltage at the generator terminals. The generator real and reactive power output will affect the relationship, and this is not dealt with in this Standard.We would like to commend the SDT for recognizing that there may be technical reasons that prevent a generator from meeting requirements 1 and 2 and allowing an exemption when technical basis is provided (R5). There is a paragraph on the second page which states that " For voltage excursions, only generator under or over voltage protective relays and volts per hertz relays would need to be evaluated to meet the draft requirements. Steady state evaluations only are expected "We have the following questions: (1) Do the relays mentioned in the statement above include auxiliary system undervoltage relays? It appears the voltage relay part of the standard is limited to only relays that directly trip the generator and not relays that trip auxiliaries. Is that the intent? What if the relay was attached to an auxiliary bus, but tripped the generator?(2) How is that only steady state evaluations are enough? How do you study voltage recovery characteristics without dynamic simulations?

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 4 Comment</th></tr>
<tr><td colspan="3">Response: Thank you for your comments. The SDT has captured what we believe are the main points of your comment sand has provided responses below:
• RC should have veto power over exemptions – The SDT believes it is the responsibility of the GO to determine the capability of the existing unit. The judgment as to validity of an exemption is a compliance matter.
• RC should have authority to decide mitigation, e.g., compensatory load shedding – The SDT believes mitigation of inability to comply with a Standard is a compliance matter.
• UFLS mis-coordination – The UFLS SDT and this Standard Drafting Team conferred and resolved the mis-coordiantion. The resolution that was mutually agreed to was for the UFLS SDT to modify its Standard to accommodate the frequency curve in this Standard.
• PRC-024 should not interfere with UFLS – The two teams have coordinated the frequency curves and strategies.
• State that settings shall be determined to prevent machine damage in consultation with manufacturers' recommendation – The SDT developed the curves in accordance with manufacturer's recommendations and the Standard includes an exemption process for existing generators.
• Are settings permitted on the curve? No, settings are not permitted on the curve/line and the Standard has been modified to reflect this more clearly. --
• POI versus generator terminal – The SDT specifically chose the point of interconnection because that is where the faults that this Standard is intended to address occur.
• Auxiliary systems relays and Steady state versus dynamic simulation – Based on industry input, the Standard has been modified to require new generators to ride through voltage and frequency excursions, addressing the auxiliary systems concern. With respect to steady state evaluations versus dynamic simulations, the Standard does not preclude the application of either. The SDT agrees and has added volts per hertz relays among the listed items in footnote 1.</td></tr>
<tr><td>SERC Dynamics Review Subcommittee (DRS)</td><td>Yes</td><td>1. We recommend deleting the proposed section R2.2.2. If not deleted, change: "meet a shorter voltage ride through" to "meet a less stringent voltage ride through".
2. In R3, change "within 30 calendar days of any change" to "at least 30 calendar days prior to any change". The changes should be provided before they are made in the field.
3. In M4, change "entities listed in Requirement 4" to "entities listed in Requirement 4 that provide a written request"</td></tr>
<tr><td colspan="3">Response: Thank you for your comments.
1. The SDT agrees and has modified the Standard to reflect this. In the revised standard, the phrase, "less stringent" is used. (See 2.1.2)
2. The SDT intends this requirement to ensure timely notification of equipment changes to the PA and 30 days is a reasonable duration for the time horizon of the PA.</td></tr>
</table>

Organization	Yes or No	Question 4 Comment
3. **The SDT agrees and has modified the standard to reflect this.**		
Kansas City Power & Light	Yes	Please consider including the Balancing Authority as an entity for the Generator Owner to provide settings information in requirements R3 & R4 since the BA is an entity that has a direct relationship with the operational status of generating stations. R5: Do not agree with the bulleted item where increasing the capability of a generator by 10% is a reason for exemption expiration. As an example, turbine or boiler enhancements can result in greater efficiencies and resulting in an increase of generator capability with no change to the generator or its protection capabilities whatsoever. Recommend removal of this bulleted item. R5: The generator exciter voltage regulator contains protective relay settings such as Volts/Hertz, undervoltage, overvoltage, underfrequency that will also trip the Unit. Is the exciter voltage regulator considered to be part of the generator protective relay system? If so, would a limitation of the exciter voltage regulator be allowed as an exception to the standard or, since the protective system is excluded, would R5 mandate that the exciter voltage regulator be replaced to remove the exception? This issue should be clarified in R5.
Response: The SDT does not observe a reliability need to provide these setting data to the Balancing Authority. **The SDT intends for a GO who decides to increase capability of its unit by a significant amount (now 10%) to also address the technical limitation cited in its exemption.** **The NERC Glossary definition of Protective System does not include voltage regulator. However, the SDT intends this Standard to include all protective functions and relays that directly trip the generator based on frequency and voltage excursions, regardless of where they are located.**		
MRO NERC Standards Review Subcommittee	Yes	It would be good to have the option of measuring the voltage at the Generator bus or POI. With the understanding that the voltage must be maintained of the POI.
Response: Thank you for your comment. The SDT agrees that it is the voltage at the POI that must be maintained. The Standard is concerned with generator response to excursions on the transmission system, so the voltage profile in Attachment 2 is defined at the transmission voltage (or POI) level. The equivalent profile at the generator terminals depends on the characteristics of the equipment at each facility.		
FirstEnergy	Yes	1. FE's consensus is that the PRC-024 allowable under-frequency vs. time tripping curve is too tight. By too tight, we mean that the LP turbine buckets and blades are much more tolerant of off freq operation than the proposed tables. Comparing them to the old ECAR curves and allowable tripping times shows they are more stringent. Given how seldom these events occur, (never happened yet in the Eastern Interconnect) expending more of this capacity appears justified. 2. Section A5 Implementation schedule - it may not give sufficient time to implement these requirements. We suggest an

Organization	Yes or No	Question 4 Comment
		additional year as follows: no less than 33% within 2 years of effective date no less than 66% within 3 years of effective date no less than 100% within 4 years of effective date 3. R1.2 Should say off-nominal not off-normal. 4. R2.1 Suggest changing the word "measured" to "experienced". 5. In R5, we suggest changing the first bullet to read: "The equipment causing the limitation is modified, upgraded or replaced with equipment that removes the technical limitation.", and then delete the second bullet. 6. Requirements 3, 4 and 6 specify that the Generator Owner shall provide information to RCs, PCs, TOPs, and TPs that monitor or model the associated unit; however, there is no requirement for these entities to identify themselves to the Generator Owner. How will the Generator Owner know they have identified all of the entities that need the information? 7. In R5, the Generator Owner is granted an exception from requirements R1 or R2 simply by providing documentation of a equipment limitations. There is no independent view of the appropriateness of this exception. The drafting team should consider requiring independent verification of the equipment limitation prior to the granting of an exception to the requirements of the standard. 8. Sec. D References - Is this intended to be part of the standard? If so, it would be helpful if it was linked to the white paper so that we can review it. 9. In Requirements R3 through R6, the SDT may want to consider adding the Transmission Owner as another entity who may need this information. 10. R2.2.1 may need to be re-worded as it requires that protection trip in no greater than 9 cycles. We are not aware of a disadvantage to the system if the tripping takes longer than 9 cycles.

Response:

1. **The SDT intends for GOs to set its relays as tight as possible and not merely on the curve/line.**
2. **The SDT set the timeframe by consensus among team members and the companies they represent. Stakeholder comments have not thus far objected to the implementation schedule. On this basis the SDT is leaving the schedule as proposed.**
3. **The SDT agrees and has made the change.**
4. **The SDT has modified the wording in R2.**
5. **The intent of R5 is to require eliminating the exception if the generator is upgraded by 10% or more.**
6. **The GO is expected to know what entity is its RC, PC, TO, and TP.**
7. **The drafting team considered requiring an independent evaluation of existing generator exceptions and determined that it is not practical.**

Organization	Yes or No	Question 4 Comment
8. No referenced documents are part of the Standard. **9. The SDT considered including the Transmission Owner and determined that the Transmission Operator is the appropriate organization to receive the information.** **10. The 9 cycle maximum clearing time is intentional. It is not a system consideration; it is because generators cannot withstand zero voltage at the POI for long periods of time.**		
IRC Standards Review Committee	Yes	a. R5: The wording "the Generator Owner is granted an exception for that unit from meeting the portion of Requirement R1 or R2 for that limitation once it provides documentation of the equipment limitation(s) to the Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners that monitor or model the associated unit, within 30 days of identifying the equipment limitation." is not written in a way to hold an entity responsible for any action. We suggest to reword it such that it places a responsibility to the Generator to seek approval for an exception, as follows: "the Generator Owner shall obtain approval for an exception for that unit from meeting the portion of Requirement R1 or R2 for that limitation through the submission of documentation of the equipment limitation(s) to the Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners that monitor or model the associated unit within 30 days of identifying the equipment limitation. Along with this proposed change, there is also a need for the entities receiving the approval request to respond to the request. Another requirement is needed to complete this process. b. The latter part of R5 should be reworded to hold an entity responsible for the needed actions associated with expiring the exception such that the requirement is measurable and enforceable. c. R6: It is unclear to us what purpose this requirement serves. If R5 is to be revised as we suggest (see above), then the "limitation" in question will be presented with technical justification in the request for approval. The receiving entities (RC, PC, TOP and TP) will have a chance to accept or reject the request with due consideration of the technical argument. This is part of the approval request process; hence we do not see the need for R6 if R5 is to be reworded. If a remand process needs to be stipulated, then inclusion in R5 a requirement for the receiving entity(ies) to respond to the request - either approving or disproving the with a rationale, would suffice.
Response: Thank you for your comment. **a. The required action is for the GO to provide documentation of the equipment limitation. The SDT believes it is the GO's responsibility to determine any limitations on existing generators' ability to meet the Standard.** **b. The GO is responsible for meeting the requirements when an exception expires.** **c. R6 (R4 in the revised standard) provides the RC, PC, TO, and TP with an opportunity to seek clarification concerning existing generator limitations in meeting the Standard.**		
Constellation Power	Yes	The 4 kV protection that includes under frequency and under voltage relays trip the generator in some of our plants. The

Organization	Yes or No	Question 4 Comment
Generation & Constellation Nuclear		SDT needs to clarify whether this standard applies to such protection.
Response: Thank you for your comment. The Standard applies to setting of voltage and frequency relays that directly protect the generator.		
Southern Company	Yes	1. We recommend deleting the proposed section R2.2.2. If not deleted, change "meet a shorter voltage ride through" to "meet a less stringent voltage ride through". 2. In R3, change "within 30 calendar days of any change" to "at least 30 calendar days prior to any change". The changes should be provided before they are made in the field. 3. In M4, change "entities listed in Requirement 4" to "entities listed in Requirement 4 that provide a written request" 4. How did the SDT translate the transient voltage excursion plot to the cumulative voltage curve? 5. The voltage ride through curve was said to be cumulative, this should be specified on the curve. 6. How can we prove that our static voltage curve coordinates with this cumulative curve 7. Implementation schedule we believe that the unit size should be considered, and that the most critical units should be worked on first. Completing 33% each year is too ambitious for those members that have > 300 units. 8. What regions are working on voltage ride through and Underfrequency (ufls and undefrequency tripping of generators) 9. Should the PRC-024 SDT wait until the regions have completed their work? 10. Generator engineers do not see a relevance for a voltage ride-through for any generator other than wind.
Response: Thank you for your comment. **1. The SDT agrees and has modified the standard to reflect this.** **2. The SDT intends this requirement to ensure timely notification of equipment changes to the PA and 30 days is a reasonable duration for the Time Horizon of the PA.** **3. The SDT agrees and has modified the Standard to reflect this.** **4. The SDT analyzed the amount of time the voltage remained outside of the required range in each of the events modeled.** **5. The SDT has clarified the language.** **6. A cumulative curve was selected to coordinate with relays that measure elapsed time.** **7. The SDT set the timeframe by consensus among team members and the companies they represent. Stakeholder comments have not thus far**		

Organization	Yes or No	Question 4 Comment
objected to the implementation schedule. On this basis the SDT is leaving the schedule as proposed. **8. At the recommendation of FERC and NERC, the SDT has coordinated the UF relay curve with the NERC UFLS SDT members input.** **9. At the recommendation of FERC and NERC, the SDT has coordinated the UF relay curve with the NERC UFLS SDT members input.** **10. The SDT has taken the direction to develop a Standard that is technology neutral.**		
Converteam Naval Systems Inc.	Yes	0. (Overall) This is a good document that has good background study and contains a lot of expertise; 1. (Voltage definition inconsistency)In the LVRT curves, it talks about the voltage at the point of interconnection. However, in R2.1 it uses voltage at the generator terminals. I think there is a little inconsistency between these two. It would be good to just use one of them, preferably the former one. The reason is that different generator plants might have different impedance between the generator terminals and the points of interconnection, so defining the voltage at the terminals poses a little unfairness. Another part of the reason is that for transmission protection purpose, it should ends at the point of interconnection. 2. (Voltage range inconsistency)The voltage range is 0.9-1.1pu in the VRT curve, but it says 0.95-1.05 in R2.1. It would be good to make it consistent. 3. (Date point missing) In the table supporting the VRT curves, the 0.95 and 1.05pu data are missing. 4. (Priority) WECC and MRO have different VRT curves. Which one will override which one at the end? Will the NERC PRC-024 take priority than the Regional Entities? 5. Was reactive power support during faults considered in the draft group? Will it be required in the future Thanks
Response: Thank you for your comment. **0. Thank you!** **1. The Standard applies to transient voltage excursions at the POI. R2.1 addresses steady state voltages at the generator terminals.** **2. The VRT curve addresses the transient voltage event. R2.1 addresses steady state conditions, outside the range of the VRT curve.** **3. The table addresses the transient voltage event and does not address steady state conditions.** **4. This proposed standard is a NERC standard. The SDT is not addressing current or future regional Standards.** **5. The Standard addresses voltage ride through. Reactive power and voltage support are important considerations in determining if a generator will meet the Standard. Methods to meet the Standard requirement are not specified in the Standard.**		
Consumers Energy	Yes	Please see comments on Question 3.

Organization	Yes or No	Question 4 Comment
Company		
Response: Thank you for your comment. Please see responses to Question 3.		
Old Dominion Electric Cooperative	Yes	Provide some insight on Technical Exceptions for generators that cannot met these requirements (the CIP TFE process might be useful in this)
Response: Thank you for your comment. The SDT believes it is the responsibility of the GO to determine the capability of the existing units to meet the Standard.		
Southern California Edison Company	Yes	The curves and tables in the attachments require additional clarification.
Response: Thank you for your comments. Additional clarification has been added.		
Progress Energy, Inc.	Yes	1. Recommend deleting proposed R2.2.2. If not deleted the language needs to be clarified as follows: "meet a shorter voltage ride through" should be changed to "meet a less stringent voltage ride through". 2. In R3, change "within 30 calendar days of any change" to "at least 30 calendar days prior to any change". The changes should be provided before they are made in the field. 3. In M4, change "entities listed in Requirement 4" to "entities listed in Requirement 4 that provide a written request" 4. The purpose and the applicability of the standard needs to be revised to clearly specify that the scope of PRC-024-1 only applies to main generator protective relaying and excludes protective functions associated with plant auxiliary equipment.
Response: Thank you for your comments. **1. The SDT agrees and has modified the Standard to reflect this.** **2. The SDT intends this requirement to ensure timely notification of equipment changes to the PA and 30 days is a reasonable duration for the Time Horizon of the PA.** **3. The SDT agrees and has modified the Standard to reflect this.** **4. The Standard has been modified and now applies to overall new generator performance.**		
NIPSCo	Yes	R4 These groups should already have this information. The coordinators or planners should have proof and be able to provide this information now.R5 Normally would not accumulate enough time in the under-frequency zone to be a danger to the turbine blades but under unusual circumstances might accumulate too much time and not be able to continue to operate

Organization	Yes or No	Question 4 Comment
		in the under-frequency region that is being specified. We might not have enough time to wait for the 30 day period.
Response: Thank you for your comment. • **The purpose of the Standard is to assure that the relay setting information is available to the groups that require it.** • **Existing generators that are not able to meet the Standard are able to obtain an exception.**		
Northeast Utilities	Yes	R2.2.1 seems to imply that a generator must set an undervoltage trip with a time delay of no more than 9 cycles. This seems to conflict with the intent of PRC-024. Is the intent perhaps to require the TO to clear Zone 1 faults in no more than 9 cycles? Or is the intent to allow the GO to set the time delay as low as 9 cycles and no less? I suggest the latter.R3, R4, and R5 - This information should be provided to the owner of any UFLS or UVLS as well.
Response: Thank you for your comment. The intent is to allow TOs to reduce the required 9 cycle ride through requirement in cases where transmission system design allows faster clearing.		
Hydro-Québec TransEnergie (HQT)	Yes	Referencing R5 and R6 of the Standard: The Reliability Coordinator should be give veto power over exceptions to the requirements herein. Should the Generator Owner/Operator not be able to, or be unwilling to, make changes to setpoints to come into compliance with this Standard, the Reliability Coordinator should be given the authority to invoke required mitigation, such as requiring the Generator Owner/Operator to contract for compensatory load shedding up to the total amount of MW of each generating unit that fails to comply with the required setpoints. In addition, The "Off-Nominal Frequency Capability Curve" in Attachment 1 does not coordinate with the underfrequency load shedding (UFLS) program design parameters proposed by the NERC Underfrequency Load Shedding Standard Drafting Team for Project 2007-01. The misccoordination occurs in the time range approximatley between 5 and 10 seconds. This miscoordination can be eliminated by extending the horizontal line at 57.8 Hz to 5 seconds and revising the diagonal line to have endpoints at 57.8 Hz/5s and 59.5 Hz/1800s. This modification will provide coordination with the UFLS program design parameters while still maintaining coordination with turbine-generator capability. Due to the time scale on the graph in Attachment 2, the curves do not indicate the time at which the transient overvoltage and undervoltage requirements end, at which point the continuous voltage requirements would be applicable. Here are several other points that have come up regarding other parts of PRC-024-1 that were not covered above:> Concerning Attachment 1, we believe this is mainly present to infer that generator tripping will not interfere with UFLS programs. There should be a statement that settings should not interfere with UFLS program in effect. Also on Attachment 1, this is now labeled "Off Nominal Frequency Capability Curve." We wish to suggest that the word "capability" in this label is potentially misleading. This is not a machine capability curve. There should be a statement that protective device settings should be based on machine damage considerations and should be arrived at in consultation with the machine manufacturer. The curve presents limits to those settings which are designed to prevent interference with UFLS programs, and the curve should be so labeled. > A.R1 and A.R2 wording could be taken to require that such relaying should be enabled and set. The phrase "Installed relaying not to trip during" could be taken to mean that such relaying is assumed to be, or should be, installed. Also, in the case of generator multifunction protective

Organization	Yes or No	Question 4 Comment
		devised, such relaying is always installed but it is not appropriate in many cases that it be enabled and set. Note this consideration applies to both frequency and voltage. In general, this Standard should take care to point out that any protection application should be based on actual specific machine protective considerations which should be arrived at in consultation with the machine manufacturer.> Concerning A.R1.2 and Attachment 1, the language refers to a 'no trip zone" between curves, and obviously there is a permissible trip zone outside the curves. Questions will arise on permissibility of settings which are actually on the curves. We would suggest that setting directly on the curves should be permitted. For example, if 1.0 s. at 57.8 Hz is directly on the curve, failure to deal with this question will result in pointless and counterproductive settings such as 1.0 s. at 57.79 Hz. We suggest "Setting directly on the curves are permitted, and settings outside the curves are permitted."> Concerning A.R2, this Standard addresses setting of voltage relays based on voltage at the point of interconnection, which is not directly translatable to voltage at the generator terminals. The generator real and reactive power output will affect the relationship, and this is not dealt with in this Standard. We would like to commend the SDT for recognizing that there may be technical reasons that prevent a generator from meeting requirements 1 and 2 and allowing an exemption when technical basis is provided (R5). There is a paragraph on the second page which states that " For voltage excursions, only generator under or over voltage protective relays and volts per hertz relays would need to be evaluated to meet the draft requirements. Steady state evaluations only are expected "We have the following questions: (1) Do the relays mentioned in the statement above include auxiliary system undervoltage relays? It appears the voltage relay part of the standard is limited to only relays that directly trip the generator and not relays that trip auxiliaries. Is that the intent? What if the relay was attached to an auxiliary bus, but tripped the generator?(2) How is that only steady state evaluations are enough? How do you study voltage recovery characteristics without dynamic simulations?

Response: Thank you for your comment.

- **The GO has the responsibility for determining the capability of existing generators and their ability to meet this Standard. How the power system deals with the inability of an existing generator to meet the Standard requirements is not addressed in this Standard.**
- **The UFLS SDT and this Standard Drafting Team conferred and have coordinated the frequency curves and strategies.**
- **The voltage curve ends at 1000 seconds. Steady state limits apply after 600 seconds.**
- **Clarification has been added that the Standard does not require voltage or frequency protective relays to be installed or enabled.**
- **Clarification has been added concerning setting relays exactly on the curve.**
- **Clarification has been added concerning assumptions to be made when calculating generator terminal voltage settings that correspond to required POI limits.**
- **The Standard has been modified to be a new generator performance Standard.**
- **With respect to steady state evaluations versus dynamic simulations, the Standard does not preclude the application of either.**

Organization	Yes or No	Question 4 Comment
AESO	Yes	In addition to the SRC ISO/RTO comments the AESO would like to add: As we understand it, the intent of this standard is to ensure that the generators ride through certain levels of frequency and voltage excursions, yet it only addresses the generator protection. We feel it must also address the protection and capabilities of the auxiliaries, unit transformers, lines, etc. If any of these trip off due to the same excursions that the generator is required to ride through, then the generator will be down and the standard will not have achieved its goal.
Response: Thank you for your comment. Based on industry input, the Standard has been modified to require new generators to ride through voltage and frequency excursions.		
Duke Energy	Yes	The issue typically addressed by international grid codes is an over-all plant performance standard and plant dynamic studies are performed to evaluate the impact on in-plant systems. Standards applicable to only generator protection might give a false sense that a plant could survive the transients and the reliability of the BES would be just as adversely impacted if large plants were to trip for causes other than a main generator relay. The basis and reliability benefit for voltage ride through transients should be clarified. Generator UF relays must coordinate with grid UFLS relaying. Some areas may apply UVLS and logic dictates that the coordination of that protection with a generator ride through criteria should be specified. Recommend that the scope of "equipment" that can be granted an exception be limited in some way or explicitly qualified. Otherwise, plant performance can be dictated by less-consequential auxiliary equipment (e.g. variable speed drives with UV settings per manufacturer standard instructions). Because R5 grants exception automatically in response to the GO providing documentation of any limitation. R5 bullet 2 - recommend changing "generator nameplate capacity rating" to "generator gross Real Power capability". The existing words are too general and including 'nameplate' is confusing.
Response: Thank you for your comment. • **The Standard has been modified to require new generators to ride through voltage and frequency excursions.** • **The UFLS SDT and this Standard Drafting Team conferred and have coordinated the frequency curves and strategies.** • **The GO has the responsibility for determining the capability of existing generators and their ability to meet this Standard.** • **The SDT used the term, "continuous capacity rating" instead of "nameplate capacity" in the revised standard.**		
New York Independent System Operator	Yes	Here are several other points that have come up regarding other parts of PRC-024-1 that were not covered above:> Concerning Attachment 1, we believe this is mainly present to insure that generator tripping will not interfere with UFLS programs. There should be a statement that settings should not interfere with UFLS program in effect. Also on Attachment 1, this is now labeled "Off Nominal Frequency Capability Curve." We wish to suggest that the word "capability" in this label is potentially misleading. This is not a machine capability curve. There should be a statement that protective device settings should be based on machine damage considerations and should be arrived at in consultation with the machine

Organization	Yes or No	Question 4 Comment
		manufacturer. The curve presents limits to those settings which are designed to prevent interference with UFLS programs, and the curve should be so labeled.> A.R1 and A.R2 wording could be taken to require that such relaying should be enabled and set. The phrase "Installed relaying not to trip during" could be taken to mean that such relaying is assumed to be, or should be, installed. Also, in the case of generator multifunction protective device, such relaying is always installed but it is not appropriate in many cases that it be enabled and set. Note this consideration applies to both frequency and Voltage. In general, this Standard should take care to point out that any protection application should be based on actual specific machine protective considerations which should be arrived at in consultation with the machine manufacturer.> Concerning A.R1.2 and Attachment 1, the language refers to a 'no trip zone" between curves, and obviously there is a permissible trip zone outside the curves. Questions will arise on permissibility of settings which are actually on the curves. We would suggest that setting directly on the curves should be permitted. For example, if 1.0 s. at 57.8 Hz is directly on the curve, failure to deal with this questions will result in pointless and counterproductive settings such as 1.0 s. at 57.79 Hz. We suggest "Setting directly on the curves are permitted, and settings outside the curves are permitted."> Concerning A.R2, this Standard addresses setting of Voltage relays based on Voltage at the point of interconnection, which is not directly translatable to Voltage at the generator terminals. The generator real and reactive power output will affect the relationship, and this is not dealt with in this Standard.

Response: Thank you for your comment.

- **The UFLS SDT and this Standard Drafting Team conferred and have coordinated the frequency curves and strategies.**
- **Determining existing generator capability is the responsibility of the GO.**
- **Clarification has been added to make it clearer that the Standard does not require installing voltage or frequency protection relays nor does it require setting any relays at the curve values.**

Organization	Yes or No	Question 4 Comment
Xcel Energy	Yes	Please clarify if there is an expectation/requirement for new units to install voltage and frequency protective relays.

Response: Thank you for your comment. There is no requirement for any generator to install or have voltage or frequency protective relays. Clarification has been added.

Organization	Yes or No	Question 4 Comment
CenterPoint Energy	Yes	a) CenterPoint Energy is concerned with what appears to be a lack of consistency and coordination between standards efforts. Considering PRC-023, CenterPoint Energy believes it is illogical to have transmission relay loadability requirements based on 0.85 pu system voltage for an extended period (such as, 15 minutes) to allow system operators to take remedial actions, while exempting generators from comparable requirements. For another example, it appears this proposed standard is not consistent with that being proposed for under-frequency load shedding systems that can help prevent cascading outages. b) Requirements, such as R2.2.1 and R2.2.2, are essentially fill-in-the-blank, location-specific criteria that are unnecessary

Organization	Yes or No	Question 4 Comment
		and could have unintended consequences. Location-specific criteria can change over time with additions and modifications of the transmission system. Entities will have no incentives to voluntarily exceed the minimum required criteria, even though their plant has a greater ride-though capability. R2.2.1 further allows relaying to be set on actual fault clearing times, instead of the 9 cycles indicated in Attachment 2. In addition, R2.2.2 allows the use of location-specific criteria, but only if such criteria are less stringent. CenterPoint Energy believes NERC reliability standards should not include fill-in-the-blank, location-specific criteria. CenterPoint Energy recommends modifying R2.2.1 to reference Attachment 2 and to clarify the ride-through criteria is zero voltage for 0.15 seconds (9 cycles). CenterPoint Energy recommends deleting R2.2.2. c) R5 allows generating plants to meet less stringent criteria if generator manufacturer literature indicates limitations, which would further erode system support from generation resources. It does not appear there is any process to substantiate the legitimacy of such limitations. CenterPoint Energy recommends deleting R5 and associated references.
Response: Thank you for your comment. **a) The Standard has been modified to require new generators to ride through voltage and frequency excursions. The SDT has coordinated the development of the UF relay curve with UFLS SDT.** **b) Requirements R2.2.1 and R 2.2.2 (new R2.1.2) allow the TO to relax the voltage ride through requirements in specific cases where the transmission system is designed to accommodate reduced generator performance.** **c) New R3 exempts existing generators that are not capable of meeting the Standard's requirements from having to do so. The GO is responsible for determining the generator's capabilities.**		
Independent Electricity System Operator	Yes	a. R5: The wording "the Generator Owner is granted an exception for that unit from meeting the portion of Requirement R1 or R2 for that limitation once it provides documentation of the equipment limitation(s) to the Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners that monitor or model the associated unit, within 30 days of identifying the equipment limitation." is not written in a way to hold an entity responsible for any action. We suggest to reword it such that it places a responsibilility to the Generator to seek approval for an exception, as follows:"the Generator Owner shall obtain approval for an exception for that unit from meeting the portion of Requirement R1 or R2 for that limitation through the submission of documentation of the equipment limitation(s) to the Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners that monitor or model the associated unit within 30 days of identifying the equipment limitation." The requirement for getting non-conforming protection approved should be so stipulated to put the onus for mitigating actions on the Generator Owners. For example, in the case of non-conforming underfrequency settings, the requesting Generator Owner should be required to demonstrate that mitigating (i.e. arrangements for additional compensating load shedding) measures have been arranged with the Balancing Authority in their submission. Equipment settings that infringe upon the curves may be implemented only after approval is granted by the appropriate entities. Along with this proposed change, there is also a need for the entities receiving the approval request to respond to the request. Another requirement is needed to complete this process.

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 4 Comment</th></tr>
<tr><td></td><td></td><td>b. The latter part of R5 should be reworded to hold an entity responsible for the needed actions associated with expiring the exception such that the requirement is measurable and enforceable.

c. R6: It is unclear to us what purpose this requirement serves. If R5 is to be revised as we suggest (see above), then the "limitation" in question will be presented with technical justification in the request for approval. The receiving entities (RC, PC, TOP and TP) will have a chance to accept or reject the request with due consideration of the technical argument. This is part of the approval request process, hence we do not see the need for R6 if R5 is to be reworded. If a remand process needs to be stipulated, then inclusion in R5 a requirement for the receiving entity(ies) to respond to the request - either approving or disproving the with a rationale, would suffice.</td></tr>
<tr><td colspan="3">Response: Thank you for your comment.

a) The required action in the new R3 is for the GO to provide documentation of the equipment limitation(s) to the RC, PC, TO, and TP. The GO is not required to seek approval.

b) The SDT believes that new R3 is measurable and enforceable.

c) The purpose of new R3 is to exempt existing generators that are not capable of meeting the Standard from having to do so.</td></tr>
<tr><td>Ameren</td><td>Yes</td><td>This standard could be ineffective if someone’s auxiliary power protection trips out on low voltage or frequency and brings the unit down before the generator protection. Those settings on the aux buses are there to protect the equipment from failure since most of the downstream loads such as motors and electronics won’t ride through an excursion as well as large T/G sets. We suggest that ANSI/IEEE Standards C37.102, C50.12, and C50.13 should be used and listed as references to this Standard. Reporting mechanism in R3 and R4 raises some commercial concerns. We prefer a secure repository of reporting to the RRO. Then only those who do have valid reasons for studies or monitoring could be granted access to the information. Footnote 1 expands 'protective relays' definition to include voltage regulator, etc. Instead state that only direct trip elements (functions) in the voltage regulator and exciter are included, if that's the intent. It should be made very clear.</td></tr>
<tr><td colspan="3">Response: Thank you for your comment.
The Standard has been modified to require new generators to ride through voltage and frequency excursions.
The SDT recognizes that the information required to be reported must be protected appropriately and expects the receiving organizations will fulfill all of their information protection obligations.
Clarification has been added to footnote 1.</td></tr>
<tr><td>PPL Energy Plus</td><td>Yes</td><td>PPL is concerned with the following concepts in the standard:

1) The standard applies equally to asynchronous and synchronous machines, salient pole and round rotor machines,</td></tr>
</table>

Organization	Yes or No	Question 4 Comment
		photovoltaic, and other resources and as such the standard does not appear to recognize that these technologies respond differently to voltage and frequency excursions. 2) Better clarity of generator owner and transmission owner roles regarding changing existing fault clearing times is needed in the proposed standard. 3) R2.2 requires further clarity regarding relay settings. 4) R3 and R4 look the same. 5) The reference paper under Section D needs a thorough review by the industry.
Response: Thank you for your comment. **1. The SDT has taken the direction to develop a Standard that is technology neutral.** **2. The TO is allowed to relax the relay setting Standard (shorter durations or higher minimum voltages and or lower maximum voltages) if the full capability of the Standards is not required in specific instances.** **3. Further clarification has been added.** **4. Old R3 and old R4 are combined into the new R6.** **5. The SDT welcomes thorough industry review of the reference paper.**		
US Bureau of Reclamation	Yes	Requirements R3 and R4 place a coordinating role on the Generator Owner to provide trip settings to four entities, the Reliability Coordinator, Planning Coordinator, Transmission Operator, and Transmission Planner. We believe it is more appropriate for the Generator Owner to coordinate settings with a single Transmission entity since the purpose of the Standard is "... to support transmission system stability during voltage and frequency excursions." and for the Transmission entity to further coordinate if necessary. The Transmission entity is in a better position to know what additional entities, if any should be involved. For the data points provided in the Attachment 2, HVRT DURATION and LVRT DURATION, we recommend both time and voltage units of measure be provided.
Response: Thank you for your comment. Old R3 and old R4 are combined into the new R6. The SDT agrees with the comment and has added clarification to the voltage and time units in Attachment 2

5. Coordination between UFLS programs and generator frequency tripping is especially a concern in islanded situations. Is the connection voltage of ≥100kV, the size threshold for generator units 20 MVA and greater and 75 MVA for multiple units at a single site, sufficient to address this concern? If not, please explain in the comment area.

Summary Consideration:

Most respondents agreed with the proposal.

The major comment issues raised are:

1) All operating units affect frequency excursion recovery regardless of size or voltage
2) Applicability should be on a case-by-case basis
3) Only large units are significant to stability

The GV SDT considerations for the major comment issues are:

- After consideration of comments and discussion with NERC staff, the SDT agrees with the majority position that the applicability of facilities that meet the Compliance Registry Criteria is sufficient to address coordination between UFLS programs and generator tripping. The language that duplicated the language from the Compliance Registry Criteria is not necessary to include in the applicability section of the standard, and was removed from the revised standard. The SDT does not believe that applicability of generating facilities should be assigned to other parties to determine on a case-by-case basis. Nor does the SDT believe that applicability should be limited to generating facilities larger than what is defined in the Compliance Registry Criteria.

Organization	Yes or No	Question 5 Comment
NERC System Protection and Control Subcommittee (SPCS)	No	The interconnection Voltage is not relevant, only the amount of generation potentially lost to the system.
Response: Thank you for your comments. After consideration of comments and discussion with NERC staff, the SDT has assigned the		

Organization	Yes or No	Question 5 Comment
applicability to Generator Owners as described in the Compliance Registry Criteria.		
Northeast Power Coordinating Council	No	Both bullets should be checked above (form will not accept).Reliability of underfrequency load shedding (UFLS) programs is dependent on assurance that the UFLS program will shed load prior to generation tripping in islanded conditions. The frequency response to generator tripping is primarily a function of the amount of generation tripped and is substantially independent of the location of the generator interconnection. Therefore, the standard should not specify a threshold on interconnection voltage. We are concerned that the generator unit capacity thresholds are set too high. Given the tolerances in UFLS program design, the unit capacity thresholds should be established to ensure that 99 percent of the generation in a system complies with the requirements of this standard. The SDT should identify unit capacity thresholds on this basis, similar to how thresholds were developed in MOD-026.The interconnection voltage is not relevant, only the amount of generation potentially lost to the system. Some sub-regions, employing a UFLS Program, are dependent on Generator Owners/Operators meeting the specifications for generator Underfrequency setpoints in order to maintain a viable UFLS Program. For sub-regions where a large percentage of the total generation fleet is comprised of individual units < 20 MVA and connected to buses < 100 kV, the contribution of these units to the overall success of the sub-regions UFLS Program are more pronounced. It is suggested that the threshold should be established by referring to the requirements of the Region or as established by the Reliability Coordinator (sub-region). As an alternative, it is suggested that all generating units operating in a Reliability Coordinators' or RTO/ISO's market system, regardless of size, shall follow this Standard based on their materiality to the reliability of the bulk power system.
Response: Thank you for your comments. After consideration of comments and discussion with NERC staff, the SDT has assigned the applicability to Generator Owners as described in the Compliance Registry Criteria.		
IRC Standards Review Committee	No	There should not be any exemption of the coordination on frequency trip setting. In an islanded situation, each generator's status is critical to ensuring that frequency decline is successfully arrested based on the assumption that all on-line generators would not trip within specific frequency bounds unless prior approval has been sought and granted to allow tripping. Not holding the smaller generators subject to the requirements associated with generator frequency tripping exposes the island to a great uncertainty on the amount of generation that can be relied upon to arrest frequency excursion.
Response: Thank you for your comments. After consideration of comments and discussion with NERC staff, the SDT has assigned the applicability to Generator Owners as described in the Compliance Registry Criteria.		
Constellation Power Generation & Constellation Nuclear	No	Reliability of underfrequency load shedding (UFLS) programs is dependent on assurance that the UFLS program will shed load prior to generation tripping in islanded conditions. The frequency response to generator tripping is primarily a function of the amount of generation tripped and is substantially independent of the location of the generator interconnection. Therefore, the standard should not specify a threshold on interconnection voltage. We are concerned that the generator unit capacity thresholds are set too high. Given the tolerances in UFLS program design, the unit capacity thresholds should be established to

Organization	Yes or No	Question 5 Comment
		ensure that 99 percent of the generation in a system complies with the requirements of this standard. The SDT should identify unit capacity thresholds on this basis, similar to how thresholds were developed in MOD-026.
Response: Thank you for your comments. After consideration of comments and discussion with NERC staff, the SDT has assigned the applicability to Generator Owners as described in the Compliance Registry Criteria. Extending the applicability to units beyond those covered under the Registry Criteria would make those units subject to all Generator Owner requirements in all other Standards.		
Southern Company	No	The unit size and plant size seem to be conservatively small. From a practical standpoint, our focus in this standard should be on the largest units, those that are most cricital in the reliability. A more reasonable limit would be 100MVA generator units and 200 MVA for multiple units at a single site.
Response: Thank you for your comment. The SDT believes that exempting units smaller than 100 MVA or sites smaller than 200 MVA would put the reliability of the Bulk Electric System at risk during a frequency excursion. This is especially true in islanding situations where smaller units may predominate within a particular island.		
E.ON U.S.	No	E.ON U.S. believes that the standard should apply to facilities at 200 kV and above in order to be consistent with equipment thresholds of other NERC standards.
Response: Thank you for your comment. The SDT believes that exempting units connected at voltages less than 200 kV would put the reliability of the Bulk Electric System at risk during a frequency excursion. This is especially true in islanding situations where units connected at less than 200 kV may predominate within a particular island.		
Veolia Environmental Services	No	Additional criteria would be useful to identify units that are critical to the BES. If a BA and/or TOP has identified a unit a non-critical, then such a unit should be exempt from this standard regardless of size and connection voltage.
Response: Thank you for your comments. After consideration of comments and discussion with NERC staff, the SDT has assigned the applicability to Generator Owners as described in the Compliance Registry Criteria. The SDT feels that all units that meet the Registry Criteria are of importance to the grid, especially during frequency excursions.		
Basin Electric Power Cooperative	No	This is likely to be something that has to be applied on a case by case basis, with consideration given to how many units we have that would not be covered by some sort of coordinated UFLS/generation protection settings. There is some latitude to make exceptions, but in the future, we may have many more units that fit this category, and then this becomes a big issue. Units which trip too soon will just impact the load shedding program unless a corresponding amount of load is shed at essentially the same time and more or less at that same location.

Organization	Yes or No	Question 5 Comment
Response: Thank you for your comments. After consideration of comments and discussion with NERC staff, the SDT has assigned the applicability to Generator Owners as described in the Compliance Registry Criteria. The SDT does not agree that requirements should be applied on a case by case basis.		
Northeast Utilities	No	Significant generator capacity may be connected at distribution voltages and set with sensitive anti-islanding frequency/voltage setpoints. These generators need to report their setpoint data to the owner of any UFLS/UVLS systems that may be affected by the generator performance. This can be a significant amount of generation relative to the size of the UFLS/UVLS program.Consideration should also be given as to whether the requirements should apply to generators where the site aggregate is >20MVA.
Response: Thank you for your comments. After consideration of comments and discussion with NERC staff, the SDT has assigned the applicability to Generator Owners as described in the Compliance Registry Criteria. Extending the applicability to units beyond those covered under the Registry Criteria would make those units subject to all Generator Owner requirements in all other Standards.		
Hydro-Québec TransEnergie (HQT)	No	Reliability of underfrequency load shedding (UFLS) programs is dependent on assurance that the UFLS program will shed load prior to generation tripping in islanded conditions. The frequency response to generator tripping is primarily a function of the amount of generation tripped and is substantially independent of the location of the generator interconnection. Therefore, the standard should not specify a threshold on interconnection voltage. We are concerned that the generator unit capacity thresholds are set too high. Given the tolerances in UFLS program design, the unit capacity thresholds should be established to ensure that 99 percent of the generation in a system complies with the requirements of this standard. The SDT should identify unit capacity thresholds on this basis, similar to how thresholds were developed in MOD-026.The interconnection voltage is not relevant, only the amount of generation potentially lost to the system.Some sub-regions, employing a UFLS Program, are dependent on Generator Owners/Operators meeting the specifications for generator Underfrequency setpoints in order to maintain a viable UFLS Program. For sub-regions where a large percentage of the total generation fleet is comprised of individual units < 20 MVA and connected to buses < 100 kV, the contribution of these units to the overall success of the sub-regions UFLS Program are more pronounced. It is suggested that the threshold should be established by refering to the requirements of the Region or as established by the Reliability Coordinator (sub-region). As an alternative, it is suggested that all generating units operating in a Reliability Coordinators' or RTO/ISO's market system, regardless of size, shall follow this Standard based on their materiality to the reliability of the bulk power system.
Response: Thank you for your comments. After consideration of comments and discussion with NERC staff, the SDT has assigned the applicability to Generator Owners as described in the Compliance Registry Criteria. Extending the applicability to units beyond those covered under the Registry Criteria would make those units subject to all Generator Owner requirements in all other Standards.		
New York Independent System	No	The interconnection Voltage is not relevant, only the amount of generation potentially lost to the system.

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 5 Comment</th></tr>
<tr><td>Operator</td><td></td><td></td></tr>
<tr><td colspan="3">Response: Thank you for your comments. After consideration of comments and discussion with NERC staff, the SDT has assigned the applicability to Generator Owners as described in the Compliance Registry Criteria. Extending the applicability to units beyond those covered under the Registry Criteria would make those units subject to all Generator Owner requirements in all other Standards.</td></tr>
<tr><td>Independent Electricity System Operator</td><td>No</td><td>In an islanded situation, each generator's status is critical to ensuring frequency decline is successfully arrested based on the assumption that all on-line generators would not trip within specific frequency bounds unless prior approval has been sought and granted to allow tripping. Not holding the smaller generators subject to the requirements associated with generator frequency tripping exposes the island to a great uncertainty on the amount of generation that can be relied upon to arrest frequency excursion.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. After consideration of comments and discussion with NERC staff, the SDT has assigned the applicability to Generator Owners as described in the Compliance Registry Criteria. Extending the applicability to units beyond those covered under the Registry Criteria would make those units subject to all Generator Owner requirements in all other Standards.</td></tr>
<tr><td>Converteam Naval Systems Inc.</td><td>No</td><td></td></tr>
<tr><td>Indiana Municipal Power Agency</td><td>Yes</td><td>A single unit not meeting these thresholds (an unregistered unit) can always be registered if a technical justification is given and proven. However, this does not mean a "blanket" registration can apply to all units (unregistered units) that do not meet these thresholds.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. The SDT agrees with your position. After consideration of comments and discussion with NERC staff, the SDT has assigned the applicability to Generator Owners as described in the Compliance Registry Criteria.</td></tr>
<tr><td>American Electric Power</td><td>Yes</td><td>The applicability appears to be from the NERC Compliance registry. This is probably okay for the requirement on voltage related tripping, but the impact of frequency related tripping is not restricted to the BES as it likely would be with voltage tripping. A separate single-size applicability, independent of BES/non-BES connection, may be more appropriate for the frequency tripping requirement.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. After consideration of comments and discussion with NERC staff, the SDT has assigned the applicability to Generator Owners as described in the Compliance Registry Criteria. Extending the applicability to units beyond those covered under the Registry Criteria would make those units subject to all Generator Owner requirements in all other Standards.</td></tr>
</table>

Organization	Yes or No	Question 5 Comment
SERC Dynamics Review Subcommittee (DRS)	Yes	All generating units with the given thresholds are registered in the NERC compliance registry. We believe that these units should adhere to the requirements in the Standard. Each system reacts differently to the loss of different sizes of generators. This Standard, which is applicable to every registered entity, should cover these situations. Hence, the given thresholds, though restrictive, are adequate.
Response: Thank you for your comments. After consideration of comments and discussion with NERC staff, the SDT has assigned the applicability to Generator Owners as described in the Compliance Registry Criteria.		
Ameren	Yes	Again from our perspective, the main objective is allow UFLS/UVLS to do their job to arrest frequency/voltage decline and retain generation on-line so as not to exacerabate the extreme disturbance. Of course, generation equipment limits must be respected. This standard should not encourage GO to augment protection or become more conservative than warranted, possibly refuting the main objective. We formerly belonged to the now defunct MAIN region. Previous MAIN requirements for generators were: Generator UF Setting (Hz) Minimum Time Delay (Sec)> 59.5 Hz Automatic tripping not permitted< 59.5 to > 59.2 Hz 2700 seconds< 59.2 to > 58.5 Hz 120 seconds< 58.5 to > 58.0 Hz 15 seconds< 58.0 Hz Owner's Discretion We have applied these to generation that has connected in the last decade unless the GO had manufacturer recommendations to the contrary.
Response: Thank you for your comment. The SDT agrees that generation equipment limits must be respected and allows exemption for documented technical limitations in Requirement R3. A phrase has been added to R1 and R2 indicating that frequency and voltage protective relaying is not required. The Frequency vs. Time curves in Attachment 1 are designed to coordinate with the curves being used by the NERC Underfrequency Load Shedding (UFLS) Standard Drafting Team.		
US Bureau of Reclamation	Yes	The threshold should be consistent with the NERC Reliability Compliance Registry Criteria.
Response: Thank you for your comments. The SDT agrees with your position. After consideration of comments and discussion with NERC staff, the SDT has assigned the applicability to Generator Owners as described in the Compliance Registry Criteria.		
Progress Energy, Inc.	Yes	All generator units with the given thresholds are registered in the NERC compliance registry. We consider that such units should adhere to the requirements in the standard. Each system reacts differently to the loss of different sizes of generators. This standard, which is applicable to every entity, should cover all such situations. Hence, the given thresholds, though restrictive, are adequate.
Response: Thank you for your comments. The SDT agrees with your position. After consideration of comments and discussion with NERC staff, the SDT has assigned the applicability to Generator Owners as described in the Compliance Registry Criteria.		

Organization	Yes or No	Question 5 Comment
Old Dominion Electric Cooperative	Yes	This is the NERC/FREC set levels, all units with this scope should have to comply with the standard. Units that are not within the above criteria should be exempt from it as they are not aware, possible to provide their input.
Response: Thank you for your comments. The SDT agrees with your position. After consideration of comments and discussion with NERC staff, the SDT has assigned the applicability to Generator Owners as described in the Compliance Registry Criteria.		
Consumers Energy Company	Yes	We believe this is sufficient to address the concern if this picks up the wind farms that are a growing part of generating capacity.
Response: Thank you for your comments. After consideration of comments and discussion with NERC staff, the SDT has assigned the applicability to Generator Owners as described in the Compliance Registry Criteria. The SDT feels most wind farms are registered due to their aggregate size and Point of Interconnection voltage.		
FirstEnergy	Yes	
Luminant Power	Yes	
AWEA	Yes	
Gainesville Regional Utilities	Yes	
American Wind Energy Association	Yes	
Southern California Edison Company	Yes	
Brazos Electric Power Cooperative	Yes	
Lakeland Electric	Yes	

Organization	Yes or No	Question 5 Comment
Manitoba Hydro	Yes	
Kansas City Power & Light	Yes	
Entergy Fossil Operations	Yes	
PJM Interconnection	Yes	
Dominion	Yes	
MRO NERC Standards Review Subcommittee	Yes	
Duke Energy	Yes	
American Transmission Company	Yes	

6. The SDT proposed a set of VRFs based on size delineation of units. Do you agree with this approach? Do you agree with the MVA levels? If you disagree with either the approach or the MVA levels, please explain in the comment area.

Summary Consideration:

There was no consensus on this issue.

The major comment issues raised are:

- There should be only a single VRF Different MVA break points or methodologies (MWh, percent of units, impact-based)

The GV SDT consideration for the major comment issues is:

- After consideration of comments and discussion with NERC staff, the SDT agrees with the minority position that a single VRF must be used for each Requirement. NERC Standard Processes Manual does not allow multiple VRFs for a Requirement regardless of the methodology used to separate them.

Organization	Yes or No	Question 6 Comment
Dominion	No I disagree with the approach	All generators identified in a transmission owner's restoration plan warrant a high VRF. Additionally, generators 500 MVA warrant a high, generators > 100 MVA but < 500 MVA warrant a medium and generators 100 MVA warranty a low VRF
Response: Thank you for your comments. Based on industry comment and conversation with NERC Staff, the SDT has determined that a single VRF is more appropriate. As such, the Violation Risk Factors (VRFs) no longer are delineated by MVA level. Instead, a single VRF level is assigned for R1, R2, and a new performance requirement (R5). These VRFs were developed using NERC's VRF Criteria.		
Northeast Power Coordinating Council	No I disagree with the approach	Both bullets should be checked above (form will not accept).
Response: Thank you for your comments. The nature of the disagreement is not understood.		
SERC Dynamics Review Subcommittee	No I disagree with	It is the aggregate impact of all an entity's units that matters. There should be only one VRF - HIGH. Consider the example where a plant consists of numerous medium sized (100-200 MVA) units with a common relay setting error.

Organization	Yes or No	Question 6 Comment
(DRS)	the approach	Even though the individual units are relatively small, there is a potentially large impact when the whole plant is considered.
Response: Thank you for your comments. Based on industry comment and conversation with NERC Staff, the SDT has determined that a single VRF is more appropriate. As such, the Violation Risk Factors (VRFs) no longer are delineated by MVA level. Instead, a single VRF level is assigned for R1, R2, and a new performance requirement (R5). These VRFs were developed using NERC's VRF Criteria.		
IRC Standards Review Committee	No I disagree with the approach	Size dependent VRFs do not reflect the potential reliability risk associated with more than one Medium size generating unit (>100 MVA and <500 MVA) failing to comply with the standard. Two of such units at, say, 400 MVA each, that trip unnecessarily will have a greater collective impact on the island frequency than the tripping of a 500 MVA unit.
Response: Thank you for your comments. Based on industry comment and conversation with NERC Staff, the SDT has determined that a single VRF is more appropriate. As such, the Violation Risk Factors (VRFs) no longer are delineated by MVA level. Instead, a single VRF level is assigned for R1, R2, and a new performance requirement (R5). These VRFs were developed using NERC's VRF Criteria.		
Veolia Environmental Services	No I disagree with the approach	The delineation should be based on actual or potential impact to the BES of a unit tripping as determined by the BA and TOP modeling.
Response: Thank you for your comments. Based on industry comment and conversation with NERC Staff, the SDT has determined that a single VRF is more appropriate. As such, the Violation Risk Factors (VRFs) no longer are delineated by MVA level. Instead, a single VRF level is assigned for R1, R2, and a new performance requirement (R5). These VRFs were developed using NERC's VRF Criteria. A VRF cannot be modified by BA's and TOP's on a case-by-case basis.		
Old Dominion Electric Cooperative	No I disagree with the approach	I assume this was because the bigger units have a bigger impact on reliability than the smaller units. I am fine with this approach, but might have a minor comment on the break levels.
Response: Thank you for your comments. Based on industry comment and conversation with NERC Staff, the SDT has determined that a single VRF is more appropriate. As such, the Violation Risk Factors (VRFs) no longer are delineated by MVA level. Instead, a single VRF level is assigned for R1, R2, and a new performance requirement (R5). These VRFs were developed using NERC's VRF Criteria.		
Basin Electric Power Cooperative	No I disagree with the approach	This may be appropriate but I have not seen the supporting technical report so I cannot say that I agree. This is likely to be something that has to be applied on a case-by-case basis, with consideration given to how many units would be excluded in some geographic area. There is some latitude to make exceptions, but in the future, we may have many more units that fit this category, and then this exclusion becomes a big issue.

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 6 Comment</th></tr>
<tr><td colspan="3">Response: Thank you for your comments. Based on industry comment and conversation with NERC Staff, the SDT has determined that a single VRF is more appropriate. delineated by MVA level. Instead, a single VRF level is assigned for R1, R2, and a new performance requirement (R5).		
Ameren	No I disagree with the approach	Are they based on the individual unit or the aggregate at the Point of Interconnection? Average annual production (MWh) is a better indicator of their threat to the BES during UF or UV events. Larger units should not be penalized just because they are large. If large and generating many MWh then they're big and likely to be on-line for an event.
Response: Thank you for your comments. Based on industry comment and conversation with NERC Staff, the SDT has determined that a single VRF is more appropriate. As such, the Violation Risk Factors (VRFs) no longer are delineated by MVA level. Instead, a single VRF level is assigned for R1, R2, and a new performance requirement (R5). These VRFs were developed using NERC's VRF Criteria.		
US Bureau of Reclamation	No I disagree with the approach	If this approach is appropriate for this standard, it seems this approach should be used for all Standards applicable to generators.
Response: Thank you for your comments. Based on industry comment and conversation with NERC Staff, the SDT has determined that a single VRF is more appropriate. As such, the Violation Risk Factors (VRFs) no longer are delineated by MVA level. Instead, a single VRF level is assigned for R1, R2, and a new performance requirement (R5). These VRFs were developed using NERC's VRF Criteria.		
Constellation Power Generation & Constellation Nuclear	No I disagree with the approach	
FirstEnergy	Yes I agree with the approach	A suggestion for SDT's consideration is that VRFs could be based on percentage of units not in compliance. A utility may have several large units (high VRF) and many small (low VRF) not in compliance.
Response: Thank you for your comments. Based on industry comment and conversation with NERC Staff, the SDT has determined that a single VRF is more appropriate. As such, the Violation Risk Factors (VRFs) no longer are delineated by MVA level. Instead, a single VRF level is assigned for R1, R2, and a new performance requirement (R5). These VRFs were developed using NERC's VRF Criteria.		
Lakeland Electric	Yes I agree with the approach	The VRF levels should range from low to high based on unit size and how the unit size impacts BES.
Response: Thank you for your comments. Based on industry comment and conversation with NERC Staff, the SDT has determined that a single VRF is more appropriate. As such, the Violation Risk Factors (VRFs) no longer are delineated by MVA level. Instead, a single VRF level is assigned for R1, R2, and a new performance requirement (R5). These VRFs were developed using NERC's VRF Criteria.

6.1 Do you agree with the MVA levels?

Summary Consideration:

There was no consensus on this issue.

The major comment issues raised are:

- There should be only a single VRF
- Lower MVA break points should be used

The GV SDT consideration for the major comment issues is:

- As discussed in the Summary Consideration to Question 6, multiple VRFs for a Requirement are not allowed, so the responses to this question is no longer applicable. The SDT developed a single VRF for Requirements R1 and R2 based on the NERC VRF Criteria.

Organization	Yes or No	Question 6.1 Comment
Northeast Power Coordinating Council	No	Both bullets should be checked above (form will not accept).Given the potential impact on survivability of an island, and the need to lower the unit capacity thresholds for which this standard is applicable, as recommended in the comment to Question 5, it is suggested that the folowing Violation Risk Factor thresholds be applied:High > 100 MVAMedium > 20 MVA and < 100 MVA Lower < 20 MVA Given the potential impact on survivability of an island, and the recommendation in our response to Question 5 to lower the unit capacity thresholds for which this standard is applicable, we recommend the following Violation Risk Factor thresholds:High >100 MVAMedium > 20 MVA and 100 MVALower 20 MVA
Response: Thank you for your comments. The SDT has determined that a single VRF is more appropriate. As such, the Violation Risk Factors (VRFs) no longer are delineated by MVA level. Instead, a single VRF level will be assigned and for R1, R2, and a new performance requirement (R5).

7. If you are aware of any regional variances that would be required as a result of this standard please identify the regional variance here.

Summary Consideration:

Most responders, knew of no required regional variances, several commented on the potential need for variances. .

The issues associated with the majority of the comments received are:

1. There are some regional geographical differences.
2. There is concern about UFLS standards that are being developed in the various regions pending the conclusion of UF studies. These study results may indicate the need for regional variances.

Some other comment issues are:

1. One commenter suggests the SDT wait for the regions to complete their UF studies before going forward with PRC-024.
2. One commenter indicates that FRCC has suspended development of the regional version of PRC-024.
3. Certain regional UFLS drafts include requirements for non-conforming generators to acquire “load-shed” service. These drafts do not identify the GO/GOP in the applicability section, and it is not certain that any entity can offer a “load-shed” service.

The GV SDT considerations for these issues are:

The SDT is aware that some regions have stopped developing their Standards because of the efforts at NERC to develop similar continent-wide standards**.**

The SDT notes that the NERC Standard Processes manual, approved by FERC on September 3, 2010 (http://www.nerc.com/docs/standards/sar/Appendix_3A_Standard_Processes_Manual_20100903_2_.pdf, see page 32) fhas provisions for entities to submit a request for a variance. However, Regional Standards will need to be addressed at the regional level unless the region desires to seek a variance through the NERC Standard Development Process.

Organization	Question 7 Regional Variance
NERC System Protection and Control	The FRCC UFLS has a requirement for generators to remain on line for 1 second with frequency down to 57.5 Hz.

Organization	Question 7 Regional Variance
Subcommittee (SPCS)	Regional differences are developing as the Regions perform studies to current UFLS strategies while considering the coordination requirements of generator underfrequency tripping. To date, NPCC and FRCC may be the only regions that have completed their studies. It is recommended that PRC- 024-1 wait on going forward in the standards process until the regions conclude their studies and develop their requirements based on their particular portions of the interconnected power system.
Response: The SDT thanks you for your comments. The SDT is aware that some regions have stopped developing their Standards because of the efforts at NERC to develop similar Standards. Therefore, it may not be practical to wait to develop NERC Standards until the regions have concluded their respective studies. The NERC Reliability Standards Development Procedure, approved by FERC on September 3, 2010 ((http://www.nerc.com/docs/standards/sar/Appendix_3A_Standard_Processes_Manual_20100903_2_.pdf, see page 32) has provisions for the Regions to submit a request for a Variance.	
Dominion	We are not aware of any. However, we are aware that a number of regions have draft UFLS standards that apply to generators despite the fact NERC Reliability Standards PRC-007, PRC-008 and PRC-009 do not contain either GO or GOP in the applicability section. These regional drafts contain provisions that require non-conforming generators to acquire 'load shed' service. We have repeatedly cited our inability to find any entity that would offer such service as well as technical difficulties in developing a UFLS predicted upon such a service. Despite our comments, the latest drafts continue to require non-conforming generators to acquire 'load shed' service.
Response: The SDT thanks you for your comments. The NERC Reliability Standards Development Procedure, approved by FERC on September 3, 2010 (http://www.nerc.com/docs/standards/sar/Appendix_3A_Standard_Processes_Manual_20100903_2_.pdf, see page 32)has provisions for the regions to submit a request for a variance. However, Regional Standards will need to be addressed at the regional level unless the region desires to seek a regional through the NERC Standard Development Process.	
Northeast Power Coordinating Council	We are aware that a number of regions have draft UFLS standards that apply to generators despite the fact NERC Reliability Standards PRC-007, PRC-008 and PRC-009 do not contain either GO or GOP in the applicability section. These regional drafts contain provisions that require non-conforming generators to acquire 'load shed' service. We have repeatedly cited our inability to find any entity that would offer such service as well as technical difficulties in developing a UFLS predicated upon such a service. Despite our comments, the latest drafts continue to require non-conforming generators to acquire 'load shed' service. The Quebec Interconnection, within the Eastern Interconnection, would need different settings from the ones listed in Attachment 1 to coordinate with its UFLS program.
Response: The SDT thanks you for your comments. The NERC Reliability Standards Development Procedure, approved by FERC on September 3, 2010 (http://www.nerc.com/docs/standards/sar/Appendix_3A_Standard_Processes_Manual_20100903_2_.pdf, see page 32)has provisions for the regions to submit a request for a variance. However, Regional Standards will need to be addressed at the regional level unless the region desires to seek a variance through the NERC Standard Development Process.	

Organization	Question 7 Regional Variance
Kansas City Power & Light	Not aware of any regional differences.
Response: The SDT thanks you for your comments.	
MRO NERC Standards Review Subcommittee	If a region has performed a detailed system study of the Under Frequency protection systems in their region and developed protective settings based off the characteristics developed in the study, the region should be allowed to deviate from the Generator Protection curve in Attachment 1.
Response: The SDT thanks you for your comments. The NERC Reliability Standards Development Procedure, approved by FERC on September 3, 2010 (http://www.nerc.com/docs/standards/sar/Appendix_3A_Standard_Processes_Manual_20100903_2_.pdf, see page 32)has provisions for the regions to submit a request for a variance.	
Constellation Power Generation & Constellation Nuclear	We are not aware of any. However, we are aware that a number of regions have draft UFLS standards that apply to generators despite the fact NERC Reliability Standards PRC-007, PRC-008 and PRC-009 do not contain either GO or GOP in the applicability section. These regional drafts contain provisions that require non-conforming generators to acquire 'load shed' service. We have repeatedly cited our inability to find any entity that would offer such service as well as technical difficulties in developing a UFLS predicted upon such a service. Despite our comments, the latest drafts continue to require non-conforming generators to acquire 'load shed' service.
Response: The SDT thanks you for your comments. The NERC Reliability Standards Development Procedure, approved by FERC on September 3, 2010 (http://www.nerc.com/docs/standards/sar/Appendix_3A_Standard_Processes_Manual_20100903_2_.pdf, see page 32) has provisions for the regions to submit a request for a variance. However, Regional Standards will need to be addressed at the regional level unless the region desires to seek a variance through the NERC Standard Development Process.	
Progress Energy, Inc.	No. FRCC has suspended work on a regional version of PRC-024. The regional version will have to reviewed and compared to the NERC standard once developed.
Response: The SDT thanks you for your comments. The NERC Reliability Standards Development Procedure, approved by FERC on September 3, 2010 (http://www.nerc.com/docs/standards/sar/Appendix_3A_Standard_Processes_Manual_20100903_2_.pdf, see page 32) has provisions for the regions to submit a request for a variance, should the regions decide to do so.	
Basin Electric Power Cooperative	See the detailed answer provided to question 2. It covers the need for regional variance.
Response: The SDT thanks you for your comments.	

Organization	Question 7 Regional Variance
Hydro-Québec TransEnergie (HQT)	Yes, the Quebec Interconnection, within the Eastern Interconnection, would need different settings than the ones depicted in the Attachment 1 to coordinate with its UFLS program.We are also aware that a number of regions have draft UFLS standards that apply to generators despite the fact NERC Reliability Standards PRC-007, PRC-008 and PRC-009 do not contain either GO or GOP in the applicability section. These regional drafts contain provisions that require non-conforming generators to acquire 'load shed' service. We have repeatedly cited our inability to find any entity that would offer such service as well as technical difficulties in developing a UFLS predicted upon such a service. Despite our comments, the latest drafts continue to require non-conforming generators to acquire 'load shed' service.
Response: The SDT thanks you for your comments. The NERC Reliability Standards Development Procedure, approved by FERC on September 3, 2010 (http://www.nerc.com/docs/standards/sar/Appendix_3A_Standard_Processes_Manual_20100903_2_.pdf, see page 32) has provisions for the Regions to submit a request for a Variance. However, Regional Standards will need to be addressed at the Regional Level unless the Region desires to seek a Variance through the NERC Standard Development Process.	
Ameren	It seems that geography (e.g. peninsulas, coastal areas) and load sparcity, and dense load served by distant generation have been significant factors in blackout events. As such, regional differences do exist.
Response: The SDT thanks you for your comments. The NERC Reliability Standards Development Procedure, approved by FERC on September 3, 2010 (http://www.nerc.com/docs/standards/sar/Appendix_3A_Standard_Processes_Manual_20100903_2_.pdf, see page 32) has provisions for the regions to submit a request for a variance, should the region decide to do so.	
IRC Standards Review Committee	None
Luminant Power	NA
Southern Company	No.

Independent Electricity System Operator	None

8. If you aware of any conflicts between the proposed standard and any regulatory function, rule order, tariff, rate schedule, legislative requirement or agreement, please identify the conflict here.

Summary Consideration:

There were several commenters who stated they were aware of agreements between some generators and their respective Transmission Owners that contain frequency coordination requirements that differ from those in Table 1. The SDT answered this concern with: “The Generator Verification SDT has worked closely with the UFLS SDT to insure coordination of this Standard with the UFLS Standard. When the UFLS standard is approved and in effect entities will be required to comply. The SDT believes the drafted standard allows for exceptions due to technical limitations per Requirement R5 (R3 in the revised standard). Several commenters gave concerns that Nuclear Plant Requirements may conflict. The SDT answered this concern with: “The SDT is aware that Nuclear Plant licensing issues may not allow a generator to meet the requirements of this Standard and this might be an acceptable basis for exclusion. However, the Nuclear Power Plant owner would be expected to review these limitations and assure that a less restrictive set-point is not possible.

Organization	Question 8 Conflict
Dominion	Yes. We are aware of agreements between some generators and their respective transmission owners that contain frequency coordination requirements that differ from those in Table 1, and that, in some cases, the transmission facility(ies) that connects the generator to the BES has underfrequency tripping that would operate prior to the levels shown in Table 1, thus negating any modification that a generator might make to conform. We suggest that this standard also exempt these GOs from meeting R1 and R2 and that R5 be modified to allow for such exception.
Response: Thank you for your comments to this question. The Generator Verification SDT has worked closely with the UFLS SDT to insure coordination of this Standard with the UFLS standard. When the UFLS Standard is approved and in effect entities will be required to comply. The SDT believes the drafted Standard allows for exceptions due to technical limitations per Requirement R5 (R3 in the revised standard).	
Northeast Power Coordinating Council	Yes. We are aware of agreements between some generators and their respective transmission owners that contain frequency coordination requirements that differ from those in Table 1, and that, in some cases, the transmission facility(ies) that connects the generator to the BES has underfrequency tripping that would operate prior to the levels shown in Table 1, thus negating any modification that a generator might make to conform. We suggest that this standard also exempt these GOs from meeting R1 and R2 and that R5 be modified to allow for such exception.
Response: Thank you for your comments to this question. The Generator Verification SDT has worked closely with the UFLS SDT to insure coordination of this Standard with the UFLS Standard. When the UFLS standard is approved and in effect entities will be required to comply. The SDT believes the drafted Standard allows for exceptions due to technical limitations per Requirement R5 (R3 in the revised standard).	
FirstEnergy	This standard may need to be coordinated with current efforts to revise standard PRC-006-1, and with the Regional

Organization	Question 8 Conflict
	standards being developed for UFLS, such as RFC's PRC-006-RFC-01.
Response: Thank you for your comments. The SDT has worked closely with the NERC UFLS team to ensure a coordinated effort is being conducted.	
Constellation Power Generation & Constellation Nuclear	Yes. We are aware of agreements between some generators and their respective transmission owners that contain frequency coordination requirements that differ from those in Table 1, and that, in some cases, the transmission facility(ies) that connects the generator to the BES has underfrequency tripping that would operate prior to the levels shown in Table 1, thus negating any modification that a generator might make to conform. We suggest that this standard also exempt these GOs from meeting R1 and R2 and that R5 be modified to allow for such exception.
Response: Thank you for your comments. The Generator Verification SDT has worked closely with the UFLS SDT to insure coordination of this Standard with the UFLS Standard. When the UFLS standard is approved and in effect entities will be required to comply. The SDT believes the drafted Standard allows for exceptions due to technical limitations per Requirement R5 (R3 in the revised standard).	
Southern Company	Nuclear Plant Requirements may conflict.
Response: Thank you for your comments. The SDT is aware that Nuclear Plant licensing issues may not allow a generator to meet the requirements of this Standard and this might be an acceptable basis for an exclusion. The Nuclear Power Plant owner would be expected to review these limitations and assure that a less restrictive set-point is not possible that would permit coordination with this Standard while still protecting the nuclear plant. The SDT will discuss and investigate the inclusion of this concern in R5 (R3 in the revised standard).	
Basin Electric Power Cooperative	The proposed generation off-nominal frequency criteria conflicts with the MRO UFLS program, and will not work for programs that need to shed more than 30% of system load. Technically this is not a conflict with regulatory functions, rule order, tariff, rate schedule, legislative requirement or agreement; but it is a conflict with our efforts to design an appropriate load shedding program for the MRO region.
Response: Thank you for your comments. The SDT has worked closely with the NERC UFLS team to ensure a coordinated effort is being conducted.	
Progress Energy, Inc.	Yes, if the standard is extended to other plant equipment NRC nuclear plant licenses will be in conflict.
Response: Thank you for your comments to this question. The SDT is aware of these concerns.	
Hydro-Québec TransEnergie (HQT)	Yes. We are aware of agreements between some generators and their respective transmission owners that contain frequency coordination requirements that differ from those in Table 1, and that, in some cases, the transmission facility(ies) that connects the generator to the BES has underfrequency tripping that would operate prior to the levels shown in Table 1, thus negating any modification that a generator might make to conform. We suggest that this

Organization	Question 8 Conflict
	standard also exempt these GOs from meeting R1 and R2 and that R5 be modified to allow for such exception.
Response: Thank you for your comments to this question. The Generator Verification SDT has worked closely with the UFLS SDT to insure coordination of this sSandard with the UFLS Standard. When the UFLS Standard is approved and in effect entities will be required to comply. The SDT believes the drafted Standard allows for exceptions due to technical limitations per Requirement R5 (R3 in the revised standard).	
Ameren	Nuclear Plant Requirements may conflict.Footnote 2 refers to the agreements for which the GO is not responsible. Also, grandfathered generation of more vertically integrated entities and/or in certain states may not have such formal agreements.
Response: Thank you for your comments to this question. The SDT is aware that Nuclear Plant licensing issues may not allow a generator to meet the requirements of this Standard and this might be an acceptable basis for an exclusion. The SDT will discuss and investigate the inclusion of this concern in R5. The SDT disagrees with the comment referencing footnote 2, and believes the GO (Generator Owner) is responsible for these actions.	
First Solar	The requirements are inconsistent with UL 1741 and IEEE 1547 as applied to existing solar PV inverter design. Compliance withn the proposed Standard would require an industry re-design and recognition from the Interconnecting Transmission Owner that projects would not meet these other standards. Additionally the Standard should provide for a phase in period for inverter based PV facilities so that such redesign can be accommodated.
Response: The standard criteria are applicable to voltage on the BES. The UL and IEEE standards will likely need to be considered if a plant performance Standard were to be developed.	
Kansas City Power & Light	Not aware of any conflicts.
MRO NERC Standards Review Subcommittee	No known conflict at this time.
IRC Standards Review Committee	None
Luminant Power	NA
Consumers Energy Company	No.
Old Dominion Electric Cooperative	No.
Lakeland Electric	No

Organization	Question 8 Conflict
Manitoba Hydro	none
American Electric Power	No known conflicts
Duke Energy	None
Independent Electricity System Operator	None

9. Are there other improvements that the SDT should consider for this revision of PRC-024-1 that you haven't already identified in response to other questions? If yes, please provide in the comment area.

Summary Consideration:

There were many different suggestions to improve upon the proposed Standard. They are summarized as follows:

- The Standard should only apply asynchronous generators.
- The Standard could lead to relays being activated needlessly.
- The Standard should apply at the generator terminals, not the POI.
- Consider other UFLS Standards activities.
- Consider over frequency setting at 63 hertz.
- Do not trip on under voltage.
- Provide additional technical detail.
- Provide clarity on relay settings.
- Clarify language.
- Concerns with generator damage, Standard exemptions, and who approves them.
- Steady state versus dynamic simulation.
- Implementation schedule concerns.
- Concerns over who reports what to whom.
- Transient vs. steady state applicability.
- Regional vs. NERC requirements.
- Reactive power requirements.

Organization	Yes or No	Question 9 Comment
Entergy Fossil Operations	Yes	Do away with this standard.

Organization	Yes or No	Question 9 Comment
Response: Thank you for comment. This Standard is an extension of work done in Phase III/IV and is deemed of value.		
NERC System Protection and Control Subcommittee (SPCS)	Yes	PRC-024 should only apply to non-synchronous machines. Coordination of synchronous generator voltage and frequency protective relay settings with transmission protection systems should be addressed along with all other coordination in PRC-001 Protection coordination. SPCS is preparing a Technical Reference paper on such coordination that is expected to be completed in June, 2009. Generator voltage and frequency protective relays are included in that that paper. The Attachment 2 voltage ride through curve was developed, to SPCS understanding, by compiling a number of system events delineating those events whereby the tripping of generators would exacerbate the event. It does not appear that the SDT analyzed data from the August 14, 2003 Northeast Blackout. Actual data from the event in Michigan, before the system cascaded and broke apart revealed 345 kV system voltages of less than 0.9 per unit. Some generators in Michigan tripped by undervoltage relays set at 0.9 per unit that significantly accelerated the cascade. Even those generators along the western fringe of the soon-to-be separated power system were of event more concern; data indicated these large units were experiencing 345-kV voltages of less than 0.9 per unit. Those generators did not trip because they did not have undervoltage relaying set to trip. Had these units tripped on undervoltage relaying, the event would have extended much further to the west of the actual impacted area. The Standard requires generator relays to be set based on a voltage at the interconnection point to the BES. However the relays are typically connected to a voltage source at the generator, not the BES interconnection. The translation from generator terminal voltage to a point of interconnection voltage is not a direct relationship. It will vary depending upon the assumption made for generator real and reactive output, or the distance to the point of interconnection. The Standard gives no direction regarding these assumptions. The voltage to be sensed must be the generator terminal voltage. IEEE C50.13 describes the standards to which the modern generators were built. This standard recommends reducing unit output after ascertaining the presence of an undervoltage alarm. This standard does not recommend unit tripping. Totally different relay settings will be obtained with different generator output assumptions. This lack of consistency will make it impossible to determine if compliance to the Standard is achieved. SPCS also have concerns with the overfrequency curve in Attachment 1 in light of the August 14, 2003 Northeast Cascade and Blackout. During the sequence of events an island formed consisting of portions of western New York and eastern Ontario with a significant generation-load mismatch. The surplus generation in the island resulted in an overfrequency condition to which several large generating units responded to arrest the overfrequency at 63 Hz. Had those units been set to trip on the proposed curve on August 14, the units would have tripped prematurely potentially leading to a collapse of the island. While the overfrequency curve may be acceptable as a floor for setting the overfrequency relays, there should also be a requirement to coordinate the overfrequency tripping with the unit controls and unit capability to maximize the ability of machines to control overfrequency while operating within their capability. Undervoltage alarms as experienced by hydro, fossil, combustion, and nuclear units are an indicator of possible thermal issues within the generator. Other alarms from RTDs and hydrogen pressure are better indicators. Manufacturers recommend operator action up to and including reduction in unit output rather than a unit trip. Tripping units on undervoltage is not recommended by the IEEE C37.102 standard on generator protection. Rather C37.102 also recommends alarm. Each type of unit, hydro, fossil, nuclear, combustion, and renewable generator have different thermal issues relating to system undervoltage. A single curve over-simplifies the issue to the point that system reliability is degraded. If any curve is included, it should be focused only on wind turbines as they have voltage ride through controls. Attachment 2 requires voltage evaluation at the system voltage level. Concerning Attachment 1, SPCS believes this is mainly present to insure that generator tripping will not interfere with UFLS programs. There should be a

Organization	Yes or No	Question 9 Comment
		statement that settings should not interfere with UFLS program in effect. Also on Attachment 1, this is now labeled "Off Nominal Frequency Capability Curve." SPCS suggests that the word "capability" in this label is potentially misleading. This is not a machine capability curve. There should be a statement that protective device settings should be based on machine damage considerations and should be arrived at in consultation with the machine manufacturer. The curve presents limits to those settings which are designed to prevent interference with UFLS programs. The SDT has not described how the curve was compiled. Technical committees within the IEEE went to great lengths to describe the turbine blading off-frequency limitation curves. Every manufacturer submitted their curve and a family of curves was created that showed distinct curves for each manufacturer. The NERC 1978 document, "Underfrequency and Undervoltage Relay Applications Large Turbine Generators included a collection of individual manufacturer which when plotted together provided a prospective on the widely varying limits of the various turbines. There is a danger of misinterpretation to use one curve. In PRC-024-1 there was no description stating how the curve was developed. If a machine is not at risk and if a UFLS simulation shows that the bottom frequency will occur outside of the "one size fits all curve" then there should be a provision to use the manufacturer's curve rather than shed more load just to fit the attachment 1 curve.A.R1 and A.R2 wording could be taken to require that such relaying should be enabled and set. The phrase "Installed relaying not to trip during" could be taken to mean that such relaying is assumed to be, or should be, installed. Also, in the case of generator multifunction protective devised, such relaying is always installed but it is not appropriate in many cases that it be enabled and set. Note this consideration applies to both frequency and Voltage. In general, this Standard should take care to point out that any protection application should be based on actual specific machine protective considerations which should be arrived at in consultation with the machine manufacturer. Concerning A.R1.2 and Attachment 1, the language refers to a “no trip zone" between curves, and obviously there is a permissible trip zone outside the curves. Questions will arise on permissibility of settings which are actually on the curves. SPCS would suggest that setting directly on the curves should be permitted. For example, if 1.0 seconds at 57.8 Hz is directly on the curve, failure to deal with this question will result in pointless and counterproductive settings such as 1.0 seconds at 57.79 Hz. SPCS suggests "Setting directly on the curves is permitted, and settings outside the curves are permitted." Concerning A.R2, this Standard addresses setting of Voltage relays based on Voltage at the point of interconnection, which is not directly translatable to Voltage at the generator terminals. The generator real and reactive power output will affect the relationship, and this is not dealt with in this Standard. Simply setting the generator protection relay at 0.90 per unit may, in fact, be an incorrect setting to achieve the desired performance. Settings must include allowances for all equipment tolerances: voltage transformer errors, relay tolerances, and testing instrumentation errors. The actual setting needed to account for such variances may require that the relay be actually set to trip at 0.84 or 0.86, or some other seemingly conflicting value, in order to achieve the goal of not tripping at 0.90 per unit.

Response: Thank you for your comment. The SDT has captured what we believe are the main points of your comment s and has provided responses below:

- **Apply only to asynchronous generators (synchronous gen goes to PRC-001) –** The SDT has taken the direction to develop a Standard that is technology neutral. PRC-001 currently addresses communication coordination review but not relay setting or generator performance specifically.
- **The Standard could lead to relays being activated needlessly –** The SDT agrees and has modified the proposed Standard to emphasize this point. If the GO has this relay equipment installed and has chosen to trip the generator with it, then the settings shall be determined in accordance with this Standard.

Organization	Yes or No	Question 9 Comment
• **POI issue –** The SDT has provided additional assumptions for the calculation of relay settings on the basis of the voltage as measured at the POI. It is provided in Attachment 2 of the revised Standard. The SDT specifically chose the point of interconnection because that is where the faults that this standard is intended to address occur. • **Over frequency setting at 63 hertz –** The SDT selected 62.5 hertz as a compromise level to account for the majority of generators installed in the system. This Standard does not require generators to set over-frequency relays. • **Alarm and not trip on under-Voltage –** The proposed Standard does not compel GOs to have or set under-voltage relays to trip generators. The SDT believes it would be inappropriate to prohibit the protection of the generator through the setting of protective relays. • **Include provision that UFLS shall not be interfered with –** At the recommendation of FERC and NERC, the SDT has coordinated the UF relay curve with the NERC UFLS SDT members' input. • **Delay this Standard until regional UFLS work is completed –** See above. The UFLS standard has been approved by stakeholders. • **Want more technical detail on development of curves –** A WECC white paper formed the basis of the development of the curves for this Standard, along with additional data from SERC, Xcel Energy, AWEA, GE and AREVA. This information is available upon request. • **Seek clarity regarding setting on the line or anywhere up to line –** We agree and the Standard was modified to provide improved clarity. • **Specify relay settings that account for various equipment tolerances –** There is room between the manufacturer capability curves and the settings limits curves that allows relays to be set to accommodate tolerances.		
PJM Interconnection	Yes	In R2.2.1, replace -greater- with -faster- or -slower-, whichever is correct. In R2.2.3 replace -intended- with -required-. In R4, replace -written- with -documented-. In R5, add an -s- to -System- in the parentheses. In R3, R4 and R5 - Concerned with the GO responsibility to send to their RC, PC, TO and TP. Would rather see the GO responsibility be to just to respond to any RC, PC, TO and TP requests.
Response: Thank you for your comment. The SDT has modified the Standard to address the language concerns. The SDT prefers the choice of "written" as opposed to "documented" in R4. The term "Protection System" is a defined NERC Glossary term. In R3 and R5 all the named entities must receive the information. In R4 we agree that only the requesting entity must receive the information.		
Dominion	Yes	We would like to commend the SDT for recognizing that there may be technical reasons that prevent a generator from meeting requirements 1 and 2 and allowing an exemption when technical basis is provided (R5). There is a paragraph on the second page which states that "For voltage excursions, only generator under or over voltage protective relays and volts per hertz relays would need to be evaluated to meet the draft requirements. Steady state evaluations only are expected" We have the following questions: (1) Do the relays mentioned in the statement above include auxiliary system under voltage relays? It appears the voltage relay part of the standard is limited to only relays that directly trip the generator and not relays that trip auxiliaries. Is that the intent? What if the relay was attached to an auxiliary bus, but tripped the generator (2) How is that only steady state evaluations are enough? How do you study voltage recovery characteristics without dynamic simulations? If the standard is intended to apply to volts per hertz

Organization	Yes or No	Question 9 Comment
		relays, suggest: 1. Revising footnote 1 to specifically include volts per hertz relays. 2. Revise Steps 4.2.1 and 4.2.2 to specifically include volts per hertz relays. 3. That the standard should incorporate specific guidance for facilities using volts per hertz logics and include a graph showing the voltage and frequency excursions in terms of volts per hertz.
Response: Based on industry input, the Standard has been modified to require new generators to ride through voltage and frequency excursions, addressing the auxiliary systems concern. With respect to steady state evaluations versus dynamic simulations, the Standard does not preclude the application of either. The SDT agrees and has added volts per hertz relays among the listed items in footnote 1.		
Northeast Power Coordinating Council	Yes	Referencing R5 and R6 of the Standard: The Reliability Coordinator should be give veto power over exceptions to the requirements herein. Should the Generator Owner/Operator not be able to, or be unwilling to, make changes to setpoints to come into compliance with this Standard, the Reliability Coordinator should be given the authority to invoke required mitigation, such as requiring the Generator Owner/Operator to contract for compensatory load shedding up to the total amount of MW of each generating unit that fails to comply with the required setpoints. In addition, The "Off-Nominal Frequency Capability Curve" in Attachment 1 does not coordinate with the underfrequency load shedding (UFLS) program design parameters proposed by the NERC Underfrequency Load Shedding Standard Drafting Team for Project 2007-01. The misccoordination occurs in the time range approximately between 5 and 10 seconds. This miscoordination can be eliminated by extending the horizontal line at 57.8 Hz to 5 seconds and revising the diagonal line to have endpoints at 57.8 Hz/5s and 59.5 Hz/1800s. This modification will provide coordination with the UFLS program design parameters while still maintaining coordination with turbine-generator capability. Due to the time scale on the graph in Attachment 2, the curves do not indicate the time at which the transient overvoltage and undervoltage requirements end, at which point the continuous voltage requirements would be applicable. Here are several other points that have come up regarding other parts of PRC-024-1 that were not covered above:> Concerning Attachment 1, we believe this is mainly present to infer that generator tripping will not interfere with UFLS programs. There should be a statement that settings should not interfere with UFLS program in effect. Also on Attachment 1, this is now labeled "Off Nominal Frequency Capability Curve." We wish to suggest that the word "capability" in this label is potentially misleading. This is not a machine capability curve. There should be a statement that protective device settings should be based on machine damage considerations and should be arrived at in consultation with the machine manufacturer. The curve presents limits to those settings which are designed to prevent interference with UFLS programs, and the curve should be so labeled. > A.R1 and A.R2 wording could be taken to require that such relaying should be enabled and set. The phrase "Installed relaying not to trip during" could be taken to mean that such relaying is assumed to be, or should be, installed. Also, in the case of generator multifunction protective devised, such relaying is always installed but it is not appropriate in many cases that it be enabled and set. Note this consideration applies to both frequency and voltage. In general, this Standard should take care to point out that any protection application should be based on actual specific machine protective considerations which should be arrived at in consultation with the machine manufacturer.> Concerning A.R1.2 and Attachment 1, the language refers to a 'no trip zone" between curves, and obviously there is a permissible trip zone outside the curves. Questions will arise on permissibility of settings which are actually on the curves. We would suggest that setting directly on the curves should be permitted. For example, if 1.0 s. at 57.8 Hz is directly on the curve, failure to deal with this question will result in pointless and counterproductive settings such as 1.0 s. at 57.79 Hz. We suggest "Setting directly on the curves are permitted, and settings outside the curves are permitted."> Concerning A.R2, this Standard addresses setting of voltage relays based on voltage at the

<table>

<tr><td colspan="3">Response: Thank you for your comments. The SDT has captured what we believe are the main points of your comment sand has provided responses below:
RC should have veto power over exemptions – The SDT believes it is the responsibility of the GO to determine the capability of the existing unit. The judgment as to validity of an exemption is a compliance matter.
RC should have authority to decide mitigation, e.g., compensatory load shedding – The SDT believes mitigation of inability to comply with a Standard is a compliance matter.
UFLS mis-coordination – The UFLS SDT and this Standard Drafting Team conferred and resolved the mis-coordination. The resolution that was mutually agreed upon is for the UFLS SDT to modify its Standard to accommodate the frequency curve in this Standard.
PRC-024 should not interfere with UFLS – The two teams have coordinated the frequency curves and strategies.
State that settings shall be determined to prevent machine damage in consultation with manufacturers' recommendation. – The SDT developed the curves in accordance with manufacturer's recommendations and the Standard includes an exemption process for existing generators.
Are settings permitted on the curve? No, settings are not permitted on the curve/line and the Standard has been modified to reflect this more clearly.
POI versus gen terminal – The SDT specifically chose the point of interconnection because that is where the faults that this standard is intended to address occur.
Aux systems relays and Steady state versus dynamic simulation – Based on industry input, the Standard has been modified to require new generators to ride through voltage and frequency excursions, addressing the auxiliary systems concern. With respect to steady state evaluations versus dynamic simulations, the Standard does not preclude the application of either. The SDT agrees and has added volts per hertz relays among the listed items in footnote 1.</td></tr>
<tr><td>SERC Dynamics Review Subcommittee (DRS)</td><td>Yes</td><td>1. We recommend deleting the proposed section R2.2.2. If not deleted, change: "meet a shorter voltage ride through" to "meet a less stringent voltage ride through".

2. In R3, change "within 30 calendar days of any change" to "at least 30 calendar days prior to any change". The changes should be</td></tr>

Organization	Yes or No	Question 9 Comment
		provided before they are made in the field. 3. In M4, change "entities listed in Requirement 4" to "entities listed in Requirement 4 that provide a written request"
Response: Thank you for your comments. **1. The SDT agrees and has modified the Standard to reflect this.** **2. The SDT intends this requirement to ensure timely notification of equipment changes to the PA and 30 days is a reasonable duration for the Time Horizon of the PA.** **3. The SDT agrees and has modified the Standard to reflect this.**		
Kansas City Power & Light	Yes	Please consider including the Balancing Authority as an entity for the Generator Owner to provide settings information in requirements R3 & R4 since the BA is an entity that has a direct relationship with the operational status of generating stations. R5: Do not agree with the bulleted item where increasing the capability of a generator by 10% is a reason for exemption expiration. As an example, turbine or boiler enhancements can result in greater efficiencies and resulting in an increase of generator capability with no change to the generator or its protection capabilities whatsoever. Recommend removal of this bulleted item. R5: The generator exciter voltage regulator contains protective relay settings such as Volts/Hertz, undervoltage, overvoltage, underfrequency that will also trip the Unit. Is the exciter voltage regulator considered to be part of the generator protective relay system? If so, would a limitation of the exciter voltage regulator be allowed as an exception to the standard or, since the protective system is excluded, would R5 mandate that the exciter voltage regulator be replaced to remove the exception? This issue should be clarified in R5.
Response: The SDT does not observe a reliability need to provide these setting data to the Balancing Authority. **The SDT intends for a GO that decides to increase capability of its unit by a significant amount (now 10%) to also address the technical limitation cited in its exemption.** **The NERC Glossary definition of Protective System does not appear to include voltage regulator. However the SDT intends this Standard to include exciter voltage regulator functions and relays that directly trip the generator based on frequency and voltage excursions.**		
MRO NERC Standards Review Subcommittee	Yes	It would be good to have the option of measuring the voltage at the Generator bus or POI. With the understanding that the voltage must be maintained of the POI.
Response: Thank you for your comment. The SDT agrees that it is the voltage at the POI that must be maintained.		

Organization	Yes or No	Question 9 Comment
FirstEnergy	Yes	1. FE's consensus is that the PRC-024 allowable under-frequency vs. time tripping curve is too tight. By too tight, we mean that the LP turbine buckets and blades are much more tolerant of off freq operation than the proposed tables. Comparing them to the old ECAR curves and allowable tripping times shows they are more stringent. Given how seldom these events occur, (never happened yet in the Eastern Interconnect) expending more of this capacity appears justified. 2. Section A5 Implementation schedule - it may not give sufficient time to implement these requirements. We suggest an additional year as follows: no less than 33% within 2 years of effective date no less than 66% within 3 years of effective date no less than 100% within 4 years of effective date 3. R1.2 Should say off-nominal not off-normal. 4. R2.1 Suggest changing the word "measured" to "experienced". 5. In R5, we suggest changing the first bullet to read: "The equipment causing the limitation is modified, upgraded or replaced with equipment that removes the technical limitation.", and then delete the second bullet. 6. Requirements 3, 4 and 6 specify that the Generator Owner shall provide information to RCs, PCs, TOPs, and TPs that monitor or model the associated unit; however, there is no requirement for these entities to identify themselves to the Generator Owner. How will the Generator Owner know they have identified all of the entities that need the information? 7. In R5, the Generator Owner is granted an exception from requirements R1 or R2 simply by providing documentation of a equipment limitations. There is no independent view of the appropriateness of this exception. The drafting team should consider requiring independent verification of the equipment limitation prior to the granting of an exception to the requirements of the standard. 8. Sec. D References - Is this intended to be part of the standard? If so, it would be helpful if it was linked to the white paper so that we can review it. 9. In Requirements R3 through R6, the SDT may want to consider adding the Transmission Owner as another entity who may need this information. 10. R2.2.1 may need to be re-worded as it requires that protection trip in no greater than 9 cycles. We are not aware of a disadvantage to the system if the tripping takes longer than 9 cycles.

Response:

1. **The SDT intends for GOs to set their relays as tight as possible and not merely on the curve/line.**
2. **The SDT set the timeframe by consensus among team members and the companies they represent. Stakeholder comments have not thus far objected to the implementation schedule. On this basis the SDT is leaving the schedule as proposed.**
3. **The SDT agrees and has made the change.**

Organization	Yes or No	Question 9 Comment
4. The SDT has modified the language in R2. **5. The intent of R5 (now R3 in the revised standard) is to require eliminating the exception if the generator is upgraded by 10% or more.** **6. The GO is expected to know what entity is its RC, PC, TO, and TP.** **7. The drafting team considered requiring an independent evaluation of existing generator exceptions and determined that it is not practical.** **8. No referenced documents are part of the Standard.** **9. The SDT considered including the Transmission Owner and determined that the Transmission Operator is the appropriate organization to receive the information.** **10. The 9 cycle maximum clearing time is intentional. It is not a system consideration, it is because generators cannot withstand zero voltage at the POI for long periods of time.**		
IRC Standards Review Committee	Yes	a. R5: The wording "the Generator Owner is granted an exception for that unit from meeting the portion of Requirement R1 or R2 for that limitation once it provides documentation of the equipment limitation(s) to the Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners that monitor or model the associated unit, within 30 days of identifying the equipment limitation." is not written in a way to hold an entity responsible for any action. We suggest to reword it such that it places a responsibility to the Generator to seek approval for an exception, as follows: "the Generator Owner shall obtain approval for an exception for that unit from meeting the portion of Requirement R1 or R2 for that limitation through the submission of documentation of the equipment limitation(s) to the Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners that monitor or model the associated unit within 30 days of identifying the equipment limitation. Along with this proposed change, there is also a need for the entities receiving the approval request to respond to the request. Another requirement is needed to complete this process. b. The latter part of R5 should be reworded to hold an entity responsible for the needed actions associated with expiring the exception such that the requirement is measurable and enforceable. c. R6: It is unclear to us what purpose this requirement serves. If R5 is to be revised as we suggest (see above), then the "limitation" in question will be presented with technical justification in the request for approval. The receiving entities (RC, PC, TOP and TP) will have a chance to accept or reject the request with due consideration of the technical argument. This is part of the approval request process; hence we do not see the need for R6 if R5 is to be reworded. If a remand process needs to be stipulated, then inclusion in R5 a requirement for the receiving entity(ies) to respond to the request - either approving or disproving the with a rationale, would suffice.
Response: Thank you for your comment. **a. The required action is for the GO to provide documentation of the equipment limitation. The SDT believes it is the GO's responsibility to determine any limitations on existing generators' ability to meet the Standard.**		

Organization	Yes or No	Question 9 Comment
b. The GO is responsible for meeting the requirements when an exception expires. **c. R6 (R4 in the revised standard) provides the RC, PC, TO, and TP with an opportunity to seek clarification concerning existing generator limitations in meeting the Standard.**		
Constellation Power Generation & Constellation Nuclear	Yes	The 4 kV protection that includes under frequency and under voltage relays trip the generator in some of our plants. The SDT needs to clarify whether this standard applies to such protection.
Response: Thank you for your comment. The Standard applies to setting of voltage and frequency relays that directly protect the generator.		
Southern Company	Yes	1. We recommend deleting the proposed section R2.2.2. If not deleted, change "meet a shorter voltage ride through" to "meet a less stringent voltage ride through". 2. In R3, change "within 30 calendar days of any change" to "at least 30 calendar days prior to any change". The changes should be provided before they are made in the field. 3. In M4, change "entities listed in Requirement 4" to "entities listed in Requirement 4 that provide a written request" 4. How did the SDT translate the transient voltage excursion plot to the cumulative voltage curve? 5. The voltage ride through curve was said to be cumulative, this should be specified on the curve.6. How can we prove that our static voltage curve coordinates with this cumulative curve 7. Implementation schedule we believe that the unit size should be considered, and that the most critical units should be worked on first. Completing 33% each year is too ambitious for those members that have > 300 units. 8. What regions are working on voltage ride through and Underfrequency (ufls and undefrequency tripping of generators) 9. Should the PRC-024 SDT wait until the regions have completed their work? 10. Generator engineers do not see a relevance for a voltage ride-through for any generator other than wind.
Response: Thank you for your comment. **1. The SDT agrees and has modified the Standard to reflect this.** **2. The SDT intends this requirement to ensure timely notification of equipment changes to the PA and 30 days is a reasonable duration for the time horizon of the PA.** **3. The SDT agrees and has modified the Standard to reflect this.**		

Organization	Yes or No	Question 9 Comment
4. The SDT analyzed the amount of time the voltage remained outside of the required range in each of the events modeled. 5. The SDT has clarified the language. 6. A cumulative curve was selected to coordinate with relays that measure elapsed time. 7. The SDT set the timeframe by consensus among team members and the companies they represent. Stakeholder comments have not thus far objected to the implementation schedule. On this basis the SDT is leaving the schedule as proposed. 8. At the recommendation of FERC and NERC, the SDT has coordinated the UF relay curve with the NERC UFLS SDT members input. 9. At the recommendation of FERC and NERC, the SDT has coordinated the UF relay curve with the NERC UFLS SDT members' input. 10. The SDT has taken the direction to develop a Standard that is technology neutral.		
Converteam Naval Systems Inc.	Yes	0. (Overall) This is a good document that has good background study and contains a lot of expertise;1. (Voltage definition inconsistency)In the LVRT curves, it talks about the voltage at the point of interconnection. However, in R2.1 it uses voltage at the generator terminals. I think there is a little inconsistency between these two. It would be good to just use one of them, preferably the former one. The reason is that different generator plants might have different impedance between the generator terminals and the points of interconnection, so defining the voltage at the terminals poses a little unfairness. Another part of the reason is that for transmission protection purpose, it should ends at the point of interconnection.2. (Voltage range inconsistency)The voltage range is 0.9-1.1pu in the VRT curve, but it says 0.95-1.05 in R2.1. It would be good to make it consistent.3. (Date point missing) In the table supporting the VRT curves, the 0.95 and 1.05pu data are missing.4. (Priority) WECC and MRO have different VRT curves. Which one will override which one at the end? Will the NERC PRC-024 take priority than the Regional Entities? 5. Was reactive power support during faults considered in the draft group? Will it be required in the future Thanks
Response: Thank you for your comment. 0. Thank you! 1. The Standard applies to transient voltage excursions at the POI. R2.1 addresses steady state voltages at the generator terminals. 2. The VRT curve addresses the transient voltage event. R2.1 addresses steady state conditions, outside the range of the VRT curve. 3. The table addresses the transient voltage event and does not address steady state conditions. 4. This proposed standard is a NERC standard. The SDT is not addressing current or future regional Standards. 5. The Standard addresses voltage ride through. Reactive power and voltage support are important considerations in determining if a generator will meet the Standard. Methods to meet the Standard requirement are not specified in the Standard.		
Consumers Energy	Yes	Please see comments on Question 3.

Organization	Yes or No	Question 9 Comment
Company		
Response: Thank you for your comment. Please see responses to Question 3.		
Old Dominion Electric Cooperative	Yes	Provide some insight on Technical Exceptions for generators that cannot met these requirements (the CIP TFE process might be useful in this)
Response: Thank you for your comment. The SDT believes it is the responsibility of the GO to determine the capability of the existing units to meet the Standard.		
Southern California Edison Company	Yes	The curves and tables in the attachments require additional clarification.
Response: Thank you for your comments. Additional clarification has been added.		
Progress Energy, Inc.	Yes	1. Recommend deleting proposed R2.2.2. If not deleted the language needs to be clarified as follows: "meet a shorter voltage ride through" should be changed to "meet a less stringent voltage ride through".2. In R3, change "within 30 calendar days of any change" to "at least 30 calendar days prior to any change". The changes should be provided before they are made in the field.3. In M4, change "entities listed in Requirement 4" to "entities listed in Requirement 4 that provide a written request"4. The purpose and the applicability of the standard needs to be revised to clearly specify that the scope of PRC-024-1 only applies to main generator protective relaying and excludes protective functions associated with plant auxiliary equipment.
Response: Thank you for your comments. **1. The SDT agrees and has modified the Standard to reflect this.** **2. The SDT intends this requirement to ensure timely notification of equipment changes to the PA and 30 days is a reasonable during for the time horizon of the PA.** **3. The SDT agrees and has modified the Standard to reflect this.** **4. The Standard has been modified and now applies to overall new generator performance.**		
NIPSCo	Yes	R4 These groups should already have this information. The coordinators or planners should have proof and be able to provide this information now.R5 Normally would not accumulate enough time in the under-frequency zone to be a danger to the turbine blades but under unusual circumstances might accumulate too much time and not be able to continue to operate in the under-frequency region that is being specified. We might not have enough time to wait for the 30 day period.

Organization	Yes or No	Question 9 Comment
Response: Thank you for your comment. • **The purpose of the Standard is to assure that the relay setting information is available to the groups that require it.** • **Existing generators that are not able to meet the Standard are able to obtain an exception.**		
Northeast Utilities	Yes	R2.2.1 seems to imply that a generator must set an undervoltage trip with a time delay of no more than 9 cycles. This seems to conflict with the intent of PRC-024. Is the intent perhaps to require the TO to clear Zone 1 faults in no more than 9 cycles? Or is the intent to allow the GO to set the time delay as low as 9 cycles and no less? I suggest the latter.R3, R4, and R5 - This information should be provided to the owner of any UFLS or UVLS as well.
Response: Thank you for your comment. The intent is to allow TOs to reduce the required 9 cycle ride through requirement in cases where transmission system design allows faster clearing.		
Hydro-Québec TransEnergie (HQT)	Yes	Referencing R5 and R6 of the Standard: The Reliability Coordinator should be give veto power over exceptions to the requirements herein. Should the Generator Owner/Operator not be able to, or be unwilling to, make changes to setpoints to come into compliance with this Standard, the Reliability Coordinator should be given the authority to invoke required mitigation, such as requiring the Generator Owner/Operator to contract for compensatory load shedding up to the total amount of MW of each generating unit that fails to comply with the required setpoints. In addition, The "Off-Nominal Frequency Capability Curve" in Attachment 1 does not coordinate with the underfrequency load shedding (UFLS) program design parameters proposed by the NERC Underfrequency Load Shedding Standard Drafting Team for Project 2007-01. The misccoordination occurs in the time range approximatley between 5 and 10 seconds. This miscoordination can be eliminated by extending the horizontal line at 57.8 Hz to 5 seconds and revising the diagonal line to have endpoints at 57.8 Hz/5s and 59.5 Hz/1800s. This modification will provide coordination with the UFLS program design parameters while still maintaining coordination with turbine-generator capability. Due to the time scale on the graph in Attachment 2, the curves do not indicate the time at which the transient overvoltage and undervoltage requirements end, at which point the continuous voltage requirements would be applicable. Here are several other points that have come up regarding other parts of PRC-024-1 that were not covered above:> Concerning Attachment 1, we believe this is mainly present to infer that generator tripping will not interfere with UFLS programs. There should be a statement that settings should not interfere with UFLS program in effect. Also on Attachment 1, this is now labeled "Off Nominal Frequency Capability Curve." We wish to suggest that the word "capability" in this label is potentially misleading. This is not a machine capability curve. There should be a statement that protective device settings should be based on machine damage considerations and should be arrived at in consultation with the machine manufacturer. The curve presents limits to those settings which are designed to prevent interference with UFLS programs, and the curve should be so labeled. > A.R1 and A.R2 wording could be taken to require that such relaying should be enabled and set. The phrase "Installed relaying not to trip during" could be taken to mean that such relaying is assumed to be, or should be, installed. Also, in the case of generator multifunction protective devised, such relaying is always installed but it is not appropriate in many cases that it be enabled and set. Note this consideration applies to both frequency and voltage. In general, this Standard should take care to point out that any protection application should be based on actual specific machine protective considerations

Organization	Yes or No	Question 9 Comment
		which should be arrived at in consultation with the machine manufacturer.> Concerning A.R1.2 and Attachment 1, the language refers to a 'no trip zone" between curves, and obviously there is a permissible trip zone outside the curves. Questions will arise on permissibility of settings which are actually on the curves. We would suggest that setting directly on the curves should be permitted. For example, if 1.0 s. at 57.8 Hz is directly on the curve, failure to deal with this question will result in pointless and counterproductive settings such as 1.0 s. at 57.79 Hz. We suggest "Setting directly on the curves are permitted, and settings outside the curves are permitted."> Concerning A.R2, this Standard addresses setting of voltage relays based on voltage at the point of interconnection, which is not directly translatable to voltage at the generator terminals. The generator real and reactive power output will affect the relationship, and this is not dealt with in this Standard. We would like to commend the SDT for recognizing that there may be technical reasons that prevent a generator from meeting requirements 1 and 2 and allowing an exemption when technical basis is provided (R5). There is a paragraph on the second page which states that " For voltage excursions, only generator under or over voltage protective relays and volts per hertz relays would need to be evaluated to meet the draft requirements. Steady state evaluations only are expected "We have the following questions: (1) Do the relays mentioned in the statement above include auxiliary system undervoltage relays? It appears the voltage relay part of the standard is limited to only relays that directly trip the generator and not relays that trip auxiliaries. Is that the intent? What if the relay was attached to an auxiliary bus, but tripped the generator?(2) How is that only steady state evaluations are enough? How do you study voltage recovery characteristics without dynamic simulations?

Response: Thank you for your comment.

- **The GO has the responsibility for determining the capability of existing generators and their ability to meet this Standard. How the power system deals with the inability of an existing generator to meet the Standard requirements is not addressed in this Standard.**
- **The UFLS SDT and this Standard Drafting Team conferred and have coordinated the frequency curves and strategies.**
- **The voltage curve ends at 1000 seconds. Steady state limits apply after 600 seconds.**
- **Clarification has been added that the Standard does not require voltage or frequency protective relays to be installed or enabled.**
- **Clarification has been added concerning setting relays exactly on the curve.**
- **Clarification has been added concerning assumptions to be made when calculating generator terminal voltage settings that correspond to required POI limits.**
- **The Standard has been modified to also be a new generator performance standard.**
- **With respect to steady state evaluations versus dynamic simulations, the Standard does not preclude the application of either.**

Organization	Yes or No	Question 9 Comment
AESO	Yes	In addition to the SRC ISO/RTO comments the AESO would like to add: As we understand it, the intent of this standard is to ensure that the generators ride through certain levels of frequency and voltage excursions, yet it only addresses the generator protection. We feel it must also address the protection and capabilities of the auxiliaries, unit transformers, lines, etc. If any of these trip off due

Organization	Yes or No	Question 9 Comment
		to the same excursions that the generator is required to ride through, then the generator will be down and the standard will not have achieved its goal.

Response: Thank you for your comment. Based on industry input, the Standard has been modified to require new generators to ride through voltage and frequency excursions.

Organization	Yes or No	Question 9 Comment
Duke Energy	Yes	The issue typically addressed by international grid codes is an over-all plant performance standard and plant dynamic studies are performed to evaluate the impact on in-plant systems. Standards applicable to only generator protection might give a false sense that a plant could survive the transients and the reliability of the BES would be just as adversely impacted if large plants were to trip for causes other than a main generator relay. The basis and reliability benefit for voltage ride through transients should be clarified. Generator UF relays must coordinate with grid UFLS relaying. Some areas may apply UVLS and logic dictates that the coordination of that protection with a generator ride through criteria should be specified. Recommend that the scope of "equipment" that can be granted an exception be limited in some way or explicitly qualified. Otherwise, plant performance can be dictated by less-consequential auxiliary equipment (e.g. variable speed drives with UV settings per manufacturer standard instructions). Because R5 grants exception automatically in response to the GO providing documentation of any limitation. R5 bullet 2 - recommend changing "generator nameplate capacity rating" to "generator gross Real Power capability". The existing words are too general and including 'nameplate' is confusing.

Response: Thank you for your comment.

- **The Standard has been modified to require new generators to ride through voltage and frequency excursions.**
- **The UFLS SDT and this Standard Drafting Team conferred and have coordinated the frequency curves and strategies.**
- **The GO has the responsibility for determining the capability of existing generators and their ability to meet this Standard.**
- **The term "nameplate capacity" is not used in the revised standard.**

Organization	Yes or No	Question 9 Comment
New York Independent System Operator	Yes	Here are several other points that have come up regarding other parts of PRC-024-1 that were not covered above:> Concerning Attachment 1, we believe this is mainly present to insure that generator tripping will not interfere with UFLS programs. There should be a statement that settings should not interfere with UFLS program in effect. Also on Attachment 1, this is now labeled "Off Nominal Frequency Capability Curve." We wish to suggest that the word "capability" in this label is potentially misleading. This is not a machine capability curve. There should be a statement that protective device settings should be based on machine damage considerations and should be arrived at in consultation with the machine manufacturer. The curve presents limits to those settings which are designed to prevent interference with UFLS programs, and the curve should be so labeled.> A.R1 and A.R2 wording could be taken to require that such relaying should be enabled and set. The phrase "Installed relaying not to trip during" could be taken to mean that such relaying is assumed to be, or should be, installed. Also, in the case of generator multifunction protective device, such relaying is always installed but it is not appropriate in many cases that it be enabled and set. Note this consideration

Organization	Yes or No	Question 9 Comment
		applies to both frequency and Voltage. In general, this Standard should take care to point out that any protection application should be based on actual specific machine protective considerations which should be arrived at in consultation with the machine manufacturer.> Concerning A.R1.2 and Attachment 1, the language refers to a 'no trip zone" between curves, and obviously there is a permissible trip zone outside the curves. Questions will arise on permissibility of settings which are actually on the curves. We would suggest that setting directly on the curves should be permitted. For example, if 1.0 s. at 57.8 Hz is directly on the curve, failure to deal with this questions will result in pointless and counterproductive settings such as 1.0 s. at 57.79 Hz. We suggest "Setting directly on the curves are permitted, and settings outside the curves are permitted."> Concerning A.R2, this Standard addresses setting of Voltage relays based on Voltage at the point of interconnection, which is not directly translatable to Voltage at the generator terminals. The generator real and reactive power output will affect the relationship, and this is not dealt with in this Standard.
Response: Thank you for your comment. • **The UFLS SDT and this Standard Drafting Team conferred and have coordinated the frequency curves and strategies.** • **Determining existing generator capability is the responsibility of the GO.** • **Clarification has been added to make it clearer that the Standard does not require installing voltage or frequency protection relays nor does it require setting any relays at the curve values.**		
Xcel Energy	Yes	Please clarify if there is an expectation/requirement for new units to install voltage and frequency protective relays.
Response: Thank you for your comment. There is no requirement for any generator to install or have voltage or frequency protective relays. Clarification has been added.		
CenterPoint Energy	Yes	a) CenterPoint Energy is concerned with what appears to be a lack of consistency and coordination between standards efforts. Considering PRC-023, CenterPoint Energy believes it is illogical to have transmission relay loadability requirements based on 0.85 pu system voltage for an extended period (such as, 15 minutes) to allow system operators to take remedial actions, while exempting generators from comparable requirements. For another example, it appears this proposed standard is not consistent with that being proposed for under-frequency load shedding systems that can help prevent cascading outages. b) Requirements, such as R2.2.1 and R2.2.2, are essentially fill-in-the-blank, location-specific criteria that are unnecessary and could have unintended consequences. Location-specific criteria can change over time with additions and modifications of the transmission system. Entities will have no incentives to voluntarily exceed the minimum required criteria, even though their plant has a greater ride-though capability. R2.2.1 further allows relaying to be set on actual fault clearing times, instead of the 9 cycles indicated in Attachment 2. In addition, R2.2.2 allows the use of location-specific criteria, but only if such criteria are less stringent. CenterPoint Energy believes NERC reliability standards should not include fill-in-the-blank, location-specific criteria. CenterPoint Energy recommends modifying R2.2.1 to reference Attachment 2 and to clarify the ride-through criteria is zero voltage for 0.15 seconds (9 cycles). CenterPoint Energy recommends deleting R2.2.2. c) R5 allows generating plants to meet less stringent criteria if generator

Organization	Yes or No	Question 9 Comment
		manufacturer literature indicates limitations, which would further erode system support from generation resources. It does not appear there is any process to substantiate the legitimacy of such limitations. CenterPoint Energy recommends deleting R5 and associated references.
Response: Thank you for your comment. **a) The Standard has been modified to require new generators to ride through voltage and frequency excursions. The SDT has coordinated the development of the UF relay curve with UFLS SDT.** **b) Requirements R2.2.1 and R 2.2.2 (new R2.1.2) allow the TO to relax the voltage ride through requirements in specific cases where the transmission system is designed to accommodate reduced generator performance.** **c) New R3 exempts existing generators that are not capable of meeting the Standard's requirements from having to do so. The GO is responsible for determining the generator's capabilities.**		
Independent Electricity System Operator	Yes	a. R5: The wording "the Generator Owner is granted an exception for that unit from meeting the portion of Requirement R1 or R2 for that limitation once it provides documentation of the equipment limitation(s) to the Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners that monitor or model the associated unit, within 30 days of identifying the equipment limitation." is not written in a way to hold an entity responsible for any action. We suggest to reword it such that it places a responsibility to the Generator to seek approval for an exception, as follows:"the Generator Owner shall obtain approval for an exception for that unit from meeting the portion of Requirement R1 or R2 for that limitation through the submission of documentation of the equipment limitation(s) to the Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners that monitor or model the associated unit within 30 days of identifying the equipment limitation." The requirement for getting non-conforming protection approved should be so stipulated to put the onus for mitigating actions on the Generator Owners. For example, in the case of non-conforming underfrequency settings, the requesting Generator Owner should be required to demonstrate that mitigating (i.e. arrangements for additional compensating load shedding) measures have been arranged with the Balancing Authority in their submission. Equipment settings that infringe upon the curves may be implemented only after approval is granted by the appropriate entities. Along with this proposed change, there is also a need for the entities receiving the approval request to respond to the request. Another requirement is needed to complete this process. b. The latter part of R5 should be reworded to hold an entity responsible for the needed actions associated with expiring the exception such that the requirement is measurable and enforceable. c. R6: It is unclear to us what purpose this requirement serves. If R5 is to be revised as we suggest (see above), then the "limitation" in question will be presented with technical justification in the request for approval. The receiving entities (RC, PC, TOP and TP) will have a chance to accept or reject the request with due consideration of the technical argument. This is part of the approval request process, hence we do not see the need for R6 if R5 is to be reworded. If a remand process needs to be stipulated, then inclusion in R5 a requirement for the receiving entity(ies) to respond to the request - either approving or disproving the with a rationale, would suffice.
Response: Thank you for your comment.		

Organization	Yes or No	Question 9 Comment
a) The required action in new R3 is for the GO to provide documentation of the equipment limitation(s) to the RC, PC, TO, and TP. The GO is not required to seek approval. **b) The SDT believes that new R3 is measurable and enforceable.** **c) The purpose of new R3 is to exempt existing generators that are not capable of meeting the Standard from having to do so.**		
Ameren	Yes	This standard could be ineffective if someone's auxiliary power protection trips out on low voltage or frequency and brings the unit down before the generator protection. Those settings on the aux buses are there to protect the equipment from failure since most of the downstream loads such as motors and electronics won't ride through an excursion as well as large T/G sets. We suggest that ANSI/IEEE Standards C37.102, C50.12, and C50.13 should be used and listed as references to this Standard. Reporting mechanism in R3 and R4 raises some commercial concerns. We prefer a secure repository of reporting to the RRO. Then only those who do have valid reasons for studies or monitoring could be granted access to the information. Footnote 1 expands 'protective relays' definition to include voltage regulator, etc. Instead state that only direct trip elements (functions) in the voltage regulator and exciter are included, if that's the intent. It should be made very clear.
Response: Thank you for your comment. • **The Standard has been modified to require new generators to ride through voltage and frequency excursions.** • **The SDT recognizes that the information required to be reported must be protected appropriately and expects the receiving organizations will fulfill all of their information protection obligations.** • **Clarification has been added to footnote 1.**		
PPL Energy Plus	Yes	PPL is concerned with the following concepts in the standard: 1) The standard applies equally to asynchronous and synchronous machines, salient pole and round rotor machines, photovoltaic, and other resources and as such the standard does not appear to recognize that these technologies respond differently to voltage and frequency excursions. 2) Better clarity of generator owner and transmission owner roles regarding changing existing fault clearing times is needed in the proposed standard. 3) R2.2 requires further clarity regarding relay settings. 4) R3 and R4 look the same. 5) The reference paper under Section D needs a thorough review by the industry.
Response: Thank you for your comment. **1. The SDT has taken the direction to develop a Standard that is technology neutral.** **2. The TO is allowed to relax the relay setting standard (shorter durations or higher minimum voltages and or lower maximum voltages) if the full capability of the standards is not required in specific instances.** **3. Further clarification has been added.**		

Organization	Yes or No	Question 9 Comment
4. Old R3 and old R4 are combined into the new R6. **5. The SDT welcomes thorough industry review of the reference paper.**		
US Bureau of Reclamation	Yes	Requirements R3 and R4 place a coordinating role on the Generator Owner to provide trip settings to four entities, the Reliability Coordinator, Planning Coordinator, Transmission Operator, and Transmission Planner. We believe it is more appropriate for the Generator Owner to coordinate settings with a single Transmission entity since the purpose of the Standard is "... to support transmission system stability during voltage and frequency excursions." and for the Transmission entity to further coordinate if necessary. The Transmission entity is in a better position to know what additional entities, if any should be involved. For the data points provided in the Attachment 2, HVRT DURATION and LVRT DURATION, we recommend both time and voltage units of measure be provided.
Response: Thank you for your comment. Old R3 and old R4 are combined into the new R6. The SDT agrees with the comment and has added clarification to the voltage and time units in Attachment 2		
American Transmission Company	No	It would be beneficial to have the option of measuring the voltage at the generator bus or point of interconnection (POI), with the understanding that the proper voltage must be maintained at the POI.
Response: Thank you for your comment. The SDT specifically chose the point of interconnection because that is where the faults occur that this Standard is intended to address. The SDT has provided additional assumptions for the calculation of relay settings on the basis of the voltage as measured at the POI.

A. Introduction

1. **Title:** Verification of Models and Data for Generator Excitation System Functions

2. **Number:** MOD-026-1

3. **Purpose:** To verify that the excitation system model (including power system stabilizer model and impedance compensator model if so installed) and the model parameters used in dynamic simulations that assess Bulk Electric System (BES) reliability accurately represent generator excitation system behavior.

4. **Applicability:**

4.1. Functional entities

4.1.1 Generator Operators of generating facilities:

4.1.1.1 Connected to Eastern or Quebec Interconnections with the following characteristics:

Each unit (including synchronous condensers) ≥ 100 MVA, connected at the point of interconnection at 100 kV or above and with an average Capacity Factor greater than 5% over the last three calendar years.

Each unit (including synchronous condensers) ≥ 20 MVA within a plant ≥ 200 MVA, connected at the point of interconnection at 100 kV or above and with an average Capacity Factor greater than 5% over the last three calendar years.

4.1.1.2 Connected to Western Interconnection with the following characteristics:

Each unit (including synchronous condensers) ≥ 75 MVA, connected at the point of interconnection at 100 kV or above and with an average Capacity Factor greater than 5% over the last three calendar years.

Each unit (including synchronous condensers) ≥ 20 MVA within a plant ≥ 150 MVA, connected at the point of interconnection at 100 kV or above and with an average Capacity Factor greater than 5% over the last three calendar years.

4.1.1.3 Connected to ERCOT Interconnection with the following characteristics:

Each unit (including synchronous condensers) ≥ 50 MVA, connected at the point of interconnection at 100 kV or above and with an average Capacity Factor greater than 5% over the last three calendar years.

Each unit (including synchronous condensers) ≥ 20 MVA within a plant ≥ 100 MVA, connected at the point of interconnection at 100 kV or above and with an average Capacity Factor greater than 5% over the last three calendar years.

4.1.2 Transmission Planners**.**

Proposed Effective Date:

In those jurisdictions where regulatory approval is required:

- By the first day of the first calendar quarter, two years following applicable regulatory approval:
  - Each Generator Operator shall verify at least 10% of its applicable units per Interconnection on a MVA basis.
- By the first day of the first calendar quarter, six years following applicable regulatory approval:
  - Each Generator Operator shall verify at least 50% (this includes the units verified in the first year) of its applicable units per Interconnection on a MVA basis.
- By the first day of the first calendar quarter, eleven calendar years following applicable regulatory approval:
  - Each Generator Operator shall verify 100% of its applicable units.

In those jurisdictions where no regulatory approval is required:

- By the first day of the first calendar quarter, two years following Board of Trustees adoption:
  - Each Generator Operator shall verify at least 10% of its applicable units per Interconnection on a MVA basis.
- By the first day of the first calendar quarter, six years following Board of Trustees adoption:
  - Each Generator Operator shall verify at least 50% (this includes the units verified in the first year) of its applicable units per Interconnection on a MVA basis.
- By the first day of the first calendar quarter, eleven calendar years following Board of Trustees adoption:
  - Each Generator Operator shall verify 100% of its applicable units.

B. Requirements

R1. The Generator Operator shall verify the excitation system model (including power system stabilizer model and impedance compensator model if so installed) which represents generator excitation system behavior in dynamic simulations per the following schedules:

1) For a new or existing unit with a new excitation system, within 180 days of the commercial operation date or new equipment commissioning date, whichever occurs first.

2) For an existing unit, once in a ten calendar year period. If multiple units have the same MVA rating that is ≤ 250 MVA, and if they have identical applicable components and settings and are sited at the same physical location, verification of one unit is sufficient for all units. Verification shall be performed on a different unit each ten calendar year cycle.

3) If verification cannot be performed within the ten year period because a unit has not been on-line, the ten year period shall be extended. It is permissible to wait until the unit is scheduled to operate in order to conduct verification so that sufficient

advance notice to make arrangements for verification is available. After verification is performed, the subsequent ten year schedule for the next verification will start.

4) For units that reach an average Capacity Factor greater than 5% over the last three calendar years, and have not been verified within the last ten calendar years, verification shall be performed within the next calendar year. The subsequent ten year schedule will start upon a successful verification.

R2. The Transmission Planner shall provide the Generator Operator a set of model data sheets for the acceptable excitation system models (models cannot be confidential or proprietary) for use in dynamic simulation software, with each data sheet including the excitation system model block diagram structure and data requirements, within 30 calendar days of a request from the Generator Operator.

R3. The Transmission Planner shall provide the Generator Operator the unit specific data contained in the Transmission Planner's dynamic database from the current in-use excitation system model, within 30 calendar days of a request from the Generator Operator.

R4. The Generator Operator shall provide to the Transmission Planner the following unit specific information within 90 calendar days of completion of the excitation system model verification:

1) Manufacturer, model number if available, and type of excitation system (for example: static, ac brushless, dc rotating).

2) Generator model structure and data (reactances, time constants, saturation factors, rotational inertia)

3) Excitation system model structure and data for the closed loop voltage regulator (including main exciter if so equipped).

4) Reactive compensation settings (for example: reactive droop, line drop, differential compensation), if utilized.

5) Model structure and data for power system stabilizer, if so equipped.

R5. The Transmission Planner shall determine if the excitation system model is useable by including the excitation system model in dynamic simulation software and substantiating that:

1) A no-disturbance simulation contains no transients.

2) For an otherwise stable simulation, a disturbance simulation results in the equipment exhibiting positive damping.

R6. The Transmission Planner shall inform the Generator Operator whether the excitation system model is useable or not within 90 calendar days of receipt (R4). If the excitation system model is not useable, the Transmission Planner shall provide the Generator Operator with a description of the problem and any relevant details.

R7. The Generator Operator shall provide a written response within 90 calendar days following notification by the Transmission Planner that the excitation system model is not useable. The Generator Operator's response shall either:

- Indicate what changes will be made to the excitation system model, or
- Provide the technical basis why no changes will be made.

R8. The Generator Operator shall provide to the Transmission Planner documentation demonstrating that the excitation system model's response matches the recorded response for a voltage excursion at the generator from either a staged test or a measured system disturbance (i.e., an ambient event) within 90 calendar days of completion of the excitation system model verification.

R9. The Generator Operator shall make documentation demonstrating that the excitation system model's response matches the recorded response for a voltage excursion at the generator from either a staged test or a measured system disturbance (i.e., an ambient event) available for inspection and technical review to the Reliability Coordinators, Transmission Operators, and Planning Coordinators that have responsibility for the area in which the associated unit is located, within 60 calendar days after receipt of a request.

R10. The Generator Operator shall provide a written response within 90 calendar days after receipt of a Transmission Planner's or a Planning Coordinator's written comments detailing technical concerns with the Generator Operator's excitation system model verification documentation. That written response shall either:

- Indicate what changes will be made to the excitation system model, or
- Provide the technical basis why no changes will be made.

R11. The Generator Operator shall perform a review of its current excitation system model when its Transmission Operator or Reliability Coordinator provides the Generator Operator dated electronic or hard copy evidence that the recorded excitation control system response to a Transmission system event did not match the predicted excitation system model response. Upon review the Generator Operator shall either:

- Provide a dated electronic or hard copy explanation detailing why the current excitation system model is still appropriate within 90 days to the commenter and the Transmission Planner whose area the generating facility is located in, or
- Perform a re-verification in accordance with R4, and R8 within 180 days. Once the re-verification is performed, the 10 year period as outlined in R1 will be reset.

R12. The Generator Operator shall perform a review of its current excitation system model and model parameters each time an activity that may alter the equipment response is performed. An activity that potentially alters the response of the excitation system and/or power system stabilizer includes but is not limited to:

- Exciter, voltage regulator or power system stabilizer control replacement including software alterations that could alter excitation system equipment response
- Plant Digital Control System addition or replacement

- Plant Digital Control System software alterations that could alter excitation system equipment response
- Exciter, voltage regulator, impedance compensator or power system stabilizer settings change

The Generator Operator shall either:

- Provide documentation that the response has not changed to the Transmission Planner within 90 days of completion of an activity that could have altered equipment response, or
- Perform a re-verification in accordance with Requirements R4 and R8 within 180 days. Once the re-verification is performed, the ten year period as outlined in Requirement R1 is reset.

C. Measures

M1. (To be developed.)

Unofficial Comment Form for the First Draft of MOD-026-1 — Verification of Models and Data for Generator Excitation System Functions (Project 2007-09)

Please **DO NOT** use this form to submit comments. Please use the **electronic comment form** located at the link below to submit comments on the proposed first draft of MOD-026-1 — Verification of Models and Data for Generator Excitation System Functions developed by the standard drafting team as part of Project 2007-09 — Generator Verification. Comments must be submitted by **April 2, 2009**. If you have questions please contact Harry Tom at Harry.Tom@nerc.net or by telephone at (860) 550-4157.

http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html

Background Information

The purpose of Project 2007-09 — Generator Verification is:

- To ensure that generators will not trip off-line during specified voltage and frequency excursions or as a result of improper coordination between generator protective relays and generator voltage regulator controls and limit functions (such coordination will include the generating unit's capabilities).
- To ensure that generator models accurately reflect the generator's capabilities and operating characteristics.

The standard drafting team (SDT) for Project 2007-09 Generator Verification based its work on two existing NERC Board approved standards:

- MOD-024 — Verification of Generator Gross and Net Real Power Capability
- MOD-025 — Verification of Generator Gross and Net Reactive Power Capability

And four draft standards developed by the Phase III & IV SDT that were field tested by four Regions from mid 2006 through mid 2007.

- PRC-019 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection
- PRC-024 — Generator Performance During Frequency and Voltage Excursions
- MOD-026 —Verification of Models and Data for Generator Excitation System Functions
- MOD-027 — Verification of Generator Unit Frequency Response

MOD-026-1 — Verification of Models and Data for Generator Excitation System Functions was developed with consideration to key issues stated in the SAR:

- Provide more details to the applicability section to identify any generators that should be exempt from compliance with the requirements in the standard,
- Replace the "fill in the blanks" requirements assigned to the Regional Reliability Organization which were appropriate when the standard was initially drafted but is

not appropriate under current requirements for approval of enforceable standards with a set of "continent-wide" requirements,

- Assign responsibility to the appropriate functional entities as a result of updates to the functional model and the replacement of the requirements assigned to the Regional Reliability Organization,
- Consider and address issues identified during Phase III & IV field testing.

The SDT first considered the functional entity "applicability". The SDT quickly recognized that assigning responsibility to appropriate entities for a continent wide standard on verifying unit excitation system models would be difficult. The reason is that there are many business model variations regarding excitation model verification in place today. Some of these business models assign the Generation entity to be ultimately responsible for verification of the excitation system model, and some assign the Transmission entity to be ultimately responsible. After lengthy discussions, the SDT decided that a Generation entity was the appropriate entity to assign ultimate responsibility. Therefore, in all instances of Requirements involving interaction (regarding the excitation system models) between the Generation entity and the Transmission entity, the Requirements are drafted such that the Generation entity has the final excitation system model responsibility and authority.

Consistent with the philosophy being proposed for MOD-024-1, the SDT concluded that while the Generator Owner may be responsible for the verified excitation system models, it is the Generator Operator that is the responsible entity to "operate" the unit in such a way as to obtain the required verification and any associated analysis; under the permission of the Generator Owner. The SDT felt that it is up to the Generator Owner and Generator Operator to work out any contractual arrangements associated with this relationship.

The SDT considered the extent of the facilities to be verified and how to reflect this in the "applicability" of this proposed standard. As a basis, the SDT recognized that the excitation system models and model data are already collected through the processes identified in MOD-012 and MOD-013. These models and data should, with few exceptions, already result in a quality dynamics database. However, as confirmed through the Field Test, performing the activities specified in the draft standard is expected to result in an improvement of the accuracy of the exciter models used in dynamic simulations. Utilizing engineering judgment, based in part on recent entity experiences in verifying excitation system models, the SDT is proposing to require verification of excitation systems associated with 80 percent or greater of the connected MVA per Interconnection. Therefore, the SDT proposes specific MVA thresholds for each interconnection. The SDT selected the MVA thresholds to correspond to 80 percent of the MVA for each interconnection. The SDT further felt that a minimum unit interconnection of >100 kV, consistent with the Compliance Registry Guidelines, was appropriate. The SDT believes that these applicability thresholds will result in substantial accuracy improvement to the excitation models and associated Reliability based limits determined by dynamic simulations, while not unduly mandating costly and time consuming verification efforts. Finally, the SDT believes that this standard should not apply to units with a low capacity factor. The SDT was unable to obtain substantiating data before this posting to substantiate the low capacity factor concept and thus is asking industry for input.

The SDT is proposing a 10 year recurring cycle for excitation system model verification. A 10 year cycle is being proposed in recognition of the expectation that as new units continue to be installed, an increasing percentage of digital excitation systems will be in service. The SDT felt that a 10 year recurring cycle, especially with technologies associated with digital excitation systems, would result in high confidence that the model represented actual equipment performance. If the inputs and outputs of an excitation system test performed on the same equipment 10 years apart are identical, and there is no technical reason to utilize a different model block diagram structure, the original verification documentation can be re-used. The SDT plans to allow this philosophy through the Measures which will be written for industry review at a later date.

The SDT recognized that observed performance of one excitation system installed for one generator should be expected, with high confidence, to have the same performance for a similar excitation system installed with identical settings for an identical generator. Based on that premise, the SDT thought that it would be prudent to allow a single unit verification to potentially count for multiple units which a) have the same MVA rating which is ≤ 250 MVA b) have identical applicable components and settings and c) are sited at the same physical location. The SDT felt that this philosophy would allow maximization of limited resources required to perform model verification without sacrificing reliability to the BES. This philosophy is expected to include units at the vast majority of combined cycle and multiple unit combustion turbine plants.

The SDT drafted the standard to capture interactions between the Generator Operator and predominately the Transmission Planner in an expected chronological order. Draft Requirements R2 and R3 ensure that the Transmission Planner supplies the Generator Owner an approved list of excitation system model data sheets and the unit specific excitation system models upon request. Requirement R4 lists the unit specific information that the Generator Operator is required to provide to the Transmission Planner upon completion of model verification. In addition to the excitation system model and model data, the Generator Operator is required to supply the generator model data used in the excitation system verification process. The reason is that the excitation system and generator that has been tested are part of a closed loop system. Thus, in reality, both the excitation system and portions of the generator dynamic models are being verified. The SDT stopped short of requiring verification of generator model data, in part because it would arguably result in an increase in scope not covered by the original Generation Verification SAR.

Once the unit specific information, including the model and model data, is received by the Transmission Planner, the Transmission Planner per Requirement R5 must determine if the model is useable. The activity to determine if the model is useable should not be confused with the model verification activity of ensuring the model response matches actual equipment response. A model is considered “useable” if it does not cause angle drift in a no-disturbance simulation or unduly causes poorly or un-damped oscillations in a dynamic simulation of a mild system fault disturbance. If the model is found to be unusable, Requirement R6 affords the opportunity for the Transmission Planner to request assistance from the Generator Operator, with the Generator Operator having the final technical authority (R7).

Based on a review of the Field Test results and experience of the SDT members, the SDT recognized that an excitation system model verification standard could be developed much like a technical procedure manual. It is anticipated that traditional staged testing as typically performed during commissioning of new equipment will be the primary form of data collection for model validation and documentation (R8 and R9) for the foreseeable future. However, the SDT felt that the standard should neither discourage innovation nor be dependent on emerging technologies. The SDT felt that the standard should be written so that applicable techniques that are under development but perhaps years away from being mainstreamed should still fit well within the standard Requirements. Thus, the SDT drafted a standard that concentrates on “stating what is required” but without “stating how to accomplish what is required". As an example, there are industry efforts to increase the use of ambient monitoring to verify excitation system models. The basic idea is to set up monitoring equipment to capture the response of the unit to naturally occurring transmission system upsets that result in an excitation system response. By capturing key electrical parameters associated with the excitation system response, the predicted model response can be compared to the actual equipment response. The use of ambient monitoring to verify excitation system models has been successfully implemented, but the implementation throughout the industry to date is extremely limited. Thus, the SDT has strived to develop the draft standard with minimal technical specificity so that ambient monitoring and other future techniques can be refined and utilized while still satisfying the Requirements. The draft standard does include a "peer review" process for the verification documentation, again, with the Generator Operator having the final technical authority (R10)

The final two Requirements deal with situations where the Generator Operator would review the excitation system model and/or model verification documentation. The review could be based either on observation of unexpected equipment performance by the Transmission Operator or Reliability Coordinator, or by activities that could result in an alteration of equipment performance. If a re-verification occurs before the 10 year recurring cycle is complete, the 10 year cycle would be re-set. The list of activities in Requirement R11 which could trigger a review includes Plant Digital Control System (DCS) additions, replacements, or software alterations. Plant DCS activities would only be relevant to excitation system modifications if they involved the addition, deletion, or modification of an outer loop control (such as power factor or reactive power set point) that alters automatic voltage regulator action.

The following questions will assist the SDT in finalizing the development of MOD-026-1. For questions where you agree with the SDT, please state that you agree with any explanatory comments and if available, please provide supporting documentation. If you disagree with the SDT, please explain why you disagree and provide data to support your position. The SDT would appreciate responses to as many of these questions as you can answer.

1. The SDT recognized that a determination had to be made regarding which entity should be ultimately responsible for model verification. The SDT was of the opinion that the Generator Operator, instead of the Transmission Planner or Generator Owner, was the appropriate entity to be responsible for the model verification. The Generator Operator operates the equipment being verified, and has direct access to the equipment. The Transmission Planner has the simulation software, but does not typically have access to the equipment or have testing capabilities. It is recognized that Generator Operators typically do not have in-house expertise and would have to either hire consultants to perform model verification, or develop in-house expertise including acquiring simulation software.

   Do you agree that the Generator Operator should be responsible for model verification? If not, please explain.

   ☐ Yes

   ☐ No

   Comments:

2. The SDT recognizes that depending on the technology of the modeled equipment, the periodicity of model verification necessary to ensure accurate models could vary. Also, the team recognizes that the majority of the resulting reliability benefit will occur during the initial verification. The drafting team determined that 10 years would be an appropriate period for re-verification in the absence of other activities listed in Requirement R12 that would require an earlier re-verification.

   Do you agree that 10 years is an appropriate period for re-verification? If you recommend a different period, please state your reasoning.

   ☐ Yes

   ☐ No

   Recommended periodicity and reasoning:

3. The SDT thought that it would be reasonable to apply a philosophy to allow maximization of limited resources required to perform excitation system model verification. The philosophy allows a single unit's actual excitation system verification to be a proxy for multiple units if the following conditions are met: a) the units have the same MVA rating, b) the units are rated at ≤ 250 MVA c) the units have identical applicable components and settings and d) the units are sited at the same physical location. For each recurring 10 year cycle, another unit must actually be verified.

   Do you agree with the proxy unit approach as used in Requirement R1 Item 2? If not, please explain.

   ☐ Yes

   ☐ No

   Comments:

4. The list of unit specific information in Requirement R4 to be provided to the Transmission Planner from the Generator Owner includes generator data used in the

excitation system verification process. The reason is that the tests, ambient or staged, which are used to verify the excitation system model, are part of a closed loop system that includes the generator. However, the SDT stopped short of requiring verification of either all generator data, or a portion of the generator data which is most applicable to excitation system testing (Transient Open Circuit Time Constant, and for PSS model verification, rotational inertia). The SDT feels that it cannot develop draft Requirements for the verification of generator data without submitting a supplementary SAR to the NERC Standards Committee.

Do you agree with the approach of requiring the Generator Owner to supply the generator data used in the excitation system model verification?

☐ Yes

☐ No

Comments:

Do you believe that the SDT should consider expanding the scope, through a supplementary SAR, to include verification of generator data? If yes, please provide the scope of generation verification the SDT should consider, along with any data that would support the reliability benefits from expansion of the existing scope which could be included in a supplementary SAR.

☐ Yes

☐ No

Comments and/or supporting data:

5. MOD-026 Requirement R8 requires the Generator Operator to provide documentation demonstrating that the provided model's response matches the recorded response. It does not specify criteria for evaluating the match. Requirement R8 assigns the task of evaluating the match to the Generator Operator. A peer review process for this documentation, detailed in Requirement R10, gives other involved parties an avenue to provide input and voice any concerns.

Do you agree with the approach of the Generator Operator determining if the match is sufficient and the peer review process?

☐ Yes

☐ No

Comments:

6. The team purposely provided minimal specificity regarding the mechanics of performing excitation system verification and the development of the documentation showing that the provided model response matches the recorded response. The team felt it was impractical to provide verification details in a mandatory Reliability Standard that needs to be applicable to all of the existing and future technologies.

Do you agree with this approach? If no, please elaborate on the additional specificity that you feel is appropriate with specific examples and/or proposed Reliability Standard language.

☐ Yes

☐ No

Comments:

7. The SDT believes that this standard should not be applicable to low capacity factor units. The SDT recognized that the excitation system models and model data are already collected through the processes identified in MOD-012 and MOD-013. These models and data should, with few exceptions, already accurately replicate actual equipment performance. By definition, low capacity factor units are expected to rarely be on-line, and even when they are, they would constitute a small portion of the interconnected MVA. As such, the SDT is of the opinion that verified excitation models for these units would not result in a substantial increase in Bulk Electric System reliability. Do you agree with this approach and the proposed 5% capacity factor?

☐ Yes, agree with approach and the 5% capacity factor

Supporting data for the proposed 5% capacity factor:

☐ Yes, agree with the approach. But use another capacity factor (include supporting data):

☐ No (disagree with approach)

Comments and/or supporting data for not agreeing with a capacity factor exemption:

8. The SDT is of the opinion, based upon sound engineering judgment, that verifying models for excitation systems of generators per the MVA thresholds specified in the Applicability section 4.1.1 will ensure satisfactory performance of Interconnection network simulation models. Do you agree with this approach? If yes, please provide any data in support of the proposed approach including supporting data that the MVA thresholds specified in the Applicability section 4.1.1 correspond to 80% of the Interconnection MVA.

☐ Yes

Supporting data:

☐ No, instead use this approach:

9. Do you believe the SDT should develop a Requirement to allow the Transmission Planner or the Planning Coordinator to identify additional applicable units beyond those specified in section 4.1.1 due to their criticality to the reliability of the Bulk Electric System? If yes, please include the criteria that should be used by the Transmission Planner or Planning Coordinator to identify critical units with MVA rating less than listed in section 4.1.1 and any supporting data.

☐ Yes

☐ No

Comments and/or supporting data:

10. The SDT is proposing an implementation plan that requires certain percentages of applicable units to be verified two, six, and eleven years after the standard is approved. The SDT also thought it would be prudent to allow the verification of excitation systems per Regional Entity procedures and guidelines within 5 years of the approval date to be sufficient for demonstrating compliance with this new Reliability Standard.
Do you agree with these approaches?

☐ Yes, agree with proposed phase in period for unit excitation system verification

☐ No, the phase in period for unit excitation system verification should be:

☐ Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standard's approval date

☐ No, instead of allowing credit for verification of excitation systems within the last 5 years of the Standard's approval date, instead would recommend:

11. If you are aware of any regional variances that would be required as a result of this standard, please identify them here.

Regional Variance:

Comments:

12. If you are aware of any conflicts between the proposed standard and any regulatory function, rule, order, tariff, rate schedule, legislative requirement, or agreement, please identify them here.

Conflict:

Comments:

13. If you have any other questions or concerns with the proposed standard that have not been addressed in responding to the questions above, please provide them here.

Field Tested Version of MOD-026 Mapped to Proposed MOD-026-1 — Verification of Models and Data for Generator Excitation System Functions

Field Tested Version of MOD-026	Comment	Proposed MOD-026-1
2. Number: MOD-026-1	Proposed standard will only cover MOD-026-1 content and will not be merged with any other standard	**2. Number:** MOD-026-1
1. Title: Verification of Models and Data for Generator Excitation System Functions	Title is unchanged	**1. Title:** Verification of Models and Data for Generator Excitation System Functions
3. Purpose: To ensure accurate information on generator excitation system functions (including voltage regulator controls, limiters, compensators, and power system stabilizers, if applicable) is available for models used to assess bulk electric system reliability.	The Purpose has been modified to emphasize verification of models, as opposed to data reporting already covered in MOD-012 and MOD-013.	**3. Purpose:** To verify that the excitation system model (including power system stabilizer model and impedance compensator model if so installed) and the model parameters used in dynamic simulations that assess Bulk Electric System (BES) reliability accurately represent generator excitation system behavior.
4. Applicability: **4.1.** Regional Reliability Organization. **4.2.** Generation Owner.	Regional Reliability Organization applicability is eliminated. Transmission Planner is added as this functional entity is involved in the iterative process of validating dynamic models. Additionally, generating facilities have been limited to those that have significant	**4. Applicability:** **4.1. Functional entities** **4.1.1** Generator Operators of generating facilities: **4.1.1.1** Connected to Eastern or Quebec Interconnections with the following characteristics**:** Each unit (including synchronous condensers) ≥ 100 MVA, connected at the point of interconnection at 100 kV or above and with an average Capacity Factor greater than 5% over the last three calendar years. Each unit (including synchronous condensers) ≥ 20 MVA within a plant ≥ 200 MVA, connected at the

Field Tested Version of MOD-026	Comment	Proposed MOD-026-1
	impact to BES reliability as they consist of approximately 80% of the connected MVA in each Interconnection	point of interconnection at 100 kV or above and with an average Capacity Factor greater than 5% over the last three calendar years. **4.1.1.2** Connected to Western Interconnection with the following characteristics**:** Each unit (including synchronous condensers) ≥ 75 MVA, connected at the point of interconnection at 100 kV or above and with an average Capacity Factor greater than 5% over the last three calendar years. Each unit (including synchronous condensers) ≥ 20 MVA within a plant ≥ 150 MVA, connected at the point of interconnection at 100 kV or above and with an average Capacity Factor greater than 5% over the last three calendar years. **4.1.1.3** Connected to ERCOT Interconnection with the following characteristics: Each unit (including synchronous condensers) ≥ 50 MVA, connected at the point of interconnection at 100 kV or above and with an average Capacity Factor greater than 5% over the last three calendar years. Each unit (including synchronous condensers) ≥ 20 MVA within a plant ≥ 100 MVA, connected at the point of interconnection at 100 kV or above and with an average Capacity Factor greater than 5% over the last three calendar years. **4.1.2** Transmission Planners**.**
R1. The regional reliability organization shall establish and maintain procedures to address	Regional applicability is eliminated and functional entity	**Requirements R1, R2, R3, R4, R5, R6, R7, R8, R9, R10, R11, & R12** define the model verification process which would have been

Field Tested Version of MOD-026	Comment	Proposed MOD-026-1
verification of models and data associated with generator excitation system functions including voltage regulator controls, limiters, compensators, and power system stabilizers. These procedures shall include the following:	responsibility is defined Verification, including reporting, is addressed throughout proposed Standard. Voltage regulator controls are inherent to excitation models. Some generators include power system stabilizer equipment that has an associated individual model and model data. Under and over excitation limiter static set points will be addressed in MOD-025 and/or PRC-019. Any reactive compensation settings are to be provided to the Transmission Planner so that the Transmission Planner can model these set points and settings as appropriate (reference IEEE 421.5-2005 for additional information).	addressed by regional procedures. Following is a high level summary of each of the Requirements: **R1.** Statement of the GOP Schedule (periodicity, extensions, exceptions) for verifying the excitation system model **R2.** TP provides a set of model data sheets to the GOP within 30 days of a request **R3**. TP provides the current unit specific excitation system dynamics data to the GOP within 30 days of a request **R4.** GOP provides the verified unit information to the TP **R5.** TP confirms that the provided models (R4) runs on its software **R6.** TP informs GOP if the provided model ran on the TP software, and if not, provides details. **R7**. If the model did not run on the TP software, the GOP provides the TP a written response with proposed solutions or a reason why no solution is offered **R8.** GOP provides TP information regarding the correlation of actual equipment to model simulated response **R9.** GOP provides RCs, TOs, and PCs information regarding the correlation of actual equipment to model simulated response within 60 days of a request **R10**. GOP responds within 90 days to a technical concern if initiated by the TP/PC **R11.** Within 90 days of receiving evidence by the TOP or RC that the equipment's response to a due to a transmission system event did not match the predicted model response, the GOP reviews its model(s) and provides the TOP or RC and applicable TP either an explanation or a re-verification of the model(s). **R12.** List of activities that potentially alter equipment response and thus could trigger a re-verification within a 10 year cycle

Field Tested Version of MOD-026	Comment	Proposed MOD-026-1
R1.1. Generating unit exemption criteria including documentation of those units that are exempt from a portion or all of these procedures.	Exemption criteria are addressed by **Applicability Section 4.1 and its sub-sections** by stating which generators are applicable to this Standard. Two criteria are utilized in specifying applicability: MVA and capacity factor. Unit MVA and plant MVA cutoffs for each NERC Interconnection are based on a total connected MVA of 80% being subjected to model verification.	**Sections 4.1 and sub sections are mapped above**
R1.2. Acceptable methods for model and data verification, including any applicable conditions under which the data should be verified. Such methods can include use of manufacturer data, commissioning data, performance tracking, engineering analysis, field verification of equipment settings, testing, simulation and comparison with test results or disturbance monitoring data, etc.	**Requirement R8** requires the Generator Operator to provide to the Transmission Planner documentation verifying that the provided model response matches the recorded response. Rather than establishing rigorous testing details, the Standard simply requires that the verification methodology chosen shall result in good correlation between model response and a recorded response. The recorded response could be from a staged test or ambient event. Additionally, **R9** requires the	**R8.** The Generator Operator shall provide to the Transmission Planner documentation demonstrating that the excitation system model's response matches the recorded response for a voltage excursion at the generator from either a staged test or a measured system disturbance (i.e., an ambient event) within 90 calendar days of completion of the excitation system model verification. **R9.** The Generator Operator shall make documentation demonstrating that the excitation system model's response

Field Tested Version of MOD-026	Comment	Proposed MOD-026-1
	Generator Operator to make the documentation available to its Transmission Planner (R9) and others (RC, TO, PC) which have responsibility for the area where the generator is located. This replaces part of a "catch-all" requirement of the Field Tested Version R3 mapped below.	matches the recorded response for a voltage excursion at the generator from either a staged test or a measured system disturbance (i.e., an ambient event) available for inspection and technical review to the Reliability Coordinators, Transmission Operators, and Planning Coordinators that have responsibility for the area in which the associated unit is located, within 60 calendar days after receipt of a request.
R1.3 Periodicity and schedule of verification and reporting, including schedules associated with field changes to existing units, and refurbished units.	Requirements **R1** and its sub requirements and **R10** address periodicity and schedules The intent of **R1 Item 1** is to provide ample time to perform verification for new equipment. Prior to verification, models and data would be made available to the Transmission Planner via Interconnection agreements and the process detailed in MOD-012 and 013. **R1 Item 2** specifies a 10 year recurring verification cycle and defines allowable opportunities to reuse the results of the validation of a unit's model for other units that meet the criteria listed in Item 2. A 250 MVA cutoff results in the inclusion of one of the most logical and likely beneficiaries of this	**R1.** The Generator Operator shall verify the excitation system model (including power system stabilizer model and impedance compensator model if so installed) which represents generator excitation system behavior in dynamic simulations per the following schedules: 1) For a new or existing unit with a new excitation system, within 180 days of the commercial operation date or new equipment commissioning date, whichever occurs first. 2) For an existing unit, once in a ten calendar year period. If multiple units have the same MVA rating that is ≤ 250 MVA and if they have identical applicable components and settings and are sited at the same physical location, verification of one unit is sufficient for all units. Verification shall be performed on a different unit each ten calendar year cycle.

Field Tested Version of MOD-026	Comment	Proposed MOD-026-1
	"proxy" unit philosophy - relatively new Combined Cycle and multiple Combustion Turbine plants (i.e., a "CT farm") with digital excitation systems **R1.3** details allowable time delays beyond the standard 10 year verification cycle for units that have not been on-line. **R1 Item 4** addresses verification schedules for units that were exempt due to a low capacity factor, but transition to having a capacity factor of greater than 5% R11 requires the Generator Owner to review the model when notified by the Transmission Operator or Reliability Coordinator that the actual equipment response observed during a transmission system event deviated from what was predicted by the model. Upon such notification, the GO must either provide an explanation or re-verify the model. The Requirement is written in such a manner to	3) If verification cannot be performed within the ten year period because a unit has not been on-line, the ten year period shall be extended. It is permissible to wait until the unit is scheduled to operate in order to conduct verification so that sufficient advance notice to make arrangements for verification is available. After verification is performed, the subsequent ten year schedule for the next verification will start. 4) For units that reach an average Capacity Factor greater than 5% over the last three calendar years, and have not been verified within the last ten calendar years, verification shall be performed within the next calendar year. The subsequent ten year schedule will start upon a successful verification. **R11.** The Generator Operator shall perform a review of its current excitation system model when its Transmission Operator or Reliability Coordinator provides the Generator Operator dated electronic or hard copy evidence that the recorded excitation control system response to a Transmission system event did not match the predicted excitation system model response. Upon review the Generator Operator shall either: • Provide a dated electronic or hard copy explanation detailing why the current excitation system model is still appropriate within 90 days to the commenter and the Transmission Planner whose area the generating facility is located in, or • Perform a re-verification in accordance with R4, and R8 within 180 days. Once the re-verification is

Field Tested Version of MOD-026	Comment	Proposed MOD-026-1
	ensure the applicable Transmission Planner has up to date information regarding the model. **R12** lists activities that could result in an alteration of equipment response which necessitates the need for model re-verification due to field changes.	performed, the 10 year period as outlined in R1 will be reset. **R12.** The Generator Operator shall perform a review of its current excitation system model and model parameters each time an activity that may alter the equipment response is performed. An activity that potentially alters the response of the excitation system and/or power system stabilizer includes but is not limited to: • Exciter, voltage regulator or power system stabilizer control replacement including software alterations that could alter excitation system equipment response • Plant Digital Control System addition or replacement • Plant Digital Control System software alterations that could alter excitation system equipment response • Exciter, voltage regulator, impedance compensator or power system stabilizer settings change The Generator Operator shall either: • Provide documentation that the response has not changed to the Transmission Planner within 90 days of completion of an activity that could have altered equipment response, or • Perform a re-verification in accordance with Requirements R4 and R8 within 180 days. Once the re-verification is performed, the ten year period as outlined in Requirement R1 is reset.
R1.4. Information to be reported related to generator excitation system functions:	**Requirements R2, R3, R4, R7, and R8** addresses information to be reported from the Generator Operator, and associated	

Field Tested Version of MOD-026	Comment	Proposed MOD-026-1
	interactions between the Generator Operator and the Transmission Planner.	
R1.4.1. Verified manufacturer and type of excitation system/voltage regulator control system (static, brushless, rotating, etc.).	Field Test Ver. R1.4.1 is covered by proposed R4.	**R4.** The Generator Operator shall provide to the Transmission Planner the following unit specific information within 90 calendar days of completion of the excitation system model verification: **1)** Manufacturer, model number if available, and type of excitation system (for example: static, ac brushless, dc rotating). **2)** Generator model structure and data (reactances, time constants, saturation factors, rotational inertia) **3)** Excitation system model structure and data for the closed loop voltage regulator (including main exciter if so equipped). **4)** Reactive compensation settings (for example: reactive droop, line drop, differential compensation), if utilized. **5)** Model structure and data for power system stabilizer, if so equipped.
R1.4.2. Verified model for each excitation system/voltage regulator control system with associated gains, time constants, and limits.	Field Test Ver. R1.4.2 is covered by proposed R4. The model data is specified as part of the list in R4. In additional to providing additional specificity, the current draft Standard's R4 contains specific reference to Generator model data that was not part of the Field Test Version of the Standard. This is because the generator and excitation system data are all included in the closed loop system being verified.	
R1.4.3. Verified static set points for under and over excitation limiters.	The information on verified static set points in Field Test Ver. R1.4.3 has been removed.	

Field Tested Version of MOD-026	Comment	Proposed MOD-026-1
	Static set points for UEL and OELs will be addressed in MOD-025 and/or PRC-019.	
R1.4.4. Verified line drop compensator settings.	R1.4.4 is covered by R4. See additional comments above for NERC Field Test Ver. R1.	
R1.4.5. Open circuit test response data showing generator field voltage and generator terminal voltage (exciter field voltage and current data for brushless units).	Additional options beyond the specific Open circuit test referenced in Field Test R1.4.5 have been included in R8.	**R8 is mapped above**
	R10 is a new requirement which provides the opportunity for a technical exchange between the GO and the TP and/or PC regarding the verified documentation specified in R8.	**R10.** The Generator Operator shall provide a written response within 90 calendar days after receipt of a Transmission Planner's or a Planning Coordinator's written comments detailing technical concerns with the Generator Operator's excitation system model verification documentation. That written response shall either: • Indicate what changes will be made to the excitation system model, or • Provide the technical basis why no changes will be made.
R1.4.6. Verified model for each power system stabilizer with associated gains, time constants, and limits.	Same comments apply to Field Test Ver. R1.4.6 as noted directly above for Field Test Ver. R1.4.2.	

Field Tested Version of MOD-026	Comment	Proposed MOD-026-1
R1.4.7. Method of verification, including the date of verification, with the voltage regulator in the automatic voltage control mode.	Field Test R1.4.7 is covered in R8 Reference to "the voltage regulator in the automatic voltage control mode" in the Field Test Version Standard was removed in this draft Standard as it is a statement of the obvious.	**R8 is mapped above**
R2. The regional reliability organization shall provide its generator excitation system data verification and reporting procedures, and any changes to those procedures, to the generator owners, generator operators, transmission operators, planning authorities, and transmission planners affected by the procedure within 30 calendar days of the approval.	Regional Reliability Organization applicability is eliminated and functional entity responsibility is defined. This proposed Reliability Standard in its entirety (**R1 – R12**) specifies continent-wide verification and reporting procedures.	**R1 – R12 are mapped above**
R3. The generator owner shall follow its regional reliability organization's procedures for verifying and reporting its models and data associated with the generator excitation system functions per requirement 1.	Regional Reliability Organization applicability is eliminated and functional entity responsibility is defined. **R1, R4, R7, R8, R9, R10, R11, and R12** defines the procedures to be followed by the Generator Operator for verifying and	**R1, R4, R7, R8, R9, R10, R11, and R12 are mapped above**

Field Tested Version of MOD-026	Comment	Proposed MOD-026-1
	reporting its model and data.	
	R2 and R3 are new requirements which, upon request of the Generator Operator: 1) Ensures the Transmission Planner provides a list of acceptable excitation system model data sheets 2) Ensures the Transmission Planner provides unit specific excitation system model data currently being utilized in the Transmission Planner's dynamic database	**R2.** The Transmission Planner shall provide the Generator Operator a set of model data sheets for the acceptable excitation system models (models cannot be confidential or proprietary) for use in dynamic simulation software, with each data sheet including the excitation system model block diagram structure and data requirements, within 30 calendar days of a request from the Generator Operator. **R3.** The Transmission Planner shall provide the Generator Operator the unit specific data contained in the Transmission Planner's dynamic database from the current in-use excitation system model, within 30 calendar days of a request from the Generator Operator.
	R5, R6 and R7 are new requirements which: 1) Ensures that the Transmission Planner tests the developed model to assess if the model is useable in the dynamic simulation software 2) Ensures the Generator Operator is promptly notified that the model is useable or not 3) Provides a process for the Generator Operator and Transmission Planner to work together to resolve usability issues.	**R5.** The Transmission Planner shall determine if the excitation system model is useable by including the excitation system model in dynamic simulation software and substantiating that: 1) A no-disturbance simulation contains no transients. 2) For an otherwise stable simulation, a disturbance simulation results in the equipment exhibiting positive damping. **R6**. The Transmission Planner shall inform the Generator Operator whether the excitation system model is useable or not within 90 calendar days of receipt (R4). If the excitation system model is not useable, the Transmission Planner shall provide the Generator Operator with a description of the problem and any relevant details. **R7**. The Generator Operator shall provide a written response within 90 calendar days following notification by the Transmission Planner that the excitation system model is not useable. The Generator Operator's response shall either:

Field Tested Version of MOD-026	Comment	Proposed MOD-026-1
	It is stressed that a "useable" model is simply a model which does not unexpectedly negatively impact otherwise stable dynamic simulation. An example might be a model which contains a parameter that has been incorrectly scaled thus causing dynamic simulation solution convergence issues. A model can be "useable", but it may or may not be representative of the installed equipment performance.	• Indicate what changes will be made to the excitation system model, or • Provide the technical basis why no changes will be made. .

Standards Announcement

Comment Periods Open
February 17 – April 2, 2009

Now available at: http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html

Two Proposed Standards for Project 2007-09 — Generator Verification

The Generator Verification Standard Drafting Team (Project 2007-09) has posted drafts of two proposed standards for 45-day comment periods. Mapping documents that compare these standards with field-tested versions are also posted. The comment periods are now **open until 8 p.m. EDT on April 2, 2009**. Please use the electronic forms (see links below) to submit comments. If you experience any difficulties in using the electronic forms, please contact Lauren Koller at 609-524-7047. Off-line, unofficial copies of the comment forms are posted on the project page: http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html

PRC-024-1 — Generator Performance During Frequency and Voltage Excursions

Electronic comment form:
https://www.nerc.net/nercsurvey/Survey.aspx?s=aaa41c53fb80462e8783344cd70f6ce0

Note: the drafting team will hold a WebEx to explain the concepts in proposed standard PRC-024-1 on February 26 from 2 p.m. to 4 p.m. EST. More information about the WebEx will be sent in a separate announcement.

MOD-026-1 — Verification of Models and Data for Generator Excitation System Functions

Electronic comment form:
https://www.nerc.net/nercsurvey/Survey.aspx?s=7b8a364e930f4c1a87a792881c9b94dd

Background

Project 2007-09 includes six standards to address generator verifications needed to support bulk power system reliability – four proposed standards and revisions to two existing standards. The purpose of the project is:

- To ensure that generators will not trip off-line during specified voltage and frequency excursions or as a result of improper coordination between generator protective relays and generator voltage regulator controls and limit functions (such coordination will include the generating unit's capabilities).
- To ensure that generator models accurately reflect the generator's capabilities and operating characteristics.

More information is available on the project Web page:
http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html

Standards Development Process

The Reliability Standards Development Procedure contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

For more information or assistance,
please contact Shaun Streeter at shaun.streeter@nerc.net or at 609.452.8060.

Russell A. Noble
Cowlitz County PUD
Yes
Did you mean to say above that Generator Owners typically do not have in-house expertise and would have to either hire...? YES - Cowlitz as a Generator Owner does not have the in house expertise. Delays result in our efforts to obtain modeling information as we try and find consultants willing to do the work. The Generator Operator is the entity which should be held responsible.
Yes
Yes
No
I think you meant for the Generator Operator to supply the generator data.
No

Yes
Yes
Yes agree with approach and the 5% capacity factor
Yes
No
Yes, agree with proposed phase in period for unit excitation system verification
Group
NERC Event Analysis & Information Exchange staff
Robert W. Cummings
NERC
No
Comments: Although verification (not validation) of generator equipment settings and testing should be the responsibility of the GO, validation of generator models response to actual system events should be done by the Reliability Coordinator. This offers independent oversight of the validation. Also, validation to system events should be done for multiple events. This provides better insight to generator excitation and control performance over a wider range of conditions than a single staged test.
Yes
Ten years is an adequate backstop for re-testing. However, it should additionally be tempered by performance differences observed during validation to actual or staged system events. Repeated matching of model performance to events should also make a ten year test unnecessary.
Yes
As long as no actual differences are observed during performance comparisons to actual system events, this is an acceptable shortcut.
No
See below.
Yes
It seems that having an overall generator testing standard in place on the dynamic parameters listed in MOD-013 would be a prerequisite for an excitation testing standard.
No
The peer review process in R10 assumes that since the GOP operates the equipment, they are a technical authority on its modeling and behavior. Historically, that has been not necessarily correct, even of the owners of the equipment. Changes to excitation system models should be peer reviewed. However, a dispute resolution process would be needed for disagreements between the owners/operators and the peer team.
Yes
No (disagree with approach)
Units with a low capacity factor may well still be frequently needed, albeit for short but crucial periods, to support the system during peak load. Further, they may often be used in â €œshoulder periodsâ€ when primary resources are out on maintenance.
No, instead use the approach below:
There are a number of units that, through switching, can operate in multiple interconnections, making it hard to decide where they belong. To reduce complexity in administration, avoid confusion, and to have a more level playing field in North America, the standard registration thresholds of units â ‰ ¥ 20 MVA per machine and â ‰ ¥ 75 MVA per plant should be applied.
Yes
It is essential that the Planning Coordinator and Reliability Coordinator be allowed to designate

other critical units. In some cases, despite their size, the aggregation of a number of small units can have a significant impact on the dynamics of an area. One example is the transfer capability across the state of Maine, which is influenced by the dynamics of the multiple small hydro units in the state. Similarly, the dynamic performance of small units may be critical to reliability in some local areas such as New Brunswick and Nova Scotia.
Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standardâ€™s approval date
It seems that having an overall generator testing standard in place on the dynamic parameters listed in MOD-013 would be a prerequisite for an excitation testing standard.
Individual
Brent Ingebrigtson
E.ON U.S.
Yes
No
E.ON U.S. believes that verification data and model results should not change over time. Therefore, a re-verification schedule is not necessary. E.ON U.S recommends that verification be required whenever new equipment is installed.
No
E.ON U.S. does believe that the proxy process described is reasonable. As expressed in the response to question 2, E.ON U.S. believes that, absent installation of new equipment, a re-verification schedule is unnecessary.
Yes
No
E.ON U.S. believes that entities have no incentive to use inaccurate data when conducting verifications studies. Strict data verification standards are in this instance an unproductive use of resources.
Yes
No
While E.ON U.S. appreciates that the concern over requirements applicable to both existing and future technologies, the lack of any specific guidance on process and verification methodologies invites differing interpretations of the standard. This lack of specificity makes compliance problematic.
Yes agree with approach and the 5% capacity factor
Yes
No
The generation owner/operator is in the best position to identify those facilities that require verification studies. Transmission providers should not be allowed to independently impose compliance obligations upon other parties. Any process to allow imposition of additional compliance responsibilities should be overseen by the appropriate regional reliability organization.
Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standardâ€™s approval date
E.ON U.S. believes that the staggered implementation time tables for the various standard requirements could needlessly complicate initial compliance efforts. E ON U.S. requests that the SDT review these deadlines and standardize using the most lenient implementation period set forth in the current draft. E.ON U.S. recommends that the standard explicitly state in the purpose statement that voltage regulators be included in excitation system models. Voltage regulators are explicitly mentioned in R4.3 and R12. E.ON U.S. recommends that study data inputs and results only be made publicly available pursuant to Requirement 2. Depending on arrangements with vendors, actual model configuration may be proprietary and require confidential disclosure

arrangements

FEUS
Yes
Yes
Yes
Yes
No
No
No, This allows for ambiguity in the interpretation of the standard by both the entity and the requlator.
No
This leaves ambiguity in the standard that can be to misinterpretation by the entity or the agency. Some guidelines should be provided for standardization to avoid confusion.
Yes agree with approach and the 5% capacity factor
No, instead use the approach below:
If the modeling methods are approved and are valid, why do entities have to prove they are right? Test the models on several units of different sizes and configurations to determine their accuracy. If modeling methods aren't accurate, fix them instead of requiring the industry go through the huge expence of testing hundreds of units that have been previously modeled. I also don't see the rationale for the differences in MVA testing requirements between RRCs. The 200 MVA rating for facilities (as specified for the eastern systems) should be the same if this standard is adopted.
No
Yes, agree with proposed phase in period for unit excitation system verification
The excitation models as currently required are comprised of testing and data collection to determine the variables for the model parameters. How does additional testing, over and above what was done to construct the model, accomplish anything and how would it be any different than original testing to complete the model?
Individual
Jianmei Chai
Consumers Energy Company
No
Generator Owners and Generator Operators do not need or use an excitation system model. This model is properly owned by those who need and use it, i.e., the Transmission Planner or Transmission Owner. The Generator Owner should be responsible only for providing input data for the model. These data include such items as: - Manufacturer (and model, if available) and type of excitation system. - Rise times, reactances, time constants, gains, and saturation factors. - Rotational inertia - Reactive compensation settings, if any. - Power system stabilizer settings, if any. - Other stability schemes, if any. Given periodic verification of these data from the Generator Operator, it should be the responsibility of the Transmission Planner to create a model that meets the needs of the Transmission Planner. Since the Generator Operator doesn't need this model, requiring the Generator Operator to hire consultants to create a model needed by other entities is simply errant nonsense. Has the SDT verified that there are adequate consultants available to meet the 2-year time window for the myriad of Generator Operators who would be tasked with creating a model they do not need?
Yes
Ten years is appropriate with the caveats listed in Requirement 12.

Yes
This looks to be a "sister unit" type of proxy. If so, it should be introduced as a new definition.
Yes
We believe that generator data must be verified; however, the concept of staged tests is troubling as such testing can provide a local challenge to the integrity of the BES. Such testing should be required to be well coordinated with the Transmission Operator. Our experience shows start-up testing of new exciters has occasionally resulted in significant local impact to the transmission system, e.g., over-voltage on 345 kV systems.
No
No
It is the Transmission Operator and the Transmission Planner's task to determine if the model matches. The Generator Operator is uniquely unsuited to monitor transmission lines and determine if the model works. If the Transmission Planner's model doesn't properly reflect reality, the Transmission Planner should be required to meet with the Generator Operator and discuss the issue. The Generator Operator should then be required to reverify the data in question.
Yes
Providing minimal specificity allows many approaches to meet the requirements. This accommodates the many present and future excitation technologies and monitoring techniques.
No (disagree with approach)
We disagree with the approach. Some systems have very large peaking units which arguably are more likely to be in service on days when the BES would be challenged. Thus, modeling data should be collected for these units and model cases run including these data. Additionally, the requirement should only apply to peaking units which meet the applicability criteria (i.e. Capacity factor greater than 5% for the last 3 years and greater than the MVA indicated in 4.0)
Yes
We believe the MVA thresholds are appropriate and pick up the vast majority of interconnection (MVA).
No
No, the phase in period for unit excitation system verification should be (please specify below)
The phase-in period of 2 years is likely to be insufficient unless there are significantly more consultants available than we think there are, as many Generator Operators may need to hire a severely constricted resource.
N/A
N/A
It is our opinion that the SDT made a fundamental error in assigning the modeling to an entity that doesn't need the results of the model. To correct this error, this Standard needs very significant revision. As it stands, the Draft Standard imposes irrational requirements upon the Generator Operator.
Individual
Ben Johnson
Wisconsin Public Service
Yes
The Generator Owners, instead of Transmission Planners, are the logical entities to verify the proper functioning of the excitation system functions, but not the verifications of hypothetical parameter values of a model used to emulate the exciters' function. The generator Owners should, for example, verify that the AVR holds set terminal voltages under normal operating system conditions, as well as response to system changes in conformance with the stated Response Ratios as designed. This does not mean, however, that it would be necessary to confirm forward gains, transducer time constants, excitation saturation constants, feedback-loop gains and time constants, etc. are indeed of the same value as used in a hypothetical model. This is due to two reasons: 1) the particular model chosen by the transmission planner is known to be an approximation of the facilities' functions, and therefore the parameters are not unique; 2) instrumentations necessary for verification of specific parameters are not generally available in the industry.
Yes
No
The sister unit philosophy should be applied to identical units within a generator operators fleet with identical settings, but not be limited to the same physical site.

Yes
No
The model generally in use to simulate generator dynamic responses is a hypothetical model based on fictitious parameters. For instance, the direct-axis and quadratual-axis impedances are calculated design values, and not a measurable physical quantity, as are the transient and subtransient time constances. The inertial constance involve the whole rotor and prime-mover assembly, and cannot be easily quantified.
Yes
Yes
I agree with the methodology of the SDT to leave the test methods required under R4 out of the standard. It is a good philosophy to not limit future advancements in testing because the standard specifially calls for a step voltage test or UEL / OEL bumps. I think the SDT should consider this methodology in future drafts as applicable.
No (disagree with approach)
Threshold should be set around 20% to remove the requirements from those operators that may have a large fleet of small CT's that operate only in minimal peakng mode, but would qualify under the multiple units on the same site provision. These units have minimal impact on the dynamic model.
No, instead use the approach below:
The provisions of multiple generators at one location requiring testing of units above 20MVA rating puts too much ownerous on operators at CT sites with multiple small CT's that would act differently during an event and have minimal effect on the dynamic models.
Yes
Determined critical in the model or in a constrained area of the system.
Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standardâ€™s approval date
At the Web-ex I thought the phase in was 10% per year with 100% by end of yr 11. This makes it sound like a different phase in will be used but no details on % at the 2, 6, and 11 year windows.
At plants with 200MW or higher capacity, it is unreasonable to assume multiple units of 20MW to malfunction simultaneously. Therefore, applying the standard to each unit of >/= 20MW if these are at the same contiguous plant of combined capacity of 200MW is placing unreasonable burden on owners of small generators. One must reason that, in the contest of the whole eastern interconnect, comprising a total capacity of 600,000MVA and higher, individual generators of less than 100MVA would not impact the system to any significant degree except for very localized regions.

The Generator Owner (GO) should be responsible for model verification. The GO has direct access to the equipment - not the GOP. The GO can schedule any required operational testing with the GOP in the same way that the GO schedules any other operational testing requirement. In addition, the GOP and the GO can be two separate companies with their only relationship established by contract. In these situations this standard, as written, would place the burden on the GOP to try to renogoiate the contract with the GO to cover the expense and pursuade the GO to perform the model verification when the real responsibility belongs to the GO.
Yes
Yes
Yes
This same approach should be used for question #1. It is the Generator Owner (GO) that has this information and access to the equipment.
No
No

This should be the role of the Generator Owner (GO) - the GO has the data, the GO has the equipment, and the GO can schedule any required operational testing through the GOP.

In ERCOT the Generation Owner should be responsible. This is a NERC Functional model issue, and I understand the GOP will be responsible in the majority of the country.
Yes
Yes
No
Luminant does not disagree that the information needs to be provided. However, the generator model data is already required in NERC Standards MOD-012 adn MOD-013 (R1.2). The Generation Owner should not be held doubly liable for the same informatin in two Standards. This requirement for the Generator data is already required elsewhere and is not needed in this standard.
No
Yes
Yes
Yes agree with approach and the 5% capacity factor
Yes
No
The SDT is tasked with developing requirements for applicability across North America. Regions have the ability to develop more stringent requirements based on regional needs, and through various regional requirements development processes. Allowing the Transmission Planner or Planning Coordinator to expand the applicability of the NERC Standard on an individual resource basis (without industry input, balloting, etc.) would circumvent the FERC approved procedures for development of reliability standards.
Yes, agree with proposed phase in period for unit excitation system verification

Note that I also agree with allowing credit for verification of excitation systems within the last 5 years of the Standard's approval. The form would not let me select both yes answers.
Possible regional variance on applicability with GOP vs. GO in ERCOT.

AEP believes that It would be more appropriate to designate the Generator Owner for these responsibilities.
No
AEP believes that the period should be longer. In fact, verification should only need to be done once on older units that do not now have good commissioning test documentation. Beyond that, it should only need to be done if there is an applicable equipment upgrade or an intentional readjustment of settings. We question predicating the periodicity on the expectation of a significant variation in equipment performance due to aging alone.
No
While AEP agrees that the proxy approach to verify multiple, identical units based on system model verification for a single unit makes sense, it is unclear why criterion "b" (the units are rated at less than or equal to 250MVA) would apply, provided criteria "a", "c", and "d" are also met. It is suggested that criterion "b" as listed in the Comment Form and as referenced in Requirement R1.2 be removed from the Standard.
Yes
Yes
Generator parameters are needed to support modeling. Later phases could pick-up unknowns identified by examining discrepancies between actual operation and modeling.
No
AEP does not agree that the Generator Operator should not be responsible to provide documentation that the system model matches the recorded response. That responsibility should lie with the Generator Owner to review and decide how to have that analysis performed and to what extent documentation will be prepared to provide the required verification.
Yes
We are agreeable since there are different kinds of excitation systems.
No (disagree with approach)
Seldom run units could end up being run at peak times in areas that may be stability limited. Applicability should be driven by need for verification which historically, has been tied to stability performance and constraints.
No, instead use the approach below:
The need for excitation data and model verification has been driven by plant and system stability needs. We believe that the applicability in the standard should be driven by the same. We would go so far as to suggest that identification of applicable units should be determined by the TP and PC through a process that includes planning study results and operating experience, and that the standard should not specify a blanket applicability unrelated to the stability driven need.
Yes
Criteria should be units or plants whose operation is limited by transient or small-signal instability, or that are located in areas that may be subject to stability constraints. Why not rather impose the applicability in the fashion of what is being asked here, that the TP and PC identify through a process which units should be verified, not a blanket applicability as is in the current draft.
No, instead of allowing credit for verification of excitation systems within the last 5 years of the Standardâ€™s approval date, instead would recommend (please specify below)
that the areas with the greatest instability be addressed first.
No known need for regional variances
CONFLICT: The added expense posed by the requirements of this standard must be sought through tariff changes with applicable regulatory authorities. COMMENTS: A strong cost-benefit analysis is required to receive the necessary cost recovery.
(1) The added expense to fulfill the requirements of this standard where such model verification is not generally being done could be high. Since this is a new imposition on the industry in that required excitation model verification has never before been imposed in many areas, this leads

to the question of cost versus reliability benefit of what is being proposed. We request that the SDT please comment more on the cost vs. reliability benefits. (2) With respect to R2, we suggest that it be revised and expanded as follows: "The Transmission Planner shall provide the Generator Operator a set of model data sheets for the acceptable excitation system models (models cannot be confidential or proprietary) for use in dynamic simulation software, with each data sheet including the excitation system model block diagram structure and data requirements and a system dynamics model, within 30 calendar days of a request from the Generator Operator." (3) With respect to R6, revise and expand the last sentence as follows: "If the TP determines the excitation system model is not useable, the TP shall provide the Generator Operator with a description of the problem and any relevant details, including the system dynamics case used in the evaluation." (4) With respect to last sentence in R9, revise and expand as follows, "â€¦. after the receipt of a request that includes the measured data following a system disturbance and a suitable system dynamics case associated with the system disturbance.

Yes, agree with proposed phase in period for unit excitation system verification
The SPP Generation Working Group members have several concerns related to this standard. The skill-set required to perform these tests do not currently exist among Generator Owners and there is a great concern that the limited subset of consultants that will be able to perform this verification will not be able to complete these tasks within the suggested ten year period. Given the limited subset of parties that will perform these tests, the cost will be onerous on the Generator Owners while not providing significant benefits. SPP Generation Working Group members do not know of any issue that these enhanced requirements would have helped avoid and therefore see little value, given the potentially high cost, to these expanded requirements. SPP Generation Working Group members generally oppose the current version of this standard.

The standard appears to be too unnecessary complicated. We have the following suggestion for simplification. 1)Requirements R1, R4, R11 and R12 are the only reliability related requirements and should be kept. 2)R8 is part of providing data and should be a part of R4 3)All other requirements are simply indicate process and do not belong in the standard. They should be part of a white paper on the subject or in an appendix.
Group
Exelon Corporation
David Schooley
Exelon Corporation
No
Exelon believes that model verification should be a coordinated effort between the generator owner and the transmission planner. Transmission planning organizations have the expertise to implement and test the models in software, while the generator owners have the necessary access to the equipment in the field. Most generator owners do not have the software and the necessary personnel with the expertise to perform the modeling and model testing required by this standard.
Yes
It is difficult to determine whether or not 10 years is an appropriate period for re-verification without knowing the details of the required testing.
No
Why there is a limitation of unit size of 250MVA or less. The proxy unit approach should be extended to identical units of any size for a two unit station as half of the capacity at that station has been verified as compared to a multi unit site say having 6 250MVAs and verifying only one unit.
Yes
No
Verification of the generator data will be useful, but needs to be considered at a later date.
No
Exelon feels that the standard should define the acceptance criteria. If the acceptance criteria is left up to the generator owners, then the TOs may have to deal with multiple acceptance criteria within a single region. At the same time, a single generator owner may have to work with multiple TOs, which will lead to inconsistency if the definition of the acceptance criteria is left up to the TO.
Yes
Yes agree with approach and the 5% capacity factor

Yes
Yes
Exelon is concerned about the use of the term "critical" in this context because it implies the same level of criticality that would be used to put a station on the critical asset list. A small generating station may be sufficiently close to another station that it affects the dynamic behavior of the generators at the second station. The Transmission Planner should be able to identify the units at the smaller station as applicable to the standard without calling them critical units. Exelon does appreciate the need for guidelines regarding the units that can be indentified as applicable to MOD-026.
Yes, agree with proposed phase in period for unit excitation system verification
The proposed standard and comment form presuppose the generator owners have the expertise necessary to model and simulate the excitiation systems on the units they own. They do not in most cases. Software requirements need to be considered. Not all transmission planners use the same software for dynamic simulations. A single generation owner may have units in multiple regions involving different transmission planners and would have to provide models for more than one simulation program. The standard needs to allow the Transmission Planner/Operator/Owner to provide expertise to the generator owner. The comment form and the WebEx meetings are more specific regarding software simulations than what is specified in the draft standard. The software simulations should be specified in more detail in the standard.

Wisconsin Electric
No
See response to Question 5. Providing model data and parameters is possible, but the requirement to validate the model for an actual switching event requires a cooperative effort between the GOP and the TP/TOP/TP. Since the stability and reliability of the overall transmission system is the goal, it is necessary for these entities to have more responsibility for proper excitation system modeling. As it stands this draft standard puts all the responsibility on the GOP.
Yes
No
We believe that units rated up to 850 MVA should be able to take advantage of this approach.
Yes
No
No
The requirements in R8 and R9 are not clear to us. The term "recorded response" needs to be defined, and the term "voltage excursion" needs to be quantified. These requirements infer that the GOP already has some documentation of what a "correct" response looks like, which is not the case. The requirement to validate the exciter model by monitoring its response to a real or staged event is not a simple matter. For a staged event such as switching a line, the TO or TOP will need to be actively involved in the process, and should have some responsibility assigned to it in the standard. Likewise, if an ambient switching event is used to validate the model, the TO/TOP would be the only entities in a position to know about it, since such operations may not be known by the GOP. In summary, this validation depends on shared responsibilities among the entities, and the requirements in this standard should properly reflect this.
Yes
Yes agree with approach and the 5% capacity factor

The Generator Operator does not have direct access to the equipment. The Generator Owner is the correct Functional Model entity that has direct access to the equipment and the authority to perform testing of equipment. All responsibilities assigned to the Generator Operator in the proposed standard should be reassigned to the Generator Owner.
Yes
A ten-year interval is acceptable given the conditions in Requirement R12.
No
Unit testing has in the past identified different responses from identical units with common settings. All units with identical design and settings should be tested unless records of actual system events demonstrate that all of the units respond the same.
Yes
The entity specified in Question 4 does not agree with the entity specified in Requirement R4. As stated in our response to Question 1, we believe the Generator Owner is the correct entity to provide the data; not the Generator Operator. We agree with the approach subject to revising the responsible entity.
No
Expanding the scope to include verification of generator data will not provide a significant improvement in the overall modeling of excitation systems.
No
As stated in our response to Question 1, we believe that the Generator Owner is the correct entity to provide the data; not the Generator Operator. We agree with the approach subject to revising the responsible entity.
Yes
Reliability Standards should focus on what is required and not how to meet the requirement. Further, it would be impractical to specify verification details universally applicable to all situations. The peer review process provides appropriate safeguards to ensure that appropriate methods are used for verification.
Yes agree with approach and the 5% capacity factor
We agree with this approach to exclude units with low capacity factors provided that Planning Coordinators or Transmission Planners are allowed to identify additional applicable units beyond those specified in section 4.1.1 based on criticality to system reliability. Cases exist where large generating units with low capacity factors are operated only during the most stressed operating conditions. In such cases accurate modeling of these units may be critical to reliable operation of the bulk electric system.
Yes
We agree with the general approach to base the number and size of applicable generating units on the objective of validating models for 80 percent of the installed capacity on an Interconnection provided that Planning Coordinators or Transmission Planners are allowed to identify additional applicable units beyond those specified in section 4.1.1 based on criticality to system reliability. In the event the Planning Coordinator or Transmission Planner is not permitted to identify additional units, the objective should be changed to validate models for a greater percentage of the installed capacity. We do not have data to verify whether the unit size thresholds specified in Requirement R4.1.1 correspond to 80 percent of the installed capacity on an interconnection, and respectfully suggest that it is the responsibility of the SDT to provide such verification.
Yes
The Planning Coordinator or Transmission Planner should be permitted to identify additional units

for applicability of the Standard based on the results of generator interconnection studies or other studies that demonstrate the criticality of correct settings on system reliability, e.g. studies demonstrating sensitivity of a stability based System Operating Limit to correct equipment settings and functionality.
No, the phase in period for unit excitation system verification should be (please specify below)
The proposed impmentation plan is too long. We recommend a five-year implementation with a requirement that units representing 20 percent of installed capacity be tested each year. We are concerned that an eleven-year implementation plan does not adequeately promote system reliability, and that having only three milestones will place a burden on system operators to schedule testing because Genator Owners may wait until years two, six, and eleven to schedule testing instead of spreading the tests out over the implementation period. The form will not accept more than one box checked above, but "Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standard's approval date" should be checked.

Progress Energy, Inc.
No
The Generator Owner is the correct entity for this responsibility. It must be the entity that would be the most able to obtain the attention of the manufacuturer and have the means to accomplish the validation. The entity must have the financial incentives to perform the function and must be knowledgable about the plant operation. The entitiy that would be the best source to coordinate the testing could be required to verify the models. In our opinion the functional model specifies Generator Owner as it requires a generator owner to "verify generating facility performance characteristics". For the foregoing reasons this responsibility should not be assigned to the Transmission Planner.
Yes
As long as there is a requirement such as R11. The second bullet of R11 might also note that the Generation Operator must verify for the model for the first time if the model was derived from a 'sister' unit or repeat the verification on one previously verified. Despite R12, some communication between the Generation Operator and the Transmission Operator within the 10 year period would be reassuring that nothing has changed. Because ten years is a long time, the Generator Owner should be required to respond upon request of the Transmission Planner confirming that nothing has changed.
No
We encourage the proxy unit approach. However, we do not agree completely to the conditions illustrating proxy unit approach. (1) MVA rating should be expanded to say "MVA nameplate rating" . We believe it would be prudent to specify that units of different manuafacturers, even if they have the same nameplate rating are not proxy units, (2) If the units are identical, we

believe the 250 MVA threshold criterion is too restrictive. We believe the limit should be at least 350 MVA to cover combined cycle units of existing technology.
Yes
Since the exciter model and the generator model are components of the closed loop system being verified, the process must ensure that the Transmission Planners dynamic database is updated with the generator data and the excitation system data utilized for verification. Relying on generator data that was originally provided for MOD-012 to be the same data that was used for model verification would not be advisable. There are countless opportunties for generator data submitted for MOD-012 to be inconsistent with generator data used in models in the excitation system verification process. In order to close this loop, we suggest that R3 be slightly modified to read: "The Transmission Planner shall provide the Generator Operator the unit specific data contained in the Transmission Plannerâ€™s dynamic database from the current in-use excitation system and generator model, including the applicable generator model parameter's MVA base, within 30 calendar days of a request from the Generator Operator." AND R4 Item 2 should have an additional sentence at the end which reads: "This data only has to be provided in those instances where generator model data was changed in order to obtain a verified excitation system model". These language modifications ensure that dynamic databases are populated with the correct data for both the excitation system and generator models that have been verified while minimizing burden on the generation entity responsible for model verification.
No
To include generator data verfication beyond excitation system modeling data is a significant burden to the Generation Owner not supported by the benefits to be gained.
Yes
The functional model entity responsible for the model's verification has to be given the responsibility of demonstrating that the provided model's response matches the recorded response. The "goodness of fit" between the model response and the equipment response should be left to the generator owner but subject to Transmission Planner review ref. R10.
Yes
We agree with the SDT approach of not developing this standard like a technology specific procedural manual. The development of verification Requirements stating "what is required" and leaving the technical details up to the personnel performing the verification will result in improved dynamic models while affording sufficient technical latitude.
No (disagree with approach)
The 5% capacity factor is an inappropriate basis for an exemption since it would allow significant blocks of generation (i.e. plants of several hundred MW) to be exempt. Such amounts of generation may have a significant impact on the stability of nearby generating units or such units may themselves have stability issues that need to be understood via valid studies. Examples would be plants with multiple combustion turbine units (particularly simple cycle oil burners) that are rarely run. However, when they are run (i.e. during peak system load times), the grid may be already be stressed and operating with reduced stability margin. The possibility also exists that while the exempted generation may have a capacity factor of less than 5%, this could quickly change due to unanticipated system conditions or the extended unavailability of other generation (due to severe damage for example). Therefore, the subject generating units could end up being run for a significant length of time without the benefit of having been properly analyzed by the Transmission Planning organization. The â€œaverage over the last three calendar yearsâ€ methodology further contributes to this possibility, introducing a time lag in the process. Based on the above discussion, the 5% capacity factor exemption should only be allowed when it would not be expected to significantly impact the results of stability studies. Allowing the Transmission Planner to make this judgement is most appropriate since A) that organization is in the best position to make the determination of the impact on stability and B) that organization is responsible (via TPL standards) for ensuring the stability of the grid and connected generating units. In lieu of the blanket 5% exemption, the following is proposed. 1. Delete â€œâ€¦ and with an average Capacity Factor of greater than 5% over the last three calendar yearsâ€ in all places in 4.1.1.1, 4.1.1.2 and 4.1.1.3 2. Add new Applicabilty 4.1.1.4 stating â€œGenerating facilities with capacity factors less than 5% over the last three calendar years may be exempted with written concurrence from the applicable Transmission Planning Authority. The written concurrence provided by the Transmission Planning Authority shall include the basis for any such exemptions.â€ alternative to (2.) could be the reponse to Q9 below.
Yes
However, the MVA values MUST be coordinated with the MVA thresholds in MOD-010 to 012 and in proposed TPL-001 standards. Supporting data (circa 2003) can be found from the link below which provides a spread sheet titled â€œExisting Generating Units in the United States by State, Company and Plant, 2003.â€ http://www.eia.doe.gov/cneaf/electricity/page/at_a_glance/gu_tabs.html
Yes

Add to Applicability a 4.1.1.4 stating â€œGenerating facilities that do not meet the applicability requirements 4.1.1.1 - .3 may be included when their performance is found to create or contribute to reduced reliability of the BES when requested by the applicable Transmission Planning Authority. The written request provided by the Transmission Planning Authority shall include the technical basis for any such inclusion (e.g. must run for reliability, voltage, or stability needs).â€
Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standardâ€™s approval date
The first time period should be 3 years (10%). It is anticipated that the first units will take significantly longer than subsequent testing. Although this factor is already being considered in proposed time periods, there will probably be a significant shortage of testing services at the beginning of the testing window.

Consider model verification for rotational inertia, which can have a significant effect on modelling.

No

As stated in our response to Question 1, we believe that the Generator Owner is the correct entity to provide the data; not the Generator Operator. We agree with the approach subject to revising the responsible entity. Agree that peer review by TP/PC is important for verifying the match.

Yes

Yes agree with approach and the 5% capacity factor

Yes

Yes

No, the phase in period for unit excitation system verification should be (please specify below)

We recommend a five or ten-year implementation with a requirement that units representing 20 or 10 percent, respectively, of installed capacity be tested each year. We are concerned that having only three milestones will place a burden on system operators to schedule testing because Genator Owners may wait until years two, six, and eleven to schedule testing instead of spreading the tests out over the implementation period.

No

The Generator Owner is the correct entity for this responsibility. It should be the entity that would be able to obtain the attention of the manufacuturer and have the means to accomplish the validation. The entity should have the financial incentives to perform the function and should be knowledgable about the plant operation. The entitiy that would be the best resource to coordinate the testing should be required to verify the models. In our opinion the functional model specifies the Generator Owner as it requires a generator owner to "verify generating facility performance characteristics". For the foregoing reasons this responsibility should not be assigned to the Transmission Planner.

Yes

We agree as long as there is a requirement such as R11. The second bullet of R11 might also note that the Generation Operator (Owner) must verify the model for the first time if the model was derived from a 'sister' unit or repeat the verification on one previously verified. Despite R12, some communication between the Generation Operator (Owner) and the Transmission Operator, within the 10 year period stating that nothing has changed would be reassuring. Because 10 years is a long time, the Generator Owner should be required to respond if requested by the Transmission Planner confirming that nothing has changed.

No

We encourage the proxy unit approach. However, we do not agree completely to the conditions illustrating the proxy unit approach. (1) "MVA rating" should be changed to say "MVA nameplate rating". We believe it would be prudent to specify that units of different manuafacturers are not proxy units, even if they have the same nameplate rating, (2) If the units are identical, we believe the 250 MVA threshold criterion is too restrictive. We believe the threshold should be at least 350 MVA to cover combined cycle units using existing technology.
Yes
Since the exciter model and the generator model are components of the closed loop system being verified, the process should ensure that the transmission planners dynamic database is updated with the generator data and the excitation system data utilized for model verification. Relying on generator data that was originally provided for MOD-012 to be the same data that was used for model verification would not be advisable. There are countless opportunties for generator data submitted for MOD-012 to be inconsistent with generator data used in the excitation system verification process. In order to close this loop, we suggest that R3 be slightly modified to read: "The Transmission Planner shall provide the Generator Operator with the unit-specific data contained in the Transmission Plannerâ€™s dynamic database from the current in-use excitation system and generator model, including the applicable generator model parameter's MVA base, within 30 calendar days of a request from the Generator Operator." AND R4 Item 2 should have an additional sentence at the end which reads: "This data only has to be provided in those instances where generator model data was changed in order to obtain a verified excitation system model". These language modifications will help ensure that dynamic databases are populated with the correct data for both the excitation system and generator models that have been verified while minimizing burden on the generation entity responsible for model verification.
No
Yes
The entity responsible for the model's verification has to be given the responsibility of demonstrating that the model's response matches the recorded response. The "goodness of fit" between the model response and the recorded response should be left to the generator owner but subject to Transmission Planner review ref. R10.
Yes
We agree with the SDT approach of not writing this standard like a technology specific procedural manual. The development of verification Requirements stating "what is required" and leaving the technical details up to the personnel performing the verification will result in improved dynamic models while affording sufficient technical latitude.
No (disagree with approach)
The 5% capacity factor is an inappropriate basis for an exemption criteria since it would allow significant blocks of generation (i.e. plants of several hundred MW) to be exempt. Units in this class of generation may have a significant impact on the stability of nearby generating units or may have stability issues that need to be understood via valid studies. Examples would be plants with multiple combustion turbine units (particularly simple cycle oil burners) that are rarely generating. However, when they are generating (i.e. during peak system load times), the grid may be already be stressed and operating with a reduced stability margin. The possibility also exists that while the exempted generation may have a historical capacity factor of less than 5%, this could quickly change due to unanticipated system conditions or the extended unavailability of other generation (due to severe damage for example). Therefore, the subject generating units could generate for a significant length of time without the benefit of having been properly analyzed by the Transmission Planning organization. The â€œaverage over the last three calendar yearsâ€ methodology further contributes to this possibility, introducing a time lag in the process.
Based on the above discussion, the 5% capacity factor exemption should only be allowed when it would significantly impact the results of stability studies. Allowing the Transmission Planner to make this judgement is most appropriate since A) this entity is in the best position to make the determination of the impact on stability and B) this entity is responsible (via TPL standards) for ensuring the stability of the grid and connected generating units. In lieu of the blanket 5% exemption, the following is proposed. 1. Delete â€œâ€¦ and with an average Capacity Factor of greater than 5% over the last three calendar yearsâ€ in all places in 4.1.1.1, 4.1.1.2 and 4.1.1.3 2. Add a new section under Applicabilty 4.1.1.4 stating â€œGenerating facilities with capacity factors less than 5% over the last three calendar years may be exempted with written concurrence from the applicable Transmission Planning Authority. The written concurrence provided by the Transmission Planning Authority shall include the basis for any such exemptions.â€ alternative to (2.) could be the reponse to Q9 below.
Yes
The MVA values should be coordinated with the MVA thresholds in MOD-10 to MOD-12 and in proposed TPL-001 standards. Supporting data (circa 2003) can be found from the link below which provides a spreadsheet titled â€œExisting Generating Units in the United States by State,

Company and Plant, 2003.â€ http://www.eia.doe.gov/cneaf/electricity/page/at_a_glance/gu_tabs.html This spreadsheet can be sorted and summed to get an estimate of the percentage generation that would be included. A preliminary look by the DRS suggests that 80% or more would be included.
No
Add a new section under Applicability 4.1.1.5 stating â€œGenerating facilities that do not meet the applicability requirements of 4.1.1.1 - .4 may be included when their performance is found to reduce the reliability of the BES by the applicable Transmission Planning Authority. A written request provided by the Transmission Planning Authority shall include the technical basis for any such inclusion (e.g. must run, reliability, voltage, or stability needs).â€
No, the phase in period for unit excitation system verification should be (please specify below)
The first time period should be 3 years (10%). It is anticipated that testing of the first units will take significantly longer than subsequent testing. Although this factor may have been considered in the proposed time periods, other factors such as the potential shortage of testing services at the beginning of the testing window may not have been considered.
Requirement 1 says testing should occur "for new or existing units within 180 days of commerical operation". We believe the testing should be done before commerical operation.

In general, there should be collaborations between the Generator Owner, Transmission Planner, Generator Operator, and Transmission Operator to meet the intent of model and data verification. However, the requirements of this standard should apply to the Generator Owner and the Transmission Planner. We have reviewed the NERC Functional Model and believe that the Generation Owner should be responsible for those requirements assigned to the Generator Operator in this draft standard. We are concerned that Generator Owners may have to acquire outside sources or develop in-house skills in order to meet the requirements of this standard. However, we feel that the proposed effective date(s) allows adequate time to address these concerns.
Yes
Yes
Yes
We believe that all requirements of this standard should apply to the Generator Owner, not the Generator Operator.
No
MOD-024 and MOD-025 address a generator's real and reactive capability verification and MOD-026 addresses the excitation system verification. It seems desirable to have a MOD standard that address the verification of generator data by the Generator Owner (not the Generator Operator). This can be handled by a new SAR since the scope change of the current SAR could delay the process. In scoping the verification of the generator dynamic data: a) If the existing generator dynamic model data is backed by documentation provided by the generator manufacturer or previous test(however old it is), no verification would be required. b) If there is no documentation (from manufacturer or previous test) supporting the existing generator dynamic model data, saturation, inertia & D-axis parameters (time constants and impedances) have to be verified at the minimum. If the measured D-axis parameters show reasonable agreement with the existing generator dynamic data, it is not required to verify the Q-axis parameters; otherwise the Q-axis parameters need to be verified as well.
Yes
Yes
Yes agree with approach and the 5% capacity factor
Yes
The proposed threshold captures at least 80.5% of the generators owned by Dominion.

Yes
If a unit exhibits transient or dynamic instability for an event but the simulation did not show the same then the excitation system shall be tested for units beyond those specified section 4.1.1.
Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standardâ€™s approval date
SERC - supplement requires members to validate the excitation system model parameters of their generating units within 7 years (dated 2007). MRO â€“draft guideline in field test, not currently in effect.
The SDT should define exactly what the "excitation model" means. At a minimum it should include the AVR, exciter, PSS (if installed) and voltage compensator (if installed). The current document appears to imply that the minimum and maximum excitation limiters (if installed) are not part of the "excitation model." 2. We are concerned that, in order to meet this standard, applicable entities may have to share data and software that may be proprietary and which may vary depending upon vendor(s) selected by the Transmission Planner. R2 states that â€œmodels cannot be confidential or proprietaryâ€. 3. We believe that applicabilty section should be modified so that it only includes entity(ies) defined in the NERC Functional Model. At 4.1.1 it states â€œGenerator Operators of generating facilities:â€ We believe it should state Generator Owner (the term used in functional model). a. We can support 4.1.1.1 if the language is revised to read â€œWith generators that are connected to Eastern or Quebec Interconnections with the following characteristicsâ€¦â€¦â€¦â€¦â€¦â€ 4. The requirement R2 should be restated to read: The Transmission Planner shall provide the Generator Owner a set of model data sheets for the standard (as opposed to acceptable)excitation system models for use in dynamic simulation software, with each data sheet including the excitation system model block diagram structure and data requirements, within 30 calendar days of a request from the Generator Owner. If the excitation system characteristic is such that it cannot be represented by one of the Standard models, the Generator Owner shall be obligated to have a user-written model developed and made it available to Transmission Planner for use in the dynamic simulation software used by the Transmission Planner.

The Generator Owner appears to be the logical choice. GO has the access to the equipment records, GOP may not.
Yes
Years of operating experience has shown that existing excitation systems that are properly maintained typically do not deteriorate to the point where performance is noticeably impacted in less than 10 years.
No
Agree with all requirements except b and d. If the GO/GOP has duplicate units at multiple sites , a re-verification test of one unit should apply to all provided they meet items a and c. The size of the unit (b) nor the physical location (d) do not matter. The MVA rating of the machine should not be an excluding factor for units of the same vintage, rating, manufacturer, and with the same type of excitation system and settings.
No
Since the exciter model and the generator model are components of the closed loop system being verified, the process should ensure that the transmission planners dynamic database is updated with the generator data and the excitation system data utilized for model verification. Relying on generator data that was originally provided for MOD-012 to be the same data that was used for model verification would not be advisable. There are countless opportunities for generator data submitted for MOD-012 to be inconsistent with generator data used in the

excitation system verification process. In order to close this loop, we suggest that R3 be slightly modified to read: "The Transmission Planner shall provide the Generator Operator with the unit specific data contained in the Transmission Plannerâ€™s dynamic database from the current in-use excitation system and generator model, including the applicable generator model parameter's MVA base, within 30 calendar days of a request from the Generator Operator." AND R4 Item 2 should have an additional sentence at the end which reads: "This data only has to be provided in those instances where generator model data was updated during the process of obtaining a verified excitation system model". These language modifications will help ensure that dynamic databases are populated with the correct data for both the excitation system and generator models that have been verified while minimizing burden on the generation entity responsible for model verification.
No
As a general rule the industry has not demonstrated a need to validate OEM supplied generator data.
Yes
Yes
Yes agree with approach and the 5% capacity factor
The idea that this standard should not be applicable to low capacity factor seems perferable. However, 5% capacity factor may be too high. For instance, there are 8760 hours in a year. A 5 % capacity factor could mean a unit running its at nameplate MW for 438 hours. Or, it could mean more than 438 hours if the unit is not running at its nameplate all the time when running. For Southern Company Generation, the current criteria would result in the standard applying to at least 80% of our generation capacity.
Yes
See comment on 7 above.
No
Yes, agree with proposed phase in period for unit excitation system verification
We agree with both Yes statements above. The software will only allow one to be marked.
Paragraph 4.1.1.1 3rd Section: The plant criteria should be assessed on a switchyard basis instead of all inclusive. For example: 5 unit station with 4 units > 100 MVA each connected at 500 kV and one unit <50 MVA connected at 115 kV. Why do I need to do the small unit? Paragraph R1.2: See discussion in question 3 above regarding the criterion of 'sited at the same physical location and MVA ratings.' We see no need for these restrictions. Paragraph R7: A third option is to do more testing/technical assessment with a longer time allowed (>90 days) should be included. Paragraph R8: The last part of this requirement is unclear: 'â€¦within 90 calender days â€¦. verification.' Change the wording from 90 calendar days of competion to 90 calendar days after completion. The requirement will than read, " The Generator Operator shall provide to the Transmission Planner documentation demonstrating that the excitation's system model's response matches the recorded response for a voltage excursion at the generator from either a staged test or a measured system disturbance (i.e., an ambient event) within 90 calendar days after completion of the excitation system model verification." Paragraph R12: The second and third bullets should be combined to cover any DCS/AVR inter-actions.

Yes
IMPA recognizes that the Generator Operator can work with the Transmission Planner when it comes to using the verified data in a proper model or simulation software program. This assistance from the Transmission Planner might mean that the Generator Operator does not need to purchase modeling software.
Yes
Yes
No
IMPA believes the generator data is important and that it is currently being provided per MOD-010 (static) and MOD-012 (dynamic). Another standard requiring this information would put the

stakeholder at a double risk factor, and FERC does not believe in this double risk factor.

No

Yes

Yes

Yes agree with approach and the 5% capacity factor

A small utility owns a GE 7EA Turbine/Generator with a nameplate rating of 101 MVA in the Eastern Interconnection. The utility uses it as a peaking unit and the capacity factor for the unit averages less than five percent over the last three years. Obviously, this unit does not play a vitale role in maintaining the reliability of the BES. Therefore, why make this utility spend thousands of dollars on testing a machine that is not important to reliability. By using a capacity factor of 5%, this unit will be exempt from this standard.

Yes

No

Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standardâ€™s approval date

IMPA is concerned about the implementation plan. The 10 percent in two years seems feasible, but what if companies decide to test all their units to save on travel cost of a contractor. Has the SDT looked at the total number of units that are covered by this standard and how many contractors can do this work? For example, if a company owns five or more peaking units in one location or in close proximity, they may decide to test all their units at the same time and pay for only one trip by the contractor. Then the next Generator Operator does the same with its units and this continues to occur throughout the two year time period. This type of mentality may hurt the Generator Operator who owns only one unit and has to wait on an available contractor to perform the test. If the Generator Operator does not get that one unit tested within the first two years, it will be non-compliant with this standard (the Generator Operator only owns one unit that this standard applies).

Yes

No

The Electric Power Research Institute has issued a report, "Power Plant Modeling and Parameter Derivation for Power System Studies", number 1015241, Final Report, June 2007; a reasonable interpretation of that work is that there may not be sufficient benefits from using a highly complex model to overcome the potential risks of the testing needed to verify the most complex models. Prototype test data obtained by manufacturers to provide the initial data, in many cases, simply can not be duplicated on operating / operational equipment. The 10 year re-verification requirement, as presently written, does not appear to allow generator owners the necessary flexibility to determine, similar to the regulatory model of 10 CFR 50.59 "Changes, Tests, and Experiments", how detailed the "re-verification" activities need to be. The requirement to re-perform the same bank of physical tests used to originally validate the generator model, absent a physical modification, does not allow sufficient flexibility to perform only those "re-verification" activities for those model parameters whose change due equipment aging has discernable effect on the outcome of the analysis using the generator model. Please note that the concern for performance of tests with little discernable analytical benefit was previously voiced in the "MAAC Position Paper on Generator Testing to Verify Data Required for System Modeling" in the Phase III-IV Planning Standards comments, which can be found on the NERC www site, where the issue of testing nuclear units in compliance with the regulatory requirements of 10 CFR 50.59 was also noted. As a result, it is recommended the SDT consider removing all references in the requirements for periodic testing when no physical changes have taken place and clarify R12 reflects to reverify the parts of the modeling affected by a change and not a reverification of the entire model. In addition, although the reason to verify generator modeling is logical, it is

requested the SDT consider the references stated above and consider the removal or modification of requirements involving testing that place an unncessary risk of generator damage. As an example, allowing vendor simulations or other testing methods by the Vendor in a suitable testing environment to suffice for obtaining generator response characteristics.
Yes
Yes
No
There are clearly benefits to having as much verified operational characteristic data as possible, however, as previously noted in response to question #2, the equipment risks associated with obtaining those benefits should be a consideration. Considering an aging generation infrastructure, the risk of obtaining parts for equipment damaged in the pursuit of modeling verification can be extremely costly in extended downtime and the availability of parts is also a concern. Again, it is recommended the SDT consider the removal or modification of requirements involving testing that place an unncessary risk of generator damage. As an example, allowing vendor simulations or other testing methods by the generator Vendor in a suitable testing environment to suffice for obtaining generator response characteristics.

ISO New England Inc.
No
The Generator Operator has the greatest ability to develop and/or provide accurate models and model parameters for its equipment. The Generator Owner should also be involved in the verification process as required. The process should ideally allow interations between the GO and TO to allow for needed adjustments to model compatability issues and settings with the GO, It should be field verified data not just a self certification of data without the field verification.
No
We recommend validation on a 5 year scale. 10 years is too long if changes are made to settings during annual outages. The whole approach of the draft standard is a bit flawed because once the model and tuned parameters are verified, no control setting changes should be made to the physical equipment without consulting with the TO to determine their acceptability. Additionally, updates should be provided if the manufacturer or GO identify improvements to the model in regard to matching the actual equipment. Having a verification in addition to the preceding is acceptable and would provide the benefit of having a written documentation from the GO and better assure that acccurate models are being used for planning the system.
Yes
Yes
No
Manufacturer's estimates of generator characteristics appear to be generally accuracte and

relatively easy to obtain.
No
The generator should provide the data to Reliability Coordinators, Transmission Operators and Planning Coordinators for verification. Generator Owners should provide factory models for excitation systems to Reliability Coordinators, Transmission Operators and Planning Coordinators and these models should be verified with the field data.
No
This may lead to "weak" submittals from certain entities.
No (disagree with approach)
These low capacity factor units may be critical during peak conditions and are almost certain to be older units that have the least accurate factory excitation system models. It is felt that having accurate models for these older units is required. Generators under 100 MVA make up about 15% of capacity in New England. Excluding low capacity factor large units may exclude more than 20% of the generators from model verification.
Yes
Currently generators over 100 MVA make up about 85% of the installed generator capacity in New England. Concentration on these units should provide an accurate representation of the system. Efforts to verify lower MVA capacity units would provide limited benefit for the work involved.
No, the phase in period for unit excitation system verification should be (please specify below)
2-1/2 years with a 5 year overall renewal of verification.

(1)Generator Operators and Generator Owners both should be included in this standard. The entitiy that would be the best source to coordinate the testing could be required to verify the models. It is possible that all functions can not be performed by the Generator Operator alone. Therefore it would be prudent to include the Generator Owners within MOD-026-1. (2) Additionally, the GO would be able to obtain the attention of the manufacuturer than GOP. In our opinion the functional model specifies Generator Owner as it requires a generator owner to "verify generating facility performance characteristics". In any case, this responsibility should not be assigned to the Transmission Planner. (3) On the other hand, GO/GOP should not perform the function of modeling or verifying dynamic simulations on the Bulk Electric System which generally is done by Transmission Planners. Generator Operators/Generator Owners should provide the data needed for model simulation. Generator Operators/Generator Owners do not possess the expertise or have the resources to perform modeling simulations.
No
(1) Many generating units are now on six year outage cycles, therefore we recommend the interval is changed to 12 years or more. (2) Concerns regarding excitation equipment are that someone at the plant may inadvertently modify settings on dials/potentiometers at some point within a 10/12 year period (or other interval that would be considered appropriate) that would cause the performance of the exciter to vary from what was originally specified in the dynamic model representation. Also, it is possible that, through aging, electrical values of circuit components in the excitation equipment could drift, even with no external change to the settings. It is uncertain what the re-verification period should be to minimize these effects, so we support the caveats listed in Requirement 11 and 12. However, despite R12, some communication between the Generation Operator and the Transmission Operator within the 10/12 year period would be reassuring that nothing has changed. Because 10/12 years is a long time, the Generator Owner should be required to respond upon request of the Transmission Planner confirming that nothing has changed. Further, the second bullet of R11 might also note that the Generation Operator must verify for the model for the first time if the model was derived from a 'sister' unit or repeat the verification on one previously verified.
Yes
We encourage the proxy unit approach. However, we do not agree completely to the conditions illustrating proxy unit approach. (1) MVA rating should be expanded to say "MVA nameplate rating" . We believe it would be prudent to specify that units of different manuafacturers, even if they have the same nameplate rating are not proxy units. Further, turbine rating should also be considered as appropriate. (2) If the units are identical, we believe the 250 MVA threshold criterion is too restrictive. We believe the limit should be at least 350 MVA to cover combined cycle units of existing technology.
Yes
(1) Generator Operators and Generator Owners should be included in this standard. It is possible that all functions can not be performed by the Generator Operator. Therefore it would be prudent to include the Generator Owners within MOD-026-1. (2) If the generator has not been modified, and the manufacturer's data is available, then there should be no need for retesting of the generator. However, if the generator has been modified since the last data set was established for the generator, (stator or rotor turns shorted, rotor replaced, etc.) then re-testing of the generator would be in order. If the turbine has been replaced, then an updated value for rotational inertia would be needed. (3) The concept of staged tests is troubling as such testing can provide a local challenge to the integrity of the BES. Such testing should be required to be well coordinated with the Transmission Operator. (4) Relying on generator data that was originally provided for MOD-012 to be the same data that was used for model verification would not be advisable. There are countless opportunties for generator data submitted for MOD-012 to be inconsistent with generator data used in models in the excitation system verification process. In order to close this loop, we suggest that R3 be slightly modified to read: "The Transmission Planner shall provide the Generator Operator the unit specific data contained in the Transmission Plannerâ€™s dynamic database from the current in-use excitation system and generator model, including the applicable generator model parameter's MVA base, within 30 calendar days of a request from the Generator Operator." AND R4 Item 2 should have an additional sentence at the end which reads: "This data only has to be provided in those instances where generator model data was changed in order to obtain a verified excitation system model". These language modifications ensure that dynamic databases are populated with the correct data for both the excitation system and generator models that have been verified while minimizing burden on the generation entity responsible for model verification.
No
None

No
(1) Generator Operators and Generator Owners should be included in this standard. It is possible that all functions can not be performed by the Generator Operator. Therefore it would be prudent to include the Generator Owners within MOD-026-1. The Generator Operator or Generator Owner should verify the model but should not be responsible for the model. (2) No issues with peer-to peer review, as this would help drive what are necessary and sufficient conditions for matching the responses. (3) The functional model entity responsible for the model's verification has to be given the responsibility of demonstrating that the provided model's response matches the recorded response. The "goodness of fit" between the model response and the equipment response should be left to the generator owner but subject to Transmission Planner review ref. R10.
Yes
We agree with the SDT approach of not developing this standard like a technology specific procedural manual. The development of verification Requirements stating "what is required" and leaving the technical details up to the personnel performing the verification will result in improved dynamic models while affording sufficient technical latitude.
No (disagree with approach)
(1) Some systems have very large peaking units which arguably are more likely to be in service on days when the BES would be challenged. Thus, modeling data should be collected for these units and model cases run including these data. (2) The 5% capacity factor is an inappropriate basis for an exemption since it would allow significant blocks of generation (i.e. plants of several hundred MW) to be exempt. Such amounts of generation may have a significant impact on the stability of nearby generating units or such units may themselves have stability issues that need to be understood via valid studies. Examples would be plants with multiple combustion turbine units (particularly simple cycle oil burners) that are rarely run. However, when they are run (i.e. during peak system load times), the grid may be already be stressed and operating with reduced stability margin. (3) The possibility also exists that while the exempted generation may have a capacity factor of less than 5%, this could quickly change due to unanticipated system conditions or the extended unavailability of other generation (due to severe damage for example). Therefore, the subject generating units could end up being run for a significant length of time without the benefit of having been properly analyzed by the Transmission Planning organization. The â€œaverage over the last three calendar yearsâ€ methodology further contributes to this possibility, introducing a time lag in the process. Based on the above discussion, the 5% capacity factor exemption should only be allowed when it would not be expected to significantly impact the results of stability studies. Allowing the Transmission Planner to make this judgement is most appropriate since A) that organization is in the best position to make the determination of the impact on stability and B) that organization is responsible (via TPL standards) for ensuring the stability of the grid and connected generating units. (4) In lieu of the blanket 5% exemption, the following is proposed. (a) Delete â€œâ€¦ and with an average Capacity Factor of greater than 5% over the last three calendar yearsâ€ in all places in 4.1.1.1, 4.1.1.2 and 4.1.1.3 (b)Add new Applicabilty 4.1.1.4 stating â€œGenerating facilities with capacity factors less than 5% over the last three calendar years may be exempted with written concurrence from the applicable Transmission Planning Authority. The written concurrence provided by the Transmission Planning Authority shall include the basis for any such exemptions.â€ (5) alternative to (b) could be the reponse to Q9 below.
Yes
(1) We believe the MVA thresholds are appropriate and pick up the vast majority of interconnection (MVA). However, the MVA values MUST be consistent with the MVA thresholds in other stanadrds, such as MOD-10 to 12. and in proposed TPL-001 standards. (2) Supporting data (circa 2003) can be found from the link below which provides a spread sheet titled â€œExisting Generating Units in the United States by State, Company and Plant, 2003.â€ http://www.eia.doe.gov/cneaf/electricity/page/at_a_glance/gu_tabs.html The spreadsheet can be sorted and summed to get an estimate of the percentage generation that would be included. A preliminary look suggests that 80% or more would be included.
No
However, add 4.1.1.5 stating â€œGenerating facilities that do not meet the applicability requirements 4.1.1.1 - .3 may be included when their performance is found to create or contribute to reduced reliability of the BES when requested by the applicable Transmission Planner. The written request provided by the Transmission Planner shall include the technical basis for any such inclusion (e.g. must run for reliability, voltage, or stability needs).â€
No, the phase in period for unit excitation system verification should be (please specify below)
(1) The term "verification" should be defined. Defining "verification" would give Generator Operators/Generator Owners a clearer understanding of what data should be verified in the model. (2) The first time period should be 3 years (10%). It is anticipated that the first units will take significantly longer than subsequent testing. Although this factor is already being considered

in proposed time periods, there will probably be a significant shortage of testing services at the beginning of the testing window. (3) The last period for 100% of appliable units should be 12 years to match with 12 years of outage cycle.
None
None
(1) Requirement 1 states that testing should occur "for new or existing units within 180 days of commerical operation". We believe the testing for the new units should be done before commerical operation. (2) In Requirement R2, the Transmission Planner would not necessarily have any idea which model would best fit the installed equipment. The only workable way to comply with this requirement is for the Transmission Planner to give the Generator Operator the data sheets for the entire library of available exciter models. The Generator Operator would then need to determine which of these models would provide the best fit for the excitation system equipment to be modeled. We believe that this requirement should recognize that deriving "acceptable" model for a specific excitation system is a cooperative effort between manufacturer, GO/GOP, and TP. (3) While wind generators would generally fall below the unit size thresholds as specified in Requirement 4.1.1, it would be very helpful in conducting dynamic simulations involving wind generators if their dynamic representations would be fit into one of the standard library models. (4) There are several 90 day periods mentioned in the Requirements. It might be helpful to be more specific as to which 90 day interval is meant. For example, Requirement R8 should read something like "â€¦within 90 days of completion of the excitation system model verification as specified in Rx." (5) This comment is in reference to MOD-026-1, R.12. We believe that Digital Control Systems do not effect excitation systems models. Therefore we suggest removing requirements associated with Digital Control Systems.

AESO
No
The AESO agrees with the SRC ISO/RTO comments.
No
The AESO agrees with the SRC ISO/RTO comments. We would also like to add: WECC requirements state every 5 years. 5 years seems more resonable than 10 years to ensure that the generating unit is still performing as intially sepceified and there has been no no component degradation causing the settings to drift.
No
The AESO believes that using a single unitâ€™s actual excitation system verification to be a proxy for multiple units will not pick up errors in settings, component failures, alterations to units, etc. Each unit should be tested individually.
Yes

The AESO agrees with the SRC ISO/RTO comments.
Yes
The exciter is only one component of the generator, testing all components (generator, exciter, PSS and governor/prime mover) is imperative so a complete picture of how the unit will react within the electrical system can be modeled. For the same reason units such as wind facilities and other types of generation that do not have an exciter must be modeled and verified.
No
The AESO agrees with the SRC ISO/RTO comments.
Yes
The AESO agrees with the SRC ISO/RTO.
No (disagree with approach)
The AESO agrees with the SRC ISO/RTO comments.
No, instead use the approach below:
Section 4.1.1.2 directly references the Western Interconnection but then uses equipment sizes as a base that far exceeds the ones used by WECC in the Generating Unit Model Validation Policy. 75 MVA units vs 10MVA by WECC 20 MVA units in a 150 MVA facility vs. 20 MVA facility by WECC 100 kV interconnection vs. 60 kV by WECC Perhaps the standard can reference the WECC guidelines.
The AESO agrees with the SRC ISO/RTO comments.
Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standardâ€™s approval date
The AESO agrees with the SRC ISO/RTO comments.
The ones we are aware of have been noted in the responses previous questions.
The AESO agrees with the SRC ISO/RTO comments. We would also like to empahsize the importance of complete unit testing as noted in our response to Question 4.

No
Based on Responsibilities in the Functional Model, responsibility for determining maintenance and verification activities is clearly assigned to the Generator Owner. It should also be noted that in some cases the GO may be able to obtain additional expertise from their TP, RTO, or Region, which adds other resource options.
No
It would seem that the need to revalidate is driven by technical issues (analog controls drift, digital doesn't). There is an EPRI guide (1004556) that specifies a 5 year frequency for analog AVR calibrations. The SDT should discuss different periods based upon different control technologies (e.g. digital versus analog). In addition to R12, some communication between the Generation Operator and the Transmission Operator within the 10 year period would be reassuring that nothing has changed.
Yes
If it could be verified that the Gains and TCs are exactly the same, but just reading dial settings on analog controls might not suffice. For digital, the gains are the number programmed in, so the proxy approach is more reasonable. Also, recommend changing MVA rating to 350 MVA so that combined cycle steam units are included.
Yes
Supplying the data itself is appropriate. Industry experience has shown that simply assuring the generator data in the model is the right data for the installed equipment is adequate for assuring the validity of the Generator Parameters, additional testing is not typically needed and any inappropriate data would show up in voltage bump test comparisons needed for AVR models validations. Also, R4.4, should say The GO shall provide the Compensation Function used on the unit (Droop, Reactive Line Drop or Resistive Line Drop) and the amount of compensation provided (% of generator voltage at rated MVA).
Yes
Per the title, this is a standard applicable to the verification of excitation system models and the industry understands this to be different than the generator parameters. Requiring testing to specifically validate that generator data might require more than a bump test, which is currently thought to be adequate to address the issues currently in this standard. The generator reactances and time constants should not need verification as long as there is valid manufacturer supplied data and the generator has not been modified (rotor replacement, etc.) or condition has not degraded, such as the unit has been identified to have shorted rotor turns which would be

expected to impact saturation curves and several of the reactance modeled. Additional testing might be appropriate when it is identified that a unit is operating with shorted turns, or if changes are made if a bump test cannot revalidate what is needed (such as a rotor replacement - do you need to verify saturation curves? or when you remove a rotating exciter, do you need a load rejection test?). NERC should consider establishing and documenting requirements for when model data validation should be re-verified and minimum tests needed for partial unit upgrades â€“ (e.g. what testing is required for a rotor replacement?). Thus, it would seem a supplementary SAR to include generator parameter validation is needed. NERC should also consider developing a guide that provides input on these issues, especially if the responsibility is assigned to a GO/GOP without the technical background in models and validation. SERC developed a guide on this subject that could be leveraged for a NERC guide.
Yes
We agree the standard should not set criteria for evaluating the match, but industry guidance on acceptable criteria would be helpful.
Yes
We agree, but industry guidance on acceptable criteria would be helpful.
No (disagree with approach)
Regarding Section 4 Applicability, drop the reference to Capacity Factor of 5% over the past 3 years. This makes no sense, because for a variety of reasons the unitâ€™s capacity factor in the very next year may be significantly higher, and having an accurate assessment of the unitâ€™s performance would be important. The units with low capacity factor would likely be on line during a peak load period when the system is most stressed and stability issues are most likely. Also, these units could be relevant to sensitivity studies. The larger units should have a model. Additionally, MMWG requires models for all units whether they are on or off in the case. Each one must have a model if the modeling criteria is satisfied. If the unit is a reasonable size and connected to the BES like others, we don't see how you can exclude testing.
Yes
We agree with the approach, but would also caution the team to consider the future composition of the Interconnection MVA. Possibly the team already considered newer types of generation and the benefit of a verified model rather than just â€˜estimated or typical manufacturerâ€™s dynamics dataâ€™ (MOD-013). The team should consider clarifying the relationship between the terms in MOD-013 and MOD-026. Is â€˜unit-specific dynamics dataâ€™ equivalent to a â€˜verified modelâ€™? Even in the case of a sister unit? If a unit does not meet the applicability for MOD-026, would they then follow MOD-013 to determine the applicable model to provide?
Yes
Add a similar requirement to R11 that allows the TO or RC to add a generator that does not meet the applicability criteria when their performance is found to create or contribute to reduced reliability. No one can foresee all future system configurations and operating conditions. This type of requirement is fundamental to analyzing and resolving issues. Additional Comment on R11 and R12. When system or plant events occur impacting transient voltage response, the GOP should evaluate actual unit/plant performance against expected performance. This is especially important when taking credit for sister units to avoid testing of similar units at the same site. With the long time between verification testing (10 years) and even longer time frame when allowing for claiming sister units, it is important to assess actual versus predicted performance. It is not sufficient to have only the TO or RC identify potential issues because they would normally only recognize issues that negatively impact the entire system and only for the specific event. Individual generating stations may have not behaved as modeled due to protection/control problems but the overall system met requirements.
Yes, agree with proposed phase in period for unit excitation system verification
We wanted to also check "YES" on allowing credit for verification of excitation systems within the last 5 years of the Standard's approval date, but this electronic form wouldn't allow us to do that.
None
None
Section 4.1 Should the standard be revised to include small units that are part of an aggregate 200 MW facility? For example : wind farms with many 1.5 MW turbines Recommend changing R5.1) to read â€œThe model initializes properly and a no-disturbance simulation contains no transients.â€ The second bullet of R7 allows an unusable model to not be corrected. Unless the point is that the unit would be out of compliance, this seems to negate requiring verification. Recommend the team to consider that all units that meet the applicability have usable models. For R12, rather than only listing the high level components, we recommend the team also note that other generator components such as a new excitation system power transformer (not a like-for-like changeout) can have an impact on aspects of the model.
Group
FirstEnergy

Sam Ciccone
FirstEnergy Corp.
Yes
Although we ultimately agree, we have the following comments: 1. The Generator Operator should be responsible to verify the dynamic data is accurate for the Generator, Turbine and Excitation system. The ultimate responsibility for the usability and accuracy of the dynamic models and how they perform in relation to the overall system model is the responsibility of the Transmission Planner. 2. Genertor operators in a centrally located dispatch office would not have direct access to the equipment. They can only arrange an actual verification test. Details of the units response to a disturbance would need to be gleaned from the Generator Owner's data. It is not appropriate to burden one entity with a potential compliance violation when another entity controls the data. Relying on agreement coordination between the two entities may not be sufficient to ensure the entity with responsibility to comply is able to comply with an uncooperative entity with data control.
No
10 years for digital excitation systems and 5 years for non-digital excitation systems.
No
1. While we agree with this approach, we do not agree it should be limited to 250 MVA units. It should allow it for any identical units of any size. Also, the requirement could be written more clearly by revising it to make it clear that verification is for similar units only and not all units owned. Based on these comments, we suggest re-wording R1 (2) to state: "For an existing unit, once in a ten calendar year period. If multiple units have identical applicable components and settings and are sited at the same physical location, verification of one unit is sufficient for all of these units. Verification shall be performed on a different unit each ten calendar year cycle." 2. This is a lot like the "Sister Unit" concept developed in the recent RFC generator verification standards. It may be helpful if this term was defined and described in more detail in the standard to allow for ease of compliance verification.
Yes
The question above has a typographical error. We assume the team means "Generator Operator".
No
Yes
1. For many GOP's, a testing contractor with experience in model fitting and selection will need be hired to do the verification. 2. The team may want to add an additional requirement for the Transmission Planner to review and confirm acceptability of the Generator Operator's excitation system model verification documentation within 90 days of submittal. This would preceed the R10 requirement.
Yes
While we agree with the approach of staying away from being too prescriptive, it may add guidance if the term "verify" (i.e. in R1) was clarified. We ask the team to consider adding "such as operational tracking or testing" after verify.
Yes agree with approach and the 5% capacity factor
No, instead use the approach below:
We feel that 80% of the Interconnection MVA is not high enough. The issue might be not including many of the CC/CT units that have a low capacity factor (above 5%). The team may want to consider 90% or further validate the 80% value.
No
Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standardâ€™s approval date
1. In R1.4 it should be clear that the unit is achieving the 5% capacity factor for the first time over the last three calendar years. 2. R9 states that the Generator Operator shall make documentation demonstrating the excitation system model's response is appropriate available for inspection and technical review 'to' the RC, TOP, and PC. The term "make available" is vague and should be revised to provide more specifics as to how this information is to be made available for inspection and technical review 'by' the RC, TOP, and PC. 3. The term "Capacity Factor" is not NERC defined and is shown as capitalized in the standard. We suggest the team develop either a

standard-specific or NERC Glossary definition. The following is a suggestion: "Capacity Factor (expressed as a percent) - The net actual energy generation (MW-hours) divided by the product of the period (hours) and the net maximum nameplate rating (MW)." 4. Sec. 4 Applicability - We do not agree with the criteria proposed for the Eastern Interconnection and believe it may leave out some important or critical units. Also, it may be better to just have one criteria throughout the interconnections. We recommend the SDT consider using the NERC Registry Criteria for all units based on plant aggregate of 75 MVA or greater and unit size of 20 MVA or greater. 5. Per Question 10 above, why wouldn't the Regional Entity procedures or guidelines be allowable for compliance after the first 5 years? [Note: It is assumed that the SDT intended to say "first" 5 years, not "last" five years in the description after Box 3 of that question]

No
The Generator Operator does not have direct access to the equipment. The Generator Owner is the correct Functional Model entity that has direct access to the equipment and the authority to perform testing of equipment. All responsibilities assigned to the Generator Operator in the proposed standard should be reassigned to the Generator Owner.
Yes
ten-year interval is acceptable given the conditions in Requirement R12.
No
Units testing has in the past identified different responses from identical units with common settings. All units with identical design and settings should be tested unless records of actual system events demonstrate that all of the units respond the same.
Yes
The entity specified in Question 4 does not agree with the entity specified in Requirement R4. As stated in our response to Question 1, we believe the Generator Owner is the correct entity to provide the data; not the Generator Operator. We agree with the approach subject to revising the responsible entity to be the GO.
No
Expanding the scope to include verification of generator data will not provide a significant improvement in the overall modeling of excitation systems. However, these data should be provided as part of an existing Standards or from another Standards if not already existing.
No
As stated in our response to Question 1, we believe that the Generator Owner is the correct entity to provide the data; not the Generator Operator. We agree with the approach subject to revising the responsible entity.
Yes
Reliability Standards should focus on what is required and not how to meeet the requirement. Further, it would be impractical to specify verification details universally applicable to all situations. The peer review process provides appropriate safeguards to ensure that appropriate methods are used for verification. As an alternative, a technical white paper could be developped for reference.
Yes agree with approach and the 5% capacity factor
We agree with this approach to exclude units with low capacity factors provided that Planning Coordinators or Transmission Planners are allowed to identify additional applicable units beyond those specified in section 4.1.1 based on criticality to system reliability. Cases exist where large generating units with low capacity factors are operated only during the most stressed operating conditions. In such cases accurate modeling of these units may be critical to reliable operation of the bulk electric system.
Yes
We agree with the general approach to base the number and size of applicable generating units on the objective of validating models for 80 percent of the installed capacity on an Interconnection provided that Planning Coordinators or Transmission Planners are allowed to identify additional applicable units beyond those specified in section 4.1.1 based on criticality to system reliability. In the event the Planning Coordinator or Transmission Planner is not permitted to identify additional units, the objective should be changed to validate models for a greater percentage of the installed capacity. We do not have data to verify whether the unit size thresholds specified in Requirement R4.1.1 correspond to 80 percent of the installed capacity on an interconnection, and respectfully suggest that it is the responsibility of the SDT to provide such verification.
Yes
The Planning Coordinator or Transmission Planner should be permitted to identify additional units

for applicability of the Standard based on the results of generator interconnection studies or other studies that demonstrate the criticality of correct settings on system reliability, e.g. studies demonstrating sensitivity of a stability based System Operating Limit to correct equipment settings and functionality.
No, the phase in period for unit excitation system verification should be (please specify below)
The proposed impmentation plan is too long. We recommend a five-year implementation with a requirement that units representing 20 percent of installed capacity be tested each year. We are concerned that an eleven-year implementation plan does not adequeately promote system reliability, and that having only three milestones will place a burden on system operators to schedule testing because Genator Owners may wait until years two, six, and eleven to schedule testing instead of spreading the tests out over the implementation period. Credit could be allowed for verification of excitation systems within the last five years of the Standards approval date.
Yes, we have a modification to propose to the Applicability section which list different value for diffferent Region or Interconnection. We propose that the two paragraphs in Applicability 4.1.1.1 be modified to: «Each unit (including synchronous condensers) â‰¥ 50 MVA, connected at the point of interconnection at 100 kV or above and with an average Capacity Factor greater than 5% over the last three calendar years.» «Each unit (including synchronous condensers) â‰¥ 20 MVA within a plant â‰¥ 100 MVA, connected at the point of interconnection at 100 kV or above and with an average Capacity Factor greater than 5% over the last three calendar years.»

Capacity Factor needs to be defined.
Individual
Dan Rochester
Independent Electricity System Operator
No
This responsibility rests with the Generator Owner. As indicated in the Background Information Section, Generator Owners may be responsible for providing accurate generator data including the excitation data for system modeling. Although it does not operate the generator, verification testing does not need to be performed under operating conditions only. The input/output measurements of the excitation system could suffice to verify the excitation system model, which may be performed during commissioning testing or under other non-production conditions. If the generator must be run by the Generator Operator to enable testing, the Generator Owner can make such an arrangement with the Generator Operator under an agreement, as the Background Information so suggests.
No
We believe a 10 year re-verification period is adequate for those exciters whose settings do not tend to drift over time. However, a shorter period, say 5 years, should apply to the analog or rotating type of exciters.
Yes
We agree with the proxy unit approach only if these units' excitation systems show identical performance based on the results of a limited number of tests. On the other hand, we do not agree with the 10-year cycle. Accurate excitation system data and verification that it performs as designed are critical to accurate modeling and simulation to support a wide range of reliability activities, including the determination of SOLs and IROLs. The 10 year recycle period is too long that risks changes to excitation system characteristics undetected. We suggests this period be shortened to 5 years.
Yes
We agree with the approach of requiring the Generator Owner to supply the data listed. We also suggest that since this data is required within 90 calendar days of completion of the excitation system model verification - the same condition for providing documentation demonstrating that the excitation system modelâ€™s response matches the recorded response for a voltage excursion at the generator as stipulated in R8 - we suggest R8 be combined with R4. Note that "Generator Owner" instead of "Generator Operator" is used in this question. While we view this as a typo, as indicated in our comment under Q1 we think it is appropriate that the Generator Owners be held responsible for the majority of the requirements in this standard.
Yes
We think that at a minimum, the generator's basic characteristics such as inertia constant, damping coefficient, saturation parameters, and direct and quadrature axes reactances and time constants), voltage regulators, turbine-governor systems, etc. as stipulated in MOD-013 that

support modeling for dynamic simulations should be verified. A good excitation system model without a valid generator model will not provide the assurance that the simulation results are valid, which may hurt reliability.
No
We have difficulty with the concept since the GOP's determination of a "match" can be subjective and subsequent peer review is time consuming and unnecessary if some matching criteria is developed up front. While we are not in a position to suggest what that criteria should be, we tend to think that a certain percentage of deviation in some output parameters may serve to provide this measure. Also, as indicated under Q4, we suggest R8 be combined with R4. It may be a moot point if some criteria are developed but if not, there are inconsistencies among R4, R8, R9 and R10 on the recipients of the documentation that the Generator Operator must provide and the feedback to be received. We suggest the SDT review the list of recipients, and if peer review is still required then the recipients/commenters should include Transmission Planners, Planning Coordinators, Transmission Operators and Reliability Coordinators since they all are users of the data and model.
Yes
The SAR could be expanded by making it more clear that it applied not only to the excitation systems on conventional synchronous generation units but also to the equipment that performs this role on non-conventional facilities such as wind-farm voltage management systems.
No (disagree with approach)
a. The Term Capacity Factor is capitalized but this term is not defined. Suggest to use lower case, or define it. b. Capacity factor reflects a generating unit's real power generation frequency and duration, but does not provide the assurance that when the generator is on line, it's excitation system has been modeled accurately such that its expected performance matches simulation results. There are generating units that are often on line but do not generate at high capacity since they provide ancillary services including operating reserve and hence tend to have a low capacity factor. There are also sizable "mothballed" units or the entire plant of multiple sizable units that, due to various reasons, were put off line for a long period but return to service when the need for capacity so dictates. Not having their data verified based on a low capacity factor and on the assumption that they constitute a small portion of the interconnection MVA may leave room for unreliability. Further, low capacity factor is a historical value which may not be a good indicator of the future. If and when these low-capacity generators are put to high capacity usage, and particularly when the system is being stressed, the non-verified excitation systems can give rise to unpredictable system performance. Moreover, having to track a unit's capacity factor for the past 5 years to determine the need for verification is an unnecessary administrative burden.
Yes
We do not have any technically sound alternatives to suggest.
Yes
In some areas on the interconnection, such as those that are sparsely populated, performance of generating units at less than 100 MVA might be critical to reliability. The criteria to allow the TP and PC to identify these units could include: a. A 5% or 10% deviation of any or several of the excitation system's parameters/settings could make an otherwise stable simulation to be unstable; b. Use of generic models for the excitation system or generator would make an otherwise stable simulation to be unstable. c. Other changes or incorrect assumptions for the excitation system or generator would make an otherwise stable simulation to be unstable.
No, the phase in period for unit excitation system verification should be (please specify below)
10 years is too long a period to phase in full compliance with this standard. We recommend this be shortened to no more than 5 years so that the continent can have a fully verified set of excitation system data by that time to support modeling and simulation. This has been long overdue, and allowing the 10-year phase in period prolongs achieving the desriable reliability objectives. We also suggest the SDT to consider shortening the re-verificaiton cycle to 5 years.
Variances are already provided in the Applicability Section (for the 3 Interconnections).
None
We offer the following comments: a. A number of points/bullets in several requirements need to be performed to meet the intent of the main requirements, even though some of them are mutually exclusive (i.e. either/or). As such, they should be labeled subrequirements. These include: - R1: Points number 1 and 2 - R4: Points number 1 to 5 - R11: All bullets - R10: Both bullets - R12: The last 2 bullets b. R5: The condition that "if the excitation system model is useable" needs further elaboration. Evidence showing either Conditions (1) or (2) may suggest that either the model incorrectly reflects the excitation system or the excitation system itself, despite being modeled correctly, gives rise to the observed condition. The word "useable" thus needs to be expanded to more properly indicate whether the data is not useable or the excitation system is not useable. c. R6: The above comment on R5 also applies to R6.

Gnerator Owners are responsible for the maintenance of the units. This testing is not an on-line normal test. It is more of a maintenance/engineering task that would use 3rd parties to help perform. This would also require special budgeting and running a unit with off normal conditions which an owner would have to approve and sanction. Generator Owners are responsible for other Modeling standards, so wht would they not be responsible here. This is also providing data that is of no use to the Generator Owner or Operator and they will not have any expertise with this work. Only the Transmission Planner needs this data and should understand it. In that aspect, they should take some responsibility for it.
No
I am OK with 10 years for analog systems. Newer digital systems should not change over time, so they should be tested upon commissioning and that should be adequate for the life of the unit.
Yes
I agree with this except for the less than or equal to 250 MVA. It should apply to all units meeting the sister unit criteria regardless of MVA. If you want a limit, then make it something higher like 80% of the single largest generator in the system.
No
I may agree if it is reasonable and list exactly what data can be requested by the TP. Remember, the GO is dependent on contractors for doing this, it costs them money, and is of no benefit to the GO, so the listing need to be specific so it can be listed in the job scope of the work and reasonable.
No
No
This should be the Transmission planner's job. The GO or GOP does not use this data or the software or the expertise and may not be aware of disturbances on the system. The TP should compare this data and furnish it to the GO if there is an issue.
No
I do agree with not making the standard too large, but somewhere the GVSDT needs to provide this detailed data or training to the GO/GOP. You are requiring them to provide things that they do not have expertise in and this will lead to problems with getting this done correctly and for a reasonable price. I'm sure the contractors that do with work see a big opportunity to make money on this.
Yes agree with approach and the 5% capacity factor
Yes
No
Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standardâ€™s approval date
I vote yes on both of the questions.
In Requirement R5 in the event that a model is determined to be unusable and is returned to the Generator Owner for further action the transmission operator should be required to also provide the steps he has taken to exercise due diligence in the integration of the exciter system model into the over all model. This should take the form of review of data inserted against data provided, model name reviewed against model provided, etc. The transmission operator should also provide the Generator operator witih text copy of the actual exciter and generator portion of the overall model.

This responsibility rests with the Generator Owner. As indicated in the Background Information Section, Generator Owners may be responsible for providing accurate generator data including the excitation data for system modeling. Although it does not operate the generator, verification does not need to be performed under operating conditions only. The input/output measurements of the excitation system could suffice to verify the excitation system model, which may be performed during commissioning testing or under other non-production conditions. If the generator must be run by the Generator Operator to enable testing, the Generator Owner can make such an arrangement with the Generator under an agreement, as the Background Information so suggests. Further, we believe both the Transmission Planner and the Planning Coordinator are primary users of the model. We suggest that the Planning Coordinators be added to the Applicability Section, and at places where Transmission Planners are assigned a responsibility.
No
While a 10 year re-verification period may be adequate for those exciters whose settings do not tend to drift over time, a shorter period, say 5 years, should apply in general since there are analog and rotating type of exciters whose settings tend to drift from time to time.
Yes
We agree with the proxy unit approach.
Yes
We agree with the approach of requiring the Generator Owner to supply the data listed. We also suggest that since this data is required 90 calendar days of completion of the excitation system model verification - the same condition for providing documentation demonstrating that the excitation system modelâ€™s response matches the recorded response for a voltage excursion at the generator as stipulated in R8, we suggest R8 be combined with R4. Note that "Generator Owner" instead of "Generator Operator" is used in this question. While we view this as a typo, as indicated in our comment under Q1 we think it is appropriate that the Generator Owners be held responsible for the majority of the requirements in this standard.
No
This standard should focus on the excitation system only. If the industry sees a need for such verification, the requirements could be added to another MOD standard or a separate standard be created through a separate SAR.
No
As the facility owner, the Generator Owners should have the authority to confirm the accuracy of the model, which when supported by documentation, should suffice. A peer review is not

necessary, and if "match" must be quantified, the industry may develop a set of criteria based on historical verification test data, and add this to the standard at a later stage.
Yes
No (disagree with approach)
a. The Term Capacity Factor is capitalized but this term is not defined. Suggest to use lower case, or define it. b. Capacity factor reflects a generating unit's real power generation frequency and duration, but does not provide the assurance that when the generator is on line, it's excitation system has been verified such that its model is accurately represented in simulations. There are also sizable "mothballed" units that, due to various reasons, were put off line for a long period but return to service when the need for capacity so dictates. Not having their data verified based on a low capacity factor and on the assumption that they constitute a small portion of the interconnection MVA may leave room for unreliability. Moreover, having to track a unit's capacity factor for the past 5 years to determine the need for verification is an unnecessary administrative burden.
Yes
We do not have any technically sound alternatives to suggest.
Yes
In some areas on the interconnection, such as those that are sparsely populated, performance of generating units at less than 100 MVA might be critical to reliability.
No, the phase in period for unit excitation system verification should be (please specify below)
We suggest that the usual implementation language be used. Requirement R1 sets the schedule for verification even for the first time based on a 10-year cycle (we suggest to be shortened to 5 years, especially for the analog and rotating type exciters). We agree with allowing credits for verification of excitation systems within the last 5 years of Standard's approval date.
None
None
We offer the following comments: a. The proposed standard lacks clarity needed for implementation as a mandatory standard. Specifically, there are different views in the industry as to what exactly is a model data sheet. Is it the block diagram of the excitation system's control system and parameters, or is it the simulation software's model sheet such as, for example, a vendor's data sheet for a specific type of exciters which it is capable of modeling in its simulation software, say, IEEEST, EXST1, or whatever name it may be, etc. We suggest clearer language be used to more specifically describe what a model data sheet means. Also, verification is subject to interpretation: is it a comparison of the expected input/output response of the excitation system versus actual response, or the expected performance of the generators when a computer simulation is conducted? b. A number of points/bullets in several requirements need to be performed to meet the intent of the main requirements, even though some of them are mutually exclusive (i.e. either/or). As such, they should be labeled sub-requirements. These include: - R1: Points number 1 and 2 - R4: Points number 1 to 5 - R11: All bullets - R10: Both bullets - R12: The last 2 bullets c. R5: The condition that "if the excitation system model is usable" needs further elaboration. Evidence showing either Conditions (1) or (2) may suggest that either the model incorrectly reflects the excitation system or the excitation system itself, despite being modeled correctly, gives rise to the observed condition. The word "usable" thus needs to be expanded to more properly indicate whether the data is not usable or the excitation system is no useable. d. R6: The above comment on R5 also applies to R6.
Individual
Jason Shaver
American Transmission Company
Yes
No
The 10 year period is too long and should be changed to 5 years in order to ensure greater model accuracy.
Yes
It provides confirmation of whether the data being used to model the generator and the generator data used in the verification test are the same.
Yes
Yes

No
Standard testing procedures should be provided as a minimum with the caveate "that the testing procedures include but are not limited to these procedures" to cover future technologies. An example would be a step response test for the exciter; swept frequecy (0.1 t0 10 Hz) response test for a PSS.
Yes agree with approach and the 5% capacity factor
No, instead use the approach below:
The threshold should be based on NERC registration criteria for Generator Owners/Operators. See Appendix 5 Organization Registration and Certification Manual. (Version 3.3) This criteria should apply across NERC. Item 2 in Requirement 1 should be set to the same level used by NERC's registration criteria for plants.
No
This standards should apply to all registered GO's and GOP's. A requirement as suggested puts the TP or PA in the position of telling NERC who should be registered. This responsibility that clearly falls to NERC and the Regional Entities and should not be expanded to any registered entity.
No, the phase in period for unit excitation system verification should be (please specify below)
20% per year for the next 5 yesrs.
ATC disagrees with portions of Requirement 2 which stipulates that the TP shall provide the excitation system model block diagram (block diagram) structure and data requirements. Many manufactures currently make their block diagrams and data requirements available to the GO/GOP. In addition, IEEE Standard Definitions for Excitation System for Synchronous Machines allows a GO/GOP to identify the type of exciter and/or PSS installed on their units along with the corresponding block diagrams and data requirements. Recommend that the words following "â€¦ dynamic simulation software." be deleted.
Individual
Jay Seitz
US Bureau of Reclamation
No
We believe the Generator Owner should be responsible for model verification. The existing NERC Standard, MOD-012-0 requires the Generator Owner to provide dynamic system modeling and simulation data to the RRO. In addition, MOD-013-0, RRO Dynamics Data Requirements and Reporting Procedures (not FERC approved), requires the RRO to coordinate with the Generator Owner to develop comprehensive dynamics data requirements and reporting procedures needed to model and analyze dynamic behavior. As such we believe this standard should be consistent and apply to Generator Owners. In addition, the NERC Reliability Functional Model - Version 4 describes the Generator Owner relationships with other entities including "Provides generator information to the Transmission Operator, Reliability Coordinator, Balancing Authority, Transmission Planner, and Resource Planner."
No
We believe the 10 year period is too long. It is hard to make the case for reliability-based need for this standard when 10 years are allowed to complete the modeling. Suggest changing the initial implementation period to 5 years which is the implementation period provided in the WECC regional policy. Ten years may then be appropriate for re-validation.
Yes
We agree the Generator Owner should provide the data and also be resposible for performing the model validation/verification.
Yes
Yes, we believe other accurrate dynamic models (e.g. generator model, governor model) are needed for valid computer simulations and should be required. Existing standards, MOD-012-0 Dynamics Data for Transmission System Modeling and Simulation and MOD-013-0, RRO Dynamics Data Requirements and Reporting Procedures (not FERC approved) already require each reliability region to determine comprehensive dynamics data requirements and Generator Owners to provide such modeling data. If these standards are being performed it is questionable what additional reliability concern is served by draft PRC-026-1.
No
Again we think the Generator Owner should be the responsible entity. This standard applies to only two entities, the Generator entity and the Transmission Planner; however actions by other

entities , Reliability Coordinator and Transmission Operator, are required to accomplish the goals of the standard. The exact requirements of these entities should be described in the Standard.
Yes
No (disagree with approach)
Capacity Factor (capitalized) is not defined in the standard nor is it defined in the NERC Glossary; we think we know what it means but if the term is used in the standard it should be defined. However we believe Capacity Factor, should not be used to exempt generators. Those times when generators of low Capacity Factor are in operation will most likely be those times when the power system is most stressed and the performance of the machines should be modeled in system studies.
No, instead use the approach below:
We believe the NERC Compliance Registry Criteria should be used as the threshold.
Yes
If a unit or facility is critical to reliability and the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator can present convincing evidence, the plant should be included. The criteria to use should be developed by the above entities.
No, the phase in period for unit excitation system verification should be (please specify below)
We recommend a 5-year phase in period.
WECC has developed a comprehensive regional machine testing and model validation policy that includes dynamic models for all the major generation components and the applicability thresholds are much more strict than those proposed in the draft MOD-026-1.
We see a blurring of the requirements between Standards MOD-012-0-Dynamics Data for Transmission System Modeling and Simulation; MOD-013-0- RRO Dynamics Data Requirements and Reporting Procedures; and the draft of MOD-026-1 - Verification of Models and Data for Generator Excitation System Functions. If entities are in compliance with MOD-012-0 and MOD-013 we see no additional enhancement to reliability by the addition of this draft standard.
Individual
Daniel J. Hansen
Reliant Energy
No
Generator Operators should not have the sole responsibility alone. With the Generator Operators typically not having the in-house expertise for the model verification, they must not only pay the cost of hiring consultants, but will also carry the burden of significant costs for low capacity factor units when trying to schedule the consultants for unpredicable run times. WECC unit verification testing has resulted in very expensive startup costs for low capacity factor units just to perform a test. There is no cost recovery method for running a unit out of the money to perform this testing.
Yes
Yes
Proxy unit ratings should go up to 500 MVA.
Yes
No
No
Peer review works well when performed by reasonable professional with the right motives. The only disagreement is that the Transmission Planner can arbitrarily reject the model and data without assuming any responsibility for the corrections or the cost.
Yes
Yes agree with the approach. But use another capacity factor (include supporting data):
Capacity factor should be raised to 15%.
No, instead use the approach below:
Each unit (including synchronous condensers) â‰¥ 100 MVA, connected at the point of interconnection at 100 kV or above and with an average Capacity Factor greater than 15% over the last three calendar years. Each unit (including synchronous condensers) â‰¥ 50 MVA within

a plant â‰¥ 250 MVA, connected at the point of interconnection at 100 kV or above and with an average Capacity Factor greater than 15%
No
Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standardâ€™s approval date

Consideration of Comments on Draft Standard MOD-026-1 for the Generator Verification Standard Drafting Team — Project 2007-09

The Generator Verification Standard Drafting Team (SDT) thanks all responders submitting comments on the proposed revision to the MOD-026-1 — Verification of Models and Data for Generator Excitation System Functions standard. This standard was posted for a 45-day public comment period from February 17, 2009 through April 2, 2009. The stakeholders were asked to provide feedback on the standards through a special Electronic Comment Form. There were 45 sets of comments, including comments from more than 100 different people from over 50 companies representing 8 of the 10 Industry Segments as shown in the Attachment on the following pages.

http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html

In the formation of the first draft of this excitation control system model verification standard, the SDT first considered the functional entity "applicability". The SDT quickly recognized that assigning responsibility to appropriate entities for a continent-wide standard on verifying unit excitation system models would be difficult. The reason is that there are many business model variations regarding excitation model verification in place today. The SDT decided that a generation entity was the appropriate entity to assign ultimate responsibility, and posed this question to industry. The vast majority of respondents did not think the Transmission Planning entity was the correct entity to perform verification. There was a significant portion of industry that thought the Generator Owner should be responsible instead of the Generator Operator. The SDT consulted the Functional Model Working Group (FMWG), who rendered the opinion that the Generator Owner should be responsible for model verification, not the Generator Operator. Based on consultation with the FMWG, and supported by the majority of industry comments, the SDT has changed the applicability from the Generator Operator to the Generator Owner.

The SDT asked the industry several questions regarding applicability and frequency of excitation control system model verification. The industry responded that the proposed ten-year periodicity, the proxy unit concept, exemption for units that have a 5% or less capacity factor, and an applicability on an Interconnection basis corresponding to at least an 80% installed MVA generation capacity are all acceptable. Based on industry comments, the SDT is proposing that the proxy unit cutoff be raised from 250 MVA to 350 MVA (the other criteria remaining unchanged). Also based on industry responses, the SDT is proposing a modified applicability to additionally include a significant MVA percentage of all generation of all technologies, including Variable Energy Resources.

The SDT also asked industry about the role of generator model data, because the excitation control system model is a closed loop system that includes the generator data. Industry stakeholders indicated that the standard needed additional clarity about the exact expectations for generator data, but indicated that expanding the scope of the standard to include verification of generator models was not appropriate.

There was support for the SDT approach of the standard "stating what is required" without "stating how to accomplish what is required". Specifically, the industry agreed that the generation entity (the Generator Owner) should be tasked with determining if the model's predicted response and the actual equipment's recorded response are sufficiently matched, and with the concept of the standard providing minimal specificity regarding the mechanics of performing excitation system verification.

The SDT asked the industry if there was a need to specify a process where additional critical units could be identified for excitation control system model verification. A majority of the industry respondents from all Regions indicated "yes". Additionally, there were some minority concerns that the drafted applicability excluded some units that are covered by the NERC Registry Criteria. In response, the SDT developed a proposed process (details contained in Requirement R5) that requires technical justification but which allows the Planning Coordinator to identify additional units whose excitation control system performance requires scrutiny by the Generator Owner. In some instances, scrutiny by the Generator Owner could lead to corrected model data that could meet the needs of the Planning Coordinator. But unless the Generator Owner can determine that the existing model structure and data requires a correction and subsequently meets the needs of the Planning Coordinator, the model must be verified. The SDT originally considered letting the Transmission Planner identify critical units along with the Planning Coordinator. However, the SDT realized that Transmission Planners could bring model issues to the attention of their Planning Coordinator so that the Planning Coordinator could make a determination about whether the model issue warranted further review by the Generator Owner.

While stakeholders generally agreed with the proposed implementation plan concepts, they expressed some concerns about sufficient start up time. Thus, the SDT decided to propose extending the time after the standard is approved for the first required set of models to be verified from "2 years following regulatory approval, 10% its applicable units per Interconnection on a MVA basis" to "4 years following regulatory approval, 30% of its applicable units per Interconnection on a MVA basis".

Finally, based in part on industry comments, the layout and the formatting of the standard have been significantly updated. Periodicity has been moved to a separate attachment, as the SDT determined that it is not a stand-alone reliability requirement. The standard no longer attempts to follow an expected chronological sequence, but instead is arranged to include the necessary results-based reliability requirements. The most visible modifications are that the numbers of Requirements have been drastically reduced.

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herb Schrayshuen, at 315-439-1390 or herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

Index to Questions, Comments, and Responses

1. **The SDT recognized that a determination had to be made regarding which entity should be ultimately responsible for model verification. The SDT was of the opinion that the Generator Operator, instead of the Transmission Planner or Generator Owner, was the appropriate entity to be responsible for the model verification. The Generator Operator operates the equipment being verified, and has direct access to the equipment. The Transmission Planner has the simulation software, but does not typically have access to the equipment or have testing capabilities. It is recognized that Generator Operators typically do not have in-house expertise and would have to either hire consultants to perform model verification, or develop in-house expertise including acquiring simulation software.** 12
2. **The SDT recognizes that depending on the technology of the modeled equipment, the periodicity of model verification necessary to ensure accurate models could vary. Also, the team recognizes that the majority of the resulting reliability benefit will occur during the initial verification. The SDT determined that 10 years would be an appropriate period for re-verification in the absence of other activities listed in Requirement R12 that would require an earlier re-verification.** 25
3. **The SDT thought that it would be reasonable to apply a philosophy to allow maximization of limited resources required to perform excitation system model verification. The philosophy allows a single unit's actual excitation system verification to be a proxy for multiple units if the following conditions are met: a) the units have the same MVA rating, b) the units are rated at≤ 250 MVA c) the units have identical applicable components and settings and d) the units are sited at the same physical location. For each recurring 10 year cycle, another unit must actually be verified.** 34
4. **The list of unit specific information in Requirement R4 to be provided to the Transmission Planner from the Generator Owner includes generator data used in the excitation system verification process. The reason is that the tests, ambient or staged, which are used to verify the excitation system model, are part of a closed loop system that includes the generator. However, the SDT stopped short of requiring verification of either all generator data, or a portion of the generator data which is most applicable to excitation system testing (Transient Open Circuit Time Constant, and for PSS model verification, rotational inertia). The SDT feels that it cannot develop draft Requirements for the verification of generator data without submitting a supplementary SAR to the NERC Standards Committee.** 43
5. **MOD-026 Requirement R8 requires the Generator Operator to provide documentation demonstrating that the provided model's response matches the recorded response. It does not specify criteria for evaluating the match. Requirement R8 assigns the task of evaluating the match to the Generator Operator. A peer review process for this documentation, detailed in Requirement R10, gives other involved parties an avenue to provide input and voice any concerns.** 61
6. **The team purposely provided minimal specificity regarding the mechanics of performing excitation system verification and the development of the documentation showing that the provided model response matches the recorded response. The team felt it was impractical to provide verification details in a mandatory Reliability Standard that needs to be applicable to all of the existing and future technologies.** 70
7. **The SDT believes that this standard should not be applicable to low capacity factor units. The SDT recognized that the excitation system models and model data are already collected through the processes identified in MOD-012 and**

MOD-013. These models and data should, with few exceptions, already accurately replicate actual equipment performance. By definition, low capacity factor units are expected to rarely be on-line, and even when they are, they would constitute a small portion of the interconnected MVA. As such, the SDT is of the opinion that verified excitation models for these units would not result in a substantial increase in Bulk Electric System reliability. Do you agree with this approach and the proposed 5% capacity factor? 76

8. **The SDT is of the opinion, based upon sound engineering judgment, that verifying models for excitation systems of generators per the MVA thresholds specified in the Applicability section 4.1.1 will ensure satisfactory performance of Interconnection network simulation models. Do you agree with this approach? If yes, please provide any data in support of the proposed approach including supporting data that the MVA thresholds specified in the Applicability section 4.1.1 correspond to 80% of the Interconnection MVA.** 91

9. **Do you believe the SDT should develop a Requirement to allow the Transmission Planner or the Planning Coordinator to identify additional applicable units beyond those specified in section 4.1.1 due to their criticality to the reliability of the Bulk Elecric System? If yes, please include the criteria that should be used by the Transmission Planner or Planning Coordinator to identify critical units with MVA rating less than listed in section 4.1.1 and any supporting data.** 100

10. **The SDT is proposing an implementation plan that requires certain percentages of applicable units to be verified two, six, and eleven years after the standard is approved. The SDT also thought it would be prudent to allow the verification of excitation systems per Regional Entity procedures and guidelines within 5 years of the approval date to be sufficient for demonstrating compliance with this new Reliability Standard. Do you agree with these approaches?** 108

11. **If you are aware of any regional variances that would be required as a result of this standard, please identify them here.** 118

12. **If you are aware of any conflicts between the proposed standard and any regulatory function, rule, order, tariff, rate schedule, legislative requirement, or agreement, please identify them here.** 121

13. **If you have any other questions or concerns with the proposed standard that have not been addressed in responding to the questions above, please provide them here.** 123

1. The SDT recognized that a determination had to be made regarding which entity should be ultimately responsible for model verification. The SDT was of the opinion that the Generator Operator, instead of the Transmission Planner or Generator Owner, was the appropriate entity to be responsible for the model verification. The Generator Operator operates the equipment being verified, and has direct access to the equipment. The Transmission Planner has the simulation software, but does not typically have access to the equipment or have testing capabilities. It is recognized that Generator Operators typically do not have in-house expertise and would have to either hire consultants to perform model verification, or develop in-house expertise including acquiring simulation software.

Do you agree that the Generator Operator should be responsible for model verification? If not, please explain.

Summary Consideration: The vast majority of respondents did not think the Transmission Planning entity was the correct entity to perform verification. There was a significant portion of the industry that thought the Generator Owner should be responsible, instead of the Generator Operator. The SDT consulted the Functional Model Working Group (FMWG), who rendered the opinion that the Generator Owner should be responsible for model verification instead of the Generator Operator. Based on consultation with the FMWG, and industry comments, the SDT changed the applicability from the Generator Operator to the Generator Owner.

Organization	Yes or No	Question 1 Comment
NERC Event Analysis & Information Exchange staff	No	Comments: Although verification (not validation) of generator equipment settings and testing should be the responsibility of the GO, validation of generator models response to actual system events should be done by the Reliability Coordinator. This offers independent oversight of the validation. Also, validation to system events should be done for multiple events. This provides better insight to generator excitation and control performance over a wider range of conditions than a single staged test.
Response: Thank you for your comments. The SDT does agree that the Reliability Coordinator has a critical role in the process of model verification. However, it is expected that any concerns raised by the Reliability Coordinator will result in a formal request by the Transmission Planner to the Generator Owner. That is why the SDT drafted Requirement R11 (reference Requirement R3 in the revised standard), which allows the Transmission Planner the ability to ask the generator entity to perform a technical review of its current excitation system model. Any concern by the Reliability Coordinator would only occur after a post-mortem review of an actual system event where the observed response of the excitation system was not as expected and so while the Reliability Coordinator may provide feedback, the Transmission Planner is deemed the responsible entity for initiating and providing feedback for this review process. The SDT agrees that validation of multiple events by the Reliability Coordinator is desirable. It is hoped that the vast majority of the time, for the vast majority of excitation system responses reviewed by the Reliability Coordinator, the excitation system response would be as expected and as such, a technical review of the excitation system model by		

Organization	Yes or No	Question 1 Comment
the generator entity would not be necessary.		
Northeast Power Coordinating Council	No	The Generator Operator does not have direct access to the equipment. The Generator Owner is the correct Functional Model entity that has direct access to the equipment and the authority to perform testing of equipment. All responsibilities assigned to the Generator Operator in the proposed standard should be reassigned to the Generator Owner.
Response: Thank you for your comments. The SDT obtained guidance from the FMWG, and as a result of that guidance, your comments, and other industry comments, the draft standard has been modified to assign responsibilities to the Generator Owner instead of the Generator Operator.		
SERC Dynamics Review Subcommittee (DRS)	No	The Generator Owner is the correct entity for this responsibility. It should be the entity that would be able to obtain the attention of the manufacuturer and have the means to accomplish the validation. The entity should have the financial incentives to perform the function and should be knowledgable about the plant operation. The entitiy that would be the best resource to coordinate the testing should be required to verify the models. In our opinion the functional model specifies the Generator Owner as it requires a generator owner to "verify generating facility performance characteristics". For the foregoing reasons this responsibility should not be assigned to the Transmission Planner.
Response: Thank you for your comments. The SDT agrees that the Transmission Planner is not the appropriate entity to be responsible for model verification. Based on your comment, other comments from industry, and input from the FMWG, the SDT has assigned the Generator Owner as the responsible entity for model verification in the second draft standard posting.		
Dominion	No	In general, there should be collaborations between the Generator Owner, Transmission Planner, Generator Operator, and Transmission Operator to meet the intent of model and data verification. However, the requirements of this standard should apply to the Generator Owner and the Transmission Planner. We have reviewed the NERC Functional Model and believe that the Generation Owner should be responsible for those requirements assigned to the Generator Operator in this draft standard. We are concerned that Generator Owners may have to acquire outside sources or develop in-house skills in order to meet the requirements of this standard. However, we believe that the proposed effective date(s) allows adequate time to address these concerns.
Response: Thank you for your comments. The SDT agrees that collaboration from various entities is required to meet the intent of model and data verification. Based on your comment, other comments from industry, and input from the FMWG, the SDT has assigned the Generator Owner as the responsible entity for model verification in the second draft standard posting.		

Organization	Yes or No	Question 1 Comment
MRO NERC Standards Review Subcommittee	No	To help differentiate the BES model from the unit specific excitation system model. The MRO NSRS suggests a change in R1 to read; "The Generator Operator shall verify their applicable excitation control system model?"
Response: Thank you for your comment. After review of IEEE 421.1, the SDT agrees that the term “excitation control system model” is more appropriate than the term “excitation system model” used in the previous draft of the standard. The reason is that the term “excitation control system model” contains the entire closed loop system including the synchronous machine. The SDT has applied the appropriate wording revision in the second draft of the standard.		
Pepco Holdings, Inc (PHI) - Affiliates	No	PHI believes that the Generator Owner should be responsible, but recognizes that the GO and GOP may be the same in most cases.
Response: Thank you for your comment. Based on comments from the industry, your comment, and input from the FMWG, the SDT has assigned the Generator Owner as the responsible entity for model verification in the second draft standard posting.		
Entergy Fossil Operations	No	Gnerator Owners are responsible for the maintenance of the units. This testing is not an on-line normal test. It is more of a maintenance/engineering task that would use 3rd parties to help perform. This would also require special budgeting and running a unit with off normal conditions which an owner would have to approve and sanction. Generator Owners are responsible for other Modeling standards, so wht would they not be responsible here. This is also providing data that is of no use to the Generator Owner or Operator and they will not have any expertise with this work. Only the Transmission Planner needs this data and should understand it. In that aspect, they should take some responsibility for it.
Response: Thank you for your comments. Based on comments from the industry, your comments, and on guidance from the FMWG, the SDT has assigned responsibility for model verification to the Generator Owner instead of the Generator Operator in the second draft of the standard. The current modeling standards address submission of models and model data, not verification of models and model data. Generator entities are also responsible for verification of MW and Mvars in the current and future draft versions of MOD-024 and MOD-025. Generator Owners have access to the equipment, along with access to the equipment’s Original Equipment Manufacturer for assistance with technical issues. Historically, the Transmission Planner and Generator Owner entities used to work for the same company, but in today’s functional model environment, Transmission Planners could easily work for a different company than the generation entity. As such, the stated access advantages for the generation entity do not transfer to the Transmission Planner.		
IRC Standards Review Committee	No	This responsibility rests with the Generator Owner. As indicated in the Background Information Section, Generator Owners may be responsible for providing accurate generator data including the excitation data for system modeling. Although it does not operate the generator, verification does not need to be performed under operating conditions only. The input/output measurements of the excitation system could suffice to verify the excitation system model, which may be performed during commissioning testing or under other non-production conditions. If the generator must be run by the Generator Operator to enable testing, the Generator Owner can

Organization	Yes or No	Question 1 Comment
		make such an arrangement with the Generator under an agreement, as the Background Information so suggests. Further, we believe both the Transmission Planner and the Planning Coordinator are primary users of the model. We suggest that the Planning Coordinators be added to the Applicability Section, and at places where Transmission Planners are assigned a responsibility.
Response: Thank you for your comments. As suggested, the SDT has assigned model verification responsibility to the Generator Owner in the second draft of the standard. While the Planning Coordinator may be a user of the model, the SDT believes that the Transmission Planner is the appropriate entity to interface with the Generator (Owner/Operator) regarding necessary activities that are required to achieve excitation control system model verification. As such, the SDT believes that the Transmission Planning entity is the correct entity assigned. Also, it should be noted that the SDT did reference the Planning Coordinator in the Requirements as appropriate.		
Luminant Power	No	In ERCOT the Generation Owner should be responsible. This is a NERC Functional model issue, and I understand the GOP will be responsible in the majority of the country.
Response: Thank you for your comment. Based on comments from industry, your comment, and on guidance from the FMWG, the SDT has assigned responsibility for model verification to the Generator Owner instead of the Generator Operator in the second draft of the standard.		
Exelon Corporation	No	Exelon believes that model verification should be a coordinated effort between the generator owner and the transmission planner. Transmission planning organizations have the expertise to implement and test the models in software, while the generator owners have the necessary access to the equipment in the field. Most generator owners do not have the software and the necessary personnel with the expertise to perform the modeling and model testing required by this standard.
Response: Thank you for your comments. The SDT agrees that a cooperative effort is required among NERC functional model entities in order to develop a robust excitation system model. As mandated by Reliability Standard process, only one entity is assigned responsibility for excitation system model verification. The SDT believes it has incorporated into the draft standard all necessary interactions with other functional model entities required for ensuring model verification success.		
Southern Company	No	The Generator Owner appears to be the logical choice. GO has the access to the equipment records, GOP may not.
Response: Thank you for your comments. Based on guidance from the FMWG, comments from industry, and your comment, the SDT has assigned responsibility for model verification to the Generator Owner instead of the Generator Operator in the second draft of the standard.		
Consumers Energy Company	No	Generator Owners and Generator Operators do not need or use an excitation system model. This model is

Organization	Yes or No	Question 1 Comment
		properly owned by those who need and use it, i.e., the Transmission Planner or Transmission Owner. The Generator Owner should be responsible only for providing input data for the model. These data include such items as:- Manufacturer (and model, if available) and type of excitation system.- Rise times, reactances, time constants, gains, and saturation factors.- Rotational inertia- Reactive compensation settings, if any.- Power system stabilizer settings, if any.- Other stability schemes, if any.Given periodic verification of these data from the Generator Operator, it should be the responsibility of the Transmission Planner to create a model that meets the needs of the Transmission Planner. Since the Generator Operator doesn't need this model, requiring the Generator Operator to hire consultants to create a model needed by other entities is simply errant nonsense. Has the SDT verified that there are adequate consultants available to meet the 2-year time window for the myriad of Generator Operators who would be tasked with creating a model they do not need?
Response: Thank you for your comments. The SDT understands that no matter who is assigned responsibility in the proposed continent-wide standard, it would potentially change the current business model of the functional entity. The majority of the SDT believes that a generation entity should have both final excitation system model responsibility and authority; Based on the majority of industry comments and guidance from the FMWG, the second draft of the standard assigns responsibility to the Generator Owner. Generator Owners have access to the equipment, along with access to the equipment's Original Equipment Manufacturer for assistance with technical issues. Historically, the Transmission Planner and Generator Owner entities used to work for the same company, but in today's functional model environment, Transmission Planners could easily work for a different company than the generation entity. As such, the stated access advantages for the generation entity do not transfer to the Transmission Planner. Note that existing business practices that utilize Transmission Planners can still exist; the only difference is that the Generator Owner would be ultimately responsible for the excitation system model verification from a compliance perspective. Also, the SDT is proposing an Implementation Plan to allow the Generator Owner time to develop in-house expertise to perform model verification if they do not desire to hire consultants.		
City of Garland, Garland Power & Light - GOP Registered Entity	No	The Generator Owner (GO) should be responsible for model verification. The GO has direct access to the equipment - not the GOP. The GO can schedule any required operational testing with the GOP in the same way that the GO schedules any other operational testing requirement. In addition, the GOP and the GO can be two separate companies with their only relationship established by contract. In these situations this standard, as written, would place the burden on the GOP to try to renogoiate the contract with the GO to cover the expense and pursuade the GO to perform the model verification when the real responsibility belongs to the GO.
Response: Thank you for your comments. As recommended, the SDT has assigned responsibility for model verification to the Generator Owner instead of the Generator Operator in the second draft of the standard.		
American Wind Energy Association	No	Because Generator Operators typically do not have in-house expertise and would have to either hire consultants to perform model verification, or develop in-house expertise including acquiring simulation software, I think it makes more sense for Transmission Planners to perform this activity.

Organization	Yes or No	Question 1 Comment
Response: Thank you for your comments. Generator Owners have access to the equipment, along with access to the equipment's Original Equipment Manufacturer for assistance with technical issues. Historically, the Transmission Planner and Generator Owner entities used to work for the same company, but in today's functional model environment, Transmission Planners could easily work for a different company than the generation entity. As such, the stated access advantages for the generation entity do not transfer to the Transmission Planner. Also, the Transmission Planner has expertise in overall power system simulation analysis but not necessarily expertise in specific excitation control system modeling. While the Transmission Planner can continue to participate in model verification to whatever extent agreements with the generator entity stipulates, the majority of the SDT (and industry, based upon comments received) does not believe the Transmission Planner should be responsible for this activity.		
American Electric Power	No	AEP believes that It would be more appropriate to designate the Generator Owner for these responsibilities.
Response: Thank you for your comment. The SDT has assigned responsibility for model verification to the Generator Owner instead of the Generator Operator in the second draft of the standard.		
Wisconsin Electric	No	See response to Question 5. Providing model data and parameters is possible, but the requirement to validate the model for an actual switching event requires a cooperative effort between the GOP and the TP/TOP/TP. Since the stability and reliability of the overall transmission system is the goal, it is necessary for these entities to have more responsibility for proper excitation system modeling. As it stands this draft standard puts all the responsibility on the GOP.
Response: Thank you for your comments. The SDT agrees that a cooperative effort is required among NERC functional model entities in order to develop a robust excitation system model. As mandated by Reliability Standard process, only one entity is assigned responsibility for excitation system model verification. The SDT believes it has incorporated into the draft standard all necessary interactions with other functional model entities required for ensuring model verification success. For the specific example referenced regarding verification of an event, the SDT believes the currently drafted standard would facilitate cooperation. Specifically, drafted Requirement R8 (reference Requirement R2 in the revised standard) does allow for the equipment's recorder response to be the result of a measured system disturbance. However, it should be pointed out that a pure "switching event" may not result in a voltage deviation of sufficient magnitude at the terminals of the generator.		
Progress Energy, Inc.	No	The Generator Owner is the correct entity for this responsibility. It must be the entity that would be the most able to obtain the attention of the manufacuturer and have the means to accomplish the validation. The entity must have the financial incentives to perform the function and must be knowledgable about the plant operation. The entitiy that would be the best source to coordinate the testing could be required to verify the models. In our opinion the functional model specifies Generator Owner as it requires a generator owner to "verify generating facility performance characteristics". For the foregoing reasons this responsibility should not be assigned to the Transmission Planner.

Organization	Yes or No	Question 1 Comment
Response: Thank you for your comments. The SDT agrees that the Transmission Planner is not the appropriate entity to be responsible for model verification. Based on your comment, other comments from industry, and input from the FMWG, the SDT has assigned responsibility for model verification to the Generator Owner instead of the Generator Operator in the second draft of the standard.		
Dynegy	No	The Generator Owner does not need or use an excitation system model. The Transmission Planner is the entity that uses and needs this model to be accurate. The Generator Owner should be responsible for collecting and providing the generator related input data for the model to the Transmission Planner. The Transmission Planner should be responsible for running the simulations required for model verification and making the judgment if the model's response matches the actual response.
Response: Thank you for your comments. It is in the best interest of all parties, transmission and generation, to develop an accurate excitation system model as these models ultimately result in the determination of acceptable secure conditions for the generator to operate. The majority of the SDT believes that the generation entity should have both final excitation system model responsibility and authority. Generator Owners have access to the equipment, along with access to the equipment's Original Equipment Manufacturer for assistance with technical issues. Historically, the Transmission Planner and Generator Owner entities used to work for the same company, but in today's functional model environment, Transmission Planners could easily work for a different company than the generation entity. As such, the stated access advantages for the generation entity do not transfer to the Transmission Planner. This makes it prohibitive for the Transmission Planner to resolve issues regarding a mismatch between the predicted model response and the actual equipment's recorded response.		
Northeast Utilities	No	The Generator Owner is the correct Functional Model entity that has direct access to the equipment and the authority to perform testing of equipment. All responsibilities assigned to the Generator Operator in the proposed standard should be reassigned to the Generator Owner.
Response: Thank you for your comments. Based on your comment, other comments from industry, and input from the FMWG, the SDT has assigned responsibility for model verification to the Generator Owner instead of the Generator Operator in the second draft of the standard.		
ISO New England Inc.	No	The Generator Operator has the greatest ability to develop and/or provide accurate models and model parameters for its equipment. The Generator Owner should also be involved in the verification process as required. The process should ideally allow interations between the GO and TO to allow for needed adjustments to model compatability issues and settings with the GO, It should be field verified data not just a self certification of data without the field verification.
Response: Thank you for your comments. The SDT obtained guidance from the FMWG, and as a result of that guidance and other industry comments, the second draft standard assigns responsibilities to the Generator Owner instead of the Generator Operator. The SDT agrees there must be interaction between transmission and generation entities; and has attempted to capture these interactions in the Requirements.		

Organization	Yes or No	Question 1 Comment
Ameren	No	(1)Generator Operators and Generator Owners both should be included in this standard. The entitiy that would be the best source to coordinate the testing could be required to verify the models. It is possible that all functions can not be performed by the Generator Operator alone. Therefore it would be prudent to include the Generator Owners within MOD-026-1. (2) Additionally, the GO would be able to obtain the attention of the manufacuturermanufacturer than GOP. In our opinion the functional model specifies Generator Owner as it requires a generator owner to "verify generating facility performance characteristics". In any case, this responsibility should not be assigned to the Transmission Planner. (3) On the other hand, GO/GOP should not perform the function of modeling or verifying dynamic simulations on the Bulk Electric System which generally is done by Transmission Planners. Generator Operators/Generator Owners should provide the data needed for model simulation. Generator Operators/Generator Owners do not possess the expertise or have the resources to perform modeling simulations.
Response: Thank you for your comments. The SDT believes only one entity can be assigned responsible for model verification. Based on comments from industry, Item 2 of your comments, and input from the FMWG, the SDT has assigned responsibility for model verification to the Generator Owner instead of the Generator Operator in the second draft of the standard. It is anticipated that the Generator Owner could delegate model verification activities to the Generator Operator by contractual agreement as appropriate. The draft standard does not require the Generator entity to perform dynamic simulations to determine Bulk Electric System limits. The generator entity is responsible for ensuring that the excitation system model response matches the response from a recorded voltage excursion. This can be accomplished through software that is much simpler than full dynamic simulation software utilized by Transmission Planners for assessing BES limits.		
AESO	No	The AESO agrees with the SRC ISO/RTO comments.
Response: Thank you for your comment. Please see the response to the SRC IRO/RTO comments.		
Duke Energy	No	Based on Responsibilities in the Functional Model, responsibility for determining maintenance and verification activities is clearly assigned to the Generator Owner. It should also be noted that in some cases the GO may be able to obtain additional expertise from their TP, RTO, or Region, which adds other resource options.
Response: Thank you for your comments. We agree. With guidance received from the FMWG, the Generator Owner is considered the appropriate entity for assigning model responsibility and this change is reflected in the second posting of the draft standard. The SDT agrees that the Generator Owner can seek expertise from others including the entities listed in your observation.		

Organization	Yes or No	Question 1 Comment
Hydro-Québec TransEnergie (HQT)	No	The Generator Operator does not have direct access to the equipment. The Generator Owner is the correct Functional Model entity that has direct access to the equipment and the authority to perform testing of equipment. All responsibilities assigned to the Generator Operator in the proposed standard should be reassigned to the Generator Owner.
Response: Thank you for your comments. We agree. The SDT has assigned responsibility for model verification to the Generator Owner instead of the Generator Operator in the second draft of the standard.		
Independent Electricity System Operator	No	This responsibility rests with the Generator Owner. As indicated in the Background Information Section, Generator Owners may be responsible for providing accurate generator data including the excitation data for system modeling. Although it does not operate the generator, verification testing does not need to be performed under operating conditions only. The input/output measurements of the excitation system could suffice to verify the excitation system model, which may be performed during commissioning testing or under other non-production conditions. If the generator must be run by the Generator Operator to enable testing, the Generator Owner can make such an arrangement with the Generator Operator under an agreement, as the Background Information so suggests.
Response: Thank you for your comments. The SDT obtained guidance from the FMWG. Based on this guidance, your comments, and other industry comments, The SDT has assigned responsibility for model verification to the Generator Owner instead of the Generator Operator in the second draft of the standard.		
Brazos Electric Power Cooperative	No	Even though a Generator Operator could possible supply and verify the information, it should be the Generator Owner who owns equipment design information that is responsible for it and be directly responsible for compliance with the requirements.
Response: Thank you for your comments. The SDT has assigned responsibility for model verification to the Generator Owner instead of the Generator Operator in the second draft of the standard.		
US Bureau of Reclamation	No	We believe the Generator Owner should be responsible for model verification. The existing NERC Standard, MOD-012-0 requires the Generator Owner to provide dynamic system modeling and simulation data to the RRO. In addition, MOD-013-0, RRO Dynamics Data Requirements and Reporting Procedures (not FERC approved), requires the RRO to coordinate with the Generator Owner to develop comprehensive dynamics data requirements and reporting procedures needed to model and analyze dynamic behavior. As such we believe this standard should be consistent and apply to Generator Owners.In addition, the NERC Reliability Functional Model - Version 4 describes the Generator Owner relationships with other entities including "Provides generator information to the Transmission Operator, Reliability Coordinator, Balancing Authority, Transmission Planner, and

Organization	Yes or No	Question 1 Comment
		Resource Planner."
Response: Thank you for your comments. The SDT agrees with your reasoning and has assigned responsibility for model verification to the Generator Owner instead of the Generator Operator in the second draft of the standard.		
Reliant Energy	No	Generator Operators should not have the sole responsibility alone. With the Generator Operators typically not having the in-house expertise for the model verification, they must not only pay the cost of hiring consultants, but will also carry the burden of significant costs for low capacity factor units when trying to schedule the consultants for unpredicable run times. WECC unit verification testing has resulted in very expensive startup costs for low capacity factor units just to perform a test. There is no cost recovery method for running a unit out of the money to perform this testing.
Response: Thank you for your comments. The SDT is currently proposing an exemption for units with a 5% or less capacity factor. By considering exemption for units with low capacity factor, and the established rating threshold for each interconnection, and also the 10-year periodicity requirement defined, the SDT believes situations will not occur where units are dispatched only to perform an excitation control system verification test. As mandated by Reliability Standard process, only one entity is assigned responsibility for excitation system model verification. The SDT believes it has incorporated into the draft standard all necessary interactions with other functional model entities required for ensuring model verification success.		
Wisconsin Public Service	Yes	The Generator Owners, instead of Transmission Planners, are the logical entities to verify the proper functioning of the excitation system functions, but not the verifications of hypothetical parameter values of a model used to emulate the exciters' function. The generator Owners should, for example, verify that the AVR holds set terminal voltages under normal operating system conditions, as well as response to system changes in conformance with the stated Response Ratios as designed. This does not mean, however, that it would be necessary to confirm forward gains, transducer time constants, excitation saturation constants, feedback-loop gains and time constants, etc. are indeed of the same value as used in a hypothetical model. This is due to two reasons: 1) the particular model chosen by the transmission planner is known to be an approximation of the facilities' functions, and therefore the parameters are not unique; 2) instrumentations necessary for verification of specific parameters are not generally available in the industry.
Response: Thank you for your comments. Based on comments from industry, your comment, and guidance from the FMWG, the SDT has assigned responsibility for model verification to the Generator Owner instead of the Generator Operator in the second draft of the standard. The SDT believes that in most cases, the excitation system control model parameters in use accurately represent the equipment. The SDT also believes that instrumentation utilized for model verification is widely available.		
FirstEnergy	Yes	Although we ultimately agree, we have the following comments:1. The Generator Operator should be responsible

Organization	Yes or No	Question 1 Comment
		to verify the dynamic data is accurate for the Generator, Turbine and Excitation system. The ultimate responsibility for the usability and accuracy of the dynamic models and how they perform in relation to the overall system model is the responsibility of the Transmission Planner.2. Genertor operators in a centrally located dispatch office would not have direct access to the equipment. They can only arrange an actual verification test. Details of the units response to a disturbance would need to be gleaned from the Generator Owner's data. It is not appropriate to burden one entity with a potential compliance violation when another entity controls the data. Relying on agreement coordination between the two entities may not be sufficient to ensure the entity with responsibility to comply is able to comply with an uncooperative entity with data control.
Response: Thank you for your comments. The SDT obtained guidance from the FMWG which recommends assigning this responsibility to the Generator Owner. Also, the majority of the industry agrees that the Generator Owner should be assigned responsibility for model verification. Therefore, the SDT has assigned responsibility for model verification to the Generator Owner instead of the Generator Operator in the second draft of the standard.		
Cowlitz County PUD	Yes	Did you mean to say above that Generator Owners typically do not have in-house expertise and would have to either hire...? YES - Cowlitz as a Generator Owner does not have the in house expertise. Delays result in our efforts to obtain modeling information as we try and find consultants willing to do the work. The Generator Operator is the entity which should be held responsible.
Response: Thank you for your comments. The SDT obtained guidance from the FMWG which recommends assigning this responsibility to the Generator Owner. Also, the majority of the industry agrees that the Generator Owner should be assigned responsibility for model verification. Therefore, the SDT has assigned responsibility for model verification to the Generator Owner instead of the Generator Operator in the second draft of the standard.		
CenterPoint Energy	Yes	CenterPoint Energy concurs with the SDT that this is a reasonable approach.
Response: Thank you for your comment. The SDT obtained guidance from the FMWG which recommends assigning this responsibility to the Generator Owner. Also, the majority of the industry agrees that the Generator Owner should be assigned responsibility for model verification. Therefore, the SDT has assigned responsibility for model verification to the Generator Owner instead of the Generator Operator in the second draft of the standard.		
Reliant Energy	Yes	Unit operation not unit ownership impacts the reliability of the grid.
Response: Thank you for your comment. The SDT obtained guidance from the FMWG which recommends assigning this responsibility to the Generator Owner. Also, the majority of the industry agrees that the Generator Owner should be assigned responsibility for model verification. Therefore, the SDT has assigned responsibility for model verification to the Generator Owner instead of the Generator Operator in the second draft of the standard.		
Indiana Municipal Power Agency	Yes	IMPA recognizes that the Generator Operator can work with the Transmission Planner when it comes to using

Organization	Yes or No	Question 1 Comment
		the verified data in a proper model or simulation software program. This assistance from the Transmission Planner might mean that the Generator Operator does not need to purchase modeling software.
Response: Thank you for your comments. Based on comments from industry and guidance from the FMWG, the SDT has assigned responsibility for model verification to the Generator Owner instead of the Generator Operator in the second draft of the standard. The SDT agrees with your statement that agreements between the Transmission Planner and the Generator Owner can be arranged for the Transmission Planning entity to perform portions of the model verification process however responsibility for model verification remains with the Generator Owner.		
Xcel Energy	Yes	
Southwest Power Pool Generation Working Group	Yes	
Kansas City Power & Light	Yes	
FEUS	Yes	
Constellation Power Generation & Constellation Nuclear	Yes	
E.ON U.S.	Yes	
AWEA	Yes	
Arizona Public Service Co.	Yes	
Manitoba Hydro	Yes	
Southern California Edison	Yes	
American Transmission Company	Yes	
Response: Thank you for your comments. The SDT obtained guidance from the FMWG which recommends assigning this responsibility to the Generator Owner.		

Organization	Yes or No	Question 1 Comment
Also, the majority of the industry agrees that the Generator Owner should be assigned responsibility for model verification. Therefore, the SDT has assigned responsibility for model verification to the Generator Owner instead of the Generator Operator in the second draft of the standard.		

2. The SDT recognizes that depending on the technology of the modeled equipment, the periodicity of model verification necessary to ensure accurate models could vary. Also, the team recognizes that the majority of the resulting reliability benefit will occur during the initial verification. The SDT determined that 10 years would be an appropriate period for re-verification in the absence of other activities listed in Requirement R12 that would require an earlier re-verification.

Do you agree that 10 years is an appropriate period for re-verification? If you recommend a different period, please state your reasoning.

Summary Consideration:

The majority of industry agreed that the proposed 10 year periodicity verification cycle is appropriate. Therefore, the SDT will maintain the 10-year periodicity verification cycle proposed in the draft standard.

Organization	Yes or No	Question 2 Recommended Periodicity and Reasoning:
Kansas City Power & Light	No	The Electric Power Research Institute has issued a report, "Power Plant Modeling and Parameter Derivation for Power System Studies", number 1015241, Final Report, June 2007; a reasonable interpretation of that work is that there may not be sufficient benefits from using a highly complex model to overcome the potential risks of the testing needed to verify the most complex models. Prototype test data obtained by manufacturers to provide the initial data, in many cases, simply can not be duplicated on operating / operational equipment. The 10 year re-verification requirement, as presently written, does not appear to allow generator owners the necessary flexibility to determine, similar to the regulatory model of 10 CFR 50.59 "Changes, Tests, and Experiments", how detailed the "re-verification" activities need to be. The requirement to re-perform the same bank of physical tests used to originally validate the generator model, absent a physical modification, does not allow sufficient flexibility to perform only those "re-verification" activities for those model parameters whose change due equipment aging has discernable effect on the outcome of the analysis using the generator model. Please note that the concern for performance of tests with little discernable analytical benefit was previously voiced in the "MAAC Position Paper on Generator Testing to Verify Data Required for System Modeling" in the Phase III-IV Planning Standards comments, which can be found on the NERC www site, where the issue of testing nuclear units in compliance with the regulatory requirements of 10 CFR 50.59 was also noted.As a result, it is recommended the SDT consider removing all references in the requirements for periodic testing when no physical changes have taken place and clarify R12 reflects to reverify the parts of the modeling affected by a change and not a reverification of

Organization	Yes or No	Question 2 Recommended Periodicity and Reasoning:
		the entire model. In addition, although the reason to verify generator modeling is logical, it is requested the SDT consider the references stated above and consider the removal or modification of requirements involving testing that place an unncessary risk of generator damage. As an example, allowing vendor simulations or other testing methods by the Vendor in a suitable testing environment to suffice for obtaining generator response characteristics.
Response: Thank you for your comments. The SDT does not believe that there is undue risk to a plant for properly executed excitation system model verification. The validation can also be done using ambient monitoring with no additional tests. The 10-year requirement for re-verification is also overwhelmingly supported by the industry. In any event, there is no requirement to “re-perform the same bank of physical tests.”		
FirstEnergy	No	10 years for digital excitation systems and 5 years for non-digital excitation systems.
Response: Thank you for your comments. The SDT believes that re-verification every 5 years is unnecessary. This position is supported by an overwhelming majority of comments received from the industry. The revised Requirements R3 and R4 contain provisions for performing re-verification earlier if justified.		
Entergy Fossil Operations	No	I am OK with 10 years for analog systems. Newer digital systems should not change over time, so they should be tested upon commissioning and that should be adequate for the life of the unit.
Response: Thank you for your comments. The SDT believes that 10 years is a reasonable re-verification requirement even for digital systems, even if model verification is based on a sister unit. This position is supported by an overwhelming majority of comments received from the industry.		
IRC Standards Review Committee	No	While a 10 year re-verification period may be adequate for those exciters whose settings do not tend to drift over time, a shorter period, say 5 years, should apply in general since there are analog and rotating type of exciters whose settings tend to drift from time to time.
Response: Thank you for your comments. The SDT believes that re-verification every 5 years is unnecessary. This position is supported by an overwhelming majority of comments received from the industry. The revised Requirements R3 and R4 contain provisions for performing re-verification earlier if justified.		
E.ON U.S.	No	E.ON U.S. believes that verification data and model results should not change over time. Therefore, a re-verification schedule is not necessary. E.ON U.S recommends that verification be required whenever new equipment is installed.
Response: Thank you for your comments. The SDT believes that 10 years is a reasonable re-verification period. Re-verification does not necessarily require a re-test and in most instances, ambient monitoring can also be used. The proposed 10 year re-verification period is also supported by an overwhelming majority of comments received from the industry.		

Organization	Yes or No	Question 2 Recommended Periodicity and Reasoning:
American Electric Power	No	AEP believes that the period should be longer. In fact, verification should only need to be done once on older units that do not now have good commissioning test documentation. Beyond that, it should only need to be done if there is an applicable equipment upgrade or an intentional readjustment of settings. We question predicating the periodicity on the expectation of a significant variation in equipment performance due to aging alone.
Response: Thank you for your comments. The SDT believes that 10 years is a reasonable re-verification period. Re-verification does not necessarily require a re-test and in most instances, ambient monitoring can also be used. The proposed 10 year re-verification period is also supported by an overwhelming majority of comments received from the industry.		
Reliant Energy	No	The period for re-verification should be based on observed performance, by activities that could result in an alteration of equipment performance or as listed in Requirement R11 which could trigger a review includes Plant Digital Control System (DCS) additions, replacements, or software alterations. Plant DCS activities would only be relevant to excitation system modifications if they involved the addition, deletion, or modification of an outer loop control (such as power factor or reactive power set point) that alters automatic voltage regulator action. If it ain't broke don't fix it!
Response: Thank you for your comments. The SDT believes that 10 years is a reasonable re-verification period. Re-verification does not necessarily require a re-test and in most instances, ambient monitoring can also be used. The proposed 10 year re-verification period is also supported by an overwhelming majority of comments received from the industry. Also, several SDT team members have observed that DCS changes can affect excitation system performance within the timing cycle of the excitation system model..		
ISO New England Inc.	No	We recommend validation on a 5 year scale. 10 years is too long if changes are made to settings during annual outages. The whole approach of the draft standard is a bit flawed because once the model and tuned parameters are verified, no control setting changes should be made to the physical equipment without consulting with the TO to determine their acceptability. Additionally, updates should be provided if the manufacturer or GO identify improvements to the model in regard to matching the actual equipment. Having a verification in addition to the preceding is acceptable and would provide the benefit of having a written documentation from the GO and better assure that acccurate models are being used for planning the system.
Response: Thank you for your comments. The SDT believes that re-verification every 5 years is unnecessary. This position is supported by an overwhelming majority of comments received from the industry. The revised Requirements R3 and R4 contain provisions for performing re-verification earlier if justified.		

Organization	Yes or No	Question 2 Recommended Periodicity and Reasoning:
Ameren	No	(1) Many generating units are now on six year outage cycles, therefore we recommend the interval is changed to 12 years or more.(2) Concerns regarding excitation equipment are that someone at the plant may inadvertently modify settings on dials/potentiometers at some point within a 10/12 year period (or other interval that would be considered appropriate) that would cause the performance of the exciter to vary from what was originally specified in the dynamic model representation. Also, it is possible that, through aging, electrical values of circuit components in the excitation equipment could drift, even with no external change to the settings. It is uncertain what the re-verification period should be to minimize these effects, so we support the caveats listed in Requirement 11 and 12. However, despite R12, some communication between the Generation Operator and the Transmission Operator within the 10/12 year period would be reassuring that nothing has changed. Because 10/12 years is a long time, the Generator Owner should be required to respond upon request of the Transmission Planner confirming that nothing has changed. Further, the second bullet of R11 might also note that the Generation Operator must verify for the model for the first time if the model was derived from a 'sister' unit or repeat the verification on one previously verified.
Response: Thank you for your comments. The SDT believes that 10 years is a reasonable re-verification period. Re-verification does not necessarily require a re-test and in most instances, ambient monitoring can also be used. The proposed 10 year re-verification period is also supported by an overwhelming majority of comments received from the industry. The SDT is not sure of the intent of the last sentence. The SDT does not believe that model verification of each unit is needed if the units satisfy the sister unit definition. The SDT also believes requiring communication for activity that does not change settings or create evidence indicating setting have changed is an unnecessary burden. However, if an activity is performed that could change settings or creates evidence of setting changes, then the revised Requirements R3 and R4 contain provisions for performing re-verification earlier if justified.		
AESO	No	The AESO agrees with the SRC ISO/RTO comments. We would also like to add: WECC requirements state every 5 years. 5 years seems more resonable than 10 years to ensure that the generating unit is still performing as intially sepceified and there has been no no component degradation causing the settings to drift.
Response: Thank you for your comments. The SDT believes that re-verification every 5 years is unnecessary. This position is supported by an overwhelming majority of comments received from the industry. The revised Requirements R3 and R4 contain provisions for performing re-verification earlier if justified.		
Duke Energy	No	It would seem that the need to revalidate is driven by technical issues (analog controls drift, digital doesn't). There is an EPRI guide (1004556) that specifies a 5 year frequency for analog AVR calibrations. The SDT should discuss different periods based upon different control technologies (e.g. digital versus analog).In addition to R12, some communication between the Generation Operator and the Transmission Operator within the 10 year period would be reassuring that nothing has changed.
Response: Thank you for your comments. The SDT believes that 10 years is a reasonable re-verification period. Re-verification does not necessarily require a		

Organization	Yes or No	Question 2 Recommended Periodicity and Reasoning:
re-test and in most instances, ambient monitoring can also be used. The proposed 10 year re-verification period is also supported by an overwhelming majority of comments received from the industry. The SDT also believes requiring communication for activity that does not change settings or create evidence indicating setting have changed is an unnecessary burden. However, if an activity is performed that could change settings or creates evidence of setting changes, then the revised Requirements R3 and R4 contain provisions for performing re-verification earlier if justified.		
American Transmission Company	No	The 10 year period is too long and should be changed to 5 years in order to ensure greater model accuracy.
Response: Thank you for your comment. The SDT believes that re-verification every 5 years is unnecessary. This position is supported by an overwhelming majority of comments received from the industry. The revised Requirements R3 and R4 contain provisions for performing re-verification earlier if justified.		
US Bureau of Reclamation	No	We believe the 10 year period is too long. It is hard to make the case for reliability-based need for this standard when 10 years are allowed to complete the modeling. Suggest changing the initial implementation period to 5 years which is the implementation period provided in the WECC regional policy. Ten years may then be appropriate for re-validation.
Response: Thank you for your comments. The purpose of the initial 10-year implementation period is to give industry sufficient time to perform verification on required units with limited expertise available. The SDT believes that 10 years is a reasonable re-verification period. Re-verification does not necessarily require a re-test and in most instances, ambient monitoring can also be used. The proposed 10-year re-verification period is also supported by an overwhelming majority of comments received from the industry.		
Independent Electricity System Operator	No	We believe a 10 year re-verification period is adequate for those exciters whose settings do not tend to drift over time. However, a shorter period, say 5 years, should apply to the analog or rotating type of exciters.
Response: Thank you for your comments. The SDT believes that with Requirements R11 and R12 in the original posting (reference Requirements R3 and R4 in the revised standard) in place, a 5 year re-verification period is unnecessary, even for analog and rotating exciters. This position is also supported by an overwhelming majority of comments received from the industry. The revised requirement R4 (reference footnote) 1 contains provision for earlier re-verification if such a need is justified.		
NERC Event Analysis & Information Exchange staff	Yes	Ten years is an adequate backstop for re-testing. However, it should additionally be tempered by performance differences observed during validation to actual or staged system events. Repeated matching of model performance to events should also make a ten year test unnecessary.
Response: Thank you for your comments. The overwhelming majority of the comments received from industry support a 10-year re-verification period. The SDT agrees that the repeated matching of model performance to events can be acceptable verification however, the required data must be submitted every 10 years to		

Organization	Yes or No	Question 2 Recommended Periodicity and Reasoning:
ensure that proper verification has been completed.		
Northeast Power Coordinating Council	Yes	A ten-year interval is acceptable given the conditions in Requirement R12.
Response: Thank you for your comment.		
SERC Dynamics Review Subcommittee (DRS)	Yes	We agree as long as there is a requirement such as R11. The second bullet of R11 might also note that the Generation Operator (Owner) must verify the model for the first time if the model was derived from a 'sister' unit or repeat the verification on one previously verified. Despite R12, some communication between the Generation Operator (Owner) and the Transmission Operator, within the 10 year period stating that nothing has changed would be reassuring. Because 10 years is a long time, the Generator Owner should be required to respond if requested by the Transmission Planner confirming that nothing has changed.
Response: Thank you for your comments. The SDT is not sure of the intent of the second sentence. The SDT does not believe that model verification of each unit is needed if the units satisfy the sister unit definition. The SDT also believes requiring communication for activity that does not change settings or create evidence indicating setting have changed is an unnecessary burden. However, if an activity is performed that could change settings or creates evidence of setting changes, then the revised Requirements R3 and R4 contain provisions for performing re-verification earlier if justified.		
Progress Energy, Inc.	Yes	As long as there is a requirement such as R11. The second bullet of R11 might also note that the Generation Operator must verify for the model for the first time if the model was derived from a 'sister' unit or repeat the verification on one previously verified. Despite R12, some communication between the Generation Operator and the Transmission Operator within the 10 year period would be reassuring that nothing has changed. Because ten years is a long time, the Generator Owner should be required to respond upon request of the Transmission Planner confirming that nothing has changed.
Response: Thank you for your comments. The SDT is not sure of the intent of the second sentence. The SDT does not believe that model verification of each unit is needed if the units satisfy the sister unit definition. The SDT also believes requiring communication for activity that does not change settings or create evidence indicating setting have changed is an unnecessary burden. However, if an activity is performed that could change settings or creates evidence of setting changes, then the revised Requirements R3 and R4 contain provisions for performing re-verification earlier if justified.		
Northeast Utilities	Yes	Consider the need to account for wind turbine generation that does not have mature models for this verification - therefore a shorter period may apply to accommodate improvements of those models.
Response: Thank you for your comments. The MVA thresholds in the Applicability section of the first posting of MOD-026 resulted in wind powered units not being		

Organization	Yes or No	Question 2 Recommended Periodicity and Reasoning:
subject to this standard because no single wind unit is rated greater than 20 MVA. However, there is an increasing number of wind farms with significantly larger aggregate MVA. As such, their impact on the reliability of the Bulk Electric System cannot be ignored – otherwise, a reliability gap would be created. Therefore, based on your comments and other industry comments, the SDT discussed the possibility of requiring verification of dynamic models that represent the aggregate of numerous small units and any necessary auxiliary equipment as required due to the technology of the small units. This could include plant dynamic voltage control and reactive support of all the units and auxiliary equipment (such as individual WTG response, plant-wide volt/var controller response, and response from separate volt/var regulation devices contained in the plant, such as SVC/STATCOM/Synchronous Condenser) contained in any technology generation plant, including a wind farm (plant), that exceeds appropriate aggregate nameplate MVA threshold. There are dynamic models that adequately replicate wind unit performance for some wind units today. However, there are many existing wind units for which there are no publicly available models supplied by the Original Equipment Manufacturer. Generic wind models (i.e., type I, II, III and IV) are in various stages of development. Also, there are ongoing efforts involving Regional Entities and manufactures to close any large gaps that may exist in current generic models. Given that there will be significant time between now and the time that this standard could be approved by FERC, it is expected that generic wind farm (plant) models will reach an appropriate state of maturity for establishing boundary conditions in Bulk System Studies. In order to mitigate the reliability gap, the Applicability section will be expanded in the second posting of the standard to include significant MVA percentage of all generation for all technologies.		
Exelon Corporation	Yes	It is difficult to determine whether or not 10 years is an appropriate period for re-verification without knowing the details of the required testing.
Response: Thank you for your comment. The SDT believes that 10 years is a reasonable re-verification period. Re-verification does not necessarily require a re-test and in most instances, ambient monitoring can also be used. The proposed 10 year re-verification period is also supported by an overwhelming majority of comments received from the industry		
Southern Company	Yes	Years of operating experience has shown that existing excitation systems that are properly maintained typically do not deteriorate to the point where performance is noticeably impacted in less than 10 years.
Response: Thank you for your comment.		
Hydro-Québec TransEnergie (HQT)	Yes	ten-year interval is acceptable given the conditions in Requirement R12.
Response: Thank you for your comment.		
CenterPoint Energy	Yes	CenterPoint Energy concurs periodic verfication every ten years is appropriate.

Organization	Yes or No	Question 2 Recommended Periodicity and Reasoning:
Response: Thank you for your comment.		
Consumers Energy Company	Yes	Ten years is appropriate with the caveats listed in Requirement 12.

3. The SDT thought that it would be reasonable to apply a philosophy to allow maximization of limited resources required to perform excitation system model verification. The philosophy allows a single unit's actual excitation system verification to be a proxy for multiple units if the following conditions are met: a) the units have the same MVA rating, b) the units are rated at ≤ 250 MVA c) the units have identical applicable components and settings and d) the units are sited at the same physical location. For each recurring 10 year cycle, another unit must actually be verified.

Do you agree with the proxy unit approach as used in Requirement R1 Item 2? If not, please explain.

Summary Considerations:

The majority of respondents agreed with using the proxy unit approach. There were several suggested adjustments to the proxy unit approach criteria proposed. The most requested adjustments was to increase the unit MVA size threshold from 250 MVA to 350 MVA. The SDT updated the second draft of the standard to reflect a unit MVA size threshold of 350 MVA; with language contained in the attached periodicity Attachment.

Organization	Yes or No	Question 3 Comment
Northeast Power Coordinating Council	No	Unit testing has in the past identified different responses from identical units with common settings. All units with identical design and settings should be tested unless records of actual system events demonstrate that all of the units respond the same.
Response: Thank you for your comments. Previous experience is noted. However, given the limited resources available for industry to execute necessary test and analysis work, the SDT believes that it is not practical to require testing of all units described as proxy units. This conclusion is supported by the majority of comments received from the industry as indicated in the Summary Considerations section above. The SDT notes that Requirement R11 (reference Requirement R3 in the revised standard) requires any unit (including those considered as "proxy" units) to be fully tested/analyzed if unit performance during a system event does not match predicted response.		
SERC Dynamics Review Subcommittee (DRS)	No	We encourage the proxy unit approach. However, we do not agree completely to the conditions illustrating the proxy unit approach. (1) "MVA rating" should be changed to say "MVA nameplate rating". We believe it would be prudent to specify that units of different manuafacturers are not proxy units, even if they have the same nameplate rating, (2) If the units are identical, we believe the 250 MVA threshold criterion is too restrictive. We believe the threshold should be at least 350 MVA to cover combined cycle units using existing technology.
Response: Thank you for your comments. The SDT notes the general agreement among industry with using the proxy unit approach. The SDT also accepts the		

Organization	Yes or No	Question 3 Comment
recommendation to incorporate the term "MVA Nameplate Rating" in the second draft of the standard. With respect to the "different manufacturers" issue, the SDT believes the language, "and if they have identical applicable components and settings", contained in the original Standard draft provides sufficient specificity on this point. We note both you and several industry responders, proposed increasing the MVA Nameplate Rating threshold to 350 MVA. The SDT agrees with the reasoning, "to cover the steam unit of multiple combined cycle plant sites using existing technology", stated for this change and has modified the standard accordingly.		
FirstEnergy	No	1. While we agree with this approach, we do not agree it should be limited to 250 MVA units. It should allow it for any identical units of any size. Also, the requirement could be written more clearly by revising it to make it clear that verification is for similar units only and not all units owned. Based on these comments, we suggest re-wording R1 (2) to state: "For an existing unit, once in a ten calendar year period. If multiple units have identical applicable components and settings and are sited at the same physical location, verification of one unit is sufficient for all of these units. Verification shall be performed on a different unit each ten calendar year cycle."2. This is a lot like the "Sister Unit" concept developed in the recent RFC generator verification standards. It may be helpful if this term was defined and described in more detail in the standard to allow for ease of compliance verification.
Response: Thank you for your comments. The SDT notes the general agreement among industry with using the proxy unit approach. The SDT also notes the recommendation to make the MVA Nameplate Rating threshold limitless, and while this recommendation was received by several responders, the SDT does not believe this recommendation represents the majority opinion of Industry. The SDT is also of the opinion that significantly large units can have a substantial impact on BES security and therefore an unlimited MVA threshold is not appropriate. The SDT has increased the Nameplate MVA Rating threshold from 250 MVA to 350 MVA as requested by the majority of industry responders. The SDT has noted the recommendation to more clearly define the "proxy (or sister) unit" concept and points out that the actual standard does not use either of these terms and simply states the requirements; which have been moved to the attached Periodicity Attachment in the second standard draft.		
Pepco Holdings, Inc (PHI) – Affiliates	No	A GOP (or GO) may have sister units (identical units) at diffrent locations. This should not be restricted to one location.
Response: Thank you for your comments. The SDT notes the general agreement among industry with using the proxy unit approach. The SDT respectfully maintains that the "same physical location" requirement is necessary since it provides a strong indication of similarity of equipment and settings (which could be verified by the same field personnel during a single site walk down). For example, a GO/GOP could own/operate otherwise similar equipment physically located in vastly different geographic locations with substantially different Reliability Coordinator or Transmission Operator requirements (e.g. requirement for PSS in-service). To ensure all GO/GOP equipment meets standard intent, the SDT maintains the "same physical location" requirement is necessary.		
Exelon Corporation	No	Why there is a limitation of unit size of 250MVA or less. The proxy unit approach should be extended to identical units of any size for a two unit station as half of the capacity at that station has been verified as

Organization	Yes or No	Question 3 Comment
		compared to a multi unit site say having 6 250MVAs and verifying only one unit.
Response: Thank you for your comments. The SDT notes the general agreement among industry with using the proxy unit approach. The SDT also notes the recommendation to make the MVA Nameplate Rating threshold limitless, and while this recommendation was received by several responders, the SDT does not believe this recommendation represents the majority opinion of Industry. The SDT is also of the opinion that significantly large units (> 250 MVA) can have a substantial impact on BES security and therefore an unlimited MVA threshold is not appropriate. The SDT has increased the Nameplate MVA Rating threshold from 250 MVA to 350 MVA as requested by the majority of industry responders.		
Southern Company	No	Agree with all requirements except b and d. If the GO/GOP has duplicate units at multiple sites , a re-verification test of one unit should apply to all provided they meet items a and c. The size of the unit (b) nor the physical location (d) do not matter. The MVA rating of the machine should not be an excluding factor for units of the same vintage, rating, manufacturer, and with the same type of excitation system and settings.
Response: Thank you for your comments. The SDT notes the general agreement among industry with using the proxy unit approach. The SDT also notes the recommendation to make the MVA Nameplate Rating threshold limitless, and while this recommendation was received by several responders, the SDT does not believe this recommendation represents the majority opinion of Industry. The SDT is also of the opinion that significantly large units (> 250 MVA) can have a substantial impact on BES security and therefore an unlimited MVA threshold is not appropriate. The SDT has increased the Nameplate MVA Rating threshold from 250 MVA to 350 MVA as requested by the majority of industry responders. The SDT respectfully maintains that the “same physical location” requirement is necessary since it provides a strong indication of similarity of equipment and settings (which could be verified by the same field personnel during a single site walk down). For example, a GO/GOP could own/operate otherwise similar equipment physically located in vastly different geographic locations with substantially different Reliability Coordinator or Transmission Operator requirements (e.g. requirement for PSS in-service). To ensure all GO/GOP equipment meets standard intent, the SDT maintains the “same physical location” requirement is necessary.		
E.ON U.S.	No	E.ON U.S. does believe that the proxy process described is reasonable. As expressed in the response to question 2, E.ON U.S. believes that, absent installation of new equipment, a re-verification schedule is unnecessary.
Response: Thank you for your comments. The SDT notes the general agreement among industry with using the proxy unit approach. The SDT maintains that the proposed re-verification schedule is appropriate to provide a means to capture changes in excitation system equipment due to component aging, calibration drift, etc.		
Wisconsin Public Service	No	The sister unit philosophy should be applied to identical units within a generator operators fleet with identical settings, but not be limited to the same physical site.

Organization	Yes or No	Question 3 Comment
Response: Thank you for your comment. The SDT notes the general agreement among industry with using the proxy unit approach. The SDT respectfully maintains that the "same physical location" requirement is necessary since it provides a strong indication of similarity of equipment and settings (which could be verified by the same field personnel during a single site walk down). For example, a GO/GOP could own/operate otherwise similar equipment physically located in vastly different geographic locations with substantially different Reliability Coordinator or Transmission Operator requirements (e.g. requirement for PSS in-service). To ensure all GO/GOP equipment meets standard intent, the SDT maintains the "same physical location" requirement is necessary.		
Wisconsin Electric	No	We believe that units rated up to 850 MVA should be able to take advantage of this approach.
Response: Thank you for your comment. The SDT notes the general agreement among industry with using the proxy unit approach. The SDT also notes the recommendation to increase the MVA Nameplate Rating threshold to 850 MVA, and while this recommendation was received by several responders, the SDT does not believe this recommendation represents the majority opinion of Industry or that the threshold should be this high. The SDT has increased the Nameplate MVA Rating threshold from 250 MVA to 350 MVA as requested by the majority of industry responders.		
American Electric Power	No	While AEP agrees that the proxy approach to verify multiple, identical units based on system model verification for a single unit makes sense, it is unclear why criterion "b" (the units are rated at less than or equal to 250MVA) would apply, provided criteria "a", "c", and "d" are also met. It is suggested that criterion "b" as listed in the Comment Form and as referenced in Requirement R1.2 be removed from the Standard.
Response: Thank you for your comments. The SDT notes the general agreement among industry with using the proxy unit approach. The SDT also notes the recommendation to remove the MVA Nameplate Rating threshold, and while this recommendation was received by several responders, the SDT does not believe this recommendation represents the majority opinion of Industry. However, based on industry comments, the SDT has increased the Nameplate MVA Rating threshold from 250 MVA to 350 MVA as requested by the majority of industry responders.		
Progress Energy, Inc.	No	We encourage the proxy unit approach. However, we do not agree completely to the conditions illustrating proxy unit approach. (1) MVA rating should be expanded to say "MVA nameplate rating" . We believe it would be prudent to specify that units of different manuafacturers, even if they have the same nameplate rating are not proxy units, (2) If the units are identical, we believe the 250 MVA threshold criterion is too restrictive. We believe the limit should be at least 350 MVA to cover combined cycle units of existing technology.
Response: Thank you for your comments. The SDT notes the general agreement among industry with using the proxy unit approach. The SDT also accepts the recommendation to incorporate the term "MVA Nameplate Rating" in the second draft of the standard. With respect to the "different manufacturers" issue, the SDT believes the language, "and if they have identical applicable components and settings", contained in the original Standard draft provides sufficient specificity on this point. We note both your comment and several industry responders propose increasing the MVA Nameplate Rating threshold to 350 MVA. The SDT agrees with the		

Organization	Yes or No	Question 3 Comment
reasoning, “to cover the steam unit of multiple combined cycle plant sites using existing technology”, stated for this change and has modified the standard accordingly.		
Northeast Utilities	No	Units testing has in the past identified different responses from identical units with common settings. All units with identical design and settings should be tested unless records of actual system events demonstrate that all of the units respond the same.
Response: Thank you for your comments. Previous experience is noted. However, given the limited resources available for industry to execute necessary test and analysis work, the SDT believes that it is not practical to require testing of all units described as proxy units. This conclusion is supported by the majority of comments received from the industry as indicated in the Summary Considerations section above. The SDT notes that Requirement R11 (reference Requirement R3 in the revised standard) requires any unit (including those considered as “proxy” units) to be fully tested/analyzed if unit performance during a system event does not match predicted response.		
Hydro-Québec TransEnergie (HQT)	No	Units testing has in the past identified different responses from identical units with common settings. All units with identical design and settings should be tested unless records of actual system events demonstrate that all of the units respond the same.
Response: Thank you for your comments. Previous experience is noted. However, given the limited resources available for industry to execute necessary test and analysis work, the SDT believes that it is not practical to require testing of all units described as proxy units. This conclusion is supported by the majority of comments received from the industry as indicated in the Summary Considerations section above. The SDT notes that Requirement R11 (reference Requirement R3 in the revised standard) requires any unit (including those considered as “proxy” units) to be fully tested/analyzed if unit performance during a system event does not match predicted response.		
AESO	No	The AESO believes that using a single unit’s actual excitation system verification to be a proxy for multiple units will not pick up errors in settings, component failures, alterations to units, etc. Each unit should be tested individually.
Response: Thank you for your comments. Previous experience is noted. However, given the limited resources available for industry to execute necessary test and analysis work, the SDT believes that it is not practical to require testing of all units described as proxy units. This conclusion is supported by the majority of comments received from the industry as indicated in the Summary Considerations section above. The SDT notes that Requirement R11 (reference Requirement R3 in the revised standard) requires any unit (including those considered as “proxy” units) to be fully tested/analyzed if unit performance during a system event does not match predicted response.		
NERC Event Analysis & Information Exchange staff	Yes	As long as no actual differences are observed during performance comparisons to actual system events, this is an acceptable shortcut.

Organization	Yes or No	Question 3 Comment
Response: Thank you for your comment. The SDT believes that the situation described will be satisfied by Requirement R2 in the revised standard.		
Entergy Fossil Operations	Yes	I agree with this except for the less than or equal to 250 MVA. It should apply to all units meeting the sister unit criteria regardless of MVA. If you want a limit, then make it something higher like 80% of the single largest generator in the system.
Response: Thank you for your comments. The SDT notes the general agreement among industry with using the proxy unit approach. The SDT also notes the recommendation to increase the MVA Nameplate Rating threshold 80% or higher of the largest system generator, and while this recommendation was received by several responders, the SDT does not believe this recommendation represents the majority opinion of Industry. The SDT is also of the opinion that significantly large units (> 250 MVA) can have a substantial impact on BES security and therefore an unlimited MVA threshold is not appropriate. The SDT has increased the Nameplate MVA Rating threshold from 250 MVA to 350 MVA as requested by the majority of industry responders. The SDT respectfully maintains that the “same physical location” requirement is necessary since it provides a strong indication of similarity of equipment and settings (which could be verified by the same field personnel during a single site walk down). For example, a GO/GOP could own/operate otherwise similar equipment physically located in vastly different geographic locations with substantially different Reliability Coordinator or Transmission Operator requirements (e.g. requirement for PSS in-service). To ensure all GO/GOP equipment meets standard intent, the SDT maintains the “same physical location” requirement is necessary.		
Ameren	Yes	We encourage the proxy unit approach. However, we do not agree completely to the conditions illustrating proxy unit approach. (1) MVA rating should be expanded to say "MVA nameplate rating" . We believe it would be prudent to specify that units of different manuafacturers, even if they have the same nameplate rating are not proxy units. Further, turbine rating should also be considered as appropriate. (2) If the units are identical, we believe the 250 MVA threshold criterion is too restrictive. We believe the limit should be at least 350 MVA to cover combined cycle units of existing technology.
Response: Thank you for your comments. The SDT notes the general agreement among industry with using the proxy unit approach. The SDT also accepts the recommendation to incorporate the term “MVA Nameplate Rating” in the second draft of the standard. With respect to the “different manufacturers” issue, the SDT believes the language, “and if they have identical applicable components and settings”, contained in the original Standard draft provides sufficient specificity on this point. We note both your comment and several industry responders propose increasing the MVA Nameplate Rating threshold to 350 MVA. The SDT agrees with the reasoning, “to cover the steam unit of multiple combined cycle plant sites using existing technology”, stated for this change and has modified the standard accordingly.		
Duke Energy	Yes	If it could be verified that the Gains and TCs are exactly the same, but just reading dial settings on analog controls might not suffice. For digital, the gains are the number programmed in, so the proxy approach is

Organization	Yes or No	Question 3 Comment
		more reasonable.Also, recommend changing MVA rating to 350 MVA so that combined cycle steam units are included.
Response: Thank you for your comments. Response: The SDT notes the general agreement among industry with using the proxy unit approach. The SDT accepts this recommendation and has increased the Nameplate MVA Rating threshold from 250 MVA to 350 MVA as requested by the majority of industry responders.		
Independent Electricity System Operator	Yes	We agree with the proxy unit approach only if these units' excitation systems show identical performance based on the results of a limited number of tests. On the other hand, we do not agree with the 10-year cycle. Accurate excitation system data and verification that it performs as designed are critical to accurate modeling and simulation to support a wide range of reliability activities, including the determination of SOLs and IROLs. The 10 year recycle period is too long that risks changes to excitation system characteristics undetected. We suggests this period be shortened to 5 years.
Response: Thank you for your comments. The SDT notes the general agreement among industry with using the proxy unit approach. The SDT maintains that the proposed re-verification schedule is appropriate to provide a means to capture changes in excitation system equipment due to component aging, calibration drift, etc. The SDT notes that Requirement R11 (reference Requirement R3 in the revised standard) requires any unit (including those considered as "proxy" units) to be fully tested/analyzed if unit performance during a system event does not match predicted response.		
Reliant Energy	Yes	Proxy unit ratings should go up to 500 MVA.
Response: Thank you for your comment. The SDT notes the general agreement among industry with using the proxy unit approach. The SDT also notes the recommendation to increase the MVA Nameplate Rating threshold to 500 MVA, and while this recommendation was received by several responders, the SDT does not believe this recommendation represents the majority opinion of Industry or that the threshold should be this high. The SDT has increased the Nameplate MVA Rating threshold from 250 MVA to 350 MVA as requested by the majority of industry responders.		
Consumers Energy Company	Yes	This looks to be a "sister unit" type of proxy. If so, it should be introduced as a new definition.
Response: Thank you for your comment. The SDT notes that the actual standard does not use either of these terms but simply states the requirements; which have been moved to the attachment Periodicity Attachment in the second draft of the revised standard.		
Constellation Power Generation & Constellation Nuclear	Yes	The proxy unit approach is quite appropriate for excitation system verification for multiple units.
Response: Thank you for your comment.		

Organization	Yes or No	Question 3 Comment
IRC Standards Review Committee	Yes	We agree with the proxy unit approach.
Response: Thank you for your comment.		
Reliant Energy	Yes	I can not see any reliability benefit to requiring the verification of sister units.
Response: Thank you for your comment. The SDT notes the general agreement among industry with using the proxy unit approach. The SDT maintains that the proposed re-verification schedule is appropriate to provide a means to capture changes in excitation system equipment due to component aging, calibration drift, etc.

4. The list of unit specific information in Requirement R4 to be provided to the Transmission Planner from the Generator Owner includes generator data used in the excitation system verification process. The reason is that the tests, ambient or staged, which are used to verify the excitation system model, are part of a closed loop system that includes the generator. However, the SDT stopped short of requiring verification of either all generator data, or a portion of the generator data which is most applicable to excitation system testing (Transient Open Circuit Time Constant, and for PSS model verification, rotational inertia). The SDT feels that it cannot develop draft Requirements for the verification of generator data without submitting a supplementary SAR to the NERC Standards Committee.

Do you agree with the approach of requiring the Generator Owner to supply the generator data used in the excitation system model verification?

Summary Consideration:

Most responders agreed there is a need for clarity regarding the specific generator data used for exciter data verification, and that it was not necessary to separately verify the generator data. Most responders felt it was appropriate to require Generator Owners to provide the generator data. Clarifying language has been added to the standard in Requirement R2, including specifying that generator data used to verify the excitation control system also be provided with the other data obtained during model verification.

Organization	Yes or No	Question 4 Comment
Southwest Power Pool Generation Working Group	No	The proposed standard states Generator Operator, as opposed to Generator Owner. The Generator Owner should be the one providing the data.
Response: Thank you for your comment. The issue of whether the Generator Owner or Generator Operator is the responsible entity is addressed by Question 1.		
Entergy Fossil Operations	No	I may agree if it is reasonable and list exactly what data can be requested by the TP. Remember, the GO is dependent on contractors for doing this, it costs them money, and is of no benefit to the GO, so the listing need to be specific so it can be listed in the job scope of the work and reasonable.
Response: Thank you for your comments. The SDT respectfully disagrees that the generator/exciter model verification is of no benefit to the Generator Owner. Although the primary purpose for model verification is to provide accurate models, there are other significant benefits which the Generator Owner will realize such		

Organization	Yes or No	Question 4 Comment
as: • Without the verification data and resulting system simulation results, transfer capabilities are uncertain and there is greater risk of generator tripping because of system issues. • Generation power sales are dependent on the transmission system transfer capability. • There have been several instances where verification efforts have discovered maintenance issues that, if not identified and corrected, would have resulted in unit tripping and possible equipment damage. The SDT asserts the knowledge and generator data required is inherent to the verification process, and as such requires the expert responsible for providing verification results to specify the required parameter list since this list is dependent on the generator and exciter models selected. It is important that this verification work is performed by individuals familiar with specifying the required parameter list associated with the model selected to best match equipment performance. As such, the SDT believes providing a detailed parameter list in the standard will create confusion.		
Luminant Power	No	Luminant does not disagree that the information needs to be provided. However, the generator model data is already required in NERC Standards MOD-012 adn MOD-013 (R1.2). The Generation Owner should not be held doubly liable for the same information in two Standards. This requirement for the Generator data is already required elsewhere and is not needed in this standard.
Response: Thank you for your comments. Regional requirements will be retired from the NERC standards. MOD-012 and MOD-013 standards do not require verification (unless the region requires it). The purpose of MOD-026 is to require verification. MOD-012 requires submission of both generator and exciter data with other dynamics data provided. Experience has shown that both excitation system data and generator data must be revised when performing the verification process. Even if revisions are not necessary, it is essential that unambiguous generator and exciter data is incorporated into the simulation tools. A simple way to ensure consistency is by requiring both generator data and exciter data be included in the verification report. Information must be updated with generator data included in the exciter verification report.		
Southern Company	No	Since the exciter model and the generator model are components of the closed loop system being verified, the process should ensure that the transmission planners dynamic database is updated with the generator data and the excitation system data utilized for model verification. Relying on generator data that was originally provided for MOD-012 to be the same data that was used for model verification would not be advisable. There are countless opportunities for generator data submitted for MOD-012 to be inconsistent with generator data used in the excitation system verification process. In order to close this loop, we suggest that R3 be slightly modified to read: "The Transmission Planner shall provide the Generator Operator with the unit specific data contained in the Transmission Planner's dynamic database from the current in-use excitation system and generator model, including the applicable generator model parameter's MVA base, within 30 calendar days of a request from the Generator Operator." AND R4 Item 2 should have an additional sentence at the end which reads: "This data only has to be provided in those instances where generator model data was updated during the process of obtaining a

Organization	Yes or No	Question 4 Comment
		verified excitation system model". These language modifications will help ensure that dynamic databases are populated with the correct data for both the excitation system and generator models that have been verified while minimizing burden on the generation entity responsible for model verification.
Response: Thank you for your comments. The SDT agrees with this recommendation and has incorporated the concept into Requirement R3 (Reference Requirement R1 in the revised standard). However, the SDT did not adopt the recommendation for R4 item 2 (Reference Requirement R2, Part 2.1 in the revised standard). To ensure consistency, it is important that the generator model data is always provided with the exciter model data even if it the data has not changed. The SDT does not believe this is a burdensome requirement given the benefit realized by ensuring necessary data is clearly communicated.		
Cowlitz County PUD	No	I think you meant for the Generator Operator to supply the generator data.
Response: Thank you for your comment. The SDT has corrected the noted error. The issue of whether the Generator Owner or Generator Operator is the responsible entity is addressed by Question 1.		
Indiana Municipal Power Agency	No	IMPA believes the generator data is important and that it is currently being provided per MOD-010 (static) and MOD-012 (dynamic). Another standard requiring this information would put the stakeholder at a double risk factor, and FERC does not believe in this double risk factor.
Response: Thank you for your comments. Regional requirements will be retired from the NERC standards. MOD-012 and MOD-013 standards do not require verification (unless the region requires it). The purpose of MOD-026 is to require verification. MOD-012 requires submission of both generator and exciter data with other dynamics data provided. Experience has shown that both excitation system data and generator data must be revised when performing the verification process. Even if revisions are not necessary, it is essential that unambiguous generator and exciter data is incorporated into the simulation tools. A simple way to ensure consistency is by requiring both generator data and exciter data be included in the verification report. Information must be updated with generator data included in the exciter verification report.		
NERC Event Analysis & Information Exchange staff	No	See below.
Response: Thank you for your comment. Refer to the response provided to the other comment(s).		
Northeast Power Coordinating Council	Yes	The entity specified in Question 4 does not agree with the entity specified in Requirement R4. As stated in our response to Question 1, we believe the Generator Owner is the correct entity to provide the data; not the Generator Operator. We agree with the approach subject to revising the responsible entity.
Response: Thank you for your comments. The issue of whether the Generator Owner or Generator Operator is the responsible entity is addressed by Question		

Organization	Yes or No	Question 4 Comment
1.		
SERC Dynamics Review Subcommittee (DRS)	Yes	Since the exciter model and the generator model are components of the closed loop system being verified, the process should ensure that the transmission planners dynamic database is updated with the generator data and the excitation system data utilized for model verification. Relying on generator data that was originally provided for MOD-012 to be the same data that was used for model verification would not be advisable. There are countless opportunties for generator data submitted for MOD-012 to be inconsistent with generator data used in the excitation system verification process. In order to close this loop, we suggest that R3 be slightly modified to read: "The Transmission Planner shall provide the Generator Operator with the unit-specific data contained in the Transmission Planner's dynamic database from the current in-use excitation system and generator model, including the applicable generator model parameter's MVA base, within 30 calendar days of a request from the Generator Operator." AND R4 Item 2 should have an additional sentence at the end which reads: "This data only has to be provided in those instances where generator model data was changed in order to obtain a verified excitation system model". These language modifications will help ensure that dynamic databases are populated with the correct data for both the excitation system and generator models that have been verified while minimizing burden on the generation entity responsible for model verification.
Response: Thank you for your comments. The SDT agrees with this recommendation and has incorporated the concept into Requirement R3 (Reference Requirement R1 in the revised standard). However, the SDT did not adopt the recommendation for R4 item 2 (Reference Requirement R2, Part 2.1 in the revised standard). To ensure consistency, it is important that the generator model data is always provided with the exciter model data even if it the data has not changed. The SDT does not believe this is a burdensome requirement given the benefit realized by ensuring necessary data is clearly communicated.		
Dominion	Yes	We believe that all requirements of this standard should apply to the Generator Owner, not the Generator Operator.
Response: Thank you for your comment. The issue of whether the Generator Owner or Generator Operator is the responsible entity is addressed by Question 1.		
FirstEnergy	Yes	The question above has a typographical error. We assume the team means "Generator Operator".
Response: Thank you for your comment. The SDT has corrected the noted error. The issue of whether the Generator Owner or Generator Operator is the responsible entity is addressed by Question 1.		
IRC Standards Review Committee	Yes	We agree with the approach of requiring the Generator Owner to supply the data listed. We also suggest that since this data is required 90 calendar days of completion of the excitation system model verification - the same condition for providing documentation demonstrating that the excitation system model's response matches the

Organization	Yes or No	Question 4 Comment
		recorded response for a voltage excursion at the generator as stipulated in R8, we suggest R8 be combined with R4. Note that "Generator Owner" instead of "Generator Operator" is used in this question. While we view this as a typo, as indicated in our comment under Q1 we think it is appropriate that the Generator Owners be held responsible for the majority of the requirements in this standard.
Response: Thank you for your comments. The SDT has corrected the noted error. The issue of whether the Generator Owner or Generator Operator is the responsible entity is addressed by Question 1. The SDT agrees with the recommendation to combine Requirement R8 with R4 (reference Requirement R2, Part 2.1 in the revised standard).		
Consumers Energy Company	Yes	We believe that generator data must be verified; however, the concept of staged tests is troubling as such testing can provide a local challenge to the integrity of the BES. Such testing should be required to be well coordinated with the Transmission Operator. Our experience shows start-up testing of new exciters has occasionally resulted in significant local impact to the transmission system, e.g., over-voltage on 345 kV systems.
Response: Thank you for your comments. There is risk associated with performing staged generation tests however, the SDT believes the benefits outweigh the risks. Exciter verification testing is essential for ensuring accurate dynamic simulations. To mitigate risk to the transmission system, the SDT recognizes that it is important to have testing personnel notify the Transmission Operator of scheduled tests, and interact as needed during the testing evolution.. System security must be maintained during the test. As example, system conditions may require the Transmission Operator to cancel planned testing. Also keep in mind verification requirements include alternatives to performing staged tests such as system performance monitoring under ambient conditions; which would be preferable to performing staged tests in some circumstances. Bench testing may be another viable option. A verification expert can evaluate available alternatives and assist with performing a situation specific risk/benefit assessment.		
City of Garland, Garland Power & Light - GOP Registered Entity	Yes	This same approach should be used for question #1. It is the Generator Owner (GO) that has this information and access to the equipment.
Response: Thank you for your comments. The SDT has corrected the noted error. The issue of whether the Generator Owner or Generator Operator is the responsible entity is addressed by Question 1.		
Progress Energy, Inc.	Yes	Since the exciter model and the generator model are components of the closed loop system being verified, the process must ensure that the Transmission Planners dynamic database is updated with the generator data and the excitation system data utilized for verification. Relying on generator data that was originally provided for MOD-012 to be the same data that was used for model verification would not be advisable. There are countless opportunties for generator data submitted for MOD-012 to be inconsistent with generator data used in models in the excitation system verification process. In order to close this loop, we suggest that R3 be slightly modified to read: "The Transmission Planner shall provide the Generator Operator the unit specific data contained in the

Organization	Yes or No	Question 4 Comment
		Transmission Planner's dynamic database from the current in-use excitation system and generator model, including the applicable generator model parameter's MVA base, within 30 calendar days of a request from the Generator Operator." AND R4 Item 2 should have an additional sentence at the end which reads: "This data only has to be provided in those instances where generator model data was changed in order to obtain a verified excitation system model". These language modifications ensure that dynamic databases are populated with the correct data for both the excitation system and generator models that have been verified while minimizing burden on the generation entity responsible for model verification.
Response: Thank you for your comments. The SDT agrees with this recommendation and has incorporated the concept into Requirement R3 (Reference Requirement R1 in the revised standard). However, the SDT did not adopt the recommendation for R4 item 2 (Reference Requirement R2, Part 2.1 in the revised standard). To ensure consistency, it is important that the generator model data is always provided with the exciter model data even if it the data has not changed. The SDT does not believe this is a burdensome requirement given the benefit realized by ensuring necessary data is clearly communicated.		
Ameren	Yes	(1) Generator Operators and Generator Owners should be included in this standard. It is possible that all functions can not be performed by the Generator Operator. Therefore it would be prudent to include the Generator Owners within MOD-026-1. (2) If the generator has not been modified, and the manufacturer's data is available, then there should be no need for retesting of the generator. However, if the generator has been modified since the last data set was established for the generator, (stator or rotor turns shorted, rotor replaced, etc.) then re-testing of the generator would be in order. If the turbine has been replaced, then an updated value for rotational inertia would be needed. (3) The concept of staged tests is troubling as such testing can provide a local challenge to the integrity of the BES. Such testing should be required to be well coordinated with the Transmission Operator. (4) Relying on generator data that was originally provided for MOD-012 to be the same data that was used for model verification would not be advisable. There are countless opportunties for generator data submitted for MOD-012 to be inconsistent with generator data used in models in the excitation system verification process. In order to close this loop, we suggest that R3 be slightly modified to read: "The Transmission Planner shall provide the Generator Operator the unit specific data contained in the Transmission Planner's dynamic database from the current in-use excitation system and generator model, including the applicable generator model parameter's MVA base, within 30 calendar days of a request from the Generator Operator." AND R4 Item 2 should have an additional sentence at the end which reads: "This data only has to be provided in those instances where generator model data was changed in order to obtain a verified excitation system model". These language modifications ensure that dynamic databases are populated with the correct data for both the excitation system and generator models that have been verified while minimizing burden on the generation entity responsible for model verification.

Organization	Yes or No	Question 4 Comment
Response: Thank you for your comments. 1) The SDT has corrected the noted error. The issue of whether the Generator Owner or Generator Operator is the responsible entity is addressed by Question 1. 2) The SDT agrees that exciter verification will also provide adequate verification of the generator model if test results match simulation results. The SDT also agrees additional effort is required to improve the generator model if results do not match. The SDT has decided that the MOD-026 standard scope is limited to the excitation system because standard development would be delay for SAR development if a generator verification standard is required. 3) There is risk associated with performing staged generation tests however, the SDT believes the benefits outweigh the risks. Exciter verification testing is essential for ensuring accurate dynamic simulations. To mitigate risk to the transmission system, the SDT recognizes that it is important to have testing personnel notify the Transmission Operator of scheduled tests, and interact as needed during the testing evolution.. System security must be maintained during the test. As example, system conditions may require the Transmission Operator to cancel planned testing. Also keep in mind verification requirements include alternatives to performing staged tests such as system performance monitoring under ambient conditions; which would be preferable to performing staged tests in some circumstances. Bench testing may be another viable option. A verification expert can evaluate available alternatives and assist with performing a situation specific risk/benefit assessment. 4) The SDT agrees with this recommendation and has incorporated the concept into Requirement R3 (Reference Requirement R1 in the revised standard). However, the SDT did not adopt the recommendation for R4 item 2 (Reference Requirement R2, Part 2.1 in the revised standard). To ensure consistency, it is important that the generator model data is always provided with the exciter model data even if it the data has not changed. The SDT does not believe this is a burdensome requirement given the benefit realized by ensuring necessary data is clearly communicated.		
AESO	Yes	The AESO agrees with the SRC ISO/RTO comments.
Response: Thank you for your comment. Please see the response to the comments provided by the SRC ISO/RTO.		
Duke Energy	Yes	Supplying the data itself is appropriate. Industry experience has shown that simply assuring the generator data in the model is the right data for the installed equipment is adequate for assuring the validity of the Generator Parameters, additional testing is not typically needed and any inappropriate data would show up in voltage bump test comparisons needed for AVR models validations. Also, R4.4, should say The GO shall provide the Compensation Function used on the unit (Droop, Reactive Line Drop or Resistive Line Drop) and the amount of compensation provided (% of generator voltage at rated MVA).
Response: Thank you for your comments. The SDT agrees inappropriate generator data would be identified during exciter verification. The SDT has revised Requirement R4.4 as follows: **Old Requirement R4.4, “**Reactive compensation settings (for example: reactive droop, line drop, differential compensation), if utilized.”		

Organization	Yes or No	Question 4 Comment
New Requirement R2, Part 2.1.5, "Compensation settings (such as droop, line drop, differential compensation), if used."		
Northeast Utilities	Yes	The entity specified in Question 4 does not agree with the entity specified in Requirement R4. As stated in our response to Question 1, we believe the Generator Owner is the correct entity to provide the data; not the Generator Operator. We agree with the approach subject to revising the responsible entity.
Response: Thank you for your comments. The SDT has corrected the noted error. The issue of whether the Generator Owner or Generator Operator is the responsible entity is addressed by Question 1.		
Reliant Energy	Yes	But to be I think it should be the GOP not the GO.
Response: Thank you for your comment. The SDT has corrected the noted error. The issue of whether the Generator Owner or Generator Operator is the responsible entity is addressed by Question 1.		
Hydro-Québec TransEnergie (HQT)	Yes	The entity specified in Question 4 does not agree with the entity specified in Requirement R4. As stated in our response to Question 1, we believe the Generator Owner is the correct entity to provide the data; not the Generator Operator. We agree with the approach subject to revising the responsible entity to be the GO.
Response: Thank you for your comments. The SDT has corrected the noted error. The issue of whether the Generator Owner or Generator Operator is the responsible entity is addressed by Question 1.		
Independent Electricity System Operator	Yes	We agree with the approach of requiring the Generator Owner to supply the data listed. We also suggest that since this data is required within90 calendar days of completion of the excitation system model verification - the same condition for providing documentation demonstrating that the excitation system model's response matches the recorded response for a voltage excursion at the generator as stipulated in R8 - we suggest R8 be combined with R4. Note that "Generator Owner" instead of "Generator Operator" is used in this question. While we view this as a typo, as indicated in our comment under Q1 we think it is appropriate that the Generator Owners be held responsible for the majority of the requirements in this standard.
Response: Thank you for your comments. The SDT has corrected the noted error. The issue of whether the Generator Owner or Generator Operator is the responsible entity is addressed by Question 1. The SDT agrees with the recommendation to combine Requirement R8 with R4 (reference Requirement R2, Part 2.1 in the revised standard).		

Organization	Yes or No	Question 4 Comment
American Transmission Company	Yes	It provides confirmation of whether the data being used to model the generator and the generator data used in the verification test are the same.
Response: Thank you for your comment.		
US Bureau of Reclamation	Yes	We agree the Generator Owner should provide the data and also be resposible for performing the model validation/verification.
Response: Thank you for your comment. The SDT has corrected the noted error. The issue of whether the Generator Owner or Generator Operator is the responsible entity is addressed by Question 1.

4.1 Do you believe that the SDT should consider expanding the scope, through a supplementary SAR, to include verification of generator data? If yes, please provide the scope of generation verification the SDT should consider, along with any data that would support the reliability benefits from expansion of the existing scope which could be included in a supplementary SAR.

Summary Consideration:

Most responders indicated that it is generally not necessary to separately verify the generator data in order to verify the excitation control system model. Most responders believed that a separate SAR would be required for a generator model verification standard. As such, the SDT decided not to expand the scope of this standard to include verification of generator model data.

Organization	Yes or No	Question 4.1 Comments and/or Supporting Data
Progress Energy, Inc.	No	To include generator data verfication beyond excitation system modeling data is a significant burden to the Generation Owner not supported by the benefits to be gained.
Response: Thank you for your comment**.** The SDT agrees separate testing is generally not required to develop a generator model. In order for simulation and measured results to match, the generator and excitation control system models must accurately represent the equipment.		
ISO New England Inc.	No	Manufacturer's estimates of generator characteristics appear to be generally accuracte and relatively easy to obtain.
Response: Thank you for your comment**.** The SDT agrees separate testing is generally not required to develop a generator model. In order for simulation and measured results to match, the generator and excitation control system models must accurately represent the equipment.		
Northeast Power Coordinating Council	No	Expanding the scope to include verification of generator data will not provide a significant improvement in the overall modeling of excitation systems.
Response: Thank you for your comment**.** The SDT agrees that separate verification of generator data is often unnecessary however, the SDT believes that a match between simulation and measured results for the excitation system model is required to indicate that the generator and excitation control system models accurately represent the equipment.		
Dominion	No	MOD-024 and MOD-025 address a generator's real and reactive capability verification and MOD-026 addresses the excitation system verification. It seems desirable to have a MOD standard that address the verification of

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 4.1 Comments and/or Supporting Data</th></tr>
<tr><td></td><td></td><td>generator data by the Generator Owner (not the Generator Operator). This can be handled by a new SAR since the scope change of the current SAR could delay the process. In scoping the verification of the generator dynamic data:a) If the existing generator dynamic model data is backed by documentation provided by the generator manufacturer or previous test(however old it is), no verification would be required. b) If there is no documentation (from manufacturer or previous test) supporting the existing generator dynamic model data, saturation, inertia & D-axis parameters (time constants and impedances) have to be verified at the minimum. If the measured D-axis parameters show reasonable agreement with the existing generator dynamic data, it is not required to verify the Q-axis parameters; otherwise the Q-axis parameters need to be verified as well.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. The SDT has corrected the noted error. The issue of whether the Generator Owner or Generator Operator is the responsible entity is addressed by Question 1. The SDT agrees that concerns regarding generator model verification should not be allowed to delay implementation of the MOD-026 proposed standard. The SDT also agrees that appropriate generator parameters are required to develop an accurate excitation system model. A match between simulation and measured results for the excitation system model is required to indicate that the generator and excitation control system models accurately represent the equipment. Further testing should not be necessary if a match is obtained between simulation and measured results, Further testing may be necessary to verify the parameters listed in your comment if a match is not obtained.</td></tr>
<tr><td>Kansas City Power & Light</td><td>No</td><td>There are clearly benefits to having as much verified operational characteristic data as possible, however, as previously noted in response to question #2, the equipment risks associated with obtaining those benefits should be a consideration. Considering an aging generation infrastructure, the risk of obtaining parts for equipment damaged in the pursuit of modeling verification can be extremely costly in extended downtime and the availability of parts is also a concern. Again, it is recommended the SDT consider the removal or modification of requirements involving testing that place an unncessary risk of generator damage. As an example, allowing vendor simulations or other testing methods by the generator Vendor in a suitable testing environment to suffice for obtaining generator response characteristics.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. The SDT believes the testing required to verify the generator and excitation system models imposes minimal risk on equipment, with testing routinely finding maintenance issues that could cause equipment damage if uncorrected. The MOD-026 standard has been designed to allow testing experts to determine appropriate verification methods for the equipment that minimizes risk associated with aged equipment. This includes ambient monitoring which results in no additional risk to the unit beyond normal operation.</td></tr>
<tr><td>IRC Standards Review Committee</td><td>No</td><td>This standard should focus on the excitation system only. If the industry sees a need for such verification, the requirements could be added to another MOD standard or a separate standard be created through a separate SAR.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. The SDT agrees that if a generator verification standard is necessary, then it should be proposed in a separate SAR in</td></tr>
</table>

Organization	Yes or No	Question 4.1 Comments and/or Supporting Data
order to prevent implementation delays for this standard.		
Exelon Corporation	No	Verification of the generator data will be useful, but needs to be considered at a later date.
Response: Thank you for your comment**.** The SDT agrees that if a generator verification standard is necessary, then it should be proposed in a separate SAR in order to prevent implementation delays for this standard.		
Constellation Power Generation & Constellation Nuclear	No	Expanding the scope to include verification of generator data will not provide any significant improvement in the modeling of excitation systems.
Response: Thank you for your comment**.** The SDT agrees separate testing is generally not required to develop a generator model. In order for simulation and measured results to match, the generator and excitation control system models must accurately represent the equipment.		
Southern Company	No	As a general rule the industry has not demonstrated a need to validate OEM supplied generator data.
Response: Thank you for your comment. The SDT agrees that separate validation of Original Equipment Manufacturer supplied generator data is generally not required however, the SDT believes a match between simulation and measured results for the excitation system model is required to indicate that the generator and excitation control system models accurately represent the equipment.		
E.ON U.S.	No	E.ON U.S. believes that entities have no incentive to use inaccurate data when conducting verifications studies. Strict data verification standards are in this instance an unproductive use of resources.
Response: Thank you for your comments. The SDT agrees that entities do not have incentive to use inaccurate data however experience indicates data representing generator and exciter models is often inaccurate, with simulation results predicting stable performance for situations where system performance was unstable. Experience has proven the need for model verification. A match between simulation and measured results for the excitation system model is required to indicate that the generator and excitation control system models accurately represent the equipment.		
Wisconsin Public Service	No	The model generally in use to simulate generator dynamic responses is a hypothetical model based on fictitious parameters. For instance, the direct-axis and quadratual-axis impedances are calculated design values, and not a measurable physical quantity, as are the transient and subtransient time constances. The inertial constance involve the whole rotor and prime-mover assembly, and cannot be easily quantified.
Response: Thank you for your comments**.** Generator parameters such as inertia are verified by testing, including ambient monitoring. For example, the inertia can be calculated using the dimensions of the rotor and prime mover assembly. A match between simulation and measured results for the excitation system model is required to indicate that the generator and excitation control system models accurately represent the equipment.		

Organization	Yes or No	Question 4.1 Comments and/or Supporting Data
Hydro-Québec TransEnergie (HQT)	No	Expanding the scope to include verification of generator data will not provide a significant improvement in the overall modeling of excitation systems. However, these data should be provided as part of an existing Standards or from another Standards if not already existing.
Response: Thank you for your comments**.** The SDT agrees separate verification of generator data is unnecessary however, the SDT believes that when a testing expert verifies the excitation system model data, the generator model data is also verified. A match between simulation and measured results for the excitation system model is required to indicate that the generator and excitation control system models accurately represent the equipment.

Ameren	No	None
American Electric Power	Yes	Generator parameters are needed to support modeling. Later phases could pick-up unknowns identified by examining discrepancies between actual operation and modeling.
Response: Thank you for your comments**.** The SDT agrees that appropriate generator parameters are essential for developing an accurate excitation system model. A match between simulation and measured results for the excitation system model is required to indicate that the generator and excitation control system models accurately represent the equipment.		
Northeast Utilities	Yes	Consider model verification for rotational inertia, which can have a significant effect on modelling.

Organization	Yes or No	Question 4.1 Comments and/or Supporting Data
Response: Thank you for your comment. The SDT agrees separate testing is generally not required to develop a generator model even though rotational inertia can have a significant effect. a match between simulation and measured results for the excitation system model is required to indicate that the generator (including the rotational inertia) and excitation control system models accurately represent the equipment.		
AESO	Yes	The exciter is only one component of the generator, testing all components (generator, exciter, PSS and governor/prime mover) is imperative so a complete picture of how the unit will react within the electrical system can be modeled. For the same reason units such as wind facilities and other types of generation that do not have an exciter must be modeled and verified.
Response: Thank you for your comments. A match between simulation and measured results for the excitation system model is required to indicate that the generator and excitation control system models accurately represent the equipment. The SDT agrees that in some circumstances it may not be necessary to perform further testing to establish appropriate models for the generator. The MOD-027 proposed standard will address modeling of the governor/prime mover. Generic models have recently been developed for wind facilities, which the SDT agrees additional work is needed to ensure appropriate models are established for wind facilities, solar facilities, etc. The standard has been modified to include verification requirements for these facilities.		
Duke Energy	Yes	Per the title, this is a standard applicable to the verification of excitation system models and the industry understands this to be different than the generator parameters. Requiring testing to specifically validate that generator data might require more than a bump test, which is currently thought to be adequate to address the issues currently in this standard. The generator reactances and time constants should not need verification as long as there is valid manufacturer supplied data and the generator has not been modified (rotor replacement, etc.) or condition has not degraded, such as the unit has been identified to have shorted rotor turns which would be expected to impact saturation curves and several of the reactance modeled. Additional testing might be appropriate when it is identified that a unit is operating with shorted turns, or if changes are made if a bump test cannot revalidate what is needed (such as a rotor replacement - do you need to verify saturation curves or when you remove a rotating exciter, do you need a load rejection test). NERC should consider establishing and documenting requirements for when model data validation should be re-verified and minimum tests needed for partial unit upgrades (e.g. what testing is required for a rotor replacement). Thus, it would seem a supplementary SAR to include generator parameter validation is needed. NERC should also consider developing a guide that provides input on these issues, especially if the responsibility is assigned to a GO/GOP without the technical background in models and validation. SERC developed a guide on this subject that could be leveraged for a NERC guide.
Response: Thank you for your comments. The SDT agrees separate verification of generator data is unnecessary however, the SDT believes that when a testing expert verifies the excitation system model data, the generator model data is also verified. A match between simulation and measured results for the excitation system model is required to indicate that the generator and excitation control system models accurately represent the equipment. Additional testing may be		

Organization	Yes or No	Question 4.1 Comments and/or Supporting Data
necessary if new data needs to be added to the generator model. The SDT agrees that the concept of a supplemental SAR should be discussed to ensure identified issues are included when performing unit upgrades.		
NERC Event Analysis & Information Exchange staff	Yes	It seems that having an overall generator testing standard in place on the dynamic parameters listed in MOD-013 would be a prerequisite for an excitation testing standard.
Response: Thank you for your comment. The SDT agrees that an accurate representation of the generator system is essential to obtain a match between simulated and measured results however, the SDT believes that a match between simulation and measured results for the excitation system model is required to indicate that the generator and excitation control system models accurately represent the equipment. If the results do not match, then further testing may be required to develop appropriate generator parameters. To prevent further delays with developing the MOD-026 standard, the SDT will not consider a generator verification standard as part of the exciter verification standard development process.		
Independent Electricity System Operator	Yes	We think that at a minimum, the generator's basic characteristics such as inertia constant, damping coefficient, saturation parameters, and direct and quadrature axes reactances and time constants), voltage regulators, turbine-governor systems, etc. as stipulated in MOD-013 that support modeling for dynamic simulations should be verified. .A good excitation system model without a valid generator model will not provide the assurance that the simulation results are valid, which may hurt reliability.
Response: Thank you for your comments. The SDT agrees that appropriate dynamic models are needed for generators, exciters, PSS, and governors. The SDT believes that when testing personnel verify the excitation system model data, they also provide verification of the generator model data. a match between simulation and measured results for the excitation system model is required to indicate that the generator and excitation control system models accurately represent the equipment. The governor model is not verified with the excitation system model since it requires a frequency excursion. Verification of the governor model will be addressed by the MOD-027 standard. Experience indicates verification required by the MOD-026 standard often results in discovery of significant changes to the representation of the generator and exciter, suggesting that model verification provides significant reliability improvement.		
US Bureau of Reclamation	Yes	Yes, we believe other accurate dynamic models (e.g. generator model, governor model) are needed for valid computer simulations and should be required. Existing standards, MOD-012-0 Dynamics Data for Transmission System Modeling and Simulation and MOD-013-0, RRO Dynamics Data Requirements and Reporting Procedures (not FERC approved) already require each reliability region to determine comprehensive dynamics data requirements and Generator Owners to provide such modeling data. If these standards are being performed it is questionable what additional reliability concern is served by draft PRC-026-1.
Response: Thank you for your comments. The SDT agrees that appropriate dynamic models are needed for generators, exciters, PSS, and governors. The SDT believes that verification of the excitation system model data also provides verification of the generator model data. A match between simulation and measured results for the excitation system model is required to indicate that the generator and excitation control system models accurately represent the equipment. The governor model is not verified with the excitation system model since it requires a frequency excursion. Verification of the governor model will be addressed by		

Organization	Yes or No	Question 4.1 Comments and/or Supporting Data
the MOD-027 standard. The MOD-026 standard requires verification, while the MOD-012 standard simply requires that the data be provided. Experience indicates verification required by the MOD-026 standard often results in discovery of significant changes to the representation of the generator and exciter, suggesting that model verification provides significant reliability improvement.		
Xcel Energy	Yes	
American Transmission Company	Yes	

5. MOD-026 Requirement R8 requires the Generator Operator to provide documentation demonstrating that the provided model's response matches the recorded response. It does not specify criteria for evaluating the match. Requirement R8 assigns the task of evaluating the match to the Generator Operator. A peer review process for this documentation, detailed in Requirement R10(R1 in the second draft of the standard), gives other involved parties an avenue to provide input and voice any concerns.

Do you agree with the approach of the Generator Operator determining if the match is sufficient and the peer review process?

Summary Consideration:

The majority of industry agrees with allowing the generator entity to evaluate how accurately the recorded equipment response matches the model predicted response; and with the peer review process. Based on industry feedback received, the Generator Owner (as discussed in Question 1) is the entity responsible for model verification in the second draft of the standard.

Organization	Yes or No	Question 5 Comments
NERC Event Analysis & Information Exchange staff	No	The peer review process in R10 assumes that since the GOP operates the equipment, they are a technical authority on its modeling and behavior. Historically, that has been not necessarily correct, even of the owners of the equipment. Changes to excitation system models should be peer reviewed. However, a dispute resolution process would be needed for disagreements between the owners/operators and the peer team.
Response: Thank you for your comments. The SDT believes that the Generator Owner has the option of either developing in-house expertise, or entering into an agreement with a consultant, or entering into an agreement with its Transmission Planner. The SDT also believes that the Generator Owner, as owner of the model, has resolution authority for any model disagreement with the peer review team.		
Southwest Power Pool Generation Working Group	No	It is understood and agreed that many differing types of units and testing exist. With that thought in mind, it is felt the standard needs to provide some guidelines of how to perform the test and what type of test results are to be reported.
Response: Thank you for your comments. The SDT does not believe it is necessary to provide guidelines on how to perform the test or how to report results given established guidelines and procedures already exist within the industry including several available papers & publications on this issue. It is not practical to provide testing details in the standard that cover all types of excitation control system technologies. If an entity is not familiar with these testing methods and procedures, then the SDT recommends that they should develop in-house expertise (e.g. working with its Transmission Planner) or hire a consultant with expertise		

Organization	Yes or No	Question 5 Comments
testing generators.		
Northeast Power Coordinating Council	No	As stated in our response to Question 1, we believe that the Generator Owner is the correct entity to provide the data; not the Generator Operator. We agree with the approach subject to revising the responsible entity.
Response: Thank you for your comments. The SDT has assigned model verification responsibility to the Generator Owner in the next posting of the standard.		
Entergy Fossil Operations	No	This should be the Transmission planner's job. The GO or GOP does not use this data or the software or the expertise and may not be aware of disturbances on the system. The TP should compare this data and furnish it to the GO if there is an issue.
Response: Thank you for your comments. The SDT disagrees and believes that since the Generator Owner has physical access to the equipment and operates the equipment, it is the proper entity to be responsible for model testing and verification activities. If an entity is not familiar with these test methods and procedures or does not possess the necessary expertise, then the SDT recommends that the entity develop in-house expertise or hire a consultant who has generator testing expertise.		
IRC Standards Review Committee	No	As the facility owner, the Generator Owners should have the authority to confirm the accuracy of the model, which when supported by documentation, should suffice. A peer review is not necessary, and if "match" must be quantified, the industry may develop a set of criteria based on historical verification test data, and add this to the standard at a later stage.
Response: Thank you for your comments. The SDT agrees with your first comment. The SDT disagrees with the second comment that “peer review is not necessary”. The SDT believes peer review is an essential part of the model verification process irrespective of criteria or guidelines available from industry since peer review provides the Transmission Planner an opportunity to review the data and identify problems or errors with information provided.		
FEUS	No	No, This allows for ambiguity in the interpretation of the standard by both the entity and the requlator.
Response: Thank you for your comments. The SDT considered ways to quantify a method for evaluating how well the equipment’s measured response matches the model’s predicted response. However, since a generally accepted technique or criteria for making this quantitative assessment does not exist, the SDT believes that the peer review process is necessary for ensuring quality. The SDT believes everyone involved in the peer review process has common motivation to develop an accurate excitation control system model.		
Exelon Corporation	No	Exelon feels that the standard should define the acceptance criteria. If the acceptance criteria is left up to the generator owners, then the TOs may have to deal with multiple acceptance criteria within a single region. At the same time, a single generator owner may have to work with multiple TOs, which will lead to inconsistency if the

Organization	Yes or No	Question 5 Comments
		definition of the acceptance criteria is left up to the TO.
Response: Thank you for your comments. The SDT has researched this concern and cannot find uniform guidelines or criteria available to industry for addressing/defining this issue. Therefore, the SDT believes the Generator Owner should use engineering judgment when addressing this issue.		
Consumers Energy Company	No	It is the Transmission Operator and the Transmission Planner's task to determine if the model matches. The Generator Operator is uniquely unsuited to monitor transmission lines and determine if the model works. If the Transmission Planner's model doesn't properly reflect reality, the Transmission Planner should be required to meet with the Generator Operator and discuss the issue. The Generator Operator should then be required to re-verify the data in question.
Response: Thank you for your comments. The SDT disagrees with the first comment that the Transmission Operator and Transmission Planner should be responsible for determining if the model is accurate. The SDT believes that since the Generator Owner owns and has physical access to the equipment, it is the proper entity to be responsible for model testing and verification activities. If an entity is not familiar with these test methods and procedures or does not possess the necessary expertise, then the SDT recommends that the entity develop in-house expertise or hire a consultant who has generator testing expertise. Regarding the second part of the comment, reference Requirement R2 in the revised standard concerning “model matching” and “verification”.		
City of Garland, Garland Power & Light - GOP Registered Entity	No	This should be the role of the Generator Owner (GO) - the GO has the data, the GO has the equipment, and the GO can schedule any required operational testing through the GOP.
Response: Thank you for your comments. The SDT agrees and has assigned this responsibility to the Generator Owner in the second draft of the standard.		
American Electric Power	No	AEP does not agree that the Generator Operator should not be responsible to provide documentation that the system model matches the recorded response. That responsibility should lie with the Generator Owner to review and decide how to have that analysis performed and to what extent documentation will be prepared to provide the required verification.
Response: Thank you for your comments. The SDT agrees and has assigned this responsibility to the Generator Owner in the second draft of the standard.		
Wisconsin Electric	No	The requirements in R8 and R9 are not clear to us. The term "recorded response" needs to be defined, and the term "voltage excursion" needs to be quantified. These requirements infer that the GOP already has some documentation of what a "correct" response looks like, which is not the case. The requirement to validate the exciter model by monitoring its response to a real or staged event is not a simple matter. For a staged event such as switching a line, the TO or TOP will need to be actively involved in the process, and should have some responsibility assigned to it in the standard. Likewise, if an ambient switching event is used to validate the model,

Organization	Yes or No	Question 5 Comments
		the TO/TOP would be the only entities in a position to know about it, since such operations may not be known by the GOP. In summary, this validation depends on shared responsibilities among the entities, and the requirements in this standard should properly reflect this.
Response: Thank you for your comments. The difference between Requirements R8 and R9 is that Requirement R9 requires the Generator Owner to make the documentation of predicted versus recorded response developed in R8 available to interested parties upon request. In the revised standard (reference Requirement R2 in the revised standard). The SDT believes that "recorded response" and "voltage excursions" are understood industry terms and there is not a need for further clarification of these terms. The SDT agrees that in order to validate the model using "staged testing" or "ambient monitoring", close coordination will be required between the Generator Owner and the TO/TP. Since the "Generator Owner" is the owner of this process, the Generator Owner has ultimate responsibility for testing and verifying the model. The SDT believes it is not practical to include a new requirement in the standard addressing shared model verification responsibilities. Also note that an "open circuit step in voltage" test is the most likely staged test that will be performed. This is a common test performed on a unit while it is at rated speed and voltage but not synchronized to the transmission system; and not a "staged test" by performing some sort of transmission system switching.		
Dynegy	No	See response to Item #1.
Response: Thank you for your comment. Please refer to the response provided to Dynegy's comment in Question 1.		
Northeast Utilities	No	As stated in our response to Question 1, we believe that the Generator Owner is the correct entity to provide the data; not the Generator Operator. We agree with the approach subject to revising the responsible entity.Agree that peer review by TP/PC is important for verifying the match.
Response: Thank you for your comments. The SDT agrees and has assigned this responsibility to the Generator Owner in the second draft of the standard.		
Reliant Energy	No	It should be the TP working with the GOP.
Response: Thank you for your comment. Requirements in the second draft of the standard define collaboration and peer review process language requiring the Transmission Planner to work with the generation entity.		
ISO New England Inc.	No	The generator should provide the data to Reliability Coordinators, Transmission Operators and Planning Coordinators for verification. Generator Owners should provide factory models for excitation systems to Reliability Coordinators, Transmission Operators and Planning Coordinators and these models should be verified with the field data.

Organization	Yes or No	Question 5 Comments
Response: Thank you for your comments. The SDT does not understand the intent of this comment. If the comment questions who should perform model verification process tasks, the SDT believes that the Generator Owner is the appropriate entity to verify the model. Please refer to Question 1 for additional explanation.		
Ameren	No	(1) Generator Operators and Generator Owners should be included in this standard. It is possible that all functions can not be performed by the Generator Operator. Therefore it would be prudent to include the Generator Owners within MOD-026-1. The Generator Operator or Generator Owner should verify the model but should not be responsible for the model.(2) No issues with peer-to peer review, as this would help drive what are necessary and sufficient conditions for matching the responses.(3) The functional model entity responsible for the model's verification has to be given the responsibility of demonstrating that the provided model's response matches the recorded response. The "goodness of fit" between the model response and the equipment response should be left to the generator owner but subject to Transmission Planner review ref. R10.
Response: Thank you for your comments. Regarding Comment #1: Based on the majority of industry comments and guidance from the FMWG, the second draft of the standard assigns responsibility to the Generator Owner. As mandated by Reliability Standard process, only one entity is assigned responsibility for excitation system model verification. Generator Owners have access to the equipment, along with access to the equipment's Original Equipment Manufacturer for assistance with technical issues. Historically, the Transmission Planner and Generator Owner entities used to work for the same company, but in today's functional model environment, Transmission Planners could easily work for a different company than the generation entity. As such, the stated access advantages for the generation entity do not transfer to the Transmission Planner. The SDT agrees with comments #2 and #3 provided.		
AESO	No	The AESO agrees with the SRC ISO/RTO comments.
Response: Thank you for your comment. Please reference responses to SRC ISO/RTO comments.		
Hydro-Québec TransEnergie (HQT)	No	As stated in our response to Question 1, we believe that the Generator Owner is the correct entity to provide the data; not the Generator Operator. We agree with the approach subject to revising the responsible entity.
Response: Thank you for your comments. For the reasons stated in response to your comment in Question 1, the Generator Owner has been assigned responsibility for model verification in the second draft of the standard.		
Independent Electricity System	No	We have difficulty with the concept since the GOP's determination of a "match" can be subjective and subsequent peer review is time consuming and unnecessary if some matching criteria is developed up front. While we are not

Organization	Yes or No	Question 5 Comments
Operator		in a position to suggest what that criteria should be, we tend to think that a certain percentage of deviation in some output parameters may serve to provide this measure.Also, as indicated under Q4, we suggest R8 be combined with R4. It may be a moot point if some criteria are developed but if not, there are inconsistencies among R4, R8, R9 and R10 on the recipients of the documentation that the Generator Operator must provide and the feedback to be received. We suggest the SDT review the list of recipients, and if peer review is still required then the recipients/commenters should include Transmission Planners, Planning Coordinators, Transmission Operators and Reliability Coordinators since they all are users of the data and model.
Response: Thank you for your comments. The SDT has researched this concern and cannot find uniform guidelines or criteria available to industry for addressing/defining this issue. Therefore, the SDT believes the Generator Owner should use engineering judgment when addressing this issue. The SDT agrees with the recommendation to combine Requirement R8 with R4 (reference Requirement R2, Part 2.1 in the revised standard). The SDT will strive to ensure the proper functional model entities are included in the peer review process.		
Brazos Electric Power Cooperative	No	The Generator Owner should be responsible.
Response: Thank you for your comment. The SDT agrees and has assigned this responsibility to the Generator Owner in the second draft of the standard.		
US Bureau of Reclamation	No	Again we think the Generator Owner should be the responsible entity. This standard applies to only two entities, the Generator entity and the Transmission Planner; however actions by other entities, Reliability Coordinator and Transmission Operator, are required to accomplish the goals of the standard. The exact requirements of these entities should be described in the Standard.
Response: Thank you for your comments. The SDT has assigned responsibility of model verification to the Generator Owner in the second draft of the standard. Also, potential interactions with the Reliability Coordinator and the Transmission Planner are also specified in the draft standard.		
Reliant Energy	No	Peer review works well when performed by reasonable professional with the right motives. The only disagreement is that the Transmission Planner can arbitrarily reject the model and data without assuming any responsibility for the corrections or the cost.
Response: Thank you for your comments. The SDT believes that in a professional environment the peer review process will function properly given it is in the best interest of the Transmission Planner to resolve model issues with the Generator Owner in an expedient manner.		

Organization	Yes or No	Question 5 Comments
Constellation Power Generation & Constellation Nuclear	No	
SERC Dynamics Review Subcommittee (DRS)	Yes	The entity responsible for the model's verification has to be given the responsibility of demonstrating that the model's response matches the recorded response. The "goodness of fit" between the model response and the recorded response should be left to the generator owner but subject to Transmission Planner review ref. R10.
Response: Thank you for your comments. The SDT agrees with your comments.		
FirstEnergy	Yes	1. For many GOP's, a testing contractor with experience in model fitting and selection will need be hired to do the verification. 2. The team may want to add an additional requirement for the Transmission Planner to review and confirm acceptability of the Generator Operator's excitation system model verification documentation within 90 days of submittal. This would preceed the R10 requirement.
Response: Thank you for your comments. Regarding comment #1. If an entity is not familiar with these test methods and procedures or does not possess the necessary expertise, then the SDT recommends that the entity develop in-house expertise or hire a consultant who has generator testing expertise. Regarding comment #2. The SDT agrees. Reference Requirement R6.		
Manitoba Hydro	Yes	This should be done in consultation with planning/operating studies groups, since invariably these groups possess the necessary expertise and are in a better position to adjust/modify the model.
Response: Thank you for your comments. The SDT notes that existing arrangements or new arrangements for model verification can be established by the Generator Owner. However, even if the Generator Owner obtains assistance from its Transmission Planner or another entity (such as a consultant) for any step of the model verification process, the Generator Owner maintains responsibility for model verification as specified in the draft standard. It should also be noted that while the Transmission Planner may have expertise running the dynamic stability software, most Transmission Planners do not possess expertise with reviewing generator model dynamic data and modifying the model.		
Progress Energy, Inc.	Yes	The functional model entity responsible for the model's verification has to be given the responsibility of demonstrating that the provided model's response matches the recorded response. The "goodness of fit" between the model response and the equipment response should be left to the generator owner but subject to Transmission Planner review ref. R10.
Response: Thank you for your comments. The SDT agrees with your comments.		

Organization	Yes or No	Question 5 Comments
Duke Energy	Yes	We agree the standard should not set criteria for evaluating the match, but industry guidance on acceptable criteria would be helpful.
Response: Thank you for your comment. Since a generally accepted technique or criteria for making this quantitative assessment does not exist, the SDT believes that the peer review process is necessary for ensuring quality. The SDT believes everyone involved in the peer review process has common motivation to develop an accurate excitation control system model. Therefore the SDT does not recommend establishing quantitative criteria for evaluating the match.

6. The team purposely provided minimal specificity regarding the mechanics of performing excitation system verification and the development of the documentation showing that the provided model response matches the recorded response. The team felt it was impractical to provide verification details in a mandatory Reliability Standard that needs to be applicable to all of the existing and future technologies.

Do you agree with this approach? If no, please elaborate on the additional specificity that you feel is appropriate with specific examples and/or proposed Reliability Standard language.

Summary Consideration:

The majority of industry responders agree only minimal verification details should be provided in the standard. Industry response indicates additional modification to the second posting of the standard is not required for this comment.

Organization	Yes or No	Question 6 Comments
Southwest Power Pool Generation Working Group	No	It is understood and agreed that many differing types of units and testing exist. With that thought in mind, it is felt the standard needs to provide some guidelines on how to perform the test and what type of test results are to be reported.
Response: Thank you for your comments. The majority of industry agrees with the SDT that it is impractical to provide sufficient technical details that would apply to all types of technology.		
Entergy Fossil Operations	No	I do agree with not making the standard too large, but somewhere the GVSDT needs to provide this detailed data or training to the GO/GOP. You are requiring them to provide things that they do not have expertise in and this will lead to problems with getting this done correctly and for a reasonable price. I'm sure the contractors that do with work see a big opportunity to make money on this.
Response: Thank you for your comments. The majority of industry agrees with the SDT that minimal technical specificity is appropriate for this standard.		
FEUS	No	This leaves ambiguity in the standard that can be to misinterpretation by the entity or the agency. Some guidelines should be provided for standardization to avoid confusion.
Response: Thank you for your comments. The SDT believes it is impractical to add sufficient technical details that would apply to all types of technology, that doing so would be counter-productive and cumbersome, and that it is best to let the technical experts determine this information.		

Organization	Yes or No	Question 6 Comments
E.ON U.S.	No	While E.ON U.S. appreciates that the concern over requirements applicable to both existing and future technologies, the lack of any specific guidance on process and verification methodologies invites differing interpretations of the standard. This lack of specificity makes compliance problematic.
Response: Thank you for your comments. The SDT believes that the majority of industry agrees that if the equipment recorded response matches the models predicted response, verification of the model has been achieved. Also, the draft standard includes a peer review process intended to ensure verification process quality. The SDT has made substantial effort to ensure the Requirements can be clearly evaluated from a compliance perspective.		
ISO New England Inc.	No	This may lead to "weak" submittals from certain entities.
Response: Thank you for your comments. The SDT believes the interactions and checks listed in the Requirements of the draft standard along with the peer review process will mitigate model verification quality concerns.		
American Transmission Company	No	Standard testing procedures should be provided as a minimum with the caveate "that the testing procedures include but are not limited to these procedures" to cover future technologies. An example would be a step response test for the exciter; swept frequecy (0.1 t0 10 Hz) response test for a PSS.
Response: Thank you for your comments. The majority of industry responses indicate the technical details should be left to the experts performing testing and model verification.		
Northeast Power Coordinating Council	Yes	Reliability Standards should focus on what is required and not how to meet the requirement. Further, it would be impractical to specify verification details universally applicable to all situations. The peer review process provides appropriate safeguards to ensure that appropriate methods are used for verification.
Response: The SDT thanks you for your comment.		
SERC Dynamics Review Subcommittee (DRS)	Yes	We agree with the SDT approach of not writing this standard like a technology specific procedural manual. The development of verification Requirements stating "what is required" and leaving the technical details up to the personnel performing the verification will result in improved dynamic models while affording sufficient technical latitude.
Response: The SDT thanks you for your comment.		
FirstEnergy	Yes	While we agree with the approach of staying away from being too prescriptive, it may add guidance if the term

Organization	Yes or No	Question 6 Comments
		"verify" (i.e. in R1) was clarified. We ask the team to consider adding "such as operational tracking or testing" after verify.
Response: Thank you for your comments. Language of Requirement R8 has been added to the list of items required for model verification (reference Requirement R2, Part 2.1). This includes a reference that either a test or ambient monitoring is an acceptable alternative to capture the actual response of the equipment.		
Consumers Energy Company	Yes	Providing minimal specificity allows many approaches to meet the requirements. This accommodates the many present and future excitation technologies and monitoring techniques.
Response: The SDT appreciates your response.		
Wisconsin Public Service	Yes	I agree with the methodology of the SDT to leave the test methods required under R4 out of the standard. It is a good philosophy to not limit future advancements in testing because the standard specifially calls for a step voltage test or UEL / OEL bumps. I think the SDT should consider this methodology in future drafts as applicable.
Response: The SDT appreciates your response.		
American Electric Power	Yes	We are agreeable since there are different kinds of excitation systems.
Response: The SDT appreciates your response.		
Progress Energy, Inc.	Yes	We agree with the SDT approach of not developing this standard like a technology specific procedural manual. The development of verification Requirements stating "what is required" and leaving the technical details up to the personnel performing the verification will result in improved dynamic models while affording sufficient technical latitude.
Response: The SDT appreciates your response.		
Reliant Energy	Yes	I susgest that the SDT consider a white paper expounding how the verification can be performed.
Response: Thank you for your comments. The SDT believes that there are many technical references available which document verification processes that have been successfully utilized. Please refer to the References section of the draft standard.		

Organization	Yes or No	Question 6 Comments
Ameren	Yes	We agree with the SDT approach of not developing this standard like a technology specific procedural manual. The development of verification Requirements stating "what is required" and leaving the technical details up to the personnel performing the verification will result in improved dynamic models while affording sufficient technical latitude.
Response: The SDT appreciates your response.		
AESO	Yes	The AESO agrees with the SRC ISO/RTO.
Response: Thank you for your comment. Please see the response to the SRC ISO/RTO comment referenced.		
Duke Energy	Yes	We agree, but industry guidance on acceptable criteria would be helpful.
Response: Thank you for your comment. See the SDT response to this same issue under Question 6.		
Hydro-Québec TransEnergie (HQT)	Yes	Reliability Standards should focus on what is required and not how to meeet the requirement. Further, it would be impractical to specify verification details universally applicable to all situations. The peer review process provides appropriate safeguards to ensure that appropriate methods are used for verification. As an alternative, a technical white paper could be developped for reference.
Response: Thank you for your comments. The SDT did not develop a white paper because many excellent subject matter references already exist. Please refer to the Reference section of the draft standard.		
Independent Electricity System Operator	Yes	The SAR could be expanded by making it more clear that it applied not only to the excitation systems on conventional synchronous generation units but also to the equipment that performs this role on non-conventional facilities such as wind-farm voltage management systems.
Response: Thank you for your comments. The Applicability section MVA thresholds provided in the first posting of the MOD-026 standard omitted wind powered units because wind unit are not rated greater than 20 MVA. There is an increasing number of wind farms with significantly larger aggregate MVA and as such, their impact on the reliability of the Bulk Electric System cannot be ignored; otherwise a reliability gap would exist. The SDT discussed the possibility of requiring verification of dynamic models that represent the aggregate of numerous small units and any necessary auxiliary equipment required of the technology. This could include plant dynamic voltage control and reactive support of all the units and auxiliary equipment (such as individual WTG response, plant-wide volt/var controller response, and response from separate volt/var regulation devices contained in the plant such as SVC/STATCOM/Synchronous Condenser) contained in any technology generation plant, including a wind farm (plant), that exceeds the appropriate aggregate nameplate MVA threshold. There are dynamic models that adequately replicate wind unit performance for some wind units today however, there are many existing wind units for which there are not publicly available models		

Organization	Yes or No	Question 6 Comments
supplied by the Original Equipment Manufacturer. Generic wind models (i.e., type I, II, III and IV) are in various stages of development. Also, there are ongoing efforts involving Regional Entities and manufactures to close any large gaps that may exist in current generic models. Given the timeframe expected to lapse while awaiting standard approval by FERC, it is expected that generic wind farm (plant) models will sufficiently mature for establishing boundary conditions in Bulk System Studies. To mitigate this reliability gap, the Applicability section will be expanded in the second posting of the standard to include a significant MVA percentage of generation regardless of technology.

7. The SDT believes that this standard should not be applicable to low capacity factor units. The SDT recognized that the excitation system models and model data are already collected through the processes identified in MOD-012 and MOD-013. These models and data should, with few exceptions, already accurately replicate actual equipment performance. By definition, low capacity factor units are expected to rarely be on-line, and even when they are, they would constitute a small portion of the interconnected MVA. As such, the SDT is of the opinion that verified excitation models for these units would not result in a substantial increase in Bulk Electric System reliability. Do you agree with this approach and the proposed 5% capacity factor?

Summary Consideration:

The majority of industry responders supported the 5% capacity factor criteria. In response to Industry comments for Question 9, the SDT has revised the standard to include a new Requirement that allows Planning Coordinators to specify, with technical justification, additional units to provide corrected model data or verify their excitation control system models. The SDT believes that this new Requirement will address the concerns expressed by several Industry responders.

Organization	Yes or No	Question 7 Comments and/or Supporting Data for Not Agreeing with a Capacity Factor Exemption:	Question 7 Supporting Data for the Proposed 5% Capacity Factor:
NERC Event Analysis & Information Exchange staff	No (disagree with approach)	Units with a low capacity factor may well still be frequently needed, albeit for short but crucial periods, to support the system during peak load. Further, they may often be used in shoulder periods when primary resources are out on maintenance.	

Response: Thank you for your comments. The reason for choosing a 5% capacity factor as a threshold for exemption in conjunction with the proposed MVA-based exemption is by SDT collective experience. The increase in excitation control system model verification is expected to result in improved accuracy of stability based security assessments. The SDT does not believe un-verified data is necessarily inaccurate or that the overall stability of the system is sensitive to that data. The excitation information from the generating units with a 5% capacity factor or less, as provided per standards MOD-012 and MOD-013, is included in the models used to analyze the system under various conditions. Even if these low capacity factor generating units are verified, the accuracy of the simulation is not guaranteed because there are other significant assumptions involved in simulation results, such as load models. As such, the verified models do not provide absolute accuracy under operating conditions other than those conditions for which verification is performed.

Additionally, the SDT has revised the draft standard to allow the Planning Coordinator to identify, through a process demonstrating technical justification, additional generating units that are critical for reliability beyond the applicability criteria established by section 4.2.

Organization	Yes or No	Question 7 Comments and/or Supporting Data for Not Agreeing with a Capacity Factor Exemption:	Question 7 Supporting Data for the Proposed 5% Capacity Factor:
IRC Standards Review Committee	No (disagree with approach)	a. The Term Capacity Factor is capitalized but this term is not defined. Suggest to use lower case, or define it.b. Capacity factor reflects a generating unit's real power generation frequency and duration, but does not provide the assurance that when the generator is on line, it's excitation system has been verified such that its model is accurately represented in simulations. There are also sizable "mothballed" units that, due to various reasons, were put off line for a long period but return to service when the need for capacity so dictates. Not having their data verified based on a low capacity factor and on the assumption that they constitute a small portion of the interconnection MVA may leave room for unreliability. Moreover, having to track a unit's capacity factor for the past 5 years to determine the need for verification is an unnecessary administrative burden.	
Response: Thank you for your comments. The reason for choosing a 5% capacity factor as a threshold for exemption in conjunction with the proposed MVA-based exemption is by SDT collective experience. The increase in excitation control system model verification is expected to result in improved accuracy of stability based security assessments. The SDT does not believe un-verified data is necessarily inaccurate or that the overall stability of the system is sensitive to that data. The excitation information from the generating units with a 5% capacity factor or less, as provided per standards MOD-012 and MOD-013, is included in the models used to analyze the system under various conditions. Even if these low capacity factor generating units are verified, the accuracy of the simulation is not guaranteed because there are other significant assumptions involved in simulation results, such as load models. As such, the verified models do not provide absolute accuracy under operating conditions other than those conditions for which verification is performed. Additionally, the SDT has revised the draft standard to allow the Planning Coordinator to identify, through a process demonstrating technical justification, additional generating units that are critical for reliability beyond the applicability criteria established by section 4.2.			
SERC Dynamics Review Subcommittee (DRS)	No (disagree with approach)	The 5% capacity factor is an inappropriate basis for an exemption criteria since it would allow significant blocks of generation (i.e. plants of several hundred MW) to be exempt. Units in this class of generation may have a significant impact on the stability of nearby generating units or may have stability issues that need to be understood via valid studies. Examples would be plants with multiple combustion turbine units (particularly simple cycle oil burners) that are rarely generating. However, when they are generating (i.e. during peak system	Based on the above discussion, the 5% capacity factor exemption should only be allowed when it would significantly impact the results of stability studies. Allowing the Transmission Planner to make this judgement is most appropriate since A) this entity is in the best position to make the determination of the impact on stability and B) this entity is responsible (via TPL standards) for ensuring the stability of the grid and connected

Organization	Yes or No	Question 7 Comments and/or Supporting Data for Not Agreeing with a Capacity Factor Exemption:	Question 7 Supporting Data for the Proposed 5% Capacity Factor:
		load times), the grid may be already be stressed and operating with a reduced stability margin.The possibility also exists that while the exempted generation may have a historical capacity factor of less than 5%, this could quickly change due to unanticipated system conditions or the extended unavailability of other generation (due to severe damage for example). Therefore, the subject generating units could generate for a significant length of time without the benefit of having been properly analyzed by the Transmission Planning organization. The average over the last three calendar years methodology further contributes to this possibility, introducing a time lag in the process.	generating units.In lieu of the blanket 5% exemption, the following is proposed.1. Delete and with an average Capacity Factor of greater than 5% over the last three calendar years in all places in 4.1.1.1, 4.1.1.2 and 4.1.1.32. Add a new section under Applicabilty 4.1.1.4 stating ?Generating facilities with capacity factors less than 5% over the last three calendar years may be exempted with written concurrence from the applicable Transmission Planning Authority. The written concurrence provided by the Transmission Planning Authority shall include the basis for any such exemptions. alternative to (2.) could be the reponse to Q9 below.
Response: Thank you for your comments. Each registered generating unit reports excitation control system model information per standards MOD-012-1 and MOD-013-1, which means the unit excitation control system model is provided to the Transmission Planners. Because of the requirements in standards MOD-012 and MOD-013, the SDT believes that units with excitation control system models that have not been verified do not necessarily lead to inaccurate results or that the overall stability of the system is sensitive to “unverified” data. The validity of simulation results depends upon many assumptions such as load and other system models. At the end of every 10 year periodicity window, if a generating unit exceeds the 5% capacity factor, it must be tested within the next year if the unit has not been tested within the previous 10 year period. This testing timeframe is similar to the effective date timeframe specified in the standard. Additionally, the SDT has revised the draft standard to allow the Planning Coordinator to identify, through a process demonstrating technical justification, additional generating units that are critical for reliability beyond the applicability criteria established by section 4.2. The SDT believes that defining a process where additional units could be identified for verification was a reasonable approach as opposed to defining a process where units with low capacity factor must apply for an exemption.			
Consumers Energy Company	No (disagree with approach)	We disagree with the approach. Some systems have very large peaking units which arguably are more likely to be in service on days when the BES would be challenged. Thus, modeling data should be collected for these units and model cases run including these data. Additionally, the requirement should only apply to peaking units which meet the applicability criteria (i.e. Capacity factor greater than 5% for the last 3 years and greater than the MVA indicated in 4.0)	
Response: Thank you for your comments. Each registered generating unit reports excitation model information per standards MOD-012 and MOD-013 and thus will be			

Organization	Yes or No	Question 7 Comments and/or Supporting Data for Not Agreeing with a Capacity Factor Exemption:	Question 7 Supporting Data for the Proposed 5% Capacity Factor:
included in stability assessments performed with the model information included in the dynamics database. Also, modeling excitation control systems is most important for stability assessments, for which the most limiting scenario is almost always off peak conditions. Additionally, for the case where large units are exempt by size, interconnection voltage, or capacity factor, the SDT is proposing a new requirement that allows the Transmission Planner or the Planning Coordinator to identify additional generating units beyond the criteria established by section 4.2 that are needed for reliability.			
Wisconsin Public Service	No (disagree with approach)	Threshold should be set around 20% to remove the requirements from those operators that may have a large fleet of small CT's that operate only in minimal peakng mode, but would qualify under the multiple units on the same site provision. These units have minimal impact on the dynamic model.	
Response: Thank you for your comments. The SDT believes that the 5% Capacity Factor threshold functions to establish a balance between verifying modeling information for units that play an important role in the reliability of the BES and units that report information which is not verified because they are seldom online and have a relatively diminished reliability role. Also, note that the draft standard MOD-026 – Attachment 1 “Excitation Control System Model Verification Periodicity” provides conditions where the verification of one unit’s excitation control system model verification will satisfy multiple units.			
American Electric Power	No (disagree with approach)	Seldom run units could end up being run at peak times in areas that may be stability limited. Applicability should be driven by need for verification which historically, has been tied to stability performance and constraints.	
Response: Thank you for your comments. The SDT has revised the draft standard to allow the Planning Coordinator to identify, through a process demonstrating technical justification, additional generating units that are critical for reliability beyond the applicability criteria established by section 4.2.			
Progress Energy, Inc.	No (disagree with approach)	The 5% capacity factor is an inappropriate basis for an exemption since it would allow significant blocks of generation (i.e. plants of several hundred MW) to be exempt. Such amounts of generation may have a significant impact on the stability of nearby generating units or such units may themselves have stability issues that need to be understood via valid studies. Examples would be plants with multiple combustion turbine units (particularly simple cycle oil burners) that are rarely run. However, when they are run (i.e. during peak system load times), the grid may be already be stressed and operating with reduced stability margin.The possibility also exists that while the exempted generation may have a capacity factor of less than	

Organization	Yes or No	Question 7 Comments and/or Supporting Data for Not Agreeing with a Capacity Factor Exemption:	Question 7 Supporting Data for the Proposed 5% Capacity Factor:
		5%, this could quickly change due to unanticipated system conditions or the extended unavailability of other generation (due to severe damage for example). Therefore, the subject generating units could end up being run for a significant length of time without the benefit of having been properly analyzed by the Transmission Planning organization. The average over the last three calendar years methodology further contributes to this possibility, introducing a time lag in the process.Based on the above discussion, the 5% capacity factor exemption should only be allowed when it would not be expected to significantly impact the results of stability studies. Allowing the Transmission Planner to make this judgement is most appropriate since A) that organization is in the best position to make the determination of the impact on stability and B) that organization is responsible (via TPL standards) for ensuring the stability of the grid and connected generating units.In lieu of the blanket 5% exemption, the following is proposed.1. Delete and with an average Capacity Factor of greater than 5% over the last three calendar years in all places in 4.1.1.1, 4.1.1.2 and 4.1.1.32. Add new Applicabilty 4.1.1.4 stating Generating facilities with capacity factors less than 5% over the last three calendar years may be exempted with written concurrence from the applicable Transmission Planning Authority. The written concurrence provided by the Transmission Planning Authority shall include the basis for any such exemptions. alternative to (2.) could be the reponse to Q9 below.	

Response: Thank you for your comments. The reason for choosing a 5% capacity factor threshold for exemption is similar to those for MVA-based exemption. This is to strike a balance between the costs and benefits. Because the excitation data of a unit has not been verified does not imply that the data is necessarily inaccurate or that the overall stability of the system is sensitive to that data. While the scenario contemplated in the comment is realistic, the SDT does not believe that the reliability of an entire interconnection will be significantly impacted by these isolated incidences. The validity of simulation results depends upon many assumptions, such as load and other system models. Even if all excitation system models were based on testing it would not guarantee absolute accuracy. Based upon the majority of responses received from the industry the SDT believes that the 5% exemption threshold is appropriate.

Additionally, the SDT has revised the draft standard to allow the Planning Coordinator to identify, through a process demonstrating technical justification, additional generating units that are critical for reliability beyond the applicability criteria established by section 4.2. The SDT believes felt that defining a process where additional

Organization	Yes or No	Question 7 Comments and/or Supporting Data for Not Agreeing with a Capacity Factor Exemption:	Question 7 Supporting Data for the Proposed 5% Capacity Factor:
units could be identified for verification was a reasonable approach as opposed to defining a process where units with low capacity factor must apply for an exemption			
Independent Electricity System Operator	No (disagree with approach)	a. The Term Capacity Factor is capitalized but this term is not defined. Suggest to use lower case, or define it.b. Capacity factor reflects a generating unit's real power generation frequency and duration, but does not provide the assurance that when the generator is on line, it's excitation system has been modeled accurately such that its expected performance matches simulation results. There are generating units that are often on line but do not generate at high capacity since they provide ancillary services including operating reserve and hence tend to have a low capacity factor. There are also sizable "mothballed" units or the entire plant of multiple sizable units that, due to various reasons, were put off line for a long period but return to service when the need for capacity so dictates. Not having their data verified based on a low capacity factor and on the assumption that they constitute a small portion of the interconnection MVA may leave room for unreliability. Further, low capacity factor is a historical value which may not be a good indicator of the future. If and when these low-capacity generators are put to high capacity usage, and particularly when the system is being stressed, the non-verified excitation systems can give rise to unpredictable system performance.Moreover, having to track a unit's capacity factor for the past 5 years to determine the need for verification is an unnecessary administrative burden.	
Response: Thank you for your comments. The term “capacity factor” is written lower case in the second draft of the standard. Units with a 5% or less capacity factor average over the last three years have relatively small likelihood of impacting the reliability of the BES. If the three-year average capacity factor of these units increases above 5%, then the unit will be required to have its excitation information verified. Generally, the tracking of a unit’s capacity factor is performed yearly by the Generator Owner due to reporting requirements for environmental regulations which means this information is generally already calculated and available. Additionally, the SDT has revised the draft standard to allow the Planning Coordinator to identify, through a process demonstrating technical justification, additional generating units that are critical for reliability beyond the applicability criteria established by section 4.2.			

Organization	Yes or No	Question 7 Comments and/or Supporting Data for Not Agreeing with a Capacity Factor Exemption:	Question 7 Supporting Data for the Proposed 5% Capacity Factor:
ISO New England Inc.	No (disagree with approach)	These low capacity factor units may be critical during peak conditions and are almost certain to be older units that have the least accurate factory excitation system models. It is felt that having accurate models for these older units is required. Generators under 100 MVA make up about 15% of capacity in New England. Excluding low capacity factor large units may exclude more than 20% of the generators from model verification.	
Response: Thank you for your comments. The SDT intended to write section 4.2 so that it applied to eighty percent of the generating units in each interconnection region. The SDT has revised the draft standard to allow Planning Coordinators to identify additional units for verification beyond section 4.2.			
Ameren	No (disagree with approach)	(1) Some systems have very large peaking units which arguably are more likely to be in service on days when the BES would be challenged. Thus, modeling data should be collected for these units and model cases run including these data.(2) The 5% capacity factor is an inappropriate basis for an exemption since it would allow significant blocks of generation (i.e. plants of several hundred MW) to be exempt. Such amounts of generation may have a significant impact on the stability of nearby generating units or such units may themselves have stability issues that need to be understood via valid studies. Examples would be plants with multiple combustion turbine units (particularly simple cycle oil burners) that are rarely run. However, when they are run (i.e. during peak system load times), the grid may be already be stressed and operating with reduced stability margin.(3) The possibility also exists that while the exempted generation may have a capacity factor of less than 5%, this could quickly change due to unanticipated system conditions or the extended unavailability of other generation (due to severe damage for example). Therefore, the subject generating units could end up being run for a significant length of time without the benefit of having been properly analyzed by the Transmission Planning organization. The average over the last three calendar years methodology further contributes to this	

Organization	Yes or No	Question 7 Comments and/or Supporting Data for Not Agreeing with a Capacity Factor Exemption:	Question 7 Supporting Data for the Proposed 5% Capacity Factor:
		possibility, introducing a time lag in the process.Based on the above discussion, the 5% capacity factor exemption should only be allowed when it would not be expected to significantly impact the results of stability studies. Allowing the Transmission Planner to make this judgement is most appropriate since A) that organization is in the best position to make the determination of the impact on stability and B) that organization is responsible (via TPL standards) for ensuring the stability of the grid and connected generating units.(4) In lieu of the blanket 5% exemption, the following is proposed.(a) Delete and with an average Capacity Factor of greater than 5% over the last three calendar years? in all places in 4.1.1.1, 4.1.1.2 and 4.1.1.3(b)Add new Applicabilty 4.1.1.4 stating ?Generating facilities with capacity factors less than 5% over the last three calendar years may be exempted with written concurrence from the applicable Transmission Planning Authority. The written concurrence provided by the Transmission Planning Authority shall include the basis for any such exemptions. (5) alternative to (b) could be the reponse to Q9 below.	
Response: Thank you for your comments. The excitation system modeling data for all registered generating units is collected per standards MOD-012-1 and MOD-013-1 and used in models by Transmission Planners. The SDT is proposing a change to the standard to allow Transmission Planners or Planning Coordinators to identify, through a process demonstrating technical justification, additional generating units that are critical for reliability beyond the applicability criteria established by section 4.2. The 5% or less average capacity factor over the last three years does not force Generator Operators to spend money on testing of units that do not contribute to the reliability of the BES. At the end of every 10 year periodicity period, if a generating unit exceeds the 5% capacity factor, it must be tested within the next year if the unit has not been tested within the previous 10 year period. This testing timeframe is similar to the effective date timeframe specified in the standard.			
AESO	No (disagree with approach)	The AESO agrees with the SRC ISO/RTO comments.	
Response: Thank you for your comments. Please see the response to the entity comment which was referenced.			
Duke Energy	No (disagree with approach)	Regarding Section 4 Applicability, drop the reference to Capacity Factor of 5% over the past 3 years. This makes no sense, because for a variety of reasons the unit's capacity factor in the very next year may be significantly higher, and having an	

Organization	Yes or No	Question 7 Comments and/or Supporting Data for Not Agreeing with a Capacity Factor Exemption:	Question 7 Supporting Data for the Proposed 5% Capacity Factor:
		accurate assessment of the unit's performance would be important.The units with low capacity factor would likely be on line during a peak load period when the system is most stressed and stability issues are most likely. Also, these units could be relevant to sensitivity studies. The larger units should have a model. Additionally, MMWG requires models for all units whether they are on or off in the case. Each one must have a model if the modeling criteria is satisfied. If the unit is a reasonable size and connected to the BES like others, we don't see how you can exclude testing.	
Response: Thank you for your comments.. The reason for choosing a 5% capacity factor threshold for exemption is similar to those for MVA-based exemption. This is to strike a balance between the costs and benefits. Because the excitation data of a unit has not been verified does not imply that the data is necessarily inaccurate or that the overall stability of the system is sensitive to that data. While the scenario contemplated in the comment is realistic, the SDT does not believe that the reliability of an entire interconnection will be significantly impacted by these isolated incidences. The validity of simulation results depends upon many assumptions, such as load and other system models. Even if all excitation system models were based on testing it would not guarantee absolute accuracy. Based upon the majority of responses received from the industry the SDT believes that the 5% exemption threshold is appropriate. Additionally, the SDT has revised the draft standard to allow the Planning Coordinator to identify, through a process demonstrating technical justification, additional generating units that are critical for reliability beyond the applicability criteria established by section 4.2.			
US Bureau of Reclamation	No (disagree with approach)	Capacity Factor (capitalized) is not defined in the standard nor is it defined in the NERC Glossary; we think we know what it means but if the term is used in the standard it should be defined. However we believe Capacity Factor, should not be used to exempt generators. Those times when generators of low Capacity Factor are in operation will most likely be those times when the power system is most stressed and the performance of the machines should be modeled in system studies.	
Response: Thank you for your comments. The use of the term "capacity factor" is written lower case in the second draft of the standard. It should be noted that infrequently operated units will still report unverified excitation information per standards MOD-012 and MOD-013 and the exciter information will be modeled in system studies.			

Organization	Yes or No	Question 7 Comments and/or Supporting Data for Not Agreeing with a Capacity Factor Exemption:	Question 7 Supporting Data for the Proposed 5% Capacity Factor:
Pepco Holdings, Inc (PHI) - Affiliates	Yes agree with the approach. But use another capacity factor (include supporting data):		PHI does not see a substantial difference in reliablity if the capacity factor is increased to 10%
Response: Thank you for your comments. The SDT believes the majority of industry supports the 5% capacity factor threshold to establish a balance between verifying modeling information for units that play an important role in the reliability of the BES and units that report information which is not verified due to relatively diminished role in reliability because they are seldom online.			
Constellation Power Generation & Constellation Nuclear	Yes agree with the approach. But use another capacity factor (include supporting data):		
Response: Thank you for your comments. Unfortunately, since another capacity factor proposal was not included, the SDT cannot make a specific reply. However, the SDT believes that industry supports the assertion that the 5% capacity factor threshold to establish the balance between verifying modeling information for units that play an important role in the reliability of the BES, and units that report information which is not verified due to having a relatively diminished role in reliability because they are seldom online.			
City of Garland, Garland Power & Light - GOP Registered Entity	Yes agree with the approach. But use another capacity factor (include supporting data):	Not sure which box to comment in: Strongly agree with your approach & reasons but believe that 10% should be the exemption level	Not sure which box to comment in: Strongly agree with your approach & reasons but believe that 10% should be the exemption level
Response: Thank you for your comments. The SDT appreciates your comments. The SDT believes that the majority of industry supports the assertion that the 5% capacity factor threshold to establish the balance between verifying modeling information for units that play an important role in the reliability of the BES, and units that report information which is not verified due to having a relatively diminished role in reliability because they are seldom online.			
Reliant Energy	Yes agree with the approach. But use another capacity factor (include	Capacity factor should be raised to 15%.	

Organization	Yes or No	Question 7 Comments and/or Supporting Data for Not Agreeing with a Capacity Factor Exemption:	Question 7 Supporting Data for the Proposed 5% Capacity Factor:
	supporting data):		
Response: Thank you for your comments.. The SDT believes that the 5% capacity factor threshold to establish the balance between verifying modeling information for units that play an important role in the reliability of the BES, and units that report information which is not verified due to having a relatively diminished role in reliability because they are seldom online.			
Northeast Power Coordinating Council	Yes agree with approach and the 5% capacity factor	We agree with this approach to exclude units with low capacity factors provided that Planning Coordinators or Transmission Planners are allowed to identify additional applicable units beyond those specified in section 4.1.1 based on criticality to system reliability. Cases exist where large generating units with low capacity factors are operated only during the most stressed operating conditions. In such cases accurate modeling of these units may be critical to reliable operation of the bulk electric system.	
Response: Thank you for your comments. The SDT has revised the draft standard to allow the Planning Coordinator to identify, through a process demonstrating technical justification, additional generating units that are critical for reliability beyond the applicability criteria established by section 4.2.			
Southern Company	Yes agree with approach and the 5% capacity factor		The idea that this standard should not be applicable to low capacity factor seems perferable. However, 5% capacity factor may be too high. For instance, there are 8760 hours in a year. A 5% capacity factor could mean a unit running its at nameplate MW for 438 hours. Or, it could mean more than 438 hours if the unit is not running at its nameplate all the time when running.For Southern Company Generation, the current criteria would result in the standard applying to at least 80% of our generation capacity.
Response: Thank you for your comments.. The SDT believes industry supports the 5% capacity factor threshold to establish a balance between verifying modeling information for units that play an important role in the reliability of the BES and units that report information which is not verified due to having a relatively diminished role in reliability because they are seldom online. Additionally, the SDT has revised the draft standard to allow the Planning Coordinator to identify, through a process demonstrating technical justification, additional			

Organization	Yes or No	Question 7 Comments and/or Supporting Data for Not Agreeing with a Capacity Factor Exemption:	Question 7 Supporting Data for the Proposed 5% Capacity Factor:
generating units that are critical for reliability beyond the applicability criteria established by section 4.2. The SDT believes that defining a process where additional units could be identified for verification was a reasonable approach as opposed to defining a process where units with low capacity factor must apply for an exemption.			
Manitoba Hydro	Yes agree with approach and the 5% capacity factor	Low capacity factor units such as wind turbines which could be part of a large MVA rated farm, should be in a separate category.	
Response: Thank you for your comment. The Applicability section MVA thresholds provided in the first posting of the MOD-026 standard omitted wind powered units because wind unit are not rated greater than 20 MVA. There is an increasing number of wind farms with significantly larger aggregate MVA and as such, their impact on the reliability of the Bulk Electric System cannot be ignored; otherwise a reliability gap would exist. The SDT discussed the possibility of requiring verification of dynamic models that represent the aggregate of numerous small units and any necessary auxiliary equipment required of the technology. This could include plant dynamic voltage control and reactive support of all the units and auxiliary equipment (such as individual WTG response, plant-wide volt/var controller response, and response from separate volt/var regulation devices contained in the plant such as SVC/STATCOM/Synchronous Condenser) contained in any technology generation plant, including a wind farm (plant), that exceeds the appropriate aggregate nameplate MVA threshold. There are dynamic models that adequately replicate wind unit performance for some wind units today however, there are many existing wind units for which there are not publicly available models supplied by the Original Equipment Manufacturer. Generic wind models (i.e., type I, II, III and IV) are in various stages of development. Also, there are ongoing efforts involving Regional Entities and manufactures to close any large gaps that may exist in current generic models. Given the timeframe expected to lapse while awaiting standard approval by FERC, it is expected that generic wind farm (plant) models will sufficiently mature for establishing boundary conditions in Bulk System Studies. To mitigate this reliability gap, the Applicability section will be expanded in the second posting of the standard to include a significant MVA percentage of generation regardless of technology.			
Indiana Municipal Power Agency	Yes agree with approach and the 5% capacity factor		A small utility owns a GE 7EA Turbine/Generator with a nameplate rating of 101 MVA in the Eastern Interconnection. The utility uses it as a peaking unit and the capacity factor for the unit averages less than five percent over the last three years. Obviously, this unit does not play a vitale role in maintaining the reliability of the BES. Therefore, why make this utility spend thousands of dollars on testing a machine that is not important to reliability. By using a capacity factor of 5%, this unit will be exempt from this standard.
Response: Thank you for your comments. The SDT agrees that the proposed thresholds, including the 5% capacity factor, will result in verification of models that are necessary for the reliability of the BES.			
Hydro-Québec	Yes agree with		We agree with this approach to exclude units with

8. The SDT is of the opinion, based upon sound engineering judgment, that verifying models for excitation systems of generators per the MVA thresholds specified in the Applicability section 4.1.1 will ensure satisfactory performance of Interconnection network simulation models. Do you agree with this approach? If yes, please provide any data in support of the proposed approach including supporting data that the MVA thresholds specified in the Applicability section 4.1.1 correspond to 80% of the Interconnection MVA.

Summary Consideration:

The majority of responder comments support the concept of requiring excitation control system model verifications for units based on unique MVA thresholds for each Interconnection that correspond to 80% of the Interconnected MVA. Some of the affirmative comments were qualified by a desire to allow a transmission entity to identify additional units for verification. This potential is addressed as a new draft process that allows the Planning Coordinator to identify additional units with excitation control system performance that affects a stability limit and/or does not match measured unit response (refer to Question 9 responses for additional details). Based on industry comments received, the SDT is proposing a modification to the Applicability section to additionally include a significant MVA percentage of all generation of all technologies, including Variable Energy Resources.

Organization	Yes or No	Question 8 Supporting Data or Alternate Approach
NERC Event Analysis & Information Exchange staff	No, instead use the approach below:	There are a number of units that, through switching, can operate in multiple interconnections, making it hard to decide where they belong.To reduce complexity in administration, avoid confusion, and to have a more level playing field in North America, the standard registration thresholds of units ? 20 MVA per machine and ? 75 MVA per plant should be applied.
Response: Thank you for your comments. Although Field Test results did confirm that verification of excitation system models does result in higher quality dynamics data, it was also noted that verification of excitation system is expensive both from a monetary and human resource viewpoint. Therefore, the SDT believes that these applicability thresholds will result in substantial accuracy improvements to the excitation models and associated Reliability, while not unduly mandating costly and time-consuming verification efforts. The SDT agrees there may be a small number of units that can be switched between two interconnections. These units will follow the more stringent of the two associated requirements. The SDT believes that applicability as written would cover the bulk of installed generators to adequately provide higher quality dynamic data.		
FirstEnergy	No, instead use the approach below:	We feel that 80% of the Interconnection MVA is not high enough. The issue might be not including many of the CC/CT units that have a low capacity factor (above 5%). The team may want to consider 90% or further validate the 80% value.
Response: Thank you for your comments. The 80% threshold has been overwhelmingly accepted by the industry. Also, based on industry responses and the SDT's concerns about a potential reliability gap, the SDT is proposing a modified Applicability section to include a significant MVA percentage of all generation of all technologies, which will additionally include approximately 80% of Variable Energy Resource plants. The SDT has developed a new draft requirement that		

Organization	Yes or No	Question 8 Supporting Data or Alternate Approach
outlines a process that requires technical justification but which allows the Planning Coordinator to identify additional units whose excitation control system performance affects a stability limit, and/or does not match measured unit response.		
FEUS	No, instead use the approach below:	If the modeling methods are approved and are valid, why do entities have to prove they are right? Test the models on several units of different sizes and configurations to determine their accuracy. If modeling methods aren't accurate, fix them instead of requiring the industry go through the huge expence of testing hundreds of units that have been previously modeled. I also don't see the rationale for the differences in MVA testing requirements between RRCs. The 200 MVA rating for facilities (as specified for the eastern systems) should be the same if this standard is adopted.
Response: Thank you for your comments. The SDT strongly believes that re-occurring validation of the excitation system is necessary to validate system performance for dynamic conditions. This process will also validate any changes and modifications to the excitation system. The SDT has also provided opportunity for an alternative method of ambient monitoring. Generator Owners are permitted to utilize operating data for validation purposes.		
Wisconsin Public Service	No, instead use the approach below:	The provisions of multiple generators at one location requiring testing of units above 20MVA rating puts too much ownerous on operators at CT sites with multiple small CT's that would act differently during an event and have minimal effect on the dynamic models.
Response: Thank you for your comments. The SDT has included in a Periodicity Attachment of the draft standard, a provision for testing multiple similar units. Verification of one unit from a group of units equal to and less than 350 MVA with identical applicable components and settings at the same physical location is sufficient. One of the key conclusions from this draft standard's Field Test is that excitation system verification results in an improvement of the accuracy of the exciter models used in dynamic simulations. If there are multiple CTs at a plant site such that the plant threshold in the Applicability section of the draft standard is exceeded, then the interconnected MVA at that plant site is likely to be a significant influence of the dynamic behavior of the local area. Thus, in order to allow for proper quantification of reliability limits, the SDT believes that excitation model verifications for such a plant site is appropriate. Typically, some of these CTs fall under the criteria specified in the Periodicity Attachment of the draft standard, which could minimize verification activities.		
American Electric Power	No, instead use the approach below:	The need for excitation data and model verification has been driven by plant and system stability needs. We believe that the applicability in the standard should be driven by the same. We would go so far as to suggest that identification of applicable units should be determined by the TP and PC through a process that includes planning study results and operating experience, and that the standard should not specify a blanket applicability unrelated to the stability driven need.
Response: Thanks you for your comment. The 80% threshold has been overwhelmingly accepted by the industry. The SDT has developed a new draft requirement that outlines a process that requires technical justification but which allows the Planning Coordinator to identify additional units with excitation control		

Organization	Yes or No	Question 8 Supporting Data or Alternate Approach
system performance that affects a stability limit, and/or does not match measured unit response.		
Wisconsin Electric	No, instead use the approach below:	In light of the size and density of the Eastern Interconnection, we are of the opinion that the MVA threshold for units should be raised to 150 MVA or higher.
Response: Thank you for your comments The SDT believes that the MVA thresholds provided in the draft standard will adequately addresses BES system reliability needs. The SDT will be glad to review any technical data provided to support your position.		
AESO	No, instead use the approach below:	Section 4.1.1.2 directly references the Western Interconnection but then uses equipment sizes as a base that far exceeds the ones used by WECC in the Generating Unit Model Validation Policy.75 MVA units vs 10MVA by WECC20 MVA units in a 150 MVA facility vs. 20 MVA facility by WECC 100 kV interconnection vs. 60 kV by WECCPerhaps the standard can reference the WECC guidelines.
Response: Thank you for your comments. Field Test has confirmed that verification of excitation system models does result in higher quality dynamics data. The Field Test also noted that verification of the excitation system is expensive both from a monetary and human resource viewpoint. Therefore, the SDT believes that these applicability thresholds will result in substantial accuracy improvements to the excitation models and associated Reliability- based limits determined by dynamic simulations, while not unduly mandating costly and time-consuming verification efforts.		
American Transmission Company	No, instead use the approach below:	The threshold should be based on NERC registration criteria for Generator Owners/Operators. See Appendix 5 Organization Registration and Certification Manual. (Version 3.3) This criteria should apply across NERC. Item 2 in Requirement 1 should be set to the same level used by NERC's registration criteria for plants.
Response: Thank you for your comments. Field Testing has confirmed that verification of excitation system models does result in higher quality dynamics data. The Field Test also noted that verification of the excitation system is expensive both from a monetary and human resource viewpoint. Therefore, the SDT believes that these applicability thresholds will result in substantial accuracy improvements to the excitation models and associated Reliability-based limits determined by dynamic simulations, while not unduly mandating costly and time-consuming verification efforts.		
US Bureau of Reclamation	No, instead use the approach below:	We believe the NERC Compliance Registry Criteria should be used as the threshold.

Organization	Yes or No	Question 8 Supporting Data or Alternate Approach
Response: Thank you for your comments. The SDT does not agree with the view that the Compliance Registry should be the sole basis for determining applicability of Reliability Standards. The SDT has made an ongoing effort to refine the applicability section of the standard in line with one of the guiding principles of NERC's Reliability Standards development process which is the principle that the obligations or requirements of a standard must be material to the Bulk Electric System reliability and measurable. Field Testing has confirmed that verification of excitation system models result in higher quality dynamics data. The Field Test also noted that verification of the excitation system is expensive both from a monetary and human resource viewpoint. Therefore, the SDT believes that these applicability thresholds will result in substantial accuracy improvements to the excitation models and associated Reliability -based limits determined by dynamic simulations, while not unduly mandating costly and time-consuming verification efforts. The vast majority of industry comments indicate agreement.		
Reliant Energy	No, instead use the approach below:	Each unit (including synchronous condensers) 100 MVA, connected at the point of interconnection at 100 kV or above and with an average Capacity Factor greater than 15% over the last three calendar years.Each unit (including synchronous condensers) 50 MVA within a plant 250 MVA, connected at the point of interconnection at 100 kV or above and with an average Capacity Factor greater than 15%
Response: Thank you for your comments. Field Testing has confirmed that verification of excitation system models does result in higher quality dynamics data. The Field Test also noted that verification of excitation system is expensive both from a monetary and human resource viewpoint. Therefore, the SDT believes that these applicability thresholds will result in substantial accuracy improvements to the excitation models and associated Reliability- based limits determined by dynamic simulations, while not unduly mandating costly and time-consuming verification efforts.		
Northeast Power Coordinating Council	Yes	We agree with the general approach to base the number and size of applicable generating units on the objective of validating models for 80 percent of the installed capacity on an Interconnection provided that Planning Coordinators or Transmission Planners are allowed to identify additional applicable units beyond those specified in section 4.1.1 based on criticality to system reliability. In the event the Planning Coordinator or Transmission Planner is not permitted to identify additional units, the objective should be changed to validate models for a greater percentage of the installed capacity. We do not have data to verify whether the unit size thresholds specified in Requirement R4.1.1 correspond to 80 percent of the installed capacity on an interconnection, and respectfully suggest that it is the responsibility of the SDT to provide such verification.
Response: Thank you for your comments. The 80% threshold has been overwhelmingly accepted by the industry. Also, based on industry responses and concerns about a potential reliability gap, the SDT is proposing a modified Applicability section to include a significant MVA percentage of all generation of all technologies, which will additionally include approximately 80% of Variable Energy Resource plants. The SDT has developed a new draft requirement that outlines a process that requires technical justification but which allows the Planning Coordinator to identify additional units with excitation control system performance that affects a stability limit and/or does not match measured unit response.		

Organization	Yes or No	Question 8 Supporting Data or Alternate Approach
SERC Dynamics Review Subcommittee (DRS)	Yes	The MVA values should be coordinated with the MVA thresholds in MOD-10 to MOD-12 and in proposed TPL-001 standards. Supporting data (circa 2003) can be found from the link below which provides a spreadsheet titled Existing Generating Units in the United States by State, Company and Plant, 2003.http://www.eia.doe.gov/cneaf/electricity/page/at_a_glance/gu_tabs.htmlThis spreadsheet can be sorted and summed to get an estimate of the percentage generation that would be included. A preliminary look by the DRS suggests that 80% or more would be included.
Response: Thank you for your comments. The SDT appreciates the supporting data reference you have provided. NERC's work plan for the MOD standards will be addressed by Project 2010-03. It is acknowledged that the MVA thresholds must be considered when the MOD standards are revised, including the current SDT work on the TPL-001 through TPL-004 standards. The GV SDT believes that each standard has its unique reliability purpose. The applicability section of the standard for the listed entities should be established according to its purpose and the risk associated with individual requirements. For example, standards MOD-010 and MOD-012 deal with the provision of data for dynamic modeling so the applicability of these standards to smaller units and facilities is quite appropriate. On the other hand, standard MOD-026 deals with mandatory periodic verification of models and data, which is a different exercise, driven by different needs. Based on these needs, the SDT continues to advocate the 80% threshold.		
Dominion	Yes	The proposed threshold captures at least 80.5% of the generators owned by Dominion.
Response: Thank you for your comment. The SDT acknowledges your affirmation for the MVA thresholds corresponding to 80% or great of the interconnected MVA owned by Dominion.		
Constellation Power Generation & Constellation Nuclear	Yes	We agree with the general approach to base the number and size of applicable generating units on the objective of validating models for 80 percent of the installed capacity on an Interconnection provided that Planning Coordinators or Transmission Planners are allowed to identify additional applicable units beyond those specified in section 4.1.1 based on criticality to system reliability. In the event the Planning Coordinator or Transmission Planner is not permitted to identify additional units, the objective should be changed to validate models for a greater percentage of the installed capacity. We do not have data to verify whether the unit size thresholds specified in Requirement R4.1.1 correspond to 80 percent of the installed capacity on an interconnection, and respectfully suggest that it is the responsibility of the SDT to provide such verification.
Response: Thank you for your comments. The 80% threshold has been overwhelmingly accepted by the industry. Also, based on industry responses and concerns about a potential reliability gap, the SDT is proposing a modified Applicability section to include a significant MVA percentage of all generation of all technologies, which will additionally include approximately 80% of Variable Energy Resource plants. The SDT has developed a new draft requirement that outlines a process that requires technical justification but which allows the Planning Coordinator to identify additional units with excitation control system performance that		

Organization	Yes or No	Question 8 Supporting Data or Alternate Approach
affects a stability limit and/or does not match measured unit response.		
Progress Energy, Inc.	Yes	However, the MVA values MUST be coordinated with the MVA thresholds in MOD-010 to 012 and in proposed TPL-001 standards. Supporting data (circa 2003) can be found from the link below which provides a spread sheet titled Existing Generating Units in the United States by State, Company and Plant, 2003.http://www.eia.doe.gov/cneaf/electricity/page/at_a_glance/gu_tabs.html
Response: Thank you for your comments. The SDT appreciates the reference to the statistical data. NERC's work plan for MOD standards will be addressed by Project 2010-03. It is acknowledged that the MVA thresholds must be considered when the MOD standards are revised, including current SDT work on the TPL-001 through TPL-004 standards. The GV SDT believes that each standard has its unique reliability purpose. The applicability section of the standard for the listed entities should be established according to its purpose and the risk associated with individual requirements. For example, standards MOD-010 and MOD-012 deal with the provision of data for dynamic modeling so the applicability section of these standards to smaller units and facilities is quite appropriate. On the other hand, the standard MOD-026 deals with mandatory periodic verification of models and data, which is a different exercise, driven by different needs. Based on these needs, the SDT continues to advocate the 80% threshold.		
Dynegy	Yes	We support SDT's approach to include aggregate MVA values. We also would like to suggest minor wording changes for SDT consideration to revise the language in the draft standard to better reflect an aggregate MVA approach. The word "same" is added to draft standard language as following: " Each unit (including synchronous generators) => 100 MVA, connected at the SAME point of interconnection at 100 Kv or above and with an".
Response: Thank you for your comments. The draft standard has been revised based on your comments and the word, "same" was added in the applicability section of the standard.		
Reliant Energy	Yes	The SDT at least has done an engineering analysis in developing the MVA thresholds. I am not sure that registration criteria was done in the same manner.
Response: Thank you for your comments. The SDT appreciates your comment..		
ISO New England Inc.	Yes	Currently generators over 100 MVA make up about 85% of the installed generator capacity in New England. Concentration on these units should provide an accurate representation of the system. Efforts to verify lower MVA capacity units would provide limited benefit for the work involved.
Response: Thank you for your comments. The SDT appreciates your comment..		

Organization	Yes or No	Question 8 Supporting Data or Alternate Approach
Ameren	Yes	(1) We believe the MVA thresholds are appropriate and pick up the vast majority of interconnection (MVA). However, the MVA values MUST be consistent with the MVA thresholds in other stanadrds, such as MOD-10 to 12. and in proposed TPL-001 standards. (2) Supporting data (circa 2003) can be found from the link below which provides a spread sheet titled Existing Generating Units in the United States by State, Company and Plant, 2003. http://www.eia.doe.gov/cneaf/electricity/page/at_a_glance/gu_tabs.htmlThe spreadsheet can be sorted and summed to get an estimate of the percentage generation that would be included. A preliminary look suggests that 80% or more would be included.
Response: Thank you for your comments. The SDT appreciates the reference to the statistical data. NERC's work plan for the MOD standards will be addressed by Project 2010-03. It is acknowledged that the MVA thresholds must be considered when any standard is developed or revised, as each standard has its unique reliability purpose. The applicability of the standard for the listed entities should be established according to its purpose and the risk associated with individual requirements. For example, standards MOD-010 and MOD-012 deal with the provision of data for dynamic modeling so the applicability of these standards to smaller units and facilities is quite appropriate. On the other hand, the standard MOD 026 deals with mandatory periodic verification of models and data, which is a different exercise, driven by different needs. Based on these needs, the SDT continues to advocate the 80% threshold.		
Duke Energy	Yes	We agree with the approach, but would also caution the team to consider the future composition of the Interconnection MVA. Possibly the team already considered newer types of generation and the benefit of a verified model rather than just estimated or typical manufacturers dynamics data (MOD-013). The team should consider clarifying the relationship between the terms in MOD-013 and MOD-026. Is unit-specific dynamics data equivalent to a verified model? Even in the case of a sister unit? If a unit does not meet the applicability for MOD-026 would they then follow MOD-013 to determine the applicable model to provide?
Response: Thank you for your comments. Unit-specific data, referenced in standard MOD-013, is not the same as a verified model. It is possible for a new unit to be installed at a site where another unit has already been installed and that all units meet the criteria in standard MOD-026 – Attachment 1 "Excitation Control System Model Verification Periodicity" Scenario 3 where one verification would meet the requirements of the draft standard. However, it is also recognized that Interconnection Agreements may often result in the verification of models as a condition of being able to interconnect to a transmission provider's system. Finally, if a new unit does not meet the applicability of standard MOD-026, then at a minimum they would be required to follow standard MOD-013 requirements to determine the applicable model to provide.		
Hydro-Québec TransEnergie (HQT)	Yes	We agree with the general approach to base the number and size of applicable generating units on the objective of validating models for 80 percent of the installed capacity on an Interconnection provided that Planning Coordinators or Transmission Planners are allowed to identify additional applicable units beyond those specified in section 4.1.1 based on criticality to system reliability. In the event the Planning Coordinator or Transmission Planner is not

Organization	Yes or No	Question 8 Supporting Data or Alternate Approach
		permitted to identify additional units, the objective should be changed to validate models for a greater percentage of the installed capacity. We do not have data to verify whether the unit size thresholds specified in Requirement R4.1.1 correspond to 80 percent of the installed capacity on an interconnection, and respectfully suggest that it is the responsibility of the SDT to provide such verification.
Response: Thank you for your comments. The SDT has developed a new draft requirement that outlines a process that requires technical justification but which allows the Planning Coordinator to identify additional units with excitation control system performance that affects a stability limit and/or does not match measured unit response.		
IRC Standards Review Committee	Yes	We do not have any technically sound alternatives to suggest.
Response: Thank you for your comment.		
Independent Electricity System Operator	Yes	We do not have any technically sound alternatives to suggest.
Response: Thank you for your comment.		
Consumers Energy Company	Yes	We believe the MVA thresholds are appropriate and pick up the vast majority of interconnection (MVA).
Response: Thank you for your comments. The SDT appreciates your comment.		
Southern Company	Yes	See comment on 7 above.
Response: Thanks you for your comment. The SDT has referred to the comment referenced.		
Kansas City Power & Light	Yes

9. Do you believe the SDT should develop a Requirement to allow the Transmission Planner or the Planning Coordinator to identify additional applicable units beyond those specified in section 4.1.1 due to their criticality to the reliability of the Bulk Electric System? If yes, please include the criteria that should be used by the Transmission Planner or Planning Coordinator to identify critical units with MVA rating less than listed in section 4.1.1 and any supporting data.

Summary Consideration:

More than half of the industry respondents representing all regions recommend inclusion of units identified by either the Transmission Planner or Planning Coordinator based on clear technical study results documenting the impact on the BES. In response, the SDT has drafted a process in the 2nd draft of the standard (reference Requirement R5) that requires technical justification but which allows the Planning Coordinator to identify additional units whose excitation control system performance requires scrutiny by the Generator Owner. In some instances, scrutiny by the Generator Owner could lead to corrected model data that could meet the needs of the Planning Coordinator. But unless the Generator Owner can determine that the existing model structure and data requires a correction and that meets the needs of the Planning Coordinator, the model must be verified. The SDT originally considered letting the Transmission Planner identify critical units along with the Planning Coordinator. However, the SDT realized that the Transmission Planner could bring model issues to the attention of its Planning Coordinator; then the Planning Coordinator could make a determination if the model issue warranted further review by the Generator Owner, thus adding another inherent “check” in the process.

Organization	Yes or No	Question 9 Comment or Supporting Data
SERC Dynamics Review Subcommittee (DRS)	No	Add a new section under Applicability 4.1.1.5 stating Generating facilities that do not meet the applicability requirements of 4.1.1.1 - .4 may be included when their performance is found to reduce the reliability of the BES by the applicable Transmission Planning Authority. A written request provided by the Transmission Planning Authority shall include the technical basis for any such inclusion (e.g. must run, reliability, voltage, or stability needs).
Response: Thank you for your comments. The SDT does agree with the basic concept, including the need for the transmission entity to provide a technical basis to support the identification of additional units required to provide a corrected model or perform excitation control system verification. The SDT has developed a new draft process that outlines a process that requires technical documentation but which allows the Planning Coordinator to identify additional units as supported by technical justification.		
Luminant Power	No	The SDT is tasked with developing requirements for applicability across North America. Regions have the ability to develop more stringent requirements based on regional needs, and through various regional requirements development processes. Allowing the Transmission Planner or Planning Coordinator to expand the applicability

Organization	Yes or No	Question 9 Comment or Supporting Data
		of the NERC Standard on an individual resource basis (without industry input, balloting, etc.) would circumvent the FERC approved procedures for development of reliability standards.
Response: Thank you for your comments. The SDT believes that the reliability of the BES could be put at risk if there is no mechanism to allow for the correction of models that do not accurately represent expected equipment performance. However, the new process (reference Requirement R5 in the revised standard) that has been drafted by the SDT requires technical justification for a limited number of scenarios.		
E.ON U.S.	No	The generation owner/operator is in the best position to identify those facilities that require verification studies. Transmission providers should not be allowed to independently impose compliance obligations upon other parties. Any process to allow imposition of additional compliance responsibilities should be overseen by the appropriate regional reliability organization.
Response: Thank you for your comments. The SDT believes that the reliability of the BES could be put at risk if there is no mechanism to allow for the correction of models that do not accurately represent expected equipment performance. However, the new process (reference Requirement R5 in the revised standard) that has been drafted by the SDT requires technical justification for a limited number of scenarios.		
AWEA	No	There would have to be very clear technical justification for such a designation or it could be perceived as discriminatory and/or preferential
Response: Thank you for your comment. The SDT believes that the reliability of the BES could be put at risk if there is no mechanism to allow for the correction of models that do not accurately represent expected equipment performance. However, the new process (reference Requirement R5 in the revised standard) that has been drafted by the SDT requires technical justification for a limited number of scenarios.		
Ameren	No	However, add 4.1.1.5 stating Generating facilities that do not meet the applicability requirements 4.1.1.1 - .3 may be included when their performance is found to create or contribute to reduced reliability of the BES when requested by the applicable Transmission Planner. The written request provided by the Transmission Planner shall include the technical basis for any such inclusion (e.g. must run for reliability, voltage, or stability needs).
Response: Thank you for your comments. The SDT agrees with the concept and has developed a process (reference Requirement R2) in the second draft that should address your concern.		
American Transmission Company	No	This standard should apply to all registered GO's and GOP's. A requirement as suggested puts the TP or PA in the position of telling NERC who should be registered. This responsibility that clearly falls to NERC and the Regional Entities and should not be expanded to any registered entity.

Organization	Yes or No	Question 9 Comment or Supporting Data
Response: Thank you for your comments. The SDT believes that the reliability of the BES could be put at risk if there is no mechanism to allow for the correction of models that do not accurately represent expected equipment performance. However, the new process (reference Requirement R5 in the revised standard) that has been drafted by the SDT requires technical justification for a limited number of scenarios.

NERC Event Analysis & Information Exchange staff	Yes	It is essential that the Planning Coordinator and Reliability Coordinator be allowed to designate other critical units. In some cases, despite their size, the aggregation of a number of small units can have a significant impact on the dynamics of an area. One example is the transfer capability across the state of Maine, which is influenced by the dynamics of the multiple small hydro units in the state. Similarly, the dynamic performance of small units may be critical to reliability in some local areas such as New Brunswick and Nova Scotia.
Response: Thank you for your comments. More than half of the industry respondents representing all NERC regions recommend inclusion of units by the Transmission Planner or Planning Coordinator based on clear technical justification. The SDT has developed a new draft process (reference Requirement R5) that outlines a process that requires technical justification but which allows the Planning Coordinator to identify additional units with excitation control system performance that affects a stability limit and/or does not match measured unit response. Once identified, the Generator Owner can provide corrected excitation control system data or verify the model.		
Northeast Power Coordinating Council	Yes	The Planning Coordinator or Transmission Planner should be permitted to identify additional units for applicability of the Standard based on the results of generator interconnection studies or other studies that demonstrate the criticality of correct settings on system reliability, e.g. studies demonstrating sensitivity of a stability-based System Operating Limit to correct equipment settings and functionality.
Response: Thank you for your comment. Your comment is very similar to a great number of other industry comments in recommending the inclusion of units by the Transmission Planner or Planning Coordinator based on clear technical study results documenting the impact on the BES. In response to these comments the SDT has drafted a new process (reference Requirement R5) that outlines a process that requires technical justification but which allows the Planning Coordinator to identify additional units with excitation control system performance requiring scrutiny by the Generator Owner. Unless the Generator Owner can determine that the existing model structure and data requires a correction, the model must be verified.		
Dominion	Yes	If a unit exhibits transient or dynamic instability for an event but the simulation did not show the same then the excitation system shall be tested for units beyond those specified in section 4.1.1.

Organization	Yes or No	Question 9 Comment or Supporting Data
Response: Thank you for your comments. The SDT has developed a new process (reference Requirement R5) which outlines a process that requires technical documentation, including identification of units which do not perform as predicted by the current excitation control system model, that allows the Planning Coordinator to identify additional units that the Generator Owner would either provide a corrected or a verified model.		
IRC Standards Review Committee	Yes	In some areas on the interconnection, such as those that are sparsely populated, performance of generating units at less than 100 MVA might be critical to reliability.
Response: Thank you for your comments. The SDT agrees with this and other comments that there are situations where the verification of excitation control system is necessary to ensure the accuracy of BES security limits. In response to these comments, the SDT has drafted a new process (reference Requirement R5). This process allows the Planning Coordinator to identify through technical justification additional units with excitation control system model requiring correction or verification. The development of technical documentation is required to ensure this request is warranted.		
AESO		The AESO agrees with the SRC ISO/RTO comments.
Response: Thank you for your comment. The SDT was unable to identify the SRC ISO/RTO comment referenced. Please refer to the intended comment for the SDT response provided..		
Exelon Corporation	Yes	Exelon is concerned about the use of the term "critical" in this context because it implies the same level of criticality that would be used to put a station on the critical asset list. A small generating station may be sufficiently close to another station that it affects the dynamic behavior of the generators at the second station. The Transmission Planner should be able to identify the units at the smaller station as applicable to the standard without calling them critical units. Exelon does appreciate the need for guidelines regarding the units that can be indentified as applicable to MOD-026.
Response: Thank you for your comments. The SDT has developed a new process (reference Requirement R5) that outlines a process that requires technical justification but which allows the Planning Coordinator to identify additional units with excitation control system performance that affects a stability limit and/or does not match measured unit response. Once identified, the Generator Owner can provide corrected excitation control system data or verify the model. The term “critical” is not used in the new draft requirement.		
Constellation Power Generation & Constellation Nuclear	Yes	The Planning Coordinator or Transmission Planner should be permitted to identify additional units for applicability of the Standard based on the results of generator interconnection studies or other studies that demonstrate the criticality of correct settings on system reliability, e.g. studies demonstrating sensitivity of stability based System Operating Limit to correct equipment settings and functionality.
Response: Thank you for your comments. The SDT agrees this type of requirement is needed and has included process (reference Requirement Rr) in the		

Organization	Yes or No	Question 9 Comment or Supporting Data
second draft.		
Wisconsin Public Service	Yes	Determined critical in the model or in a constrained area of the system.
Response: Thank you for your comments. The SDT agrees and has drafted a new process (reference Requirement R2) to address this concern.		
American Electric Power	Yes	Criteria should be units or plants whose operation is limited by transient or small-signal instability or that are located in areas that may be subject to stability constraints. Why not rather impose the applicability in the fashion of what is being asked here, that the TP and PC identify through a process which units should be verified, not blanket applicability as is in the current draft.
Response: Thank you for your comments. More than half of the industry respondents representing all NERC regions recommend inclusion of units by the Transmission Planner or Planning Coordinator based on clear technical justification. The SDT has developed a new draft requirement that outlines a process that requires technical justification but which allows the Planning Coordinator to identify additional units with excitation control system performance that affects a stability limit and/or does not match measured unit response. Once identified, the Generator Owner can provide corrected excitation control system data or verify the model.		
Progress Energy, Inc.	Yes	Add to Applicability a 4.1.1.4 stating Generating facilities that do not meet the applicability requirements 4.1.1.1 - .3 may be included when their performance is found to create or contribute to reduced reliability of the BES when requested by the applicable Transmission Planning Authority. The written request provided by the Transmission Planning Authority shall include the technical basis for any such inclusion (e.g. must run for reliability, voltage, or stability needs).
Response: Thank you for your comments. The SDT agrees and has developed a new process (reference Requirement R5) in the second draft that should address this concern.		
Reliant Energy	Yes	Units that have an RMR. If they do not have an RMR (in unorganized markets) then how can they be called critical?
Response: Thank you for your comments. More than half of the industry respondents representing all NERC regions recommend inclusion of units by the Transmission Planner or Planning Coordinator based on clear technical justification. The SDT has developed a new process (reference Requirement R5) which outlines a process that requires technical justification but which allows the Planning Coordinator to identify additional units for certain scenarios. Once identified, the Generator Owner can provide corrected excitation control system data or verify the model.		
Duke Energy	Yes	Add a similar requirement to R11 that allows the TO or RC to add a generator that does not meet the applicability

Organization	Yes or No	Question 9 Comment or Supporting Data
		criteria when their performance is found to create or contribute to reduced reliability. No one can foresee all future system configurations and operating conditions. This type of requirement is fundamental to analyzing and resolving issues. Additional Comment on R11 and R12. When system or plant events occur impacting transient voltage response, the GOP should evaluate actual unit/plant performance against expected performance. This is especially important when taking credit for sister units to avoid testing of similar units at the same site. With the long time between verification testing (10 years) and even longer time frame when allowing for claiming sister units, it is important to assess actual versus predicted performance. It is not sufficient to have only the TO or RC identify potential issues because they would normally only recognize issues that negatively impact the entire system and only for the specific event. Individual generating stations may have not behaved as modeled due to protection/control problems but the overall system met requirements.
Response: Thank you for your comments. The SDT has developed a new process (reference Requirement R5) that requires technical documentation but which allows the Planning Coordinator to identify additional units as supported by technical justification. This includes the scenario when the simulated unit response does not match measured unit response. There are currently no provisions for the Generator Owner to evaluate actual performance during a transient voltage response type of event, unless it is through observation of performance. The SDT believes that while your suggestion represents good utility practice, it is beyond the scope of this standard.		
Hydro-Québec TransEnergie (HQT)	Yes	The Planning Coordinator or Transmission Planner should be permitted to identify additional units for applicability of the Standard based on the results of generator interconnection studies or other studies that demonstrate the criticality of correct settings on system reliability, e.g. studies demonstrating sensitivity of a stability based System Operating Limit to correct equipment settings and functionality.
Response: Thank you for your comments. The SDT agrees and has drafted a new process (reference Requirement R5) to address your comment.		
Xcel Energy	Yes	Yes, we agree, however the SDT needs to give consideration to whether the Generator Owner has any rights to dispute such designation from its TP or PC.
Response: Thank you for your comments. The SDT agrees that the reliability of the BES could be put at risk if there is no mechanism to allow for the correction of models that do not accurately represent expected equipment performance. In order to ensure that the mechanism is not misused, a new requirement has been drafted by the SDT that requires technical justification for a limited number of scenarios.		
Independent Electricity System Operator	Yes	In some areas on the interconnection, such as those that are sparsely populated, performance of generating units at less than 100 MVA might be critical to reliability. The criteria to allow the TP and PC to identify these units could include: a. A 5% or 10% deviation of any or several of the excitation system's parameters/settings could make an otherwise stable simulation to be unstable; b. Use of generic models for the excitation system or

Organization	Yes or No	Question 9 Comment or Supporting Data
		generator would make an otherwise stable simulation to be unstable. c. Other changes or incorrect assumptions for the excitation system or generator would make an otherwise stable simulation to be unstable.
Response: Thank you for your comments. After reviewing provided details, the SDT encourages you to review the new process draft (reference Requirement R2) and provide additional comments as appropriate.		
US Bureau of Reclamation	Yes	If a unit or facility is critical to reliability and the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator can present convincing evidence, the plant should be included. The criteria to use should be developed by the above entities.
Response: Thank you for your comments. The SDT agrees and has drafted a new requirement that outlines a process requiring technical justification but which allows the Planning Coordinator to identify additional units with excitation control system performance requiring scrutiny by the Generator Owner. Unless the Generator Owner can determine that the existing model structure and data requires a correction, the model must be verified.		
Kansas City Power & Light	Yes	
American Wind Energy Association	Yes	
Northeast Utilities	Yes	

10. The SDT is proposing an implementation plan that requires certain percentages of applicable units to be verified two, six, and eleven years after the standard is approved. The SDT also thought it would be prudent to allow the verification of excitation systems per Regional Entity procedures and guidelines within 5 years of the approval date to be sufficient for demonstrating compliance with this new Reliability Standard.

Do you agree with these approaches?

Summary Consideration:

While industry is in general agreement with the principles of the proposed implementation plan, concern was expressed regarding development time for processes this standard would require. The SDT decided to extend the initial timeframe following standard approval for model verification from “2 years following regulatory approval, 10% of its applicable units per Interconnection on a MVA basis” to “4 years following regulatory approval, 30% of its applicable units per Interconnection on a MVA basis”.

Organization	Yes or no	Question 10 Additional Comments or Recommendations:
American Electric Power	No, instead of allowing credit for verification of excitation systems within the last 5 years of the Standard’s approval date, instead would recommend (please specify below)	that the areas with the greatest instability be addressed first.
Response: Thank you for your comment. The SDT was not able to interpret your comment and therefore could not provide a response.		
Northeast Power Coordinating Council	No, the phase in period for unit excitation system verification should be (please specify below)	The proposed impmentation plan is too long. We recommend a five-year implementation with a requirement that units representing 20 percent of installed capacity be tested each year. We are concerned that an eleven-year implementation plan does not adequeately promote system reliability, and that having only three milestones will place a burden on system operators to schedule testing because Genator Owners may wait until years two, six, and eleven to schedule testing instead of spreading the tests out over the implementation period.The form will not accept more than one box checked above, but "Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standard's approval date" should be checked.

Organization	Yes or no	Question 10 Additional Comments or Recommendations:
Response: Thank you for your comments. The SDT believes, and the majority of industry responders agreed, that the current implementation plan provides proper balance between the need to verify excitation control system models and the fact that there are Generator Owners that currently do not have the expertise to perform model verification required. It may not be feasible to rely entirely on consultants to assist the industry with performing unit verification within a short timeframe such as a 5 year period; possibly leading to compliance violations by unfortunate Generator Owners. The 10 year implementation timeframe will provide the industry adequate time to verify the models and data for the excitation control systems and also develop expertise for performing these verifications. System operators are not necessarily required nor expected to be involved in scheduling model verification. The Generator Owner will determine the verification method and most likely related testing will be done with the unit off line as part of a scheduled maintenance outage; which will result in testing being satisfactorily distributed over the 11 year phase-in period. The SDT notes your concurrence with allowing credit for model verification occurring within the last 5 years of the Standard approval date.		
SERC Dynamics Review Subcommittee (DRS)	No, the phase in period for unit excitation system verification should be (please specify below)	The first time period should be 3 years (10%). It is anticipated that testing of the first units will take significantly longer than subsequent testing. Although this factor may have been considered in the proposed time periods, other factors such as the potential shortage of testing services at the beginning of the testing window may not have been considered.
Response: Thank you for your comments. The second draft of the standard extends the initial timeframe following standard approval for compliance to 4 years (which includes a one year allowance to allow entities time to put processes in place) for verifying 30% of required units. The SDT believes this additional time will better position the Generator Owners to leverage the planned outage schedule.		
IRC Standards Review Committee	No, the phase in period for unit excitation system verification should be (please specify below)	We suggest that the usual implementation language be used. Requirement R1 sets the schedule for verification even for the first time based on a 10-year cycle (we suggest to be shortened to 5 years, especially for the analog and rotating type exciters). We agree with allowing credits for verification of excitation systems within the last 5 years of Standard's approval date.
Response: Thank you for your comments. The SDT believes, and the majority of industry responders agreed, that the current implementation plan provides proper balance between the need to verify excitation control system models and the fact that there are Generator Owners that currently do not have the expertise to perform model verification required. It may not be feasible to rely entirely on consultants to assist the industry with performing unit verification within a short timeframe such as a 5 year period; possibly leading to compliance violations by unfortunate Generator Owners. The 10 year implementation timeframe will provide the industry adequate time to verify the models and data for the excitation control systems and also develop expertise for performing these verifications.		
Consumers Energy	No, the phase in period for unit excitation system	The phase-in period of 2 years is likely to be insufficient unless there are significantly more consultants available than we think there are, as many Generator

Organization	Yes or no	Question 10 Additional Comments or Recommendations:
Company	verification should be (please specify below)	Operators may need to hire a severely constricted resource.
Response: Thank you for your comment. The second draft of the standard extends the initial timeframe following standard approval for compliance to 4 years (which includes a one year allowance to allow entities time to put processes in place) for verifying 30% of required units. The SDT believes this additional time will better position the Generator Owners to leverage the planned outage schedule.		
Dynegy	No, the phase in period for unit excitation system verification should be (please specify below)	If the Generator Owner is assigned the responsibility for model verification, there will not be enough consultants to handle the resulting workload placed on Generator Owners.
Response: Thank you for your comment. The SDT recognizes the issue with assigning responsibility for model verification and has extensively discussion the issue. The collective industry response to Question 1 did not indicate significant issue with the Generator Owner being responsible for model verification. Nevertheless, in response to a number of industry responders regarding the transition period, The second draft of the standard extends the initial timeframe following standard approval for compliance to 4 years (which includes a one year allowance to allow entities time to put processes in place) for verifying 30% of required units. The SDT believes this additional time will better position the Generator Owners to leverage the planned outage schedule.		
Northeast Utilities	No, the phase in period for unit excitation system verification should be (please specify below)	We recommend a five or ten-year implementation with a requirement that units representing 20 or 10 percent, respectively, of installed capacity be tested each year. We are concerned that having only three milestones will place a burden on system operators to schedule testing because Genator Owners may wait until years two, six, and eleven to schedule testing instead of spreading the tests out over the implementation period.
Response: Thank you for your comments. Your response indicates that you are not necessarily opposed to a 10 year implementation plan however you are concerned that the scheduling flexibility afforded by not having yearly milestones would allow Generator Owners to procrastinate and perform model verification activities at the last minute. Keep in mind the majority of industry appears to agree with the SDT that the milestones specified are appropriate because a) the first milestone provides Generator Owners preparation time for performing model verification, including the potential to develop in-house expertise; and b) the milestones specified allow model verification activities to be performed during scheduled maintenance outages, especially when electing to perform staged tests. The SDT expects the Generator Owner to manage model verification scheduling in a responsible manner to remain compliant.		
ISO New England Inc.	No, the phase in period for unit excitation system verification should be (please specify below)	2-1/2 years with a 5 year overall renewal of verification.
Response: Thank you for your comments. The SDT believes, and the majority of industry responders agreed, that the current implementation plan provides proper balance between the need to verify excitation control system models and the fact that there are Generator Owners that currently do not have the expertise to perform model verification required. It may not be feasible to rely entirely on consultants to assist the industry with performing unit verification within a short timeframe such as a		

Organization	Yes or no	Question 10 Additional Comments or Recommendations:
5 year period; possibly leading to compliance violations by unfortunate Generator Owners. The 10 year implementation timeframe will provide the industry adequate time to verify the models and data for the excitation control systems and also develop expertise for performing these verifications. Regarding your recommendation to shorten the re-verification cycle to 5 years, the SDT did not find evidence indicating a shorter cycle would materially improve model quality.		
Ameren	No, the phase in period for unit excitation system verification should be (please specify below)	(1) The term "verification" should be defined. Defining "verification" would give Generator Operators/Generator Owners a clearer understanding of what data should be verified in the model.(2) The first time period should be 3 years (10%). It is anticipated that the first units will take significantly longer than subsequent testing. Although this factor is already being considered in proposed time periods, there will probably be a significant shortage of testing services at the beginning of the testing window. (3) The last period for 100% of appliable units should be 12 years to match with 12 years of outage cycle.
Response: Thank you for your comments. The second draft of the standard lists unit-specific information required to be documented following completion of excitation system model verification. This information should resolve any confusion of the term “verification.” Regarding your second comment, the second draft of the standard extends the initial timeframe following standard approval for compliance to 4 years (which includes a one year allowance to allow entities time to put processes in place) for verifying 30% of required units. The SDT believes this additional time will better position the Generator Owners to leverage the planned outage schedule. Your third comment is unique in terms of specifying a 12 year outage cycle. The SDT, support by industry comments, believes that the 10 year implementation timeframe will provide the industry adequate time to verify excitation control system model and data and also develop expertise to perform verification in-house.		
Hydro-Québec TransEnergie (HQT)	No, the phase in period for unit excitation system verification should be (please specify below)	The proposed impmentation plan is too long. We recommend a five-year implementation with a requirement that units representing 20 percent of installed capacity be tested each year. We are concerned that an eleven-year implementation plan does not adequeately promote system reliability, and that having only three milestones will place a burden on system operators to schedule testing because Genator Owners may wait until years two, six, and eleven to schedule testing instead of spreading the tests out over the implementation period.Credit could be allowed for verification of excitation systems within the last five years of the Standards approval date.
Response: Thank you for your comments. The SDT believes, and the majority of industry responders agreed, that the current implementation plan provides proper balance between the need to verify excitation control system models and the fact that there are Generator Owners that currently do not have the expertise to perform model verification required. It may not be feasible to rely entirely on consultants to assist the industry with performing unit verification within a short timeframe such as a		

<table>
<tr><th>Organization</th><th>Yes or no</th><th>Question 10 Additional Comments or Recommendations:</th></tr>
<tr><td colspan="3">5 year period; possibly leading to compliance violations by unfortunate Generator Owners. The 10 year implementation timeframe will provide the industry adequate time to verify the models and data for the excitation control systems and also develop expertise for performing these verifications.

The Generator Owner will determine the verification method and most likely related testing will be done with the unit off line as part of a scheduled maintenance outage; which will result in testing being satisfactorily distributed over the 10 year phase-in period.

Regarding your concern that the scheduling flexibility afforded by not having yearly milestones would allow Generator Owners to procrastinate and perform model verification activities at the last minute. Keep in mind the majority of industry appears to agree with the SDT that the milestones specified are appropriate because a) the first milestone provides Generator Owners preparation time for performing model verification, including the potential to develop in-house expertise; and b) the milestones specified allow model verification activities to be performed during scheduled maintenance outages, especially when electing to perform staged tests. The SDT expects the Generator Owner to manage model verification scheduling in a responsible manner to remain compliant.

The SDT notes your concurrence with allowing credit for verification occurring within the last 5 years of the Standard approval date.</td></tr>
<tr><td>Independent Electricity System Operator</td><td>No, the phase in period for unit excitation system verification should be (please specify below)</td><td>10 years is too long a period to phase in full compliance with this standard. We recommend this be shortened to no more than 5 years so that the continent can have a fully verified set of excitation system data by that time to support modeling and simulation. This has been long overdue, and allowing the 10-year phase in period prolongs achieving the desriable reliability objectives. We also suggest the SDT to consider shortening the re-verificaiton cycle to 5 years.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. The SDT does agree that implementation of an enforceable excitation control system model verification standard is overdue. The SDT believes, and the majority of industry responders agreed, that the current implementation plan provides proper balance between the need to verify excitation control system models and the fact that there are Generator Owners that currently do not have the expertise to perform model verification required. It may not be feasible to rely entirely on consultants to assist the industry with performing unit verification within a short timeframe such as a 5 year period; possibly leading to compliance violations by unfortunate Generator Owners. Organization	Yes or no	Question 10 Additional Comments or Recommendations:
model verification required. It may not be feasible to rely entirely on consultants to assist the industry with performing unit verification within a short timeframe such as a 5 year period; possibly leading to compliance violations by unfortunate Generator Owners. The 10 year implementation timeframe will provide the industry adequate time to verify the models and data for the excitation control systems and also develop expertise for performing these verifications.		
US Bureau of Reclamation	No, the phase in period for unit excitation system verification should be (please specify below)	We recommend a 5-year phase in period.
Response: Thank you for your comments. The SDT believes, and the majority of industry responders agreed, that the current implementation plan provides proper balance between the need to verify excitation control system models and the fact that there are Generator Owners that currently do not have the expertise to perform model verification required. It may not be feasible to rely entirely on consultants to assist the industry with performing unit verification within a short timeframe such as a 5 year period; possibly leading to compliance violations by unfortunate Generator Owners. The 10 year implementation timeframe will provide the industry adequate time to verify the models and data for the excitation control systems and also develop expertise for performing these verifications.		
Entergy Fossil Operations	Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standard's approval date	I vote yes on both of the questions.
Response: Thank you for your comment. The SDT appreciates your comment.		
AESO	Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standard's approval date	The AESO agrees with the SRC ISO/RTO comments.
Response: Thank you for your comment. The SDT was unable to identify the other commenter mentioned – but if their comments are included, please reference the response.		
Wisconsin Public Service	Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standard's approval date	At the Web-ex I thought the phase in was 10% per year with 100% by end of yr 11. This makes it sound like a different phase in will be used but no details on % at the 2, 6, and 11 year windows.
Response: Thank you for your comments. For details please see the proposed effective dates in the second draft of the Standard.		
AWEA	Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standard's approval date	I agree with both the phase in period and allowing credit for units verified within the last 5 years via regional standards

Organization	Yes or no	Question 10 Additional Comments or Recommendations:
Response: Thank you for your comment. The SDT appreciates your comment.		
Progress Energy, Inc.	Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standard's approval date	The first time period should be 3 years (10%). It is anticipated that the first units will take significantly longer than subsequent testing. Although this factor is already being considered in proposed time periods, there will probably be a significant shortage of testing services at the beginning of the testing window.
Response: Thank you for your comments. The second draft of the standard extends the initial timeframe following standard approval for compliance to 4 years (which includes a one year allowance to allow entities time to put processes in place) for verifying 30% of required units. The SDT believes this additional time will better position the Generator Owners to leverage the planned outage schedule.		
Indiana Municipal Power Agency	Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standard's approval date	IMPA is concerned about the implementation plan. The 10 percent in two years seems feasible, but what if companies decide to test all their units to save on travel cost of a contractor. Has the SDT looked at the total number of units that are covered by this standard and how many contractors can do this work? For example, if a company owns five or more peaking units in one location or in close proximity, they may decide to test all their units at the same time and pay for only one trip by the contractor. Then the next Generator Operator does the same with its units and this continues to occur throughout the two year time period. This type of mentality may hurt the Generator Operator who owns only one unit and has to wait on an available contractor to perform the test. If the Generator Operator does not get that one unit tested within the first two years, it will be non-compliant with this standard (the Generator Operator only owns one unit that this standard applies).
Response: Thank you for your comments. The second draft of the standard extends the initial timeframe following standard approval for compliance to 4 years (which includes a one year allowance to allow entities time to put processes in place) for verifying 30% of required units. The SDT believes this additional time will better position the Generator Owners to leverage the planned outage schedule.		
NERC Event Analysis & Information Exchange staff	Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standard's approval date

Organization	Yes or no	Question 10 Additional Comments or Recommendations:
Kansas City Power & Light	Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standard's approval date	
MRO NERC Standards Review Subcommittee	Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standard's approval date	
FirstEnergy	Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standard's approval date	
Constellation Power Generation & Constellation Nuclear	Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standard's approval date	
E.ON U.S.	Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standard's approval date	
Arizona Public Service Co.	Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standard's approval date	
Wisconsin Electric	Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standard's approval date	
Reliant Energy	Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standard's approval date	
Reliant Energy	Yes, agree with allowing credit for verification of excitation systems within the last 5 years of the Standard's approval date	

Organization	Yes or no	Question 10 Additional Comments or Recommendations:
Luminant Power	Yes, agree with proposed phase in period for unit excitation system verification	Note that I also agree with allowing credit for verification of excitation systems within the last 5 years of the Standard's approval. The form would not let me select both yes answers.
Response: Thank you for your comment. The SDT appreciates your comment.		
Southern Company	Yes, agree with proposed phase in period for unit excitation system verification	We agree with both Yes statements above. The software will only allow one to be marked.
Response: Thank you for your comment. The SDT appreciates your comment.		
City of Garland, Garland Power & Light - GOP Registered Entity	Yes, agree with proposed phase in period for unit excitation system verification	Agree with both "Yes" statements - form will only allow one to be selected - if the 2 "Yes" statements are mutually exclusive, then I must not understand your statements & will go with the 1st "Yes"
Response: Thank you for your comment. The SDT appreciates your comment.		
Duke Energy	Yes, agree with proposed phase in period for unit excitation system verification	We wanted to also check "YES" on allowing credit for verification of excitation systems within the last 5 years of the Standard's approval date, but this electronic form wouldn't allow us to do that.
Response: Thank you for your comment. The SDT appreciates your comment.		
Pepco Holdings, Inc (PHI) - Affiliates	Yes, agree with proposed phase in period for unit excitation system verification	
Southwest Power Pool Generation Working Group	Yes, agree with proposed phase in period for unit excitation system verification	
FEUS	Yes, agree with proposed phase in period for unit excitation system verification	
Cowlitz County PUD	Yes, agree with proposed phase in period for unit excitation system verification	

Organization	Yes or no	Question 10 Additional Comments or Recommendations:
Exelon Corporation	Yes, agree with proposed phase in period for unit excitation system verification	
American Wind Energy Association	Yes, agree with proposed phase in period for unit excitation system verification	
Manitoba Hydro	Yes, agree with proposed phase in period for unit excitation system verification	
Southern California Edison	Yes, agree with proposed phase in period for unit excitation system verification	
Xcel Energy	Yes, agree with proposed phase in period for unit excitation system verification	

11. If you are aware of any regional variances that would be required as a result of this standard, please identify them here.

Summary Consideration:

No regional variances were identified by industry.

Organization	Yes or No	Question 11 Regional Variance and Comment
Northeast Power Coordinating Council		None.
Dominion		SERC - supplement requires members to validate the excitation system model parameters of their generating units within 7 years (dated 2007).MRO draft guideline in field test, not currently in effect.
Response: Thank you for your comment. The SERC DRS has been notified by the SDT. The SERC DRS indicates they do not have plans to pursue a Regional Variance.		
Kansas City Power & Light		Not aware of any regional differences.
Response: Thank you for your comment.		
MRO NERC Standards Review Subcommittee		No
IRC Standards Review Committee		None
Luminant Power		Possible regional variance on applicability with GOP vs. GO in ERCOT.
Response: Thank you for your comment. Based on guidance provided by the FMWG, the SDT has designated the Generator Operator as the applicable entity in the second posting of the standard.		
Constellation Power Generation & Constellation Nuclear		None.

Organization	Yes or No	Question 11 Regional Variance and Comment
Consumers Energy Company		N/A
American Electric Power		No known need for regional variances
Response: Thank you for your comment.		
Manitoba Hydro		none
Progress Energy, Inc.		No.
Dynegy		None at this time.
Ameren		None
AESO		The ones we are aware of have been noted in the responses previous questions.
Response: Thank you for your comments..		
Duke Energy		None
Hydro-Québec TransEnergie (HQT)		Yes, we have a modification to propose to the Applicability section which list different value for diffferent Region or Interconnection.We propose that the two paragraphs in Applicability 4.1.1.1 be modified to: Each unit (including synchronous condensers) 50 MVA, connected at the point of interconnection at 100 kV or above and with an average Capacity Factor greater than 5% over the last three calendar years. Each unit (including synchronous condensers) 20 MVA within a plant 100 MVA, connected at the point of interconnection at 100 kV or above and with an average Capacity Factor greater than 5% over the last three calendar years.
Response: Thank you for your comments. The SDT believes that the industry has overwhelmingly accepted the model verification 80% threshold which would result based on the draft language of the Applicability section.		
Independent Electricity System Operator		Variances are already provided in the Applicability Section (for the 3 Interconnections).

Organization	Yes or No	Question 11 Regional Variance and Comment
Response: Thank you for your comment.		
US Bureau of Reclamation		WECC has developed a comprehensive regional machine testing and model validation policy that includes dynamic models for all the major generation components and the applicability thresholds are much more strict than those proposed in the draft MOD-026-1.
Response: Thank you for your comments. The SDT understands WECC is not planning to submit a regional variance at this time.		

12. If you are aware of any conflicts between the proposed standard and any regulatory function, rule, order, tariff, rate schedule, legislative requirement, or agreement, please identify them here.

Summary Consideration:

No substantial conflicts were identified by industry.

Organization	Yes or No	Question 12 Conflict
Northeast Power Coordinating Council		None.
Kansas City Power & Light		Not aware of any conflicts.
MRO NERC Standards Review Subcommittee		No
IRC Standards Review Committee		None
Luminant Power		NA
Constellation Power Generation & Constellation Nuclear		None.
Consumers Energy Company		N/A
American Electric Power		CONFLICT: The added expense posed by the requirements of this standard must be sought through tariff changes with applicable regulatory authorities. COMMENTS: A strong cost-benefit analysis is required to receive the necessary cost recovery.
Response: Thank you for your comment. The SDT believes that the Applicability section has been structured so that industry cost is minimized, which the majority of industry responders agree.		
Manitoba Hydro		none
Progress Energy, Inc.		No.
Dynegy		None at this time.

Organization	Yes or No	Question 12 Conflict
Ameren		None
Duke Energy		None
Independent Electricity System Operator		None

13. If you have any other questions or concerns with the proposed standard that have not been addressed in responding to the questions above, please provide them here.

Summary Consideration:

Based in part on industry comments received to this question, the following modifications to the proposed standard have been made by the SDT. (note: some of these issues and listed modifications are addressed by other consideration of comments questions):

1) Use the term “excitation control system” as appropriate to be consistent with terminology used in IEEE 421.1 (includes the voltage regulator, exciter, and generator).

2) Clarify the new Applicability section (including footnotes) to indicate that only units with 5% or less capacity factor are exempt with status reaffirmed every ten years. including new requirement (reference Requirement R5 in the revised standard) providing a mechanism for low capacity factor units identified by the Planning Coordinator to require model verification.

3) Modify the Applicability section to include “same point of interconnection” language.

4) Clarify the SDT position regarding the potential reliability gap with wind generation. Based on industry comments and concerns expressed by NERC staff, the SDT has expanded the Applicability section to include a large percentage of small units which would include variable energy resources such as wind generation.

5) Requirements have been restructured for clarity in the second posting of the standard.

Organization	Question 13 Comments
NERC Event Analysis & Information Exchange staff	It seems that having an overall generator testing standard in place on the dynamic parameters listed in MOD-013 would be a prerequisite for an excitation testing standard.
Response: Thank you for your comment. The SDT agrees an accurate representation of the generator system is essential for obtaining a match between simulated and measured results however, the SDT believes that a match between simulation and measured results for the excitation system model validation indicates that the generator and excitation control system models are both representative of the equipment. If the results do not match, then the SDT agrees further testing may be required to obtain appropriate generator parameters. To prevent further delays with developing the MOD-026 standard, the SDT will not consider a generator verification standard as part of the exciter verification standard development process.	
Southwest Power Pool Generation Working	The SPP Generation Working Group members have several concerns related to this standard. The skill-set required to perform these tests do not currently exist among Generator Owners and there is a great concern that the limited subset of consultants that will be able to perform this

Organization	Question 13 Comments
Group	verification will not be able to complete these tasks within the suggested ten year period. Given the limited subset of parties that will perform these tests, the cost will be onerous on the Generator Owners while not providing significant benefits.SPP Generation Working Group members do not know of any issue that these enhanced requirements would have helped avoid and therefore see little value, given the potentially high cost, to these expanded requirements. SPP Generation Working Group members generally oppose the current version of this standard.
Response: Thank you for your comments. Field testing confirmed that verification of excitation system models does result in higher quality dynamics data that will result in more accurate dynamic simulations that can define security limits so the SDT believes that these requirements positively contribute to BES reliability. Field test also indicated there is a cost to perform excitation system model verification so the SDT believes that the NERC Compliance Registry should not be referenced in the Applicability section. Instead, the Applicability section will identify a subset of units defined by the Compliance Registry which are expected to have significant impact on BES reliability.	
SERC Dynamics Review Subcommittee (DRS)	Requirement 1 says testing should occur "for new or existing units within 180 days of commerical operation". We believe the testing should be done before commerical operation.
Response: Thank you for your comments. The SDT notes some areas have existing grid code that require excitation control system model verification before commercial operation occurs. The SDT recognizes transmission entities can adopt more stringent requirements.	
Dominion	The SDT should define exactly what the "excitation model" means. At a minimum it should include the AVR, exciter, PSS (if installed) and voltage compensator (if installed). The current document appears to imply that the minimum and maximum excitation limiters (if installed) are not part of the "excitation model." 2. We are concerned that, in order to meet this standard, applicable entities may have to share data and software that may be proprietary and which may vary depending upon vendor(s) selected by the Transmission Planner. R2 states that models cannot be confidential or proprietary. 3. We believe that applicabilty section should be modified so that it only includes entity(ies) defined in the NERC Functional Model. At 4.1.1 it states Generator Operators of generating facilities: We believe it should state Generator Owner (the term used in functional model). a. We can support 4.1.1.1 if the language is revised to read With generators that are connected to Eastern or Quebec Interconnections with the following characteristics 4. The requirement R2 should be restated to read: The Transmission Planner shall provide the Generator Owner a set of model data sheets for the standard (as opposed to acceptable)excitation system models for use in dynamic simulation software, with each data sheet including the excitation system model block diagram structure and data requirements, within 30 calendar days of a request from the Generator Owner. If the excitation system characteristic is such that it cannot be represented by one of the Standard models, the Generator Owner shall be obligated to have a user-written model developed and made it available to Transmission Planner for use in the dynamic simulation software used by the Transmission Planner.
Response: Thank you for your comments. After reviewing IEEE 421.1, the SDT believes that the term “excitation control system model” is more appropriate to use in the standard then “excitation system model.” This is because the term “excitation control system model” references the entire closed loop system including the synchronous machine. The SDT has adopted this language in the second draft of the standard; which also includes excitation system limiters that are part of the exciter. This language does not include excitation protective devices that are independent of the excitation system. Independent protective devices will be addressed in the initial	

Organization	Question 13 Comments
posting of the draft standard PRC-019. Regarding your second comment, the SDT believes proprietary models cannot be allowed and that the static block diagram must be selected from the list of models provided by the Transmission Planner. Regarding your third comment on the Applicability section, the SDT believes that the combination of the Functional Model entity and the criteria statement of unit size per interconnection is appropriate. The SDT recognizes that user written models are sometimes necessary however this is not desirable. The SDT purposely changed Requirement language such that the Generator Owner would have to propose a user written model to its Transmission Planner for incorporation on the acceptable list of model data sheets.	
Kansas City Power & Light	Where specific codes and standards are referenced as either the technical basis for, or an acceptable means to comply with the NERC requirements, such as IEEE 421 referenced directly in Draft 1 of MOD-026-1, or IEEE 1110 and IEEE 415, please clarify these are references only and the content of these references in no way add to the requirements proposed here.
Response: Thank you for your comments. Please note that the References section contains the disclaimer: "The following documents contain technical information beyond the scope of this Standard on excitation control system functionality, modeling, and testing.".
