This provides all the information needed to allow the TO to rate the machines at whatever ambient temperature may be needed. Per #2, the DRS recommends that TO be changed to TP. In attachment

1 item 3.4, the DRS recommends that "correction factor" be changed to "adjustment method," to allow real power determination at multiple temperatures.
No
The use of sister units should be allowed by the standard. Also, verification should apply on the 75 MVA units, and above. Units smaller than this have very little impact on grid reliability.
Yes
These 4 points should provide adequate testing of the generator. The DRS does not believe that verification for leading capability should be required where operational practices preclude operation in a leading mode.
Yes
Yes
Yes
Synchronous condensers supply reactive power to the grid. Therefore, the Transmission Planner needs to know a verified capability for the device.
No
A 50 MVA criteria for synchronous condensers is not in the standard. The standard says 20 MVA. However, a criteria of 75 MVA would be a more reasonable number. Units smaller than 75 MVA will have little impact to the reliability of the grid.
Yes
No
The 20 % requirement is too restrictive. Any operational data should be allowed to be used if it is accompanied by engineering analysis which calculates appropriate expected limits. This will be more useful to the Transmission Planner than a value from operational data within 20% which does not give the appropriate expected limit.
No
No
Yes
The VSL for R2 is missing a needed component. The Severe category needs to include the following: "The Transmission Owner verified and recorded the Real and Reactive Power capability of its applicable synchronous condenser, but submitted the data to its Transmission Planner more than 120 calendar days from the date the data was recorded." GO's should be required to provide expected values for reactive capability in addition to the demonstrated values (this should be included in R1). Without this, the data is useless to the Transmission Planners. Item 3.4 in Attachment 1 refers to Transmission Owner. It should say Transmission Planner to match Requirements 1 & 2. Only one verification is needed for sister (identical) units. The standard currently requires verification for all units.
No
The DRS agrees that the intended generating units would be covered by reasonable interpretation of the applicability section 4.2. However, the DRS recommends that footnote 3 be changed to read "The common transmission voltage level bus (i.e. 100 kV or greater) to which the step up transformer(s) is connected." This more clearly includes "step up" transformers for some types of variable energy plants which may not be "generator step up" transformers.
Yes
Yes
We agree that it shouldn't be included. However, it appears that there is an error in the question. Synchronous condensers cannot be used to control frequency. Was this a "cut and paste" error from

MOD-026?
No
No
Yes
For Requirement R1, the SERC DRS recommends that the time be changed from 30 calendar days to 90 calendar days. Relative to the time allowed for accomplishing other requirements, there is no benefit for only allowing 30 days for requirement R1. 90 days would allow for more communications between the requesting Generator Owner, the providing Transmission Planner and other entities (such as the software vendor or turbine manufacturer) to coordinate obtaining the necessary items listed in requirement R1. Additionally, 90 days would be consistent with the “more than 90 days” VSL level for this requirement. Relative to R3, bullet three, this covers the situation where predicted response does not match recorded response for three or more events. We suggest this be one or more events because significant events are so rare in the eastern interconnection. Relative to the VSL for R2, the first paragraph in the “Severe column” has confusing words "failed to provide the verified models no more than 90 days late." We recommend changing the words to "provided more than 90 days late". In multiple locations in Attachment 1, 730 days seems to be an excessive amount of time from capturing an event to sending documentation to the TP. We recommend a period of 180 days. In two places in Attachment 1, excitation control system is referred to. Shouldn't this be turbine/ governor control system?

Yes
The intent of the question is not well understood. The answer is complicated by the inability to replicate the system condition that will demand the unit operating limits, creating artificial lower limits under the test conditions.
Yes

No
Yes
No
No
Disagree strongly: It is overreach to make this a generator protection standard; the standard is not comprehensive enough to take on that task. As a result, the SDT has overstated the purpose and intent of this standard. Simple is better and appropriate. Purpose: To improve reliability through coordination of generator protection systems with unit/facility voltage regulating limiter functions and protection.
Yes
Yes
In some ways, the requirements are too subjective in determining what protection and limiters are subject to coordination. In other ways, the standard provides insufficient or contradictory requirements in defining how coordination is achieved, even for well established protection practices. It is difficult to define all-inclusive coordination principles with so many variables in a simple straightforward standard. As written, the standard is a compliance risk to the applicable entities based upon future arbitrary and subjective interpretation by compliance organizations. Vivid examples are provided in Attachment 1. Loss-of-Excitation Zones 1 & 2 does not “coordinate” with the Steady State Stability Limit. In the diagram of the generator capability curve, SSSL is reached prior to the Loss-of-Excitation protection, contrary to R1.1.1, requiring the protection to operate ahead of the SSSL. Also, Loss-of-Excitation Zones 1 & 2 exceeds the generator capability curve, and does not fulfill R1.1.1 that requires protection to operate before conditions exceed equipment capabilities. Other variables with indirectly relationships are subject to future interpretation. A generator stator may have overvoltage protection set at 118% with a 2 second time delay, allowing it to meet PRC-024-1 ride through capability. Overvoltage protection also has a correlation to field current limiters. To insure and demonstrate absolute “coordination” with a field current limiter under all circumstances, it may be necessary to reduce the field current limit. The move will be counter productive to system performance in most transient conditions, but may be required to insure “coordination.” The SDT should make specific requirements of defined scope rather than broad, subjective, and open-ended requirements, i.e. 1) Volts/Hz limiters shall coordinate with Volts/Hz protection, 2) Under excitation limiters shall coordinate with steady state stability limits and loss-of-field protection, and 3) field current limiters shall coordinate with field current capability. The standard should exclude statements that the protection must operate before conditions exceed equipment capability. It will be difficult to provide definitive evidence of compliance for the use of many protection elements on older equipment with no documentation of equipment capability to withstand conditions such as Volts/Hz. If a generating unit is rated for +/- 5% terminal voltage, how is the generator’s overvoltage withstand capability demonstrated to PRC-024-1 criteria. In a compliance world of absolutes, Generator Owners may not be allowed to use general “rules of thumb” when coordinating protection. In ways that are

counterproductive to reliability and equipment protection, Generator Owners could end up removing protection elements when it cannot be demonstrated that it operates before the condition exceeds equipment capabilities. Calculation of the steady state stability limit requires the transmission system Thevenin equivalent impedance. Therefore, it is necessary for the standard to require Transmissions Owners to provide Generator Owners this impedance within 30 days of request. Likewise, the allocated time for Generator Owners to perform coordination studies should increase by 30 days or more to 120 days. In R1.2, a five year coordination study interval is an unnecessarily short duration for generating units without significant changes in the generator protection or an AVR replacement. A company with 150 generating units will average 2.5 coordination studies per month on a non-stop continuous rotation. Ten years is a more appropriate cycle for a coordination study on a unit with no changes. The wording used to trigger an examination should be specific and defined, rather than the ambiguous and nondescript statement of “changes that are expected to affect this coordination.” To meet compliance, it will be necessary to expend needless effort for the possible interpretations of “changes” that otherwise will have little or no impact for the intent or purpose of this standard. Suggest rewording R1.2, “Each Generator Owner or Transmission Owner shall verify the coordination indentified in Requirement R1 at least once every ten years or within 120 calendar days following modifications impacting coordination when the following activities occur: 1) a change in AVR limiters or AVR protection for over-excitation, underexcitation, Volts/Hertz, stator voltage, or field current, or 2) generator protection changes for stator voltage, loss-of-excitation, or Volts/Hertz protection.” For only 30 days of differences (90 to 120), VSLs expand from Lower to Severe. Considering the justifiable allowance for 20% of the fleet to go 5 years without demonstrated coordination, the logic for the acceleration of severity over such a short time duration is not understood.

Yes
No
PacifiCorp believes that the four points proposed by the SDT are adequate with respect to thermal and hydro generation units; however, the proposed points do not adequately take operating conditions for wind generation facilities into consideration.
No
First, PacifiCorp believes that over-excited reactive capability at rated Real Power verification should be performed on the same basis as for under-excited reactive capability and over-excited reactive capability at expected minimum Real Power output – that such data should be recorded as soon as a limit is reached. Second, this does not adequately take operating conditions for wind facilities into consideration.
Yes
Yes
Yes
Yes

No
No
Yes
Section 4.2 of proposed Standard MOD-025-2 contemplates the inclusion of large wind farms within the scope of the proposed standard, as it is applicable to generating units above individual and aggregate nameplate rating thresholds (as the commentary seems to indicate is intended). The specific requirements for verifying Real and Reactive Power capabilities, however, do not make any allowance for operating differences of wind generation units. If wind generating resources are to be included within the scope of this proposed standard, then the standard should include express allowances for verification methodologies that are applicable to wind generating units.
No
Yes
Yes
No
No
Yes
Section 4.2 of proposed Standard MOD-027-1 provides that units or plants with an average capacity factor greater than 5% over the last three calendar years, that also meet other characteristics, will be considered “applicable units.” However, the term “capacity factor” is not defined in proposed Standard MOD-027-1. Proposed Standard MOD-026-1, on the other hand, uses the term “Capacity Factor,” suggesting it is a defined term but without an accompanying definition in the NERC Glossary of Terms or otherwise. PacifiCorp believes that the Standards Drafting Teams should make the use of the term “capacity factor” consistent across all proposed standards and define the term as necessary for additional clarity.

Yes
No
Requirement R1, part 1.3 and Requirement R2, part 2.3 indicate that data is to be submitted to the Transmission Planner. We agree that the data should be submitted to the Transmission Planner, not the Transmission Owner. Further, we believe that the data should be provided to all entities that have need of the data, including the Transmission Operators and Reliability Coordinators who need the data for their operational planning and real-time models.
No
It is not necessary to specify a temperature for which submitted data should be adjusted because one temperature will not be appropriate for all regions or for all types of studies. Providing the recorded value and a temperature correction factor or correction table is appropriate.
No
While we agree that all units connected at voltage <100 kV need not be tested and modeled, any units >20 MVA and plants/facilities >75 MVA should be tested and modeled accurately regardless of interconnection voltage. The reliability impact of generating units is more directly related to unit capability than interconnection voltage.
No
Reactive Power capability is not a linear function of Real Power. The reactive capability curve and minimum excitation limiter settings for each machine should be used to determine the expected gross reactive capability.
No
Often, on larger units, temperatures do not stabilize within one hour. It is important for this test to assure that temperatures have stabilized and that the unit capability is sustainable, so the overexcited reactive capability test should be conducted for a minimum of two hours or until the temperatures have stabilized.
Yes
Yes
Although the penetration of synchronous condensers in North America is low, in most cases they are applied to address a reliability need, making it necessary to have accurate models of these devices for system studies. Although other devices may be outside the scope of this standard, accurate models are similarly necessary for devices such as static var compensators (SVCs) and static compensators (STATCOMs).
No
Section 4.2.1 indicates the standard is applicable to synchronous condensers greater than 20 MVA. We agree that the standard should be applicable to synchronous condensers greater than 20 MVA rather than 50 MVA.
Yes
No
We agree the standard should provide flexibility to the Generator Owner; however, the need for flexibility must be balanced against the need for valid models for system studies. Accuracy must be at least as stringent as required for market dispatch. When operational data cannot be verified within 5% of the expected value, an entity should be required to provide data based on staged testing.
No

No
Yes
The violation risk factors associated with Requirements R1 and R2 should be at least medium. Use of invalid models resulting from violation of these standards can produce erroneous results and adversely affect assumptions of the electrical state or capability of the bulk electric system, or the ability to effectively control or restore the bulk electric system, particularly under emergency, abnormal, or restorative conditions. This can result in operating beyond the true stability limits of the system. The models validated by application of this standard are used in both the long-term planning and the operations planning horizon. The time horizon for Requirements R1 and R2 should include the operations planning horizon. The SDT should consider use of the word “verification” versus “validation” and assure that the term used in this standard is consistent with other standards.
No
We are not aware of other units types at this time, but the applicability should be written broadly enough to not preclude applicability to other types of resources that may be connected in the future.
No
The standard should include a requirement that provides the Planning Coordinator the ability to request a review of any turbine/governor and load control or active power/frequency control system model for a unit not specified in the standard Applicability section. Accurate turbine-governor models can be critical to valid underfrequency load shedding assessments and other studies requiring accurate frequency response. This is particularly important for large units that operate infrequently, but are committed for critical operating conditions such as peak load or other times of capacity deficiency.
Yes
We agree that it is not necessary to validate synchronous condenser models in MOD-027 since synchronous condensers do not provide frequency response. However, the discussion supporting this question refers to verification of excitation control systems. Validation of synchronous condenser excitation control systems should be required in MOD-026.
No
No
Yes
It is not possible to accurately model system frequency response with valid models for only 80% of the installed system capacity. System frequency perturbations are experienced by and responded to by all frequency responsive generators, regardless of interconnection voltage. The standard should be applicable to all units greater than 20 MVA and all plants greater than 75 MVA regardless of interconnection voltage. Per SDT estimates, this will assure accurate modeling for approximately 95% of installed capacity. The interconnection voltage is not relevant to frequency response and should not be a condition for applicability. We also disagree with the exemption for units with <5% capacity factor for the past three years. Some large, less efficient units may only run during peak load conditions giving them lower capacity factors. However, those will also be the units loaded at lower levels, making them the units with head-room to respond, thereby making them critical to frequency response during those conditions. They may be of a lower priority in the implementation plan. The violation risk factors associated with Requirements R1 through R5 should be at least medium. Use of invalid models resulting from violation of these standards can produce erroneous results and adversely affect assumptions of the electrical state or capability of the bulk electric system, or the ability to effectively control or restore the bulk electric system, particularly under emergency, abnormal, or restorative conditions. This can result in operating beyond the true stability limits of the system. The models validated by application of this standard are used in both the long-term planning and the operations planning horizon. The time horizon for Requirements R1 through R5 should include the operations planning horizon. In Requirement R2, part 2.1.1, it appears the comparison should be between recorded response and simulated modeled response rather than between on-line response and recorded response. Further clarification is necessary. In Requirement R4, when the

turbine/governor and load control or active power/frequency control system are modified as part of a planned project, the Generator Owner should be required to provide a revised model prior to placing the revised equipment back in service. In Requirement R5, part 5.2, the reference to negligible transients is not measurable. We recommend modifying this to ". . . results in a response that varies less than the numerical stability of the program used for the simulation." In Requirement R5, part 5.3, the introductory phrase "For an otherwise stable simulation" is not necessary and a potential source of confusion. We recommend deleting this phrase and starting the sentence with "A disturbance simulation results in . . ." The SDT should consider use of the word "verification" versus "validation" and assure that the term used in this standard is consistent with other standards. Validation of models only every 10 years is far too long a period. Models should be calibrated as often as possible, preferably with every significant system frequency disturbance. Experience in the WECC region has shown that validation by observation against system events yields more accurate model performance than relying on a single staged test because the events provide for a wide variety of system conditions for the comparison. The background material suggests that more frequent validation against frequency events is impractical because of the scarcity of events. That is incorrect; there are several frequency events each year in all of the interconnections where frequency deviates beyond the short-term trigger limits set forth by the Resources Subcommittee, which indicate that generators should have exceeded the traditional deadband of ±36 mHz and responded. The initial completion of validation for all applicable units should be within 5 years, not 10 years. The 10 year time is excessive. Validation or calibration after a measured system event should occur within 6 to 9 months of the event, not 2 years. Experience in the WECC regions shows this to be sufficient and achievable.
Yes
No
The posted standard references synchronous condensers rated 20 MVA in Applicability section 4.2.1. We agree with the 20 MVA threshold in the posted standard.
Yes
Devices such as static var compensators (SVCs) and static compensators (STATCOMs) have equipment limitations, control systems, and protections that must be coordinated to assure system reliability. The reliability impact of unnecessarily tripping reactive support from a variable static resource is similar to tripping reactive support from a generator or synchronous condenser. Also, the standard must remain neutral as to the type of reactive resource, allowing for other technologies such as storage and demand-side regulation through electronically coupled loads that are relied upon for reliability purposes in the same vain as other reactive sources cited.
Yes
No
As written, the standard only addresses 80% compliance on generation and reactive sources that are not subject to regulatory approval. It appears that a section 5.2.5, similar to section 5.1.5, is missing from the Effective Dates section.
No
The diagrams need to incorporate the permissible voltage and frequency ranges. For example, the P-Q diagram probably is based on 1 pu voltage and frequency. Further, Section G should address the system concerns described in Table 2 of the SPCS Technical Reference Document "Power Plant and Transmission System Protection Coordination," for the generator protection functions that must be coordinated.
Yes
No
Yes
The standard lacks clarity on which types of protection functions must be coordinated. The standard should specify which types of protection functions must be coordinated if they are present on the

generating unit, such as the list in Section G.This should be consistent with protection coordination described in the SPCS Technical Reference “Power Plant and Transmission System Protection Coordination.” Additionally, Attachment 2 could be interpreted to require coordination for protection systems that cannot be coordinated (e.g., the generator backup distance and backup overcurrent functions are required to detect faults that may result in an apparent impedance inside the SSSL) or do not require coordination (e.g., the generator out-of-step function will operate only for an unstable power swing and will not operate for stable operation within its operating characteristic). These protection functions should be removed from the figure or clarification should be added that the standard does not require coordination of these protection functions. Requirement R1, part 1.1.1: The standard emphasizes preventing tripping of generating units and generating facilities due to miscoordination. Another aspect of coordination is to coordinate the protections and controls to coordinate with the equipment capability. Without guidance or direction, the standard could have the unintended consequence of overly conservative settings that limit the ability of the facilities to respond to system disturbances, or inadvertently create a common-mode failure trip point across a generation fleet. Requirement R1, part 1.1.2: The word “check” is subject to interpretation and step 1.1.1 in some cases will verify existing settings rather than determine settings. Part 1.1.2 should be revised to address these issues, such as “Demonstrate that the settings used to verify coordination in part 1.1.1 are applied to the in-service equipment.” Requirement R1, part 1.2: When the generating unit equipment or settings are modified as part of a planned project, the Generator Owner or Transmission Owner should be required to verify coordination PRIOR to placing the revised equipment or settings back in-service. It is important to note that protection setting changes on the transmission system may necessitate generating unit protection setting changes which in turn require a review of coordination with the generating unit or plant voltage regulating controls. While coordination between the transmission system and generating unit protection settings is outside the scope of this standard it is important that this coordination is required by in a reliability standard. The examples emphasize steady-state limits and capability curves without mention of the short-term generating unit capabilities. Proper coordination should also apply to transient response of the generating unit and its associated limiters to meet the reliability objective of this standard. Focusing examples on steady-state coordination may be misleading and result in miscoordination for transient events. Of particular concern is the transient response of exciters in field-forcing during system disturbances; loss of reactive support from generation during such events can be catastrophic and lead to cascading. The foremost reason for protective relaying is to protect power system equipment. There is a concern that the real purpose of relaying may be lost in the overwhelming emphasis of its coordination with controlling equipment throughout the document. The generator protective relays are there to protect the generator and its associated equipment and the standard should acknowledge that this primary objective cannot be violated to obtain the desired coordination.

The standard should allow the provision of ambient temperature during the verification be provided to the Transmission Owner as well as a correction factor to allow the Transmission Owner to adjust the Real Power data to a different ambient temperature if needed OR Real Power data submitted be temperature adjusted to some other than ambient temperature as requested by the TO.
Yes
The Applicability of this standard should be to BES Generating Units and Facilities. Section 4.2 should not restate components of the proposed BES definition.
Yes
No
To obtain more realistic rated real power and over-excited reactive power ratings, the minimum

verification time should be 2 hours or until temperatures have stabilized. For under-excitation, the test duration should be 1 hour.
Yes
Yes
To cover all configurations, the standard should also include and stipulate that synchronous machines that operate as generators at some times and as synchronous condensers at other times must perform a reactive capability test in each operating mode. This may be covered in Applicability 4.2.1 however the current wording should be modified to make this clear.
No
The 50MVA criteria in question 9 does not appear in the draft standard (only in the implementation plan). If the question is valid and 50MVA is not a typo, it is not clear why the size of applicable synchronous condensers should be different from that of synchronous generators. Also 50 MVA seems like an arbitrary number with no basis. MH proposes that the applicable MVA rating of synchronous generators and synchronous condensers be identical. This eliminates confusion associated with units capable of operating in either mode.
Yes
Yes
No
Yes
A number of Canadian Entities have the BES defined within their provincial legislation. This may introduce differences between the elements that are included in the BES (and elements that are therefore applicable to this standard) according to provincial legislation and the NERC definition. As well, since Canadian Entities are not under FERC jurisdiction, the effective date of this standard may differ for Canadian entities and entities under FERC jurisdiction.
No
No
Yes
Yes
-MOD-027-1 cannot be applicable to units dedicated as synchronous condensers since such units do not have turbine/governor and load control or active power/frequency control functionality installed. For generator units which can be operated as synchronous condensers MOD-027-1 already includes such units therefore reference to synchronous condenser operation is not necessary.
No
Yes
A number of Canadian Entities have the BES defined within their provincial legislation. This may introduce differences between the elements that are included in the BES (and elements that are therefore applicable to this standard) according to provincial legislation and the NERC definition. As well, since Canadian Entities are not under FERC jurisdiction, the effective date of this standard may differ for Canadian entities and entities under FERC jurisdiction.
Yes
-MH disagrees with the SDT's assumption that the majority of turbine/governor and load control functions will be verified through ambient monitoring. If both turbine/governor and load control functions as well as excitation control functions are to be verified through staged tests then having different effective dates for MOD-027-1 and MOD-026-1 introduces an unacceptable level of

complication in testing and documentation. MH recommends that the effective dates for both standards be identical and that MOD-026-1 effective dates be applied to MOD-027-1 to accommodate entities which will utilize more ambient monitoring than staged tests. -The SDT provides no information regarding testing and model verification which was completed under the regional guidelines (such as the MRO Generator Testing Guidelines) and the previous versions of the generator verification standards and which comply with the current version of the standard. With the amount of effort and costs which went into this exercise, MH proposes that such compliance information be accepted if completed within the past 10 years of regulatory approval of the proposed standards. Entities should not be penalized for lengthy SDT delays in developing these proposed standards. -For Section 4.2 “Facilities”, the section should refer to ‘BES Generating Units and Facilities’ instead of restating components of the proposed BES definition.
Yes
No
The 50MVA criteria in question 2 does not appear in the draft standard. If the question is valid and 50MVA is not a typo, it is not clear why the size of applicable synchronous condensers should be different from that of synchronous generators. Also 50 MVA seems like an arbitrary number with no basis. MH proposes that the applicable MVA rating of synchronous generators and synchronous condensers be identical. This eliminates confusion associated with units capable of operating in either mode.
No
Static VAr compensators do not belong in a generation standard.
Yes
No
-MH recommends that the effective dates for this standard be identical to MOD-026. This will allow entities to schedule all work and required outages simultaneously.
Yes
Yes
No
Yes
-The standard should take into account generating units whose capacity is determined based upon the run of the river where it may be difficult to test at design capacity. We suggest that an engineering methodology/calculation be acceptable for these units. -Wind generation should be excluded from the applicability of this standard or a calculation should be allowed due to the difficulty in testing wind units. -The SDT provides no information regarding testing which was completed under the regional guidelines (such as the MRO Generator Testing Guidelines) and the previous versions of the generator verification standards and which comply with the current version of the standard. With the amount of effort and costs which went into this exercise, MH proposes that such compliance information be accepted if completed within the past 5 years of regulatory approval of the proposed standards. Entities should not be penalized for lengthy SDT delays in developing these proposed standards. -The Applicability of this standard should be to BES Generating Units and Facilities. Section 4.2 should not restate components of the proposed BES definition.

Yes
Yes, however need to define "Rated Real Power" so that entities are using a consistent basis for data reporting. MW validation is intrinsically connected to governor response issues and thus should be instead be combined with MOD-27 frequency response efforts and the following modelling parameters

defined and addressed: – Pmax • The continuous operating limit • The ultimate max emergency output. • Should there consider weather conditions (summer or winter, etc.). • PMAX associated with Transient stability – is it the same as for LF • Is this on the order of 105% or 110% or ??% of normal max loading Please clarify if real and reactive verification can be performed at different times.
No
The TP or the PC (PA) is the entity needing the data, rather than the TO. R1.3 and R2.3 specifies that the TP be given this data. Both the TPs and Transmissions Operations entities need to have accurate model information and the Operating studies are much more critical for BES reliability.
No
System models are used for reliability purposes beyond planning purposes, which are at best, an educated guess at what the system will look like out in the future. The real time and day ahead models are most significant for assuring reliable system operation. It would seem that if the TP needs model data different than the Transmission Operations needs, the 1st step is for them to define a technical basis for that data. Once that is done, then the GO/GOPs can develop numbers that match those conditions. Pmax will vary on ambient temp for some types of generation, lake temps for other types and hydo conditions for those units. Without a defintion of the data based on the studies to be performed, all the GO can do is guess. If the Q capacity is determined using a staged test, the ambient temperature during the test should be provided. The planning entity can adjust to other temperatures if they desire.
No
Obviously, all units which are critical to reliability should be included, but what is critical is dependent upon system configurations. The continent wide standard should specify the largest size units critical in an interconnection and then regional standards might tighten the number based on that region's need. The SERC region currently requires real & reactive verification only for units > 75 MVA (RFC uses 85 MVA). The use of "sister" (essentially identical) units should be allowed by the standard (as is allowed in SERC's current MOD-025 procedure). Independent verification of essentialy identical units should not be required. Blackstart units (4.2.3 of Section 4 above) should not be covered under the MOD standards. They are covered under the EOP standards (EOP-005-2).
Yes
We agree that four points are sufficient to provide a straight line approximation over a unit's operating range at points from Pmax and below, but additional consideration is needed for operation above Pmax. We don't agree that four points are needed for baseload units. We strongly agree with the Commission's statement that "such a requirement for all generators may not be necessary." The lagging capability curves have a break at rated pf. Trying to represent that with a single line with end point at Pmin and Pmax would eliminate a large portion of the available capability curve around rated pf. The leading capability might be more reasonably estimated by a linear assumption. Technically, nuclear units are base load plants as are some very large coal units and thus would not be expected to operate for any significant period of time at pmin, thus the term base load is more appropriate than nuclear for excluding testing at Pmin First, we believe 2.2, of Attachment 1 to the standard, should exempt all base load units (not just nuclear units) from verification of reactive capability at minimum real power output. There are other units that the industry should be able to exempt based on their normal operating modes. Examples are peaker CTs and units that have restrictions (environmental, run of the river, etc.) preventing operation at minimum load. Finally, for units where verification of multiple points are needed, the analytical approach to verification,discussed in our responses to Questions 10, 11, and 14, serves this purpose very well. This concern is addressed in Paragraph 1321 of the FERC Order which states: "...other than baseload units, most generating units rarely operate at full MW loading. It is unclear what reactive capability is available throughout a unit's real power (MW) operating range. Therefore, we believe a clearer standard would require a verification of MVAR capability throughout a unit's real power (MW) operating range. However, we share concern with several commenters that such a requirement for all generators may not be necessary."
Yes
Provided that the verification is accomplished through staged testing or through operational data review and a unit is capable of reaching the expected over excited capability, 1 hour should be adequate to determine if equipment temps that might limit capability are stabilized. This requirement would not apply if the verification is accomplished using an engineering analysis method (see this

proposal in comments to Question 14).
Yes
We believe that there is little value to a minimum load, vars-out requirement. Also, it will be difficult to achieve since the system usually has minimum VAR output requirements when operating at minimum load. Experience has shown that a large unit cannot reach the full available lagging (many times) or leading (most times) reactive capability values due to voltage limitations. That does not mean that that capability is not available. This is exemplified by the testing of a large fossil unit (Graphic has been provided to the SDT). There needs to be standards on how model values are selected, such as, • The lagging capabilitiy values should be based on 90% of gross generator capability at minimum normal Hydrogen pressure minus aux system loads and xfmr losses • The leading capability values being modeled should be based on (UEL limiter setpoints as documented by PRC-19 coordination is probably appropriate).
Yes
No
As the draft is currently written, these two methods are understood to be allowed, but experience has shown may not be able to fully validate the available capabilites. We believe engineering analysis could be used in order for GOs to be able to verify generating unit reactive capabilities that are suitable for transmission system planning studies. The answer may be to test or operate as far as you can based on system voltage and then evaluate margin to unit thermal limts (Generator, Bus, GSUs, etc) and determine if you could reasonably have reached full capability if system conditions warrented the need.
No
We have model validation requirements but no definitions to what we are needing to validate to. The "expected value" is not clearly defined, so it is not possible to determine if 20% of this value is appropriate. Furthermore, if the "expected value" is the "D curve" for lagging Vars, we believe this is not a realistic expectation since operational data for most generating units does not approach 80% of the "D curve" value in normal operating conditions (or even in staged testing based on our experience). A recent survey of the SERC region has shown that only 34% of 85 generators surveyed performing staged Q production tests could reach 80% of their D curve lagging Q capability. The same survey showed that only 19% of 32 generators surveyed performing staged Q absorption tests could reach 80% of their underexcitation limit (UEL) characteristic setting. Therefore, the "within 20% of the expected value" requirement should be deleted. If an engineering analysis (which uses operational data for analytical model confirmation) is allowed as an alternative verification method, the 20% tolerance given above is not needed. Reference our response to Question #10.
Yes
There have historically been regional differences in unit criticality size.
No
Yes
1) This requirement will require units that normally do not run or have a very low capacity factor to be verified. Please add a provision for excluding these requirements for units that do not regularly run, similar to other NERC standard exemption requirements. 2) MVAR validation issues should be combined with generation FAC-8 issues to eliminate confusion that these seperate standards have caused. 3) Specifying Normal Operating H2 pressure in Attachment 1, section 2.5 may not produce the desired maximum Q cap results - consider changing "normal operating " to "maximum sustainable (within design limits)" 4) We suggest revising Requirements R1.3 and R2.3. Data should be submitted to the TP at the next annual update provided on MOD-010 model data. 5) Revise attachement 1 section 5.1 and 5.2 to change “last more than 6 months” to “last more than 1 year,” to align with the typical long-term planning horizon. 6) It is noted that MOD-11 which is supposed to clarify modeling data requirements has not yet been completed and approved. Yet MOD-25 is requiring verification of this data. It is also recognized that generator verification methods are producing results that are not being directly used in the models (due to various operating or system limitations). As a result, it is not clear that MOD-025 is achieving the reliablity purpose intended. 7) Since GO/GOPs do not always

model electrical systems, nor participate in interconnected system models groups such as the Master Model Working Group (MMWG), there probably needs to be a guide that clearly identifies the steps a GO/GOP needs to take to maintain models up to date. The NATF and EPRI/NAGF is considering a collaboration to do so.
No
We are not convinced that wind plants need to be included at all due to a) the uncertainty of the wind availability during a frequency excursion and b) the transient nature of any contribution that the a wind turbine may be able to provide to correct or affect the frequency excursion. It is believed that the time frame of the frequency excursion will far exceed the wind turbine's ability to sustain a correcting action.
Yes
Yes
Not sure why this question is in the CF, other than it was accidently copied from the MOD-26 CF? Synchronous condendors are MVAR devices not MW devices and thus should be covered by MOD-26, not 27, if their dynamic response is signficant to grid reliability. Since they are typically applied in weak spots of the transmission system, it's difficult to believe they would not be critical by their presence.
No
No
Yes
1) Requirement 2.1.1 requires a comparison of the on-line response to the recorded response. The comparison needs to be between the on-line recorded response and the model simulated response. 2) The VSL table for R1 has time frames that don’t match the Requirement R1 30 calendar day time frame. 3) The first paragraph of the Severe VSL for R2 needs to be split into two parts to form an additional OR statement which reads: "The GO failed to provide its verified model(s)" OR "The GO provided the verified model(s) more than 90 calendar days late to its TP in accordance with the periodicity timeframe specificed in MOD-027 Attachment 1." 4) The second paragraph of the Severe VSL for R3 is not grammatically correct and does not match the Requirement R3. Please consider changing it to read: "The GO's written response failed to contain one of the following: the technical basis for maintaining the current model, a list of future model changes, or a plan to perform another model verification." 5) For the Lower, Moderate, and Higher VSLs for R5, please consider placing "including a technical description if the model is not useable" within parenthesis to aide in understanding the measure. 6) For the second paragraph of the Severe VSL for R5, please consider rephrasing to read: "The TP provided a written response without including confirmation of all specified model criteria listed in R5, parts 5.1 through 5.3." 7) Attachment 1 contains multiple copy/paste errors (from MOD-026) and was difficult to constructively comment on due to these. 8) The frequency response of a generation unit is intrinsically connected to the Pmax values used in various system models (old MOD-24). These 2 validation efforts should be connected and the following modeling parameters defined and addressed: Pmax • The continuous operating limit • The ultimate max emergency output. • Should there consider weather conditions (summer or winter, etc.). • PMAX associated with Transient stability – is it the same as for LF • Is this on the order of 105% or 110% or ??% of normal max loading A graphic illustrating this point has been provided to the SDT.
No
See response to Question #2 below.
No
We feel that this standard is not applicable for solar facilities or induction type generators used in some wind farms. Several different exemption criteria are specified in the various GVSDT standards. We understand the distinction made for MOD-26/27 (100MVA) from the MOD-25 criteria (75MVA). The standard likely should be consistent with one or the other, rather than having a 3rd criteria (50MVA). For this standard, we recommend that only units > 75MVA be included. If the significant aggregated plant MVA size is > 75 MVA, then an individual unit included as significant should also be 75 MVA. Consider the case where a 21 MVA machine would be included in the scope, yet a 'five unit,

15 MVA each' plant (totaling 75 MVA) would be excluded. A 20MVA machine today can not impact the system like it could have 20 years ago. A technical basis for including units as small as 20MVA in all regions needs to be provided. NERC is focusing on standard requirements that have significant impacts on system reliability, and including units less than 75MVA seems to be inconsistent with this philosophy. We do acknowledge that in some areas of the BES, some units ≤ 75MVA may be identified by a transmission entity as critical for BES reliability. Regional criteria are allowed to address these concerns to make requirements applicable to such units identified as critical for BES reliability in that region.
No
See the purpose of the standard. It's not clear why a generation protection/control coordination requirement would be applicable to non-generation resources, other than maybe synchronous condensors.
Yes
Yes
Yes
No
Electronic documentation of coordination efforts should be considered accecptible as long as a revision history is maintained. Past history is not significant to present/future reliability. Only the presentation documentation of coordinations is needed along with proof that the results have been implemented. The bullet listed under 1.2 Data Retention implies that all records need to be kept indefinitely.
Yes
There may be regional variations in regional critical size criteria.
Yes
1) In several places in the posting documents there is a discrepancy in the size of the synchronous condensor that is in the scope of the standard, some places list the size criteria at 20 MVA, and others state 50MVA. 2) The Implementation plan document effective date is incorrect for the 20% completion step - it states two years rather than the appropriate one year. 3) Section 5.2.5 is missing from effective date in the draft standard. 4) R1.1.1.1 seems to infer that the 40 relays should be set inside the Capability curves and the SSSL. The 40 relay should be set inside the SSSL but may be outside the capability curves as it is intended to prevent a pole slip. AVR protective functions may be set to protect the capability curves.

Lincoln Electric System
Yes
Yes, but the verification periods should be different for Real and Reactive Power. It is not unreasonable to expect a Real Power verification test on an annual basis, as this data is usually available annually at some time when the unit is operated to serve load. It states the purpose of the Project 2007-09 Generator Verification is: “To ensure that generator models accurately reflect the generator’s capabilities and operating characteristics.” Without annual operation to verify Real Power it appears difficult to ensure this objective with a high degree of confidence.
Yes
The Real Power Data should be adjusted based on temperature to indicate what the output for the generating unit would be for peak summer conditions for a summer peaking utility and peak winter conditions for a winter peaking utility. Humidity is also factor that affects the output of units with evaporative cooling as well as the performance of cooling towers. Previously as part of the Mid-continent Area Power Pool our utility was required to submit monthly capacity accreditation of the generating units that was adjusted based on the ten-year average of the high temperature for the peak load day of the month. For the summer months this provided a fairly accurate estimate of the

actual generating capabilities of the unit in the summer months. In the winter using the high temperature for the peak day was not quite as accurate, since the peak on the winter day does not usually coincide with the peak temperature for the day, but the ambient high temperature on these days is usually quite low. Even in the shorter months the output data may be beneficial to the Transmission Planner when large units in a region are out for maintenance. It is questionable as to how easy it would be for the Transmission Owner to apply the correction factors to other ambient temperatures if they are only given the temperature at the time of verification test. For gas turbine units without some form of inlet cooling the output may vary by as much as 30 percent from summer to winter ambient conditions. This is a significant amount of generating capacity.
No
The definition of “expected value” needs to be more clearly defined as it is somewhat unclear. The verification should probably be within at least 5% of the expected output of the generating unit for a given ambient temperature, rather than 20% as stated in this draft. For a simple-cycle gas turbine the real power output for the verification test would in most cases be greater than what it would be for summer peak conditions due to the higher generator output that typically occurs with these units as the turbine inlet temperature decreases. It is usually desirable to test the unit with the same conditions that the unit will be most needed. For summer peaking utilities this would be with reasonably high ambient conditions. When only recording real power data it is usually not that difficult to recordthe data in the summer when the units are already operating to serve the load. The coordination to record reactive power data at this time may be more difficult.
Yes
Under the Applicability Section, 4.2 Facilities, the “applicable units” are stated to have an average capacity factor greater than 5% over the last three calendar years and that the “majority of industry agreed with the standard MOD-026-1 5% capacity factor threshold” (Background Information: “Standard MOD-027-1” - #3). LES is concerned that the industry builds power flow models for future summer peak conditions, and therefore, LES is not convinced that the capacity factor threshold of less than 5% is a good indication of what units are on-line in these future models. Therefore, the goal for verification of the dynamic models associated with 80% or greater of the connected MVA per Interconnection may not be achieved. LES believes that a check (i.e., survey) of the ERAG MMWG models would be a good indication of whether or not the capacity factor threshold satisfies this objective.

MOD-025-2 requires that data be submitted by GOs or TOs to their respective Transmission Planner

(R2.3). It should not require that it be submitted to the Transmission Owner as the TO has no need for this data.
Yes
We believe that the Real Power data submitted should be corrected to a temperature specified by the entity that requires the verification of Real Power capability. That entity is probably the Resource Planner or the Planning Coordinator– see the Functional Model, version 5 posted at http://www.nerc.com/files/Functional_Model_V5_Final_2009Dec1.pdf. For Generation Owners that belong to Regional Transmission organization that has a reserve margin criterion, it is probably registered as a Resource Planner and Planning Coordinator. For example, PJM, NYISO, and ISO-NE are each registered as a Resource Planner and a Planning Coordinator.
Yes
No
For clarification, Attachment 1, paragraph 2.2 does not require Reactive Power capability verification for wind and photovoltaic at minimum Real Power output. It also appears that Nuclear Units are also exempt. “Nuclear Units” has the term “Units” capitalized, but it is not in the NERC Glossary and should probably be lower case. We suggest that R2.2 be redrafted as follows: “Verify Reactive Power capability of all generating units other than nuclear, wind and photovoltaic for maximum overexcited (lagging) and under-excited (leading) reactive capability at the minimum Real Power output at which they could normally be expected to operate. In addition, nuclear units should be exempted from under-excited Reactive Power verification at maximum Real Power capability because such verification may lead to concerns with unit stability and potential under-voltage conditions on internal nuclear plant safety buses. This would require a change in paragraph 2.1 For other units, these points are acceptable.
Yes
The drafting team should provide the rationale for the one hour minimum for over-excited reactive capability.
Yes
This documents the system conditions and unit conditions when limits are reached.
Yes
A 50 MVA minimum size for synchronous condensers was not found in the proposed standard – see paragraph 4.2.1 which has a 20 MVA minimum. Whether the limit was intended to be 50 MVA or the 20 MVA limit stated in the draft, the SDT should provide a justification of basis for that MVA threshold. The impact that such smaller units would have on the BES is not substantial enough to justify requiring their inclusion in this standard.
Yes
No
Attachment 1 is unclear as to the implementation of the 20% requirement. Paragraph 2 states “Operational data from within the year prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is within 20% of the expected value:” As written, it appears that the 20% only applies to operational data “within the year prior to the verification date.” Does the 20% apply also to staged tests? If not, why not? Paragraph 5.2 in Attachment 1, regarding operational tests, is also relevant: “If data for different points is recorded on different days, the Generator Owner shall designate one of the dates as the verification date, and report that date as the verification date on MOD-025- Attachment 2 for periodicity purposes.” Is the SDT proposing to comingle operational data from one-year prior to the verification date as long as it is within 20% of the expected value? If so, what value would be reported – the test data that may be up to 20% higher or lower than the expected value or the expected value?
No
Yes

We have listed several concerns and questions below: a. We believe that Reactive Power capability at minimum Real Power output needs to be verified when a unit is installed and only verified thereafter when the generator itself is modified. Performing such tests will be difficult to run due to system voltage limitations at minimum Real Power generator output. This would require a modification or Attachment 1, paragraph 2.2, and paragraph 5. b. For the VSL's for requirement R2, the last paragraph of a Severe VSL should be modified as follows: "The TO verified and recorded the Reactive Power capability of its applicable synchronous condenser, but submitted the data to its Transmission Planner more than 120 calendar days from the date the data was recorded." c. The comments below reference Attachment 1. i. Paragraph 2 and its subparts would be more easily understandable if companion tables were provided that summarized the information. At last two tables would be helpful – one for traditional dispatchable resources and one for variable resources. ii. In paragraph 3, whether the verification is staged or operational should be provided. iii. In paragraph 3.2, the requirement to supply the voltage schedule provided by the Transmission Operator would not appear to be applicable for a staged test. Trying to test Reactive Power limits while maintaining a prescribed voltage schedule in not practical.
No
Yes
Yes
No
No
Yes
Nuclear units are often prohibited by their NRC licenses from having their governors engaged for frequency response. Since the Purpose of the standard is to "accurately represent generator unit real power response to system frequency," nuclear units with the restriction described above will have no response. These units should be explicitly exempted from the standard in the Applicability section.
Yes
No
The question and the standard contradict each other. The standard states that it applies to "synchronous condensers > 20 MVA" not "rated > 50 MVA. We do not agree with the threshold MVA applicability for generators. Field testing and industry history do not warrant the need for such a low MVA threshold. We suggest that the threshold be for larger units (rated > 500 MVA) that have the ability to significantly impact BES reliability. The resources required to apply this standard to smaller units compares to the benefits to the BES and the GO are generally not justified in most regions. However, it can be argued that smaller units can have a significant impact on the BES, especially in weak systems. Therefore, we recommend that an inclusion criteria be developed that would require units in such regions to be included.
No
First, the inclusion of "variable static reactive resources located at asynchronous generating facilities (e.g. wind and solar sites)" was not noted in the standard. Second, we do not believe that including other static reactive resources that are not located at generating sites would materially impact reliability
Yes
Yes
Yes

Yes
Yes
Yes
The SDT should review R1. As it reads now, the phrasing of the first paragraph makes it difficult to understand what equipment is included for generator units and what is included for synchronous condensers.

Independent Electricity System Operator
Yes
We support this approach. The real and reactive power capabilities are related and hence having them addressed in one standard would enhance verification efficiency.
No
(1) The receiving entity cited in this question (Transmission Owner) seems different than the entity indicated in the standard (Transmission Planner). If it is not a typo, then we may be missing something. Regardless, we commented previously (on MOD-024-2) on a related subject in which we indicated that given the purpose of the standard, which now reads: “To ensure that planning entities have accurate generator Real and Reactive Power capability data when assessing Bulk Electric System (BES) reliability”, we believe that the data is used for planning assessments that could entail both resource adequacy and transmission reliability, and may even include short or near-term transmission reliability assessments. In view of the facility ownership and potential users, submitting the data to the Transmission Owner does not seem to be logical from the following standpoints: a. The TO does not own the generators and may not actually use the data at all if it does not perform transmission planning assessments; b. The Transmission Planner is the entity that conducts transmission planning assessments; c. Other planning entities that use this data are the Planning Coordinators and Resource Planners. For the above reasons, a more logical entity to receive this data and be the one that requests for data is made by other entities that have a need for the data such as Transmission Planners, Resource Planners, Reliability Coordinator and Transmission Operator, would be the Planning Coordinator. We suggest to change Transmission Owner to Planning Coordinator. (2) And also in view of the potential use of this data, we suggest the purpose of the standard be reverted back to its previous version: “To ensure accurate information on generator gross and net Real Power capability is available for steady-state models used to assess Bulk Electric System reliability.”, or be revised to: “To ensure that [the word planning removed] entities have accurate generator Real and Reactive Power capability data when assessing Bulk Electric System (BES) reliability”.
No
(1) We do not support the notion that a Transmission Owner has the technical expertise to adjust a generator’s real power capability to reflect a difference in ambient temperature. If anyone, it should be the Generator Owner. (2) There seems to be little value in reporting the ambient temperature for the purpose of making adjustments to measured Real Power capability since it is only one of the several factors that could affect the real power output of a generator. (3) Notwithstanding the concerns expressed above, to make such an adjustment with some degree of accuracy, the responsible entity needs to have the information on that capability which corresponds to the ambient temperature for which the adjustment is to be made. It thus suggests that a capability-temperature curve be first established to provide credible references, implying that the Generator Owners must conduct a series of verification tests under different ambient temperature conditions. This is overly cumbersome,and creates unnecessary burden to the GOs. We suggest that this requirement be removed from Attachment 1.
No
The Applicability section is not clear enough to expect consistent application. When the facility that makes the connection at 100 kV or above is not owned by the Generator Owner (e.g. a Distribution Provider might own this facility) the present expression of the standard will lead to inconsistencies. Facilities with identical electrical characteristics may or may not be subject to this standard only because of the structure of the ownership of assets. To address this, we propose revising section 4.2

by removing the condition for interconnection at 100 kV and above and aligning with the standard's purpose: 4.2.1 Individual generating unit or synchronous condenser > 20 MVA (gross nameplate rating) considered in BES reliability assessments.. 4.2.2 Generating plant/Facility > 75 MVA (gross aggregate nameplate rating) considered in BES reliability assessments. 4.2.3 Blackstart units, regardless of size that are included in a Transmission Operator's restoration plan.
No
One of the purposes of Project 2007-09 is to ensure that generator models accurately reflect the generator's capabilities and operating characteristics. To achieve this, it is important that at least the minimum data requirements of entities that require these data are satisfied. This includes verifying the generating unit's capability curve or at least that portion of the curve between its minimum and maximum real power capability. We therefore recommend including a new bullet 2.3 in MOD-025 Attachment 1 similar to bullet 2.1 that requires verification of Real and Reactive Power capability of all generating units at maximum over-excited and under-excited reactive capability at maximum gross Real Power capability (PMAX) where this is different from the generating unit's rated gross Real Power capability. The additional data points provided by this measurement (i.e. Qmax and Qmin at PMAX) will allow for a more complete verification of the generating unit's capability curve. Footnote 1 of MOD-025 Attachment 1 seems to use "rated gross Real Power" and "maximum [gross] Real Power" interchangeably. In general these two ratings may be different. We suggest deleting the footnote.
Yes
Yes
Yes
The standard should also be applicable to static var compensators and similar equipment used in reliability assessments of the BES.
No
There is no technical justification provided to support the 50 MVA criterion. Absent this, we propose to use the 20 MVA for generators as a general criterion for synchronous condensers as well.
Yes
No
We have difficulty interpreting the 20% in Item 2 of Attachment 1, which says: "Operational data from within the year prior to the verification date is acceptable for the verification as long as IT (emphasis added) meets the criteria in 2.1 through 2.5 below and is within 20% of the expected value:" We interpret that the "IT" refers to the operational data. As such, we do not understand the "within 20% of the expected value". Does it mean the generator's real power output during the period from which operational data was collected must be within 20% of the generator's declared or name plate capability, or what? We need clarification, and suggest a revision to this Item 2 to provide the clarity. As written, we are unable to comment on the acceptability of the 20%.
No
No
Yes
In our previous comments, we raised a concern over the detailed requirements in Attachment 1 which in our view are overly prescriptive. Specifically, the requirements listed in Item 3 of Attachment 1 are too detailed, and some of the items listed in 3.1 to 3.6 are not needed or relevant to the provision of verified data for modeling or BES reliability assessment, but they create unnecessary administrative burden. For example, what would be the use of voltage at the high side of the generator step-up and/or system interconnection transformer(s) and the tap settings of these transformers in the application of the recorded real and reactive capabilities to modeling and reliability assessments? And what would be the required actions if the voltage levels and/or the transformer tap setting in the loadflow model or in real time are different from the reported values? Imposing the reporting requirement without a clear statement of the intended use, with justification, is unnecessary and

should be dropped. Further, we request clarification regarding the phrase “at the end of the verification period” in 3.1 and 3.3? Does it mean the time when the verification test ends, i.e. at the end of the 1-hour period referred to in Attachment 1, bullet 2.3? If the verification is provided by operational data, what would constitute “the end of the verification period”? We believe Attachment 1 needs only to specify the sustainability (Items 1 and 2) and the periodicity (Item 5). We also respectfully disagree with the SDT’s response to our previous comments on Attachment 1. The SDT’s view that (excerpt from Comment Report) “The SDT believes that attachment one does not contain requirements but provides clarity to the Requirements of the Standard.” is incorrect since it is clearly indicated in Requirement 1.1 to “Verify the Real and Reactive Power capability of its generating units and shall verify the Reactive Power capability of its synchronous condenser units in accordance with Attachment 1.” According to the general rule for NERC standards, an attachment is a part of the standard that must be complied with, and hence any items contained in an attachment are mandatory requirements. With that understanding and with the way Attachment 1 is included in Requirement 1.1 that the items in Attachment 1 are not there for clarity but are requirements that must be complied with, we urge the SDT to remove the entire Item 3 from Attachment 1 as the information required in that item does not add to the intended use of the verified data. We do not have the same concern over Attachment 2 since it is made clear in Requirement 2.2 and in the Attachment itself that use of other forms is acceptable and hence use of the diagram is not mandatory. In Attachment 1, step 2.4 seems to be inconsistent. For the over-excited check, record should be taken at min. and max. real power output (i.e. it should state... data required in 2.1 and 2.2.) The table in Attachment 2 should be improved to match data to be recorded in Attachment 1 (i.e. there should be two columns for MVAR to record lagging and leading reactive power for a given MW). MOD-025 Attachment 1 bullets 2.1 and 2.2 should stipulate that Generator Owners and Transmission Owners conduct verification at generator terminal voltages as close as possible to rated terminal voltage. Finally, the standard should use SI units (e.g. active power not real power, Mvar not MVAR).
No
No, we are not aware of any, but the Applicability Section of the draft standard does not contain specific references to variable energy resource plants/facilities. It only covers generating units and plants of certain sizes for the three (and Quebec) Interconnections without any specificity on generator types. Was it an oversight or did the SDT suggest that the “generating units” suffice to generally include all types of energy resources?
No
We do not agree with this approach. Currently, the applicability threshold of nameplate rating greater that 100MVA is too high. The combined performance of many units smaller than the threshold identified in the applicability section will have a material effect on the system frequency response. Even if the standard leads to the provision of useable model to the Transmission Planner for the applicable generating units, without sufficient good models, it might not be possible to meet the goals of accurately represent generating unit active power response to system frequency variations and predicting system frequency response to contingencies. We repeat the concern we expressed in our comments to MOD-025-2 related to the applicability criteria “connected at the point of interconnection at greater than 100 kV.” This condition will lead to the exclusion of units that are material in dynamic simulations and to which the applicability should extend. Also, we wonder whether the inclusion of Planning Coordinator in the question is a typo or the standard is missing the Planning Coordinator as an applicable entity. Please clarify.
Yes
No
No
Yes
We do not agree with some of the requirements. i. R1: Standards should stipulate the “what’s” not the ”how’s”. To avoid the perception that the requirement is prescribing the “how”, we suggest simplifying the language of Requirement R1 by replacing “Instruction on how to obtain” with “Instructions for obtaining”. Further, are all three bullets meant to be complied with or are they listed as options? We understand that the general rule for NERC standards is that those items that must be

complied with are labeled as parts (e.g. 1.1, 1.2, etc.) while those that are options or examples that do not need to be complied with are placed in bullets. Please verify this with the Director of Standards Process. ii. R2.1: The phrase “models acceptable to its Transmission Planner” begs the question on what is deemed acceptable and what if the GO disagrees with the TP’s determination. To address the two issues, we suggest adding a requirement for the TP to specify the models (or change the second bullet in R1 to achieve this), and change the wording in R2.1 to “in accordance with the models specified by the TP (or referencing the requirement part that contains the specification). Another possibility would be to remove this phrase altogether since the Transmission Planner would in any case have to declare the model “useable” pursuant to Requirement R5. iii. R5.3: It stipulates as a criterion that a disturbance simulation results in the turbine/governor and Load control or active power/frequency control model exhibiting positive damping. We do not agree with the condition that the simulate must exhibits positive damping. Even with an accurate turbine/governor and Load control or active power/frequency control model, system damping is affected by many other dynamic performance contributors such as other generators, system topology, power flow levels, voltage levels, excitation system and power system stabilizer settings, etc. In short, having an accurate turbine/governor and Load control or active power/frequency control model does not necessary guarantee or equate to positive damping. Similar arguments may also apply to R5.1 and R5.2, i.e., that having an accurate model does not necessarily mean that the modeling data can be initialized without errors, and a no-disturbance simulation always results in negligible transients. We suggest the SDT to revise the determination criteria, based solely on the models specified by the TP, the data provided by the GO meeting the specified model requirements, and the tracking of actual performance, where applicable. iv. We decide not to comment on the Measures and other compliance elements at this time in view of the comments, above.
Yes
No
There is no technical justification provided to support the 50 MVA criterion. Absent this, we propose to use the 20 MVA for generators as a general criterion for synchronous condensers as well.
No
The SVCs serve quite different purpose and react to system conditions quite differently compared to their generator/synchronous condenser counterparts. Further, SVCs do not “trip”, per se, they vary their reactive outputs including going to and crossing 0 MVar and hence some of the interactions between the device and its protection systems in the case of generators/synchronous condensers are not applicable to SVCs.
Yes
We do not have any real issues with the purpose statement; however, we offer an alternative to add a bit more positive spin (as opposed to preventing tripping): To improve the reliability of the Bulk Electric System by ensuring proper coordination of generating unit/facility voltage regulating controls and limit functions with generator capabilities and protection system settings.
No
We interpret the wording “shall retain the latest and the prior evidence of compliance with Requirement R1, Measure M1” to mean the evidence for the last and the one before last compliance assessments. We question the need to keep the two sets of evidence. Keeping only the evidence for the last compliance assessment would suffice.
No
Yes
1. The standard introduces a local definition: “in-service”, that is subject to interpretation. Does “in-service” mean: - Installed but may or may not be put to service (e.g. mothballed)? - Installed and can be put to service at any time? - Installed and on-line? Generators/synchronous condensers will have a reliability impact only when they are connected to the grid (put on-line). However, the timing of these facilities to be put on-line is at the discretion of the GOs and perhaps under some conditions specified by other entities such as the TOP or RC. It is thus conceivable that installed facilities can be

put on-line at any time. To ensure proper reliability performance, we suggest to change “in-service” to “installed” to make sure the facilities meet the standard requirements if and when they are put on-line. 2. R1.2: The wording: “verify the existence of the coordination” does not drive home the intent of ensuring the settings are coordinated and reviewed once every 5 years or as changes occur. We suggest to change R1.2 to read: “shall review and revise as necessary the coordinated settings identified in Requirement R1 at least once every five years or within….”

Both the Transmission Owner and Transmission Planner should receive it.
Yes
The ambient temperature at which the testing is performed would be an important data item. Because of greater familiarity with the equipment and its capabilities, any temperature adjustment to arrive at a different specified real power value should be performed by the Generator Owner. The Transmission Owner/Transmission Planner, who would be performing system modeling and study work, would be the entity most appropriate to specify temperature values for which temperature adjustment factors would be determined. Capabilities at different ambient temperatures need to be provided to meet the modeling requirements of the MMWG, and that the GO and TO should agree on what ambient temperatures to assume for the temperature adjustment.
No
The allowance for exemption of sister units should be permitted. Only one verification for sister units should be required. Testing for units less than 75 MVA should not be required, as these have little impact on grid reliability.
No
While the testing regimen for the generator owners should not be made unduly burdensome, the four point test, if used to provide a straight line approximation of the generator capability, could result in somewhat more conservative reactive power operating limits for other real power levels as compared to a generating unit’s published capability curve. The accuracy of the straight line approximation would vary on a generator-by-generator basis.
Yes
No
(1) From transmission perspective: If a plant limit is encountered in the testing, and it is a hard limit not to be exceeded, then the capability at this limit should be recorded. If a limit is identified on the transmission system such that the testing cannot be completed, then the capability should be noted but this would not be a firm limit. (2) From GO perspective : Our testing people won't know if the

transmission system is causing the limit because they aren't allowed to "see" the transmission system. Second, they are not allowed to test at time of seasonal peak because their testing may jeopardize the availability of the unit and testing during the fall and spring will mean higher voltages and frequently some type of testing limit is reached. Engineering calculations and justification should be allowed. Finally, we thought the 20% "margin" was to allow for these unavoidable risk restraints on testing the units. If a plant limit is encountered in the testing, then the capability at this limit should be recorded. However, it is unclear how this data, and the 20% margin, should be used in the verification process. We request the SDT clarify how data readings within the 20% margin should be used to determine the Real and Reactive capabilities of a generator or plant.
Yes
No
The size of synchronous condensers to be verified should be consistent with generator sizes which need to be verified. Testing for units less than 75 MVA should not be required.
No
While these two methods are acceptable, there is not enough flexibility included to allow for engineering support if necessary.
No
While the 20% margin is appropriate and appreciated, it is unclear if verifying the output of a generator at 80% of real rated output will satisfy regulator rating requirements at the time of seasonal peak. Thus, from the user of this data (e.g. planners), this % is too great. From the generator owner and testing personnel , this % makes sense and seems appropriate. We would suggest the SDT provide basis for this % and a guidance how it should be used for all conditions.
No
Yes
There may be a conflict with MISO Module E as it relates to duration of the testing, e.g. one hour versus longer than hour duration.
Yes
(1)If a demonstrated value is less than the corresponding expected value, then the generator owner should be required to provide calculated values for reactive capability in addition to the demonstrated values (this should be included in R1). Without this, the data is useless to the Transmission Owners for system modeling use. (2) There may be different usage of the term 'point of interconnection" in the industry. We suggest the SDT to consider proposing a formal definition of this term. (3) We understand the 20% and 10% variances allowed in the draft are for testing purposes. However, it's unclear how they should be used. For example, are they relative to the results at time of seasonal peak, or just maximum output at the time of testing? (4) Notes 1 and 2 should be Requirements. It is difficult to determine how compliance with footnotes will be audited. (5) Engineering judgement should be clearly allowed when meter data (for example no meter at the high side of a GSU), auxiliary data, etc. is not available as required in Attachment 1. (6) Sister Unit exemptions should be allowed for generators that are essentially identical and operated in an identical fashion.
No
Yes
Yes
The question does not appear to be worded correctly. Draft Standard MOD-027-1 deals with turbine/governor and load control, rather than excitation control systems.
Yes
(1) There may be different usage of the term 'point of interconnection" in the industry. We suggest the SDT to consider proposing a formal definition of this term. (2) R4 of the Draft references footnote

5. It appears this footnote is overly broad and requires editing to precisely identify equipment systems that can truly impact system reliability. This footnote should be edited so it becomes either a new Requirement or a new set of sub-requirements. No other systems should be included.
Yes
Yes
Yes
Question should be directed at transmission planners. I would believe the static VAr compensators are required for system voltage support, similar to synchronous condenser or generation.
Yes
Yes
Yes, only if settings need to be verified. No if testing needs to be done to verify settings.
No
(1)Volts per hertz and stator overvoltage protection are more applicable during unit start-up, not running conditions, where the system maintains the voltage and frequency. These should be eliminated. (2) The standard needs to be clear on what relay elements need to be included if enabled. (3) The standard needs to be clear on how to plot the diagrams to incorporate operating voltage. For example the generation is most stable while maintaining maximum permissible voltage and producing the most VAr's possible. Therefore should the plot be at maximum voltage of 1.05pu. (4) It would be helpful to have some reference for where the development of the Steady State Stability Limit equations in the draft standard could be found. None could be found on the NERC website. We are concerned that the method proposed for calculating steady state stability limits does not include sufficient conservatism.
No
Retaining studies for 10 years seems unreasonable and could lead to confusion. Retaining data from previous audit seems reasonable to assure studies are being done every 5 years. Regarding R1.1.2, in order to limit the need to take unnecessary outages, which may be required to verifying settings, verification of settings should be limited to a one time only, upon installation or setting change.
No
Yes
(1) Standard needs to be more specific and clear on what evidence is need for 1.1.2. (2) Violation Severity Levels seem arbitrary and need to be reviewed, considering the standard is giving four years to be 100% complete. The system is presently operating with few if any miss-coordination on these protection systems. (3) There may be different usage of the term 'point of interconnection" in the industry. We suggest the SDT to consider proposing a formal definition of this term. (4) R1.2 states there must be verification of coordination within 90 calendar days following "...identification or implementation..." of systems or changes. There is typically an enormous difference between the "identification" and the "implementation" of these systems. Would the SDT please clarify what is expected? (5) Sister Unit exemptions should be allowed for plants with multiple identical units that have identical equipment and control systems. (6) This Standard should only apply to generators with a nameplate rating of > 75 MVA and a connection to the interconnected transmission grid > 100 kV. (7) The use of "Stead state stability limit" in bullet #4 in R1 and the use of the phrase "...system steady state operating conditions." in R1.1.1, seem to conflict. Is the term in R1 intended to represent system conditions AFTER an N-1 contingency, or during N-0 conditions?
Group
SERC Generation sub-committee
Joe Spencer - SERC staff
Yes
Please clarify if real and reactive verification can be performed at different times.
No

The TP or the PC (PA) is the entity needing the data, rather than the TO. R1.3 and R2.3 specifies that the TP be given this data.
No
Providing the ambient temperatures at the time data is collected is acceptable. However, there is no simple correction factor that can be provided. Reactive capabilities under different conditions cannot be assumed to be the same.
No
We believe that Section 4 Applicability (4.2.1 and 4.2.2) for this standard should be revised to match the Section 4 Applicability for MOD-026-1 and MOD-027-1. NERC is focusing on standard requirements that have significant impacts on system reliability. Including smaller units without demonstrating their criticality to the system appears inconsistent with this philosophy. Verification for smaller units should only be required if technically justified by the Planning Coordinator as specified in 4.2.4 of MOD-026-1. The use of "sister" (essentially identical) units should be allowed by the standard (as is allowed in SERC's current MOD-025 procedure). Independent verification of essentially identical units should not be required. Blackstart units (4.2.3 of Section 4 above) should not be covered under the MOD standards. They are covered under the EOP standards (EOP-005-2).
No
Although we agree that four points are sufficient to provide a straight line approximation over a unit's operating range, we don't agree that four points are needed for baseload units. We strongly agree with the Commission's statement that "such a requirement for all generators may not be necessary." First, we believe 2.2, of Attachment 1 to the standard, should exempt all base load units (not just nuclear units) from verification of reactive capability at minimum real power output. There are other units that the industry should be able to exempt based on their normal operating modes. Examples are peaker CTs and units that have restrictions (environmental, run of the river, etc.) preventing operation at minimum load. Finally, for units where verification of multiple points are needed, the analytical approach to verification,discussed in our responses to Questions 10, 11, and 14, serves this purpose very well. This concern is addressed in Paragraph 1321 of the FERC Order which states: "...other than baseload units, most generating units rarely operate at full MW loading. It is unclear what reactive capability is available throughout a unit's real power (MW) operating range. Therefore, we believe a clearer standard would require a verification of MVAR capability throughout a unit's real power (MW) operating range. However, we share concern with several commenters that such a requirement for all generators may not be necessary." Also, The GS does not believe that verification for leading capability should be required where operational practices preclude operation in a leading mode.
Yes
Provided that the verification is accomplished through staged testing or through operational data review. This requirement would not apply if the verification is accomplished using an engineering analysis method (see this proposal in comments to Question 14).
Yes
But, we believe that there is little value to a minimum load, vars-out requirement. Also, it will be difficult to achieve since the system usually has minimum VAR output requirements when operating at minimum load. Experience has shown that a large unit cannot reach the full available lagging (many times) or leading (most times) reactive capability values due to voltage limitations. That does not mean that that capability is not available. This is exemplified by the testing of a large fossil unit below (attempted to include graphic).
No GS comment
No
It is noted that this criteria is not consistent with the criteria for generators or with 4.2.1 of the draft standard.
No
As the draft is currently written, these two methods are understood to be allowed. However, we believe a third alternative, engineering analysis, is needed in order for GOs to be able to verify generating unit reactive capabilities that are suitable for transmission system planning studies (See our Comment 2 under Question 14 for additional discussion on the verification methods.). It is proposed that Requirement R1.1 be re-written as follows: "Verify the Real and Reactive Power

capability of its generating units and shall verify the Reactive Power capability of its synchronous condenser units in accordance with either Attachment 1 (staged testing or operational data) or by a new Attachment 3 (addressing engineering analysis)." The SERC GS could provide a template for this. Requirement R1.2 could then be qualified to be limited to reporting the results from staged testing or the use of operational data, and a new R1.3 could be inserted to require suitable reporting of the results from an engineering analysis. The time horizon of the two requirements in this standard are Long-Term Planning. MOD-025-2 does not have to focus solely upon operational testing to determine capabilities used for planning entity models. It is noted that TOP-002-2a R13 now requires the GOP to perform real and reactive capability testing at the request of the BA or TOP. The test can be specified if determined to be necessary by the BA or TOP.
No
Since the "expected value" is not clearly identified, it is not possible to determine if 20% is an appropriate value. Furthermore, if the "expected value" is the "D curve" for lagging Vars, we believe this is not a realistic expectation since operational data for most generating units does not approach 80% of the "D curve" value in normal operating conditions (or even in staged testing based on our experience). A recent survey of the SERC region has shown that only 34% of 85 generators surveyed performing staged Q production tests could reach 80% of their D curve lagging Q capability. The same survey showed that only 19% of 32 generators surveyed performing staged Q absorption tests could reach 80% of their under excitation limit (UEL) characteristic setting. Therefore, the "within 20% of the expected value" requirement should be deleted. If an engineering analysis (which uses operational data for analytical model confirmation) is allowed as an alternative verification method, the 20% tolerance given above is not needed. Reference comment 2 under Question 14 for additional discussion on the verification methods. Any operational data should be allowed if accompanied by engineering analysis that calculates appropriate expected limits. This will be more useful to the Transmission Planner than a value from operational data within 20% which does not give the appropriate expected limit.
No
No
Yes
1) This requirement will require units that normally do not run or have a very low capacity factor to be verified. Please add a provision for excluding these requirements for units that do not regularly run, similar to other NERC standard exemption requirements. 2) The standard needs to allow the inclusion of engineering analysis (with operational data) to supplement or replace testing when appropriate (see comments to question #10). It is noteworthy that the original NERC Board Approved version of this standard states in requirement R1.3 that acceptable methods for reactive capability verification "include use of commissioning data, performance tracking, engineering analysis, testing, etc." This represents the "allowance to use of all the tools in the toolbox" approach which is appropriate when no single tool is sufficient to accomplish the stated reliability objectives, consistent with the FERC Acceptance Criteria of a Reliability Standard (reference Paragraphs 321, 324, 328, 332). This approach is reflected in the SERC regional procedure for MOD-025-1 which was developed by a joint transmission-generation task force. 3) The 5 year test interval should be changed to a 10 year interval since there is a provision for re-verification with an associated 10% system change. 4) In R1.2 and R2.2, the phrase "same information" is used, while in M1 and M2 the phrase "equivalent information" is used - we suggest changing R1.2 and R2.2. to match the M1 and M2. 5) Specifying Normal Operating H2 pressure in Attachment 1, section 2.5 may not produce the desired maximum Q cap results - consider changing "normal operating " to "maximum sustainable (within design limits)" 6) In Attachment 1, section 2.2, we suggest changing "they could normally be expected to operate" to "they are normally expected to operate". 7) We suggest revising Requirements R1.3 and R2.3 to read: "Submit the capability information to its TP within 90 calendar days of completion of the verification." to clarify these requirements and to make them consistent. We also believe 90 days will create an undue hardship for GOs who own a large number of generators and thus we also request that this requirement be revised to allow additional time when authorized by the TP or PC. 8) The first paragraph of the Compliance Data Retention Section D 1.2 is difficult to understand. Please simplify using multiple sentences, if possible. 9) In the VSL table for R1 and R2, we suggest changing the

phrasing "from the date the data was recorded" to "from the verification date" each time it is used (7 times). 10) In the VSL table for R1, both the first and fourth items are not needed in the list of the four items which make up the OR statement. It is sufficient to measure if the data is more than 30 days late to be categorized as Severe. 11) In the VSL table for R2, we suggest replacing the second item in the list of the two items which make up the OR statement to match the corresponding item in R1 relative to the tardiness of the submission to the TP greater than 30 days late (> 120 days total). 12) Revise attachment 1 section 5.1 and 5.2 to change “last more than 6 months” to “last more than 1 year,” to align with the typical long-term planning horizon. 13) It is noted that MOD-11which is supposed to clarify modeling data requirements has not yet been completed and approved. Yet MOD-25 is requiring verification of this data. It is also recognized that generator verification methods are producing results that are not being directly used in the models (due to various operating or system limitations) .As a result, it is not clear that MOD-025 is achieving the reliability purpose intended. 14) This standard establishes a periodic generator testing regime which, when implemented on a large number of generators, creates a continuous state of testing across the BES. We question if this approach really improves the reliability of the BES. The use of normal operational data, supplemented by analysis, represents a better approach to verify reactive capability for most generators. Targeted testing can then be used on a limited basis.

No
Testing will be more difficult if combined.
No
TP
No
No temperature adjustment can be done reliably with real and reactive power. Real power may be adjusted, but not with reactive. Generator can make the adjustment if there is a nationwide standard. If not, then regional standards will be required to specify the values.
No
Some standards need to apply to all registered generators. These do not. The minimum unit size should be at the NERC Reportable Disturbance level for the control area. Variations in any other sized unit need not even be reported. This isn't about treating all generators fairly, it is about what is affecting BPS reliability.
No
We don't agree that four points are needed for baseload units. We strongly agree with the Commission's statement that "such a requirement for all generators may not be necessary." First, we

believe 2.2, of Attachment 1 to the standard, should exempt all base load units (not just nuclear units) from verification of reactive capability at minimum real power output. There are other units that the industry should be able to exempt based on their normal operating modes. Examples are peaker CTs and units that have restrictions (environmental, run of the river, etc.) preventing operation at minimum load. This concern is addressed in Paragraph 1321 of the FERC Order which states: "...other than baseload units, most generating units rarely operate at full MW loading. It is unclear what reactive capability is available throughout a unit's real power (MW) operating range. Therefore, we believe a clearer standard would require a verification of MVAR capability throughout a unit's real power (MW) operating range. However, we share concern with several commenters that such a requirement for all generators may not be necessary." Also, we not believe that verification for leading capability should not be required where operational practices preclude operation in a leading mode. Finally, for units where verification of multiple points are needed to satisfy the FERC directive, we agree that 2 points are sufficient to verify the lagging capability and 2 points are sufficient to verify the leading capability across the generator MW operating range. However, trying to represent that with a straight line approximation between the two points could eliminate a large portion of the available capability curve around rated pf when rated MW for the unit falls within the stator rating segment of the capability curve, especially when it approaches the stator limit (which can occur for some units).
Yes
No
Only if they are required for particular units.
No
They are owned and registered differently.
No
No
Engineering analysis should also be available
No
The point is that the rating should be changed to the value tested. If a unit can't reach it, it's not a rating.
Yes
The temperature adjustment probably varies by region. There is no basis in the ROP for members on one region to vote on requirements for another region. There are nationwide standards or regional standards. The SDT can't have it both ways.
Yes
For a plant with fewer than 5 units, implementation should be at the point that the unit finally satisfies the requirement, stated differently, a single unit station would comply at the 5 year point, not at the 1 year point. Why should multiple unit plants be given more time than single unit plants. If having the units done in 5 years meets the BPS reliability need, then it should apply this alternative way. If BPS reliability needs compliance in 1 year, then all should comply.
Yes
Yes
Yes
The standard as drafted contains regional standards (ERCOT vs WECC). The ROP doesn't permit members of one region to vote on regional requirements for other regions. Regional standards will be required to implement regional differences.
Yes
Regional differences violate the ROP.

Yes
This standard imposes significant costs on generators and requires them to, in many cases unless they are also a transmission company, to hire consultants to conduct the verification. There is no evidence that unverified model data for units smaller than the level of the NERC Reportable Disturbance for the control area will have any impact on BPS reliability.
No
Not sync condensers
No
Not registered
No
There is no evidence that this needs to be done to any unit less than the NERC Reportable Disturbance level for the control area.
No

In the ERCOT Region, Oncor believes that the appropriate entity to receive this information is the Planning Authority.
Yes
Oncor believes that this information should be submitted to the Planning Authority in the ERCOT Region and that they (the Planning Authority) should coordinate with the Generator Owner in the development of any correction factor and the appropriate temperature value that should be used.
Yes
No
Unit reactive capability is limited by many factors and cannot be estimated using a straight line approach, a region of reactive capability over various power levels using actual operating limits is more realistic.
Yes
Yes
No
Oncor does not believe that there is a reliability based need for the verification of synchronous condensers under this standard
No
Oncor does not believe that there is a reliability based need for the verification of synchronous condensers under this standard therefore we believe this criterion is not applicable to this standard.
Yes
No
Any operational varation from expected should be explained by the Generator Owner and a solution to provide full capability be presented.
Yes
Oncor also recommends that consideration be given to a regional variance in that the information required of the Generator Owner as specified in R1 should be provided to the Planning Authority in the ERCOT region and not the Transmission Planner. This would align with current protocols, operating guide and planning guide as it relates to resource testing.
Yes
In the ERCOT Region, resource testing and most all communications regarding unit performance is facilitated by the Independent System Operator who is the Planning Authority. This is consistent with current, ERCOT protocols, operating guide and planning guide.
No
No
Yes
No

Oncor does not believe that the inclusion of dynamic reactive devices such as SVC's should be included in MOD-027-1
Yes
Oncor is in general agreement of the standards however, Oncor believes that the Transmission Planner in the ERCOT Region is not the appropriate receiving entity of test verification data from the Generator Owner. Oncor believes that a regional variance should be given strong consideration such that the Planning Authority would be the receiving entity of all testing data from the Generator Owner. This would align with current ERCOT protocols, operating guide and planning guide at it relates to resource testing and verification.
Yes
Sections 3.2.1 and 3.2.2 of the ERCOT Operating Guides direct resource entities to communicate operating capabilities directly to the ERCOT ISO. The ERCOT ISO is registered as the Planning Authority. Section 3.3 of the ERCOT Operating Guides direct resource entities to communicate changes to operating capabilities to the ERCOT ISO. Various resource test requirements as listed in Section 8 of the ERCOT Operating Guides indicate data submissions to the ERCOT ISO.

Indiana Municipal Power Agency
Yes
IMPA supports combining MOD-024-1 and MOD-025-1 into a single standard MOD-025-2.
No
According to VAR-002-1, the Transmission Operator is responsible for providing the voltage schedule to the Generator Operator. This voltage schedule is to ensure generators provide reactive and voltage control necessary to ensure voltage levels, reactive flows, and reactive resources are maintained. It seems like the TOP should know what the generating units are capable of producing when it comes to reactive power. IMPA recommends adding the TOP entity to the requirement 1.3.
No
The owner or operator of the generating unit should do the temperature correction to a specified temperature as directed. The owner will possess the curves and be better acquainted with the unit's limitation and temperature correction.

Yes
IMPA supports the SDT’s decision to have the standard be applicable to the compliance registry.
No
IMPA believes that four point testing is excessive and that only two points need to be verified. Those two points would be over-excitged (lagging) and under-excited (leading) reactive capability at the rated Real Power capability only. The two points verified at the expected minimum Real Power output is excessive. Reactive power support happens when load is high and generating units are running at maximum Real Output capability.
Yes
Yes
Yes
Yes
Yes
Yes
IMPA believes that the first sentence of requirement 2.1. does not read correctly in the sense that it is requiring the verification of Real Power Capability at maximum over-excited and under-excited reactive capability at rated gross Real Power Capability. This sentence would make sense if Real was removed at the beginning of the sentence and read “Perform verification of Reactive Power capability of all generating…”. Requirement 2.2 covers real power testing requirements. Since Real power needs to be removed from 2.1 then requirement 2.3 needs to have the requirement 2.2 added to it to cover the Real power testing time.
Yes
IMPA supports the application of the standard to generating units/facilities that meet the compliance registry criteria and to synchronous condensers rated 50MVA and greater.
Yes
Yes
No
IMPA is answering this question in conjunction with question 9. IMPA believes that the study should happen initially and only if a change is made or equipment is modified. If using this approach, the previous evidence and the new evidence should be retained.

Yes
IMPA does not understand the need to perform the coordination type of study every five years. It should be performed initially and only if something changes that would require a new coordination study. IMPA could see the need to verify the settings on the voltage regulating equipment, etc. just as you would with relay testing but why go through a complete study every 5 years. IMPA recommends performing the coordination study initially as per the timetable listed in the effective dates (section 5) and then again prior to the implementation of systems, equipment, setting changes, etc. IMPA recommends not using the words “verify the existence” in requirement 1.2. This wording is very vague in the sense that it may require just a review of the document to ensure no changes or does it mean that another coordination study needs to be performed. IMPA recommends using the wording “shall review the coordination identified in Requirement R1 at least once every five years or perform the coordination identified in Requirement R1 within 90 calendar days… ” if this is the intent of the SDT.

LADWP does not have a position on this question at this time.
Yes
MOD-025 Attachment 1 Sec. 2.1 During normal operations, it is typical to have many wind and solar units not working due to equipment malfunctions such as faults. How will failures that prevent the testing of 90% of equipment integrate with the standard? MOD-025 Attachment 1 Sec. 4 Will As-Built Project Drawings suffice for the requirement? The development of new one-line diagrams for a simplified version could have a significant impact because it will require the support of drafting resources which might not be available potentially delaying the submittals of Models and Data Reports. The requirement of directional arrows for Reactive Power Flows can be superimposed on the As-Built drawings. MOD-025 Attachment 1, Sec. 5 From a user’s perspective, it would be useful to get some language from the ERO that quantifies and qualifies what type of control system conditions would trigger the need for a new model and data verification, and also to have access to a comprehensive sample of a model and data verification test plan. This would allow the user to better manage its compliance implementation phase.

Yes
Yes
No
Should only be required if it impacts the data or test performed. For most generation it would not.
No
For multi-unit hydro and wind plants this can become a large effort. A "type" test where one of an identical family of units is verified is more practical and should provide sufficient data.
Yes
It is adequate, but variation from testing at the extremes should be permitted due to conditions - in some applications it is difficult to go to full buck or boost without absorbine/providing the reactive power from another unit without impacting the voltage schedule. Should testing cause the voltage schedule to be violated (or worse an unacceptable voltage condition), what should govern? It is unreasonable to expect that every plant over 75MVA can go to these conditions and hold them for an hour.
No
What is the basis for an hour? It should be tested to demonstrate stability at that point and not trip. After that why stay at an extreme condition? If you are concerned about MVA verification that can be done at any value, certainly design output and power factor is a better point.
Yes
Yes
For hydro, 20% of min and max reactive may be difficult to achieve. Salient pole machines have much greater lattitude than thermal, but system and bus conditions dictate if it is possible. Allowance should be made for realities in these cases. Again, what will dictate - voltage schedule or testing requirements?
Voltage schedule requirements may conflict.
No

Consideration of Comments on Generator Verification (MOD-025-2) — Project 2007-09

The Generator Verification drafting team thanks all commenters who submitted comments on the first posting of MOD-025-2, Verification and Data Reporting of Generator Real and Reactive Power Capability (Project 2007-09). This standard was posted for a 30-day public comment period from June 15, 2011 through July 15, 2011. The stakeholders were asked to provide feedback on the standards through a special electronic comment form. There were 65 sets of comments, including comments from approximately 182 different people from approximately 95 companies representing nine of the 10 industry segments as shown in the table on the following pages.

http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President of Standards and Training, Herb Schrayshuen, at 404-446-2563 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

SUMMARY CONSIDERATION:

A number of commenters suggested revisions for clarity that were accepted by the GVSDT. Minor changes were made to the standard to incorporate those suggestions.

- Language was added to recommend that the AVR be in automatic control while conducting reactive capability testing, but that reactive capability testing must be done even if the AVR is not available. The following language was also added to allow flexibility if 90 percent of the generation is not available when testing wind turbines or photovoltaic inverters:

  "If verification of wind turbines or photovoltaic inverter Facility cannot be accomplished meeting the 90 percent threshold, the Generator Owner must document the reasons it was unable to meet the threshold and test to the full capability at the time of the test. The Generator Owner shall retest the Facility within six months of being able to reach the 90 percent threshold."

- When polled, most stakeholders agree with combining MOD-024-1 and MOD-025-1 into a single standard. Several commenters suggested that the standard be clarified to indicate that Real and Reactive Power testing may be performed under separate tests. The GVSDT agrees and has separated R1 into two requirements to allow for separate Real and Reactive Power testing. The intent of these requirements remains unchanged. R1 now deals with Real Power testing only while R2 deals with Reactive Power testing. The measure and VSL for R1 were also revised to match the requirements.

[1] The appeals process is in the Standard Processes Manual: http://www.nerc.com/files/Appendix_3A_Standard_Processes_Manual_20110825.pdf.

R1. Each Generator Owner shall provide its Transmission Planner with verification of the Real Power capability of its applicable Facilities as follows: [Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]

1.1. Verify the Real Power capability of its generating units in accordance with Attachment 1.

1.2. Submit a completed Attachment 2 (or a form containing the same information as identified in Attachment 2) to its Transmission Planner within 90 calendar days of either the date the data is recorded for a staged test or the date the data is selected for verification using historical operational data.

R2. Each Generator Owner shall provide its Transmission Planner with verification of the Real Power capability of its applicable Facilities as follows: [Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]

2.1. Verify the Reactive Power capability of its generating units and shall verify the Reactive Power capability of its synchronous condenser units in accordance with Attachment 1.

2.2. Submit a completed Attachment 2 (or a form containing the same information as identified in Attachment 2) to its Transmission Planner within 90 calendar days of either the date the data is recorded for a staged test or the date the data is selected for verification using historical operational data.

- A statement was also added to the beginning of Attachment 1 for additional clarity:

  "It is intended that Real Power testing be performed at the same time as full Load Reactive Power testing, however separate testing is allowed for this standard."

- There was an error in the question relating to the Transmission Owner on the previous comment form. The question should have asked if the Transmission Planner was the appropriate entity rather than the Transmission Owner. Most stakeholders suggested that the Transmission Planner is the appropriate entity to receive the data required by MOD-025-1. The GVSDT will confirm this with an additional question on this topic in the next posting.

- With regard to correction factors for verifications, many commenters pointed out there are many factors that affect generator Real Power output, and these factors are different for different types of generating units. The GVSDT has revised the standard to include any parameter that the Generator Owner determines is required to make the ambient correction in Attachment 1:

  3.4. The ambient conditions at the end of the verification period the Generator Owner requires to perform corrections to Real Power for different ambient conditions such as:

  - Ambient air temperature
  - Relative humidity
  - Cooling water temperature

  The standard gives the Transmission Planner the discretion to request ambient condition correction at time of verification.

- There was overwhelming stakeholder support for verifying synchronous condensers as a reactive resource under MOD-025-2. Some stakeholders suggested that consideration be given under this or a different standard for verification of other reactive resources.

  The SDT added the following sentence to Attachment 1 in response to a stakeholder comment for clarity:

  "If a unit is operated in synchronous condenser mode as well as generation mode, the unit should be verified in both modes."

- There was an error in the comment form for the question regarding Synchronous Condenser size. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit. While some commenters suggested values higher than 20 MVA, technical justification was not provided for a value exceeding the generator registration criterion of 20 MVA. The GVSDT will confirm this with an additional question on this topic in the next posting.

Commenters have identified regional variances currently in effect as required by MOD-024 and MOD-025. It is anticipated that these regional standards will be retired once MOD-025-2 is approved. Language provided by Reliability*First* staff has been added to the Implementation plan concerning the Reliability*First* standards:

> "It is the intent of Reliability*First* to perform a review of both the MOD-024-RFC-01 and MOD-025-RFC-01 standards upon NERC Board of Trustees approval of the associated NERC MOD-025-2 standard. The purpose of the review would be to ensure that any duplicative requirements or any requirements which are less restrictive or do not add additional detail will be considered for retirement. The steps outlined in the Reliability*First* Reliability Standards Development Procedure will be followed for any such revisions or retirements."

Index to Questions, Comments, and Responses

1. The SDT has proposed that the requirements of MOD-024-1 and MOD-025-1 be combined into a single standard MOD-025-2. Do you agree with this approach? If not, please explain. 17
2. The SDT has proposed that the data from MOD-025-2 be submitted to the Transmission Owner. Do you believe the Transmission Owner is the appropriate entity to receive this data? If not, please explain. 26
3. The SDT has proposed that the ambient temperature during the verification be provided to the Transmission Owner as well as a correction factor to allow the Transmission Owner to adjust the Real Power data to a different ambient temperature if needed. Do you feel the standard should require that the Real Power data submitted be temperature adjusted to some other than ambient temperature? If yes, please explain and include which entity you think should perform the correction and which entity should determine the temperature value that should be used for the correction.43
4. The SDT believes that verification should be performed on units that are connected down to 100 kV. The SDT has also provided how verification should be handled in plants/facilities that are greater than 75 MVA in aggregate gross nameplate rating. The Standard requires a separate verification for every unit greater than 20 MVA gross nameplate rating. This is consistent with the current Compliance Registry. Units 20 MVA and smaller, in a plant/Facility greater than 75 MVA, can be verified separately or in aggregate as the Generator Owner chooses. Do you agree with the SDT's decision to have the Standard be applicable to the compliance registry? If not, please explain. ... 61
5. The draft standard requires that the Reactive Power capability be verified at four points: over-excited (lagging) and under-excited (leading) reactive capability at (1) the rated Real Power capability and (2) expected minimum Real Power output. The SDT believes that this is consistent with the FERC directive in Order 693 at P1321, "Therefore, we adjust the proposal in the NOPR and direct the ERO to modify MOD-025-1 to require verification of reactive power capability at multiple points over a unit's operating range." Do you agree that the four points proposed by the SDT is adequate to provide a straight line approximation to a unit's Reactive Power capability over its actual operating range? If not, please explain. 74
6. Verification of over-excited reactive capability at rated Real Power Capability is required to be conducted over a minimum of one hour. Do you agree with the verification time? If not, please explain. 89
7. Verification of (1) under-excited reactive capability at rated Real Power of the most recent gross verified Real Power capability reported, (2) under-excited reactive capability at expected minimum Real Power output and (3) over-excited reactive capability at expected minimum Real Power output, are all to be recorded as soon as a limit is encountered. Do you agree that such data recorded as soon as a limit is encountered is appropriate for such verification? If not, please explain.................... 98
8. Synchronous condensers are also reactive resources that may be important to reliability, but they are not generators. The SDT proposes that synchronous condensers be verified under MOD-025-2. Do you feel that this is appropriate?....................... 109
9. The SDT proposes that the size of synchronous condensers to be verified be limited to those greater than 50 MVA. Do you feel that this size criterion for synchronous condenser verification is appropriate? 115

10. Either operational data or staged testing is allowed by the standard for verification. Do you agree that these two methods of verification are acceptable? If not, please explain. 122

11. If operational data is utilized, the standard requires the verification be within 20% of the expected value. Do you agree with the 20% requirement? If not, please explain. 131

12. Are you aware of any regional variances that would be required for this standard? .. 149

13. Are you aware of any conflicts between the proposed standard and any regulatory function, rule, order, tariff, rate schedule, legislative requirement, or agreement? ... 155

14. Do you have any other questions or concerns with the proposed standard that have not been addressed? If yes, please provide a reference to the section, requirement or subrequirement that you believe should be changed, added or deleted and the rationale for your proposal. 161

The Industry Segments are:

1 — Transmission Owners
2 — RTOs, ISOs
3 — Load-Serving Entities
4 — Transmission-dependent Utilities
5 — Electric Generators
6 — Electricity Brokers, Aggregators, and Marketers
7 — Large Electricity End Users
8 — Small Electricity End Users
9 — Federal, State, Provincial Regulatory or other Government Entities
10 — Regional Reliability Organizations, Regional Entities

1. The SDT has proposed that the requirements of MOD-024-1 and MOD-025-1 be combined into a single standard MOD-025-2. Do you agree with this approach? If not, please explain.

Summary Consideration: Most stakeholders agree with combining MOD-024-1 and MOD-025-1 into a single standard. Several commenters suggested that the standard be clarified to indicate that Real and Reactive testing may be performed under separate tests. The GVSDT agrees and separated R1 into two requirements to allow for separate Real and Reactive testing. The intent of these requirements remains unchanged. R1 now deals with Real Power testing only, while R2 deals with Reactive Power testing. The measure and VSL for R1 were also revised to match the requirements.

R1. Each Generator Owner shall provide its Transmission Planner with verification of the Real Power capability of its applicable Facilities as follows: [Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]

1.1. Verify the Real Power capability of its generating units in accordance with Attachment 1.

1.2. Submit a completed Attachment 2 (or a form containing the same information as identified in Attachment 2) to its Transmission Planner within 90 calendar days of either the date the data is recorded for a staged test or the date the data is selected for verification using historical operational data.

R2. Each Generator Owner shall provide its Transmission Planner with verification of the Real Power capability of its applicable Facilities as follows: [Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]

2.1. Verify the Reactive Power capability of its generating units and shall verify the Reactive Power capability of its synchronous condenser units in accordance with Attachment 1.

2.2. Submit a completed Attachment 2 (or a form containing the same information as identified in Attachment 2) to its Transmission Planner within 90 calendar days of either the date the data is recorded for a staged test or the date the data is selected for verification using historical operational data.

A statement was also added to the beginning of Attachment 1:

"It is intended that Real Power testing be performed at the same time as full Load Reactive Power testing, however separate testing is allowed for this standard. For synchronous condensers, perform only the Reactive Power capability verifications as specified below. If an applicable Facility is operated in synchronous condenser mode as well as generation mode, the unit should be verified in both modes."

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 1 Comment</th></tr>
<tr><td>IRC Standards Review Committee (joint comments)</td><td>No</td><td>It is not a matter of whether the requirements for real power verification is in one numbered standard and reactive verification is in another numbered standard, the important point is that the requirements be clear and separate. The posted standard fails that test by combining two requirements into one. It may look cleaner writing the two together; the problem is with the fact that such a format has the potential to needlessly risk getting some data when the other data is NOT available. If an asset owner could provide real data but not reactive data, the standard as written would incent the owner from providing either data (why waste a test when the owner knows it will be non-compliant anyway? By separating the two actions, the owner would be compliant with one and non-compliant with the other requirement - but the planner would have at least half the information.</td></tr>
<tr><td colspan="3">Response: The GVSDT thanks you for your comment. The GVSDT has separated R1 into two separate requirements for real and reactive testing. A statement was also added to the beginning of Attachment 1 stating, "It is intended that Real Power testing be performed at the same time as full Load Reactive Power testing, however separate testing is allowed for this standard."</td></tr>
<tr><td>PPL Generation</td><td>No</td><td>MOD-024 has already been incorporated into a regional standard by RFC (MOD-024-RFC); and, as is implicit in the term "standard," these documents should change only infrequently.</td></tr>
<tr><td colspan="3">Response: The GVSDT thanks you for your comment. The GVSDT is coordinating with RFC regarding the regional standard. The following statement was provided by RFC and will be added to the implementation plan for MOD-025-2.

"It is the intent of ReliabilityFirst to perform a review of both the MOD-024-RFC-01 and MOD-025-RFC-01 standards upon NERC Board of Trustees approval of the associated NERC MOD-025-2 standard. The purpose of the review would be to ensure that any duplicative requirements or any requirements which are less restrictive or do not add additional detail will be considered for retirement. The steps outlined in the ReliabilityFirst Reliability Standards Development Procedure will be followed for any such revisions or retirements."</td></tr>
<tr><td>Associated Electric Cooperative, Inc.</td><td>No</td><td>Real power verification is typically done using historical operating data because units commonly operate at full real power capability. Reactive power verification will most likely not be done using historical operating data. This standard implies that these verifications will be done at the same time. Applicable standards should allow for real and reactive verifications at different times.</td></tr>
<tr><td colspan="3">Response: The GVSDT thanks you for your comment. The GVSDT has separated R1 into two separate requirements for Real and Reactive testing. A statement was also added to the beginning of Attachment 1 stating, "It is intended that Real Power testing be performed at the same time as full load Reactive Power testing, however separate testing is allowed for this standard."</td></tr>
</table>

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 1 Comment</th></tr>
<tr><td>Exelon</td><td>No</td><td>The requirements of MOD-024-1 and MOD-025-1 should remain separate. The testing periodicities and the reporting requirements for both of the existing Standards are different. In addition, the SDT needs to closely coordinate with existing testing and reporting requirements 1) Regional requirements and reporting criteria (e.g., MOD-024-RFC-01.1) and 2) Transmission Planner requirements (e.g., PJM has separate reporting criteria).If the SDT continues to push for a combined Standard, then consideration must be given to splitting out the requirements (i.e., separate Attachments) for Real and Reactive Testing.</td></tr>
<tr><td colspan="3">Response: The GVSDT thanks you for your comment.

1) The GVSDT is coordinating with RFC regarding the regional standard. The following statement was provided by RFC and will be added to the Implementation plan for MOD-025-2.

“It is the intent of ReliabilityFirst to perform a review of both the MOD-024-RFC-01 and MOD-025-RFC-01 standards upon NERC Board of Trustees approval of the associated NERC MOD-025-2 standard. The purpose of the review is to ensure that any duplicative requirements or any requirements which are less restrictive or do not add additional detail will be considered for retirement. The steps outlined in the ReliabilityFirst Reliability Standards Development Procedure will be followed for any such revisions or retirements.”

2) Requirements other than NERC or regional standards are outside the scope of the GVSDT. The GVSDT has separated R1 into two separate requirements for Real and Reactive testing. A statement was also added to the beginning of Attachment 1 stating, ”It is intended that Real Power testing be performed at the same time as full Load Reactive Power testing, however separate testing is allowed for this standard.”</td></tr>
<tr><td>Wisconsin Electric</td><td>No</td><td>The testing of reactive power capability has inherent risks due to the need for coordination with relaying and excitation limiters, and requires more technical resources than real power testing. Therefore the verification of real and reactive power would best be addressed in separate standards.</td></tr>
<tr><td colspan="3">Response: The GVSDT thanks you for your comment. The GVSDT has separated R1 into two separate requirements for Real and Reactive testing. We believe that this change will address your concern. A statement was also added to the beginning of Attachment 1 stating, “It is intended that Real Power testing be performed at the same time as full Load Reactive Power testing, however separate testing is allowed for this standard.”</td></tr>
<tr><td>Indeck Energy Services</td><td>No</td><td>Testing will be more difficult if combined.</td></tr>
<tr><td colspan="3">Response: The GVSDT thanks you for your comment. The GVSDT has separated R1 into two separate requirements for Real and Reactive testing. A statement was also added to the beginning of Attachment 1 stating, ”It is intended that Real Power testing be performed at the same time as full Load Reactive Power testing, however separate testing is allowed for this standard.”</td></tr>
</table>

Organization	Yes or No	Question 1 Comment
FirstEnergy	Yes	We agree that a “one-stop-shop” approach is appropriate for Real and Reactive Generator Verification requirements.
Response: The GVSDT thanks you for your comment.		
SERC Dynamics Review Sub-committee	Yes	Consolidating standards is beneficial
Response: The GVSDT thanks you for your comment.		
SERC Generation sub-committee	Yes	Please clarify if real and reactive verification can be performed at different times.
Response: The GVSDT thanks you for your comment. The GVSDT has separated R1 into two separate requirements for Real and Reactive testing. The tests can be performed separately. A statement was also added to the beginning of Attachment 1 stating, “It is intended that Real Power testing be performed at the same time as full Load Reactive Power testing, however separate testing is allowed for this standard.”		
Cowlitz County PUD	Yes	Combination of closely related standards simplifies compliance program development, and is welcome.
Response: The GVSDT thanks you for your comment.		
American Electric Power	Yes	In general, AEP is not opposed to combining MOD-024-1 and MOD-025-1 into a single MOD-025-2 standard.
Response: The GVSDT thanks you for your comment.		
Ingleside Cogeneration LP	Yes	Ingleside Cogeneration LP agrees that generator reactive testing necessarily requires validation at the real power extremes. This means there is no benefit to require separate testing.
Response: The GVSDT thanks you for your comment.		
Duke Energy	Yes	Yes, however need to define "Rated Real Power" so that entities are using a consistent basis for data reporting. MW validation is intrinsically connected to governor response issues and thus should be instead be combined with MOD-27 frequency response efforts and the following modeling parameters defined and

Organization	Yes or No	Question 1 Comment
		addressed:- Pmax o The continuous operating limit o The ultimate max emergency output. o Should there consider weather conditions (summer or winter, etc.). o PMAX associated with Transient stability - is it the same as for LF o Is this on the order of 105% or 110% or ??% of normal max loading. Please clarify if real and reactive verification can be performed at different times.
Response: The GVSDT thanks you for your comment. To address your concern, Step 2.1 of Attachment 1 was modified by adding the phrase "(not emergency)" to the first sentence; which states, "The generating unit's normal (not emergency) expected maximum Real Power at the time of the verification." **The tests can be performed separately.**		
Lincoln Electric System	Yes	Yes, but the verification periods should be different for Real and Reactive Power. It is not unreasonable to expect a Real Power verification test on an annual basis, as this data is usually available annually at some time when the unit is operated to serve load. It states the purpose of the Project 2007-09 Generator Verification is: "To ensure that generator models accurately reflect the generator's capabilities and operating characteristics." Without annual operation to verify Real Power it appears difficult to ensure this objective with a high degree of confidence.
Response: The GVSDT thanks you for your comment. The GVSDT has separated R1 into two separate requirements for Real and Reactive testing. A statement was also added to the beginning of Attachment 1 stating, "It is intended that Real Power testing be performed at the same time as full Load Reactive Power testing, however separate testing is allowed for this standard." **Regarding periodicity, the verification data is being utilized for the planning time horizon; and as such, the GVSDT believes that there is little, if any, reliability benefit associated with performing more frequent Real Power verification.**		
Independent Electricity System Operator	Yes	We support this approach. The real and reactive power capabilities are related and hence having them addressed in one standard would enhance verification efficiency.
Response: The GVSDT thanks you for your comment.		

Organization	Yes or No	Question 1 Comment
Indiana Municipal Power Agency	Yes	IMPA supports combining MOD-024-1 and MOD-025-1 into a single standard MOD-025-2.

Los Angeles Department of Water and Power		LADWP does not have a position on this question at this time.

2. The SDT has proposed that the data from MOD-025-2 be submitted to the Transmission Owner. Do you believe the Transmission Owner is the appropriate entity to receive this data? If not, please explain.

Summary Consideration: There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity. Most stakeholders suggested that the Transmission Planner is the appropriate entity to receive the data required by MOD-025-1. A few commenters suggested that the information should be provided to other reliability entities, such as the Reliability Coordinator. As this is a long-term planning standard, it is envisioned that the TP receives the data and develops the appropriate models for use by other entities. The TP then hands these models off to entities that are concerned with the planning and Real-time time horizons. Per the NERC Reliability Functional Model (V5, Page 25), the Transmission Planner has the following relationships with other entities:

2. Collects information including:

    c. Generator unit performance characteristics and capabilities from Generator Owners.

5. Coordinates the evaluation of BES expansion plans with Transmission Service Providers, Transmission Owners, Reliability Coordinators, Resource Planners, and other Transmission Planners.

6. Reports on and coordinates its BES expansion plan implementation with affected Planning Coordinators, Transmission Planners, Resource Planners, Transmission Service Providers, Transmission Owners, Transmission Operators and Reliability Assurers.

The GVSDT has not revised the requirement with respect to submitting the data to the Transmission Planner. The requirement continues to require the data be submitted to the Transmission Planner.

Organization	Yes or No	Question 2 Comment
LG&E and KU Energy	No	Either the Planning Authority of the Transmission Planner are the more likely entity to submit data rather than the Transmission Owner as indicted in R2.3
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity. You are correct that the Transmission Planner is the appropriate entity to receive the data required by MOD-025-1.		
Northeast Power Coordinating	No	The Transmission Operator (TOP) and Transmission Planner (TP) are far more likely to need and use the

Organization	Yes or No	Question 2 Comment
Council		data and models identified and dispatch the units in their market area. In New York, the NYISO as the TOP is responsible for real-time modeling and dispatch (specifying both real and reactive schedules), and as TP the longer term modeling. The Transmission Owners (TO's) do not have this type of relationship with the Generation Owners (GO's) and Generation Operators (GOP's). R1: A standard should be developed that makes reactive power testing mandatory for all units above 75 MVA. This standard will provide the TOP with critical information on the total dynamic reactive capability of dispatched generation.
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity. Most stakeholders suggested that the Transmission Planner is the appropriate entity to receive the data required by MOD-025-1. A few commenters suggested that the information should be provided to other reliability entities such as the Reliability Coordinator or Transmission Operator. As this is a long-term planning standard, it is envisioned that the TP receives the data and develops the appropriate models for use by other entities. The TP then hands these models off to entities that are concerned with the planning and Real-time operations time horizons. Per the NERC Reliability Functional Model (V5, Page 25), the Transmission Planner has the following relationships with other entities: **2. Collects information including:** **c. Generator unit performance characteristics and capabilities from Generator Owners.** **5. Coordinates the evaluation of BES expansion plans with Transmission Service Providers, Transmission Owners, Reliability Coordinators, Resource Planners, and other Transmission Planners.** **6. Reports on and coordinates its BES expansion plan implementation with affected Planning Coordinators, Transmission Planners, Resource Planners, Transmission Service Providers, Transmission Owners, Transmission Operators and Reliability Assurers.**		
IRC Standards Review Committee (joint comments)	No	MOD-025 is a requirement on owners to verify data, nowhere does the requirement state who the data goes to. Of course the owner is NOT the appropriate entity to send the data to since they are the ones that are responsible for generating the information. This standard has many issues related to who gets what data and why. There is no requirement to have the data in the first place. The standard would be better to require a planning entity to request the data that that entity needs to do its mandated functions. Once the planner asks for the data, then the owner can provide / verify the information being asked for. The SDT has rejected the comments that other standards already provide this information. The SDT has parsed the terms "capability" and "rating". However, the NERC Glossary defines Rating as strictly a transmission line term, and the word capability is not defined. Capability does show up within other

Organization	Yes or No	Question 2 Comment
		definitions related to Transfers and other transmission terms. The SDT is asked to review their findings in light of the above, and in light of the FAC and TOP standards purposes. The TOP standard has developed the flexible approach of having an entity ask for the data it needs, and for the receiver of the request to provide the needed information. This approach eliminates the idea of a common requirement for all planners (whether or not they want the data elements in the posted Attachment 2).Our proposal is to have a requirement (if it does not already exist) mandating entities asks for what they want, and a separate requirement for the receivers to provide just that data. If the revised standard is written in that fashion than the new MOD-025 COULD replace the old MOD-024 because there would be no need to specify reactive data from real data, because the entities who are asking for the data will do that for you. Editorial :(1) The receiving entity cited in this question (Transmission Owner) seems different than the entity indicated in the standard (Transmission Planner). If it is not a typo, then we may be missing something. Regardless, we commented previously (on MOD-024-2) on a related subject in which we indicated that given the purpose of the standard, which now reads: “To ensure that planning entities have accurate generator Real and Reactive Power capability data when assessing Bulk Electric System (BES) reliability”, we believe that the data is used for planning assessments that could entail both resource adequacy and transmission reliability, and may even include short or near-term transmission reliability assessments. In view of the facility ownership and potential users, submitting the data to the Transmission Owner does not seem to be logical from the following standpoints: a. The TO does not own the generators and may not actually use the data at all if it does not perform transmission planning assessments; b. The Transmission Planner is the entity that conducts transmission planning assessments; c. Other planning entities that use this data are the Planning Coordinators and Resource Planners. For the above reasons, a more logical entity to receive this data and be the one that requests for data is made by other entities that have a need for the data such as Transmission Planners, Resource Planners, Reliability Coordinator and Transmission Operator, would be the Planning Coordinator. We suggest to change Transmission Owner to Planning Coordinator. (2) And also in view of the potential use of this data, we suggest the purpose of the standard be reverted back to its previous version: “To ensure accurate information on generator gross and net Real Power capability is available for steady-state models used to assess Bulk Electric System reliability.”, or be revised to: “To ensure that [the word planning removed] entities have accurate generator Real and Reactive Power capability data when assessing Bulk Electric System (BES) reliability”.
Response: The GVSDT thanks you for your comment.		

Organization	Yes or No	Question 2 Comment
(First paragraph) The GVSDT points out that Requirement R1, Parts 1.3 and 2.3 both specify that the responsible entity shall, "Submit within 90 calendar days of the date the data is recorded to its Transmission Planner." **(Second Paragraph) The GVSDT has revised the MOD-024-1 and MOD-025-1 planning standards. Early in the project, the GVSDT considered the approach suggested of having entities requiring the verified data to also specify the data that they require. This approach was universally opposed by the members of the GVSDT who work in Transmission Planning because (1) it is common knowledge that Real and Reactive Power data is required, and (2) any communication requesting data from the generating entity will need to be documented and verified; which is a burdensome task without reliability benefit.** **(Editorial 1) There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity. As this is a long-term planning standard, it is envisioned that the TP receives the data and develops the appropriate models for use by other entities. Planners, Transmission Service Providers, Transmission Owners, Transmission Operators and Reliability Assurers. **The GVSDT believes that the Transmission Planner is the appropriate entity.** **(Section 2) The purpose statement has been revised to:** **1.** To ensure accurate information on generator gross and net Real and Reactive Power capability and synchronous condenser Reactive Power capability is available for planning models used to assess BESreliability. .		
Pepco Holdings Inc Affiliates	No	The standard in Sec B-R1.3 and R2.3 state to submit the data to the TP not the TO. The TP is the appropriate entity. However, the TOP and the TOP also have need of the data. Should dissemination to these entities be covered in the requirements also?
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity. As this is a long-term planning standard, it is envisioned that the TP receives the data and develops the appropriate models for use by other entities. The TP then hands these models off to entities that are concerned with the operations planning and Real-time operations time horizons.		
NERC System Protection and Control Subcommittee		
Midwest Reliability Organization's NERC Standards Review Forum (NSRF)	No	The standard states that the data be submitted to the Transmission Planner and we agree with that approach.
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity.		
SPP Reliability Standards Development Team	No	Is there a typo in the question? Should Transmission Owner be Transmission Planner? If not then adding the Transmission Owner as an intermediate step before submitting data to the Transmission Planner isn't needed.
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity.		

Organization	Yes or No	Question 2 Comment
SERC Planning Standards Subcommittee	No	The PSS believes that the Transmission Planner (TP) should receive this information initially (which is what the standard currently requires).
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity.		
PPL Generation	No	PPL Generation, LLC's Registered Entities are already performing VAR testing and reporting the results to our RTO (PJM), in accordance with Manual PJM-14D, and PJM then makes this information available to other entities. It would be very confusing to have to conduct two different VAR tests (PJM and NERC), possibly resulting in two different values (depending on the final wording of MOD-025), reported to two different entities.
Response: The GVSDT thanks you for your comment. The GVSDT is not aware of the testing required by PJM. If the testing requirements are the same, then a single test could be performed and reported to satisfy both PJM and NERC requirements.		
Dominion	No	R1.3 and R2.3 require submittal to Transmission Planner, not Transmission Owner. We believe it is also appropriate to submit these results to the Resource Planner as we are unaware of an existing reliability standard that requires this information be provided to that entity (even though aware that version 5 of the Functional Model (on page 28) states the Resource Planner "Coordinates with Transmission Planners, Transmission Service Providers, Reliability Coordinators, and Planning Coordinators on resource adequacy plans."Further, we believe it is also appropriate to submit these results to the Balancing Authority and Transmission Operator despite the fact that they may request verification pursuant to TOP-002a @R13. We believe that, given the owner is being required to verify real and reactive capability, and report the results to one entity, requiring reporting to additional entities who could find the information useful in its reliability assessment (whether in the planning or operating time horizon) adds significant value at little additional effort.
Response: The GVSDT thanks you for your comment. **(First part) There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity.** **(Second part)** As this is a long-term planning standard, it is envisioned that the TP receives the data and develops the appropriate models for use by		

Organization	Yes or No	Question 2 Comment
other entities. The TP then hands these models off to entities that are concerned with the operations planning and Real-time operations time horizons.		
FirstEnergy	No	The standard in Subpart 1.3 says that the Transmission Planner is the entity that shall receive this information. We agree that it should be the TP. Also, we question whether or not the Planning Coordinator should also receive this information. Furthermore, with respect to how this information will be used by the planning entities, the team needs to assure that there is no duplication of efforts with MOD-010-0 and MOD-011-0. We suggest that MOD-010-0 and MOD-011-0 get revised to remove redundancies, or make it clear that the entity may supply existing MOD-010/-011 compliance evidence to show compliance with MOD-025-2.
Response: The GVSDT thanks you for your comment. Please see responses above. **(First part) There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity.** **(Second part) MOD-010-0 and MOD-011-0 pertain to data and equipment characteristics, not validation requirements; therefore, the standards do not duplicate requirements.**		
SERC Dynamics Review Sub-committee	No	The DRS believes that the Transmission Planner (TP) should receive this information initially (which is what the standard currently requires).
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity.		
NERC Staff	No	Requirement R1, part 1.3 and Requirement R2, part 2.3 indicate that data is to be submitted to the Transmission Planner. We agree that the data should be submitted to the Transmission Planner, not the Transmission Owner. Further, we believe that the data should be provided to all entities that have need of the data, including the Transmission Operators and Reliability Coordinators who need the data for their operational planning and real-time models.
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity. As this is a long-term planning standard, it is envisioned that the TP receives the data and develops the appropriate models for use by other entities. The TP then hands these models off to entities that are concerned with the operations planning and Real-time operations time horizons. Per the NERC Reliability Functional Model (V5, Page 25), the Transmission Planner		

Organization	Yes or No	Question 2 Comment
has the following relationships with other entities: 2. Collects information including: c. Generator unit performance characteristics and capabilities from Generator Owners. 5. Coordinates the evaluation of BES expansion plans with Transmission Service Providers, Transmission Owners, Reliability Coordinators, Resource Planners, and other Transmission Planners. 6. Reports on and coordinates its BES expansion plan implementation with affected Planning Coordinators, Transmission Planners, Resource Planners, Transmission Service Providers, Transmission Owners, Transmission Operators and Reliability Assurers. The GVSDT believes that the Transmission Planner is the appropriate entity.		
Public Service Enterprise Group	No	MOD-025-2 requires that data be submitted by GOs or TOs to their respective Transmission Planner (R2.3). It should not require that it be submitted to the Transmission Owner as the TO has no need for this data.
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity.		
SERC Generation sub-committee	No	The TP or the PC (PA) is the entity needing the data, rather than the TO. R1.3 and R2.3 specifies that the TP be given this data.
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity.		
ACES Power Members	No	The requirements appear to correctly show the data being submitted to the TP. However, Transmission Owner in 3.4 of Attachment 1 should be Transmission Planner.
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity. Attachment 1, Step 3.4 was revised to change responsibility from the Transmission Owner to the Generator Owner. This adjustment is made before the data is sent to the Transmission Planner.		
South Carolina Electric and Gas	No	SCE&G believes that the Transmission Planner (TP) should receive this information, consistent with the current version of the standard.

Organization	Yes or No	Question 2 Comment
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity.		
Associated Electric Cooperative, Inc.	No	The TP or PA seems more appropriate.
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity.		
New York Independent System Operator	No	In section B, R1.3, results are required to be submitted to the Transmission Planner. The NYISO agrees with R1.3.
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity.		
Westar Energy	No	We agree data should be submitted to the Transmission Planner as written in the draft of the standard.
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity.		
Southern Company	No	The TP or the PC is the entity who needs the data, not the TO. R1.3 and R2.3 specifies that the TP be given this data.
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity.		
Tennessee Valley Authority GO	No	The TP or the PC (PA) is the entity who will use the data. R1.3 and R2.3 specifies that the TP be given this data.
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity.		
Luminant Power	No	This is not applicable in the ERCOT region. Data should be submitted to TOP and BA. They are currently responsible to utilizing the information for grid reliability.

Organization	Yes or No	Question 2 Comment
Response: The GVSDT thanks you for your comment. MOD-025-2 is a long-term planning standard. The TOP and BA entities do not perform long-term planning functions.		
Cowlitz County PUD	No	Not all Transmission Owners have a complete system view of the BES, let alone modeling software. The standard as written specifies the Transmission Planner, and so the question appears to be in error. Following the purpose statement of the standard, the Planning Coordinator (formerly Planning Authority) might also need the data along with the Transmission Planner. To further complicate the matter, in WECC CUG meetings it has been brought up that entities are experiencing difficulty in identifying their Planning Coordinator and Transmission Planner. Such entities have been rebuffed when approaching the obvious candidates. Therefore, Cowlitz suggests that a mechanism must be devised such that Generator Owners will not left in a compliance quandary in their endeavors to identify the appropriate planner(s).
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity. As this is a long-term planning standard, it is envisioned that the TP receives the data and develops the appropriate models for use by other entities. The TP then hands these models off to entities that are concerned with the operations planning and Real-time operations time horizons. Per the NERC Reliability Functional Model (V5, Page 25), the Transmission Planner has the following relationships with other entities: **2. Collects information including:** **c. Generator unit performance characteristics and capabilities from Generator Owners.** **5. Coordinates the evaluation of BES expansion plans with Transmission Service Providers, Transmission Owners, Reliability Coordinators, Resource Planners, and other Transmission Planners.** **6. Reports on and coordinates its BES expansion plan implementation with affected Planning Coordinators, Transmission Planners, Resource Planners, Transmission Service Providers, Transmission Owners, Transmission Operators and Reliability Assurers.** **The GVSDT believes that the Transmission Planner is the appropriate entity. The GVSDT suggest contacting your regional Entity for help identifying your Planning Coordinator and Transmission Planner.**		
Exelon	No	The Transmission Planner should be the appropriate entity to receive this data.
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity.		
Georgia Transmission	No	This question seems to have identified the TO in error. MOD025-2 requires data to be submitted to the TP.

Organization	Yes or No	Question 2 Comment
Corporation		TP is the appropriate entity to receive the data.
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity.		
Austin Energy	No	We believe question #2 may contain a typo. The Proposed Standard Requirement 1.3 correctly requires data submittal to the Transmission PLANNER (in our case ERCOT). The data should be submitted to the Transmission Planner as currently written in the Proposed Standard, not the Transmission Owner as stated in the comment questionnaire.
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity.		
BC Hydro	No	Not clear why data would be submitted to TO. Based on Functional Model, TP, TOP or PC would be more applicable.
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity.		
Northeast Utilities	No	The Transmission Operator (TOP) and Transmission Planner (TP) are far more likely to need and use the data and models identified and dispatch the units in their market area. In New York, the NYISO as the TOP is responsible for real-time modeling and dispatch (specifying both real and reactive schedules), and as TP the longer term modeling. The Transmission Owners (TO's) do not have this type of relationship with the Generation Owners (GO's) and Generation Operators (GOP's). R1: A standard should be developed that makes reactive power testing mandatory for all units above 75 MVA. This standard will provide the TOP with critical information on the total dynamic reactive capability of dispatched generation.
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity. **The standard applies to units greater than 20 MVA directly connected to the bulk power system.**		
Consolidated Edison Co. of NY, Inc.	No	The Transmission Operator (TOP) and Transmission Planner (TP) are far more likely to need and use the data and models identified and dispatch the units in their market area. In New York, the NYISO as the TOP is

Organization	Yes or No	Question 2 Comment
		responsible for real-time modeling and dispatch (specifying both real and reactive schedules), and as TP the longer term modeling. The Transmission Owners (TO's) do not have this type of relationship with the Generation Owners (GO's) and Generation Operators (GOP's). R1: A standard should be developed that makes reactive power testing mandatory for all units above 75 MVA. This standard will provide the TOP with critical information on the total dynamic reactive capability of dispatched generation.
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity. The standard applies to units greater than 20 MVA directly connected to the bulk power system.		
Ingleside Cogeneration LP	No	Cogeneration LP believes that the proper recipient is the Transmission Planner. The Transmission Planner in turn must supply the information to the Planning Authority, Reliability Coordinator, and/or Transmission Operator as needed. There is no apparent reason why the Transmission Owner should be in the loop. Attachment 1, Item 3.4 seems to be the only place in MOD-025-2 that the Transmission Owner is shown as the recipient of generator verification data. It should be changed to Transmission Planner - consistent with the rest of the standard.
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity.		
ISO New England	No	The data from MOD-25-2 should be submitted to the Transmission Operator. The Transmission Owner does not appear to be the correct functional entity. The Transmission Owner may not have the area view required for this testing. Real and Reactive Power Testing must be coordinated with the Transmission Operator to ensure that the system remains within all operating limits.
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity. MOD-025-2 is a long-term planning standard.		
Duke Energy	No	The TP or the PC (PA) is the entity needing the data, rather than the TO. R1.3 and R2.3 specifies that the TP be given this data. Both the TPs and Transmissions Operations entities need to have accurate model information and the Operating studies are much more critical for BES reliability.
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should

the following relationships with other entities: **2. Collects information including:** **c. Generator unit performance characteristics and capabilities from Generator Owners.** **5. Coordinates the evaluation of BES expansion plans with Transmission Service Providers, Transmission Owners, Reliability Coordinators, Resource Planners, and other Transmission Planners.** **6. Reports on and coordinates its BES expansion plan implementation with affected Planning Coordinators, Transmission Planners, Resource Planners, Transmission Service Providers, Transmission Owners, Transmission Operators and Reliability Assurers.** **The GVSDT believes that the Transmission Planner is the appropriate entity.**		
Indiana Municipal Power Agency	No	According to VAR-002-1, the Transmission Operator is responsible for providing the voltage schedule to the Generator Operator. This voltage schedule is to ensure generators provide reactive and voltage control necessary to ensure voltage levels, reactive flows, and reactive resources are maintained. It seems like the TOP should know what the generating units are capable of producing when it comes to reactive power. IMPA recommends adding the TOP entity to the requirement 1.3.
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity. MOD-025-2 is a long-term planning standard. It is inappropriate to include operating entities as applicable entities under MOD-025-2.		
Lakeland Electric	Yes	A Transmission Owner may need to size conductors according to Generator output.
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity. Your concern is addressed by the Interconnection agreements between TOs and GOs.		
Tri-State Generation and Transmission, In.	Yes	The standard also calls for the data to be submitted to the Transmission Planner, so this question seems ambiguous.
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity.		
American Electric Power	Yes	Draft Standard MOD-025-2 provisions 1.3 and 2.3 both state that the data be provided to the Transmission Planner, rather than the Transmission Owner as stated within this question #2. We agree that the

Organization	Yes or No	Question 2 Comment
		Transmission Planner is the correct recipient for this data.
Response: The GVSDT thanks you for your comment. There was an error in the question relating to the Transmission Owner. The question should have asked if the Transmission Planner was the appropriate entity.

Los Angeles Department of Water and Power		LADWP does not have a position on this question at this time.

3. The SDT has proposed that the ambient temperature during the verification be provided to the Transmission Owner, as well as a correction factor to allow the Transmission Owner to adjust the Real Power data to a different ambient temperature, if needed. Do you feel the standard should require that the Real Power data submitted be temperature-adjusted to some other-than-ambient temperature? If yes, please explain and include which entity you think should perform the correction and which entity should determine the temperature value that should be used for the correction.

Summary Consideration: Many commenters pointed out there are many factors that affect generator Real Power output, and these factors are different for different types of generating units. The SDT modified the standard to assign responsibility for making the ambient condition (including ambient temperature) adjustments to the Generator Owner, rather than the Transmission Owner. The GVSDT has revised the standard to include any parameter that the GO determines is required to make ambient correction in Attachment 1:

3.4. The ambient conditions, if applicable, at the end of the verification period the Generator Owner requires to perform corrections to Real Power for different ambient conditions such as:

- Ambient air temperature
- Relative humidity
- Cooling water temperature

The standard gives the Transmission Planner the discretion to request ambient condition correction at time of verification.

Organization	Yes or No	Question 3 Comment
IRC Standards Review Committee (joint comments)	No	See comment to Q2. The planner should ask for the data that it needs to comply with NERC standards (nothing more and nothing less). There is no need for the requirement to get into the details. The Planning standards will force the Planner to ask for the data that it needs for its models. This approach limits the Planners from asking for data that they do not use in their Planning Models or that is not needed to comply with a NERC standard. This approach also allows the Planner to tailor its requests to the Models and technologies that it has and needs. (1) We do not support the notion that a Transmission Owner has the technical expertise to adjust a generator’s real power capability to reflect a difference in ambient temperature. If anyone, it should be the

Organization	Yes or No	Question 3 Comment
		Generator Owner. (2) Reporting the ambient temperature is unnecessary since it is only one of the many factors that could affect the real power output of a generator. Adjusting the real power capability for a different ambient temperature does not really provide a more accurate value, and can be misleading. (3) Notwithstanding the concerns expressed above, to make such an adjustment with some degree of accuracy, the responsible entity needs to have the information on that capability which corresponds to the ambient temperature for which the adjustment is to be made. It thus suggests that a capability-temperature curve be first established to provide credible references, implying that the Generator Owners must conduct a series of verification tests under different ambient temperature conditions. This is overly cumbersome, and creates unnecessary burden to the GOs. We suggest that this requirement be removed from Attachment 1.
Response: The GVSDT thanks you for your comment. Early in the project, the GVSDT considered the approach suggested of having entities requiring the verified data to also specify the data that they require. This approach was universally opposed by the members of the GVSDT who work in Transmission Planning because (1) it is common knowledge that Real and Reactive Power data is required, and (2) any communication requesting data from the generating entity will need to be documented and verified; which is a burdensome task without reliability benefit. **The SDT modified the standard to assign responsibility for making the ambient condition (including ambient temperature) adjustments, if applicable, to the Generator Owner in support of your suggestion.** **There are many factors that affect generator Real Power output, and these factors are different for different types of generating units. The reason why the GVSDT incorporated temperature correction consideration into the draft standard is because most Planners specify ambient temperature conditions when performing planning case studies.**		
Independent Electricity System Operator	No	(1) We do not support the notion that a Transmission Owner has the technical expertise to adjust a generator's real power capability to reflect a difference in ambient temperature. If anyone, it should be the Generator Owner. (2) There seems to be little value in reporting the ambient temperature for the purpose of making adjustments to measured Real Power capability since it is only one of the several factors that could affect the real power output of a generator. (3) Notwithstanding the concerns expressed above, to make such an adjustment with some degree of accuracy, the responsible entity needs to have the information on that capability which corresponds to the ambient temperature for which the adjustment is to be made. It thus suggests that a capability-temperature curve be first established to provide credible references, implying that the Generator Owners must conduct a series of verification tests under different ambient temperature conditions. This is overly cumbersome, and creates unnecessary burden to the GOs. We suggest that this requirement be removed from Attachment 1.

Organization	Yes or No	Question 3 Comment
Response: The GVSDT thanks you for your comment. The SDT modified the standard to assign responsibility for making the ambient condition (including ambient temperature) adjustments to the Generator Owner in support of your suggestion. **The reason why the GVSDT incorporated temperature correction consideration into the draft standard is because most Planners specify ambient temperature conditions when performing planning case studies. The GVSDT believes that Transmission Planners have sufficient expertise to properly apply temperature correction factor information provided by the GO. All data needed for adjusting MW capability is now required in Attachment 2 per FERC Order 693, Paragraph 1310.** **The GVSDT does not intend for entities to perform multiple tests. Instead, the GO simply provides a temperature correction factor with test data collected. As a matter of practicality, temperature correction factor information should already be captured as part of the internal process used for performing Real Power testing.** **Temperature correction is only intended to be applied during engineering analysis of collected data. Additional testing is not required or necessary.**		
Midwest Reliability Organization's NERC Standards Review Forum (NSRF)	No	We recommend that in Item 3.4 of Attachment 1 the wording be changed from "to allow the Transmission Owner" to "to allow the Transmission Planner". We support the position that the ambient temperature at the end of the verification period and the correction factor should be provided to the Transmission Planner so that the Transmission Planner can adjust the verification results to the ambient temperature that is appropriate for its system planning assessments.
Response: The GVSDT thanks you for your comment. Item 3.4 in Attachment 1 provides guidance with respect to correction factors and has been revised to assign responsibility for making a temperature correction, if applicable, to the Generator Owner rather than the Transmission Owner: **3.4. The ambient conditions, if applicable, at the end of the verification period the Generator Owner requires to perform corrections to Real Power for different ambient conditions such as:** **• Ambient air temperature** **• Relative humidity** **• Cooling water temperature**		
PPL Generation	No	The correction of real power capability to other-than-tested ambient conditions, as is currently performed by PPL Generation Registered Entities for MOD-024-RFC, is a complex matter involving the wet-bulb temperature, condenser cleanliness and other factors beyond simply the dry-bulb temperature, especially when using a total-unit thermodynamic computer model for this purpose. One must also consider low-

Organization	Yes or No	Question 3 Comment
		ambient limitations; wintertime predicted capabilities must be truncated if they would otherwise exceed the generator or GSU rating. Corrections to other-than-tested ambients should be performed by the GO, using an on-request basis.
Response: The GVSDT thanks you for your comment. Early in the project, the GVSDT considered the approach suggested of having entities requiring the verified data to also specify the data that they require. This approach was universally opposed by the members of the GVSDT who work in Transmission Planning because (1) it is common knowledge that Real and Reactive Power data is required, and (2) any communication requesting data from the generating entity will need to be documented and verified; which is a burdensome task without reliability benefit. **There are many factors that affect generator Real Power output, and these factors are different for different types of generating units. The reason why the GVSDT incorporated temperature correction consideration into the draft standard is because most Planners specify ambient temperature conditions when performing planning case studies.** **The GO can include any or all of the factors mentioned in the comment when providing data correction factor information. The SDT modified the standard to assign responsibility for making the ambient condition (including ambient temperature) adjustments, if requested, to the Generator Owner in support of your suggestion.**		
Idaho Power-Power Production	No	No
LG&E and KU Energy		GO's typically correct to back pressure. Any other adjustments should be performed by Transmission Operator
Response: The GVSDT thanks you for your comment. There are many factors that affect generator Real Power output, and these factors are different for different types of generating units. The reason why the GVSDT incorporated temperature correction consideration into the draft standard is because most Planners specify ambient temperature conditions when performing planning case studies. Since the GO will not know the temperature as specified by the Planner for a particular scenario, the GVSDT believes the best solution for this concern is to have the GO record the ambient temperature at time of verification and also provide correction factor information so the Planner can extrapolate data to a different temperature basis when performing studies. The SDT modified the standard to assign responsibility for making the ambient condition (including ambient temperature) adjustments to the Generator Owner, rather than the Transmission Owner.		
FirstEnergy	No	We believe that it is the responsibility of the Generator Owner to have an appropriate Ambient Adjustment Methodology and make the necessary corrections to the data per its methodology before submitting it to the Transmission Owner. We suggest similar requirement regarding ambient adjustments as found in regional standards MOD-024-RFC-01 and MOD-025-RFC-01.

Organization	Yes or No	Question 3 Comment
Response: The GVSDT thanks you for your comment. The GVSDT has revised the standard to capture additional ambient condition parameters which could be used for correction in addition to ambient air temperature; however, the requirements are less stringent than required by the RFC standard. As specified by the NERC Rules of Procedure, regional standards can incorporate more stringent requirements than required by NERC, if necessary, for regional reliability. **The SDT did modify the standard to assign responsibility for making ambient condition (including ambient temperature) adjustments to the Generator Owner rather than the Transmission Owner.**		
SERC Dynamics Review Sub-committee	No	This provides all the information needed to allow the TO to rate the machines at whatever ambient temperature may be needed. Per #2, the DRS recommends that TO be changed to TP. In attachment 1 item 3.4, the DRS recommends that "correction factor" be changed to "adjustment method," to allow real power determination at multiple temperatures.
Response: The GVSDT thanks you for your comment. The SDT modified the standard (Attachment 1, Step 3.4) to assign responsibility for making the ambient condition (including ambient temperature) adjustments to the Generator Owner rather than the Transmission Owner. The language of 3.4 in Attachment 1 was revised to "perform corrections to Real Power for different ambient conditions."		
NERC Staff	No	It is not necessary to specify a temperature for which submitted data should be adjusted because one temperature will not be appropriate for all regions or for all types of studies. Providing the recorded value and a temperature correction factor or correction table is appropriate.
Response: The GVSDT thanks you for your comment. The GVSDT agrees with your comment and has revised item 3.4 in Attachment 1 to: **3.4. The ambient conditions, if applicable, at the end of the verification period the Generator Owner requires to perform corrections to Real Power for different ambient conditions such as:** **• Ambient air temperature** **• Relative humidity** **• Cooling water temperature**		
SERC Generation sub-committee	No	Providing the ambient temperatures at the time data is collected is acceptable. However, there is no simple correction factor that can be provided. Reactive capabilities under different conditions cannot be assumed to

Organization	Yes or No	Question 3 Comment
		be the same.
Response: The GVSDT thanks you for your comment. The GVSDT agrees that the correction factor methodology could be complex, but also points out that simply accounting for the effects of ambient temperature can be sufficient for long-term planning. The standard currently does not require a complex correction factor methodology because the GVSDT did not identify evidence indicating that use of such a methodology would increase reliability. While the GVSDT agrees with your assertion regarding reactive capabilities, the GVSDT does not believe that the standard needs to incorporate these assumptions; instead believing existing practice is sufficient for compliance.		
Westar Energy	No	We believe data should be submitted to the Transmission Planner as written in the draft of the standard.
Response: The GVSDT thanks you for your comment. The TP is the correct entity and is shown in the requirements and Attachment 1.		
Southern Company	No	The verification data is required by R1.3 and R2.3 to be given to the TP, not the TO. If the Q capacity is determined using a staged test, the ambient temperature during the test should be provided. The planning entity can adjust to other temperatures if they desire.
Response: The GVSDT thanks you for your comment. The TP is the correct entity and is shown in the requirements and Attachment 1.		
Tennessee Valley Authority GO	No	Providing the ambient temperatures at the time data is collected is acceptable. However, there is no simple correction factor that can be provided. Reactive capabilities under different conditions cannot be assumed to be the same.
Response: The GVSDT thanks you for your comment. Item 3.4 in Attachment 1 provides guidance with respect to correction factors: **3.4. The ambient conditions at the end of the verification period the Generator Owner requires to perform corrections to Real Power for different ambient conditions such as:** • **Ambient air temperature** • **Relative humidity** • **Cooling water temperature**		
Luminant Power	No	Luminant agrees that ambient test temperature and temperature correction information should be submitted to the appropriate entities. In ERCOT, this would be TOP and BA.
Response: The GVSDT thanks you for your comment.		

Organization	Yes or No	Question 3 Comment
Lakeland Electric	No	It should be acceptable that the Real Power data collected during credible, high-ambient temperature conditions be used to establish Real Power output limits throughout the year, including during lower temperature ambient conditions. By limiting Real Power output to that determined for high-ambient conditions, system reliability will not be compromised during lower ambient temperature conditions/scenarios.
Response: The GVSDT thanks you for your comment. This standard does not address the issue of Real Power output limits to be used in Real-time operations.		
Associated Electric Cooperative, Inc.	No	There is no simple correction factor that can be provided that will allow correction to other ambient temperatures. If necessary, a special request could be made to the GO/GOP for correction to another ambient temperature.
Response: The GVSDT thanks you for your comment. The GVSDT agrees there is not a simple correction factor that can account for all temperature effects; however, the GVSDT also believes it is not necessary to account for all temperature effects in order to maintain reliability.		
New York Independent System Operator	No	Temperature correction shall be performed as required by the Transmission Operator. The NYISO requires ambient temperature data only for Real Power Tests for combined cycle, combustion, and turbine units.
Response: The GVSDT thanks you for your comment. This is a long-term planning standard, and the data verified under MOD-025 is to be used in planning studies. The SDT modified the standard (Attachment 1, Step 3.4) to assign responsibility for making the ambient condition (including ambient temperature) adjustments to the Generator Owner rather than the Transmission Owner.		
Exelon	No	The Standard needs to address correction factors for "ambient conditions" instead of "air temperature." Specifically, large generating units are typically water cooled and therefore the correction factor should be revised as such. In addition, as stated in the response to question 2 above, the Transmission Planner should be the appropriate entity instead of the Transmission Owner.
Response: The GVSDT thanks you for your comment. The SDT modified the standard (Attachment 1, Step 3.4) to change “ambient temperature” to “ambient conditions” and to assign responsibility for making the ambient condition adjustments to the Generator Owner rather than the Transmission Owner. Item 3.4 in Attachment 1 provides guidance with respect to correction factors: **3.4. The ambient conditions at the end of the verification period the Generator Owner requires to perform corrections to Real Power for different ambient conditions such as:** **• Ambient air temperature**		

Organization	Yes or No	Question 3 Comment
• Relative humidity • Cooling water temperature		
Tacoma Power	No	Tacoma Power is not aware of any industry accepted standard air ambient real power correction factor for hydro units.
Response: The GVSDT thanks you for your comment. Correction factor consideration does not apply for units that are not affected by ambient temperature effects. The GVSDT will revise standard language to clarify this point.		
Georgia Transmission Corporation	No	The ambient temperature and other factors that influence the output should be included. The GO should provide temperature dependent and other data tables/graphs to the TP. Again, the comment form and attachment seem to conflict with R1 and R2 to provide data to the TP not the TO.
Response: The GVSDT thanks you for your comment. The intent of the standard is for the GO to create a correction factor from the data normally used for such purpose. The SDT modified the standard (Attachment 1, Step 3.4) to change "ambient temperature" to "ambient conditions" and to assign responsibility for making the ambient condition adjustments to the Generator Owner rather than the Transmission Owner.		
Austin Energy	No	Ambient temperature will have a less direct effect on water cooled generators with cooling water sources not directly affected by ambient temperature.
Response: The GVSDT thanks you for your comment. Item 3.4 in Attachment 1 provides guidance with respect to correction factors (note these have been revised so that the phrase, "ambient temperature" was replaced with the broader phrase, "ambient conditions"): **3.4. The ambient conditions at the end of the verification period the Generator Owner requires to perform corrections to Real Power for different ambient conditions such as:** • **Ambient air temperature** • **Relative humidity** • **Cooling water temperature**		
BC Hydro	No	Generating facilities are already designed and ratings determined based on maximum expected ambient temperatures. Besides, equipment cooling may not be directly dependent on ambient temperature. Providing the details to other entities would be of no practical value. GOs have to meet declared capabilities as registered or derate their facilities if needed.

Organization	Yes or No	Question 3 Comment
Response: The GVSDT thanks you for your comment. Temperature correction is more important for some units, such as gas turbines. The GO may omit the correction factor if unit Real Power output is not dependent, or is minimally dependent on, temperature. If the TP does not require temperature correction, then uncorrected data is used.		
Constellation Power Generation	No	Constellation Power Generation (CPG) agrees with this approach.
Response: The GVSDT thanks you for your comment. Please see the proposed revisions which identify a broader scope of ambient conditions and assign responsibility for making adjustments to the Generator Owner rather than the Transmission Owner.		
Indiana Municipal Power Agency	No	The owner or operator of the generating unit should do the temperature correction to a specified temperature as directed. The owner will possess the curves and be better acquainted with the unit's limitation and temperature correction.
Response: The GVSDT thanks you for your comment. The GVSDT believes that the Transmission Planner has unilateral authority for determining the correction temperature used, given the Transmission Planner selects the temperature value used for planning studies. The Generator Owner provides the correction factor so the TP can simply perform the work without having to track and verify the communication exchange that would otherwise have to occur with the GO. The SDT modified the standard (Attachment 1, Step 3.4) to change "ambient temperature" to "ambient conditions" and to assign responsibility for making the ambient condition adjustments to the Generator Owner rather than the Transmission Owner.		
Chelan County PUD	No	Should only be required if it impacts the data or test performed. For most generation it would not.
Response: The GVSDT thanks you for your comment. The TP has discretion to perform or not perform temperature correction.		
ISO New England	No	We maintain that temperature correction should be performed as required by the Transmission Operator. The standard must ensure that accurate data for gas turbine and combined cycle generators is obtained which can be adjusted to reflect the ambient temperature presumed in Planning Assessments.
Response: The GVSDT thanks you for your comment. The SDT modified the standard (Attachment 1, Step 3.4) to change "ambient temperature" to "ambient conditions" and to assign responsibility for making the ambient condition adjustments to the Generator Owner rather than the Transmission Owner. The data collected through this standard is intended for use in long-term planning studies.		
Duke Energy	No	System models are used for reliability purposes beyond planning purposes, which are at best, an educated guess at what the system will look like out in the future. The real time and day ahead models are most significant for assuring reliable system operation. It would seem that if the TP needs model data different than the Transmission Operations needs, the 1st step is for them to define a technical basis for that data.

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 3 Comment</th></tr>
<tr><td></td><td></td><td>Once that is done, then the GO/GOPs can develop numbers that match those conditions. Pmax will vary on ambient temp for some types of generation, lake temps for other types and hydo conditions for those units. Without a defintion of the data based on the studies to be performed, all the GO can do is guess. If the Q capacity is determined using a staged test, the ambient temperature during the test should be provided. The planning entity can adjust to other temperatures if they desire.</td></tr>
<tr><td colspan="3">Response: The GVSDT thanks you for your comment. The GVSDT believes that the standard satisfies most of your recommendations. The TP has discretion whether or not to use the correction factor provided, so the GO does not need to know the Transmission Planners intention. Keep in mind this standard is a planning standard, not a Real-time operations standard.</td></tr>
<tr><td>Indeck Energy Services</td><td>No</td><td>No temperature adjustment can be done reliably with real and reactive power. Real Power may be adjusted, but not with reactive. Generator can make the adjustment if there is a nationwide standard. If not, then regional standards will be required to specify the values.</td></tr>
<tr><td colspan="3">Response: The GVSDT thanks you for your comment. The GVSDT agrees the temperature correction factor provided is only used for adjusting Real Power values. Item 3.4 in Attachment 1 provides guidance with respect to correction factors:
3.4. The ambient conditions at the end of the verification period the Generator Owner requires to perform corrections to Real Power for different ambient conditions such as:
• Ambient air temperature
• Relative humidity
• Cooling water temperature</td></tr>
<tr><td>Gainesville Regional Utilities</td><td>No</td><td></td></tr>
<tr><td>Xcel Energy</td><td>No</td><td></td></tr>
<tr><td>American Wind Energy Association</td><td>No</td><td></td></tr>
<tr><td>Wisconsin Electric</td><td>No</td><td></td></tr>
<tr><td>Tri-State Generation and Transmission, In.</td><td>No</td><td></td></tr>
</table>

Organization	Yes or No	Question 3 Comment
Arizona Public Service Company	No	
Salt River Project	No	
PacifiCorp	No	
Northeast Power Coordinating Council	Yes	Real and reactive power output is affected by the thermal conditions in effect a t the time of testing and dispatch. The output of a generator, and therefore the model of its output, can be more or less temperature dependent, e.g., a combustion turbine with versus the same combustion turbine without inlet chillers. Attachment 1 specifies that the temperature only be recorded at the end of the verification period. Temperatures can vary significantly over the course of the verification period, and at a minimum the ambient temperatures at the beginning and end of a verification period should be recorded. It would also be meaningful and helpful to record ambient temperatures at intermediate points during a verification period. The Real Power data submitted should not be adjusted to a temperature other than ambient. When collecting real time data, it should be "what you see is what you get"; adjustments should not be accepted.
Response: The GVSDT thanks you for your comment. The GVSDT does not believe there is any difference between historical data and staged test data with regards to this issue. Either set of data should be correctable to a different ambient temperature basis than the ambient temperature value existing at time of recording. Also keep in mind that the Transmission Planner is the entity that decides if data is temperature corrected to a different basis when performing studies. The GO only provides collected data and a temperature correction factor to the Transmission Planner.		
Imperial Irrigation District (IID)	Yes	THE REAL POWER DATA OBTAINED FROM GENERATORS IS BASED ON AMBIENT TEMPERATURE AND ADDITIONAL ENVIRONMENTAL AND SYSTEMATIC CONDITIONS. BECAUSE OF THIS REASON, OBTAINING A CORRECTION FACTOR CORRESPONDING SOLELY TO THE AMBIENT TEMPERATURE FOR CALCULATION OF THE REAL POWER WILL NOT BE AN EFFECTIVE APPROACH. IN ADDITION, DUE TO SEVERAL PARAMETERS AS A FUNCTION OF THE REAL POWER AND THE TEMPERATURE, CALCULATION OF AN ACCURATE CORRECTON FACTOR WOULD BE SOMEWHAT DIFFICULT AND COSTLY AS IT MAY REQUIRE SEVERAL GENERATOR TESTING.
Response: The GVSDT thanks you for your comment. There are many factors that affect generator Real Power output, and these factors are different for different types of generating units. The reason why the GVSDT incorporated temperature correction consideration into the draft standard is because most Planners specify ambient temperature conditions when performing planning case studies. The GVSDT does not intend for entities to perform multiple tests. Instead, the GO simply provides a temperature correction factor with test data collected. As a matter of practicality, temperature correction factor information should already be captured as part of the internal process used for performing Real Power testing.		

Organization	Yes or No	Question 3 Comment
Pepco Holdings Inc Affiliates	Yes	The ambient temp and correction factor should be provided to the TP with all the data as stated in Question 2.
Response: The GVSDT thanks you for your comment.		
SPP Reliability Standards Development Team	Yes	We feel that the entity should be the Transmission Planner, but there is a need for the Generator Owner to provide an adjustment factor. The standard should address the temperature to bring the data to and then the Generator Owner could provide the factor to adjust the data. The standard also needs to address the fact that the temperature will not be a single set number and will vary depending on the season and geographic location.
Response: The GVSDT thanks you for your comment. The SDT modified the standard (Attachment 1, Step 3.4) to change "ambient temperature" to "ambient conditions" and to assign responsibility for making the ambient condition adjustments to the Generator Owner rather than the Transmission Owner. Item 3.4 in Attachment 1 provides guidance with respect to correction factors: **3.4. The ambient conditions at the end of the verification period the Generator Owner requires to perform corrections to Real Power for different ambient conditions such as:** • **Ambient air temperature** • **Relative humidity** • **Cooling water temperature**		
SERC Planning Standards Subcommittee	Yes	The Transmission Planner should be allowed to require that the Generator Owner provide an adjusted real power value (instead of an adjustment factor) based on different ambient temperature(s).
Response: The GVSDT thanks you for your comment. The SDT modified the standard (Attachment 1, Step 3.4) to change "ambient temperature" to "ambient conditions" and to assign responsibility for making the ambient condition adjustments to the Generator Owner rather than the Transmission Owner. The intent of the temperature correction factor provision is to allow the Transmission Planner make any correction to collected data deemed necessary during engineering analysis. Item 3.4 in Attachment 1 provides guidance with respect to correction factors: **3.4. The ambient conditions at the end of the verification period the Generator Owner requires to perform corrections to Real Power for different ambient conditions such as:** • **Ambient air temperature** • **Relative humidity**		

Organization	Yes or No	Question 3 Comment
• Cooling water temperature		
Dominion	Yes	We believe that, if the Resource Planner or Transmission Planner desire use of any correction factor, other than ambient, they be allowed to request the GO or TO adjust for that (those) correction factor(s) but that compliance with this standard be based solely upon the requirements contained within. If a RE desires to impose additional correction factor(s), it should file for a regional variance to this standard.
Response: The GVSDT thanks you for your comment. The GVSDT has revised the standard to capture additional ambient condition parameters which could be used for correction in addition to ambient air temperature and to change the responsibility for making adjustments from the Transmission Owner to the Generator Owner. Item 3.4 in Attachment 1 provides guidance with respect to correction factors: **3.4. The ambient conditions at the end of the verification period the Generator Owner requires to perform corrections to Real Power for different ambient conditions such as:** • **Ambient air temperature** • **Relative humidity** • **Cooling water temperature**		
Public Service Enterprise Group	Yes	We believe that the Real Power data submitted should be corrected to a temperature specified by the entity that requires the verification of Real Power capability. That entity is probably the Resource Planner or the Planning Coordinator- see the Functional Model, version 5 posted at http://www.nerc.com/files/Functional_Model_V5_Final_2009Dec1.pdf. For Generation Owners that belong to Regional Transmission organization that has a reserve margin criterion, it is probably registered as a Resource Planner and Planning Coordinator. For example, PJM, NYISO, and ISO-NE are each registered as a Resource Planner and a Planning Coordinator.
Response: The GVSDT thanks you for your comment. The SDT modified the standard (Attachment 1, Step 3.4) to change "ambient temperature" to "ambient conditions" and to assign responsibility for making the ambient condition adjustments to the Generator Owner rather than the Transmission Owner. As this is a long-term planning standard, it is envisioned that the TP receives the data and develops the appropriate models for use by other entities. The TP then hands these models off to entities that are concerned with the operations planning and Real-time operations time horizons. **Per the NERC Reliability Functional Model (V5, Page 25), the Transmission Planner has the following relationships with other entities:** **2. Collects information including:**		

Organization	Yes or No	Question 3 Comment
c. Generator unit performance characteristics and capabilities from Generator Owners. **5. Coordinates the evaluation of BES expansion plans with Transmission Service Providers, Transmission Owners, Reliability Coordinators, Resource Planners, and other Transmission Planners.** **6. Reports on and coordinates its BES expansion plan implementation with affected Planning Coordinators, Transmission Planners, Resource Planners, Transmission Service Providers, Transmission Owners, Transmission Operators and Reliability Assurers.**		
South Carolina Electric and Gas	Yes	The Transmission Planner should be allowed to require that the Generator Owner provide an adjusted real power value (instead of an adjustment factor) based on different ambient temperature(s).
Response: The GVSDT thanks you for your comment. The GVSDT believes that the Transmission Planner has sufficient flexibility to perform engineering analysis if only a correction factor is provided.		
Cowlitz County PUD	Yes	As long as correction factors may be documented from normal run history, this would not be burdensome to produce. As currently written, MOD-0025-2 appears to allow the Generator Owner to make a judgment call on whether ambient air temperature plays a significant role in generation capacity. If this is the case, then the report form should have a specific question: Is ambient air temperature correction factor applicable? ______ If yes, include in remarks below correction factors for different temperatures. Also, water coolant temperature may play a greater role. A quick passing hot or cool day during testing may not have any effect on the water coolant temperature. Where water temperature has a greater impact on capability, seasonal trends may be of greater significance. Finally, there is no criterion stipulated to define when ambient temperature correction factors are significant and should be provided. Cowlitz suggests that ambient temperature should only be considered significant if it affects Real or Reactive Power capability more than 10% between the lowest and highest expected ambient temperature extremes.
Response: The GVSDT thanks you for your comment. The revised standard (see Requirement R1, Part 1.3) allows the Transmission Planner to use discretion when determining if ambient condition correction is necessary for Real Power verification.		
Northeast Utilities	Yes	Real and reactive power output is affected by the thermal conditions in effect a t the time of testing and dispatch. The output of a generator, and therefore the model of its output, can be more or less temperature dependent, e.g., a combustion turbine with versus the same combustion turbine without inlet chillers. Attachment 1 specifies that the temperature only be recorded at the end of the verification period. Temperatures can vary significantly over the course of the verification period, and at a minimum the ambient

Organization	Yes or No	Question 3 Comment
		temperatures at the beginning and end of a verification period should be recorded. It would also be meaningful and helpful to record ambient temperatures at intermediate points during a verification period. The Real Power data submitted should not be adjusted to a temperature other than ambient. When collecting real time data, it should be "what you see is what you get"; adjustments should not be accepted.
Response: The GVSDT thanks you for your comment. The data is not required to be adjusted. The TP is not required to use the correction factor provided.		
Consolidated Edison Co. of NY, Inc.	Yes	Real and reactive power output is affected by the thermal conditions in effect a t the time of testing and dispatch. The output of a generator, and therefore the model of its output, can be more or less temperature dependent, e.g., a combustion turbine with versus the same combustion turbine without inlet chillers. Attachment 1 specifies that the temperature only be recorded at the end of the verification period. Temperatures can vary significantly over the course of the verification period, and at a minimum the ambient temperatures at the beginning and end of a verification period should be recorded. It would also be meaningful and helpful to record ambient temperatures at intermediate points during a verification period. The Real Power data submitted should not be adjusted to a temperature other than ambient. When collecting real time data, it should be "what you see is what you get"; adjustments should not be accepted.
Response: The GVSDT thanks you for your comment. The data is not required to be adjusted. The TP is not required to use the correction factor provided.		
American Electric Power	Yes	Again, we believe the question should be associated with the providing of ambient temperature and correction factor information to the Transmission Planner and the Resource Planner rather than the Transmission Owner. We believe the Resource Planner should provide the ambient temperature value, while the Generator Owner should provide the correction.
Response: The GVSDT thanks you for your comment. As noted in the GVSDT responses to Question Number 2, the TP is the correct entity. As revised, the standard requires the GO to supply a correction factor that the TP may use to extrapolate data to the desired temperature required for engineering analysis. As this is a long-term planning standard, it is envisioned that the TP receives the data and develops the appropriate models for use by other entities. The TP then hands these models off to entities that are concerned with the operations planning and Real-time operations time horizons. **Per the NERC Reliability Functional Model (V5, Page 25), the Transmission Planner has the following relationships with other entities:** **2. Collects information including:** **c. Generator unit performance characteristics and capabilities from Generator Owners.**		

Organization	Yes or No	Question 3 Comment
5. Coordinates the evaluation of BES expansion plans with Transmission Service Providers, Transmission Owners, Reliability Coordinators, Resource Planners, and other Transmission Planners. **6. Reports on and coordinates its BES expansion plan implementation with affected Planning Coordinators, Transmission Planners, Resource Planners, Transmission Service Providers, Transmission Owners, Transmission Operators and Reliability Assurers.**		
Ingleside Cogeneration LP	Yes	As with question #2, we believe the appropriate recipient of generator verification data is the Transmission Planner, not the Transmission Owner. Secondly, the Generator Owner providing the validation data must also be responsible for any corrections based on ambient temperature - as there may complexities beyond temperature correction factors. In these cases, if the TP performs the calculation, they may otherwise assume more capacity is available in their contingency assessments. The GO should have the option to provide the actual validation results to the TP with a temperature correction factor, but ultimately that decision rests with them. Third, the Transmission Planner must provide the required operating temperature range necessary for their system models. This will assure consistency among generators operating within their planning jurisdiction. If there are any discrepancies between the GO's and TP's expected range of operation, they can work that out through an iterative resolution process - similar to the structure suggested in MOD-026-1 and MOD-027-1.
Response: The GVSDT thanks you for your comment. As revised, the standard requires the GO to supply a correction factor. The GVSDT believes that simply having the GO supply a correction factor for TP discretional use will result in accurate data for planning purposes.		
Manitoba Hydro	Yes	The standard should allow the provision of ambient temperature during the verification be provided to the Transmission Owner as well as a correction factor to allow the Transmission Owner to adjust the Real Power data to a different ambient temperature if needed OR Real Power data submitted be temperature adjusted to some other than ambient temperature as requested by the TO.
Response: The GVSDT thanks you for your comment. The SDT modified the standard (Attachment 1, Step 3.4) to change "ambient temperature" to "ambient conditions" and to assign responsibility for making the ambient condition adjustments to the Generator Owner rather than the Transmission Owner. **Item 3.4 in Attachment 1 provides guidance with respect to correction factors:** **3.4. The ambient conditions at the end of the verification period the Generator Owner requires to perform corrections to Real Power for different ambient conditions such as:**		

Organization	Yes or No	Question 3 Comment
• Ambient air temperature • Relative humidity • Cooling water temperature		
Lincoln Electric System	Yes	The Real Power Data should be adjusted based on temperature to indicate what the output for the generating unit would be for peak summer conditions for a summer peaking utility and peak winter conditions for a winter peaking utility. Humidity is also factor that affects the output of units with evaporative cooling as well as the performance of cooling towers. Previously as part of the Mid-continent Area Power Pool our utility was required to submit monthly capacity accreditation of the generating units that was adjusted based on the ten-year average of the high temperature for the peak load day of the month. For the summer months this provided a fairly accurate estimate of the actual generating capabilities of the unit in the summer months. In the winter using the high temperature for the peak day was not quite as accurate, since the peak on the winter day does not usually coincide with the peak temperature for the day, but the ambient high temperature on these days is usually quite low. Even in the shorter months the output data may be beneficial to the Transmission Planner when large units in a region are out for maintenance. It is questionable as to how easy it would be for the Transmission Owner to apply the correction factors to other ambient temperatures if they are only given the temperature at the time of verification test. For gas turbine units without some form of inlet cooling the output may vary by as much as 30 percent from summer to winter ambient conditions. This is a significant amount of generating capacity.
Response: The GVSDT thanks you for your comment. The SDT modified the standard (Attachment 1, Step 3.4) to change “ambient temperature” to “ambient conditions” and to assign responsibility for making the ambient condition adjustments to the Generator Owner rather than the Transmission Owner. **The GVSDT believes that the Transmission Planner has unilateral authority for determining the correction temperature used given the Transmission Planner selects the temperature value used for planning studies. The Generator Owner provides the correction factor so the TP can simply perform the work without having to track and verify the communication exchange that would otherwise have to occur with the GO.**		
CPS Energy	Yes	Generator owner should perform the correction and determine the temperature value.
Response: The GVSDT thanks you for your comment. The SDT modified the standard (Attachment 1, Step 3.4) to change responsibility for making the ambient condition adjustments to the Generator Owner rather than the Transmission Owner. **The GVSDT believes that the Transmission Planner has unilateral authority for determining the correction temperature used given the Transmission Planner selects the temperature value used for planning studies. The Generator Owner provides the correction factor so the TP can simply perform**		

Organization	Yes or No	Question 3 Comment
the work without having to track and verify the communication exchange that would otherwise have to occur with the GO.		
Ameren	Yes	The ambient temperature at which the testing is performed would be an important data item. Because of greater familiarity with the equipment and its capabilities, any temperature adjustment to arrive at a different specified real power value should be performed by the Generator Owner. The Transmission Owner/Transmission Planner, who would be performing system modeling and study work, would be the entity most appropriate to specify temperature values for which temperature adjustment factors would be determined. Capabilities at different ambient temperatures need to be provided to meet the modeling requirements of the MMWG, and that the GO and TO should agree on what ambient temperatures to assume for the temperature adjustment.
Response: The GVSDT thanks you for your comment. The SDT modified the standard (Attachment 1, Step 3.4) to change responsibility for making the ambient condition adjustments to the Generator Owner rather than the Transmission Owner. **The GVSDT agrees that the TP is the appropriate entity to determine the temperature correction value used for planning studies. The GVSDT believes that the TP can perform any correction that is needed with the correction factor provided by the GO.**		
Oncor Electric Delivery Company LLC	Yes	Oncor believes that this information should be submitted to the Planning Authority in the ERCOT Region and that they (the Planning Authority) should coordinate with the Generator Owner in the development of any correction factor and the appropriate temperature value that should be used.
Response: The GVSDT thanks you for your comment. The SDT modified the standard (Attachment 1, Step 3.4) to change responsibility for making the ambient condition adjustments to the Generator Owner rather than the Transmission Owner.		
Wisconsin Public Service Corp	Yes	
Los Angeles Department of Water and Power		LADWP does not have a position on this question at this time.
APS		being intentionally left blank (no answer to be provided)

4. The SDT believes that verification should be performed on units that are connected down to 100 kV. The SDT has also provided how verification should be handled in plants/Facilities that are greater than 75 MVA in aggregate gross nameplate rating. The Standard requires a separate verification for every unit greater than 20 MVA gross nameplate rating, this is consistent with the current Compliance Registry. Units 20 MVA and smaller, in a plant/Facility greater than 75 MVA can be verified separately or in aggregate as the Generator Owner chooses. Do you agree with the SDT's decision to have the standard be applicable to the compliance registry? If not, please explain.

Summary Consideration: A majority of stakeholders disagreed with making the standard applicability match the same Facility thresholds as specified in the compliance registry. Several stakeholders suggested that the applicable generator size should be 75 MVA, or determined by the Planning Coordinator for its planning area or Interconnection (as specified in other proposed standards). Several stakeholders also suggested that the "sister" unit concept should be allowed for essentially identical units to minimize the number of units tested. Multiple stakeholders suggested referring to the Registry Criteria instead of restating Registry Criteria in the standard in the event criteria changes at a later date. A few stakeholders suggested that generator applicability should be independent of the voltage at the point where the unit is connected. None of the suggestions received include strong justification for having standard applicability deviate from the Compliance Registry, thus the SDT did not change the thresholds in the applicability of the standard.

Several commenters suggested that the applicability of this standard should mimic that of MOD-026 and MOD-027. The GVSDT at one point used direct language referencing the registry criteria, but were advised by NERC to state it as it is currently shown because the compliance registry doesn't address ownership of synchronous condensers. If the registry criteria changes, then changes may be made to the standard. The intent of testing all units is to discover unintended differences or deficiencies with unit capabilities or control systems that can only be identified by testing. The SDT believes that the applicability is different because MOD-026 and MOD-027 verify dynamic response, while MOD-025 verifies capability. The same basis does not apply.

Blackstart units were removed from the applicability because of redundancies with the requirements of EOP-005-2

R1.4. Identification of each Blackstart Resource and its characteristics including, but not limited to, the following: The name of the Blackstart Resource, location, megawatt and megavar capacity, and type of unit.

R6. Each Transmission Operator shall verify, through analysis of actual events, steady state and dynamic simulations, or testing that its restoration plan accomplishes its intended function. This shall be completed every five years at a minimum. Such analysis, simulations, or testing shall verify: [Violation Risk Factor = Medium] [Time Horizon =Long-term Planning]

R6.1. The capability of Blackstart Resources to meet the Real and Reactive Power requirements of the Cranking Paths and the dynamic capability to supply initial Loads.R9. Each Transmission Operator shall have Blackstart Resource testing requirements to verify that each Blackstart Resource is capable of meeting the requirements of its restoration plan. These Blackstart Resource testing requirements shall include:

[Violation Risk Factor = Medium] [Time Horizon = Operations Planning]

R9.1. The frequency of testing such that each Blackstart Resource is tested at least once every three calendar years.

R9.2. A list of required tests including:

R9.2.1. The ability to start the unit when isolated with no support from the BES, or when designed to remain energized without connection to the remainder of the System.

R9.2.2. The ability to energize a bus. If it is not possible to energize a bus during the test, the testing entity must affirm that the unit has the capability to energize a bus, such as verifying that the breaker close coil relay can be energized with the voltage and frequency monitor controls disconnected from the synchronizing circuits.

R9.3. The minimum duration of each of the required tests.

Organization	Yes or No	Question 4 Comment
LG&E and KU Energy	No	Blackstart unit testing is covered in he EOP standards, and should not be included in the MOD standards. Most of these are smaller units that don’t have much impact on the BES but are important because they are blackstart-not for the VARs.
Response: The GVSDT thanks you for your comment. VAR testing is important for line charging when considering small black start units.		
Northeast Power Coordinating Council	No	Generally, only units larger 75 MVA are impactful. It is recommended making 75 MVA the reporting floor [regardless of connected voltage]. This is consistent with current draft BES definition being prepared by the BES SDT.
Response: The GVSDT thanks you for your comment. The GVSDT has no basis to exclude any units included in the registration criteria from testing.		

Organization	Yes or No	Question 4 Comment
IRC Standards Review Committee (joint comments)	No	See comment to Q2. The planner should ask for the data that it needs to comply with NERC standards (nothing more and nothing less). There is no need for the requirement to get into the details. The Planning standards will force the Planner to ask for the data that it needs for its models. This approach limits the Planners from asking for data that they do not use in their Planning Models or that is not needed to comply with a NERC standard. This approach also allows the Planner to tailor its requests to the Models and technologies that it has and needs.
Response: The GVSDT thanks you for your comment. Please see the response to Question 2.		
Midwest Reliability Organization's NERC Standards Review Forum (NSRF)	No	There may be generating units or facilities that are included or excluded as BES elements either by the latest BES definition or the latest BES exception procedure that differ from 4.2.1 and 4.2.2. So we recommend adding anItem 4.2.4 to the Applicability section that states, “Generating Facility, generating unit or synchronous condenser that are designated as a BES Element according to the BES definition or BES exception procedure.”
Response: The GVSDT thanks you for your comment. The GVSDT has no basis to exclude any units included in the registration criteria from testing.		
Cowlitz County PUD	No	The Compliance Registry Criteria was hastily put together without proper reliability justification. The end result has created a registration process that assumes reliability impact where there is none, and allows exemptions where reliability impact does exist. Cowlitz believes in a protective backbone approach to reliability, the bulk power system (BPS) as a whole need not be completely protected in order to assure its reliability. There exists a core “backbone” subset from the BPS which must be protected; this is known as the Bulk Electric System (BES) and is currently undergoing revision in Project 2010-17. Once this project is complete, it may be necessary to revise the Compliance Registry Criteria to clearly identify entities as users of the BES who must participate in BES protective standard compliance activities. In other words, the Compliance Registry objective should be to identify all entities who must participate in the protection of the BES to assure reliability of the BPS, not identify elements of the BES. Cowlitz is not convinced that the Standard be applicable to the compliance registry of Generator Owners. For example, an entity owning a single small 500 KVA generation plant currently is exempt from registration; however it may own a transmission protection system protecting a BES element from a fault originating on the high side of the step up transformer. Therefore it should register as it is material to the reliability of the bulk power system. From the extensive reference of 20 MVA and 75 MVA in the Standard from the Compliance Registry Criteria, it appears that the SDT would not see a need for the 500 KVA generation plant to verify its capability. Further, pointing to the Compliance Registry Criteria’s generator MVA name plate ratings is also questionable. Cowlitz can find no reliability justification; it appears to be completely arbitrary. After reviewing the Field Test

Organization	Yes or No	Question 4 Comment
		Results, Cowlitz finds that WECC set the line at 10 MVA and SERC recommended 75 MVA with no substantiating arguments. Also noted in the Field Test Results was a problem in getting the dynamic models to return data results that agreed with actual events. With the Field Test Results dated in 2007, Cowlitz is unsure on the current accuracy of dynamic model predictions. However, if models are currently accurate it should be a simple process to verify the size of generation that can be ignored. Looking over the data requirements of MOD-25, Cowlitz can see that there will be considerable consultant cost - $25,000 - to comply. Using the Compliance Registry Criteria for applicability is not acceptable. Unwarranted compliance efforts will reduce overall reliability results. Cowlitz recommends the SDT consult with Planning Coordinators (Planning Authorities) and Transmission Planners on the current status of modeling accuracy and request documentation for generation that can be ignored. Also, it may be permissible for smaller generation to simply report seasonal historical Real and Reactive Power output.
Response: The GVSDT thanks you for your comment. MOD-025 calls for verification of static points that the unit is capable of reaching. Transmission or unit equipment limitations may prevent a unit from reaching its design basis. As generating equipment ages, its operating characteristics change. Over time, unit performance degrades unless upgrades to the unit are made. In order to ensure that planning models have accurate, dependable data, verifications need to be performed. The GVSDT has no basis to exclude any units included in the registration criteria from testing. The GVSDT also believes that a five-year testing interval would not be a burden.		
SERC Planning Standards Subcommittee	No	The use of sisters units should be allowed by the standard. Also, verification should apply on the 75 MVA units, and above. Units smaller than this have very little impact on grid reliability. However, the standard should apply to designated blackstart units included in a system restoration plan, regardless of size.
Response: The GVSDT thanks you for your comment. The intent of testing all units is to discover unintended differences or deficiencies with unit capabilities or control systems that can only be identified by testing all units, including sister units. The GVSDT has no basis to exclude any units included in the registration criteria from testing.		
Ameren	No	The allowance for exemption of sister units should be permitted. Only one verification for sister units should be required. Testing for units less than 75 MVA should not be required, as these have little impact on grid reliability.
Response: The GVSDT thanks you for your comment. The intent of testing all units is to discover unintended differences or deficiencies with unit capabilities or control systems that can only be identified by testing all units, including sister units. The GVSDT has no basis to exclude any units included in the registration criteria from testing.		
Indeck Energy Services	No	Some standards need to apply to all registered generators. These do not. The minimum unit size should be at the NERC Reportable Disturbance level for the control area. Variations in any other sized unit need not

Organization	Yes or No	Question 4 Comment
		even be reported. This isn't about treating all generators fairly, it is about what is affecting BPS reliability.
Response: The GVSDT thanks you for your comment. The GVSDT has no basis to exclude any units included in the registration criteria from testing.		
Chelan County PUD	No	For multi-unit hydro and wind plants this can become a large effort. A "type" test where one of an identical family of units is verified is more practical and should provide sufficient data.
Response: The GVSDT thanks you for your comment. The intent of testing all units is to discover unintended differences or deficiencies with unit capabilities or control systems that can only be identified by testing all units, including sister units.		
Santee Cooper	No	Recommend changing Section 4.2 Facilities to match Section 4.2 Facilities as it is written in MOD-026-1 and MOD-027-1 below: 4.2. Facilities For the purpose of this standard, the following Facilities are considered, “applicable units.” Units or plants with an average capacity2factor greater than 5% over the last three calendar years that meet the following: 4.2.1 Generating units connected to the Eastern or Quebec Interconnections with the following characteristics: o Each generating unit with a gross nameplate rating greater than 100 MVA, connected at the point of interconnection3at greater than 100 kV. o For each plant with a gross aggregate nameplate rating greater than 100 MVA, connected at the same point of interconnection at greater than 100 kV: o Each unit with a gross nameplate rating greater than 20 MVA; and o The remainder of the plant as an aggregate. There should also be some allowance for Units which are nearly identical and therefore model the same.
Response: The GVSDT thanks you for your comment. The GVSDT at one point used direct language referencing the registry criteria, but were advised by NERC to state it as it is currently shown because the compliance registry doesn’t address ownership of synchronous condensers. If the registry criteria changes, then changes may be made to the standard. The intent of testing all units is to discover unintended differences or deficiencies with unit capabilities or control systems that can only be identified by testing. The SDT believes that the applicability is different because MOD-026 and MOD-027 verify dynamic response while MOD-025 verifies capability. The same basis does not apply.		
PPL Generation	No	The applicability of this standard should include, "and having a capacity factor for the past three years averaging over 10%." As presently written this standard would require VAR testing of a small, emergency genset if located in a baseload facility interconnected greater than 100 kV.

Organization	Yes or No	Question 4 Comment
Response: The GVSDT thanks you for your comment. The GVSDT believes that a five-year testing frequency is reasonable for any unit. The GVSDT does not believe that emergency generators are connected at 100 kV and would therefore not be included. The GVSDT believes that when the capacity is needed the most and therefore most critical to reliability is the time when these units would be running, and, therefore, should be verified.		
SERC Dynamics Review Sub-committee	No	The use of sister units should be allowed by the standard. Also, verification should apply on the 75 MVA units, and above. Units smaller than this have very little impact on grid reliability.
Response: The GVSDT thanks you for your comment. The intent of testing all units is to discover unintended differences or deficiencies with unit capabilities or control systems that can only be identified by testing all units, including sister units. The GVSDT has no basis to exclude any units included in the registration criteria from testing.		
NERC Staff	No	While we agree that all units connected at voltage <100 kV need not be tested and modeled, any units >20 MVA and plants/facilities >75 MVA should be tested and modeled accurately regardless of interconnection voltage. The reliability impact of generating units is more directly related to unit capability than interconnection voltage.
Response: The GVSDT thanks you for your comment. The GVSDT has no basis to exclude any units included in the registration criteria from testing.		
SERC Generation sub-committee	No	We believe that Section 4 Applicability (4.2.1 and 4.2.2) for this standard should be revised to match the Section 4 Applicability for MOD-026-1 and MOD-027-1. NERC is focusing on standard requirements that have significant impacts on system reliability. Including smaller units without demonstrating their criticality to the system appears inconsistent with this philosophy. Verification for smaller units should only be required if technically justified by the Planning Coordinator as specified in 4.2.4 of MOD-026-1. The use of "sister" (essentially identical) units should be allowed by the standard (as is allowed in SERC's current MOD-025 procedure). Independent verification of essentially identical units should not be required. Blackstart units (4.2.3 of Section 4 above) should not be covered under the MOD standards. They are covered under the EOP standards (EOP-005-2).
Response: The GVSDT thanks you for your comment. The GVSDT at one point used direct language referencing the registry criteria, but were advised by NERC to state it as it is currently shown because the compliance registry doesn't address ownership of synchronous condensers. If the registry criteria changes, then changes may be made to the standard. The intent of testing all units is to discover unintended differences or deficiencies with unit capabilities or control systems that can only be identified by testing. The SDT believes that the applicability is different because MOD-026 and MOD-027 verify dynamic response while MOD-025 verifies capability. The same basis does not apply.		

Organization	Yes or No	Question 4 Comment
Black start units were removed from applicability because they are addressed in EOP-005, as you suggest.		
Arizona Public Service Company	No	Verification on units less than 50 MVA is an unnecessary burden and does not add significantly to reliability of the BES. Many of these units are not even modeled because of the availability of other units for a given schedule.
Response: The GVSDT thanks you for your comment. The GVSDT has no basis to exclude any units included in the registration criteria from testing.		
Southern Company	No	We believe that Section 4 Applicability for this standard should be revised to match the Section 4 Applicability for MOD-026-1 and MOD-027-1 with respect to inidividual unit size of 100 MVA for the Eastern Interconnection. However, for plants with a gross aggregate nameplate rating â‰¥ 100, we question the need to perform verification for individual units as small as 20 MVA. A 20MVA machine today can not impact the system like it could have 20 years ago. A technical basis for verification of units as small as 20MVA needs to be provided. NERC is focusing on standard requirements that have significant impacts on system reliability, and including smaller units without demonstrating their criticality to the system seems to be inconsistent with this philosophy. Verification for smaller units should only be required if technically justified by the Planning Coordinator as specified in 4.2.4 of MOD-026-1.
Response: The GVSDT thanks you for your comment. The GVSDT at one point used direct language referencing the registry criteria, but were advised by NERC to state it as it is currently shown because the compliance registry doesn't address ownership of synchronous condensers. If the registry criteria changes, then changes may be made to the standard. The intent of testing all units is to discover unintended differences or deficiencies with unit capabilities or control systems that can only be identified by testing. The SDT believes that the applicability is different because MOD-026 and MOD-027 verify dynamic response while MOD-025 verifies capability. The same basis does not apply.		
Tennessee Valley Authority GO	No	We believe that Section 4 Applicability (4.2.1 and 4.2.2) for this standard should be revised to match the Section 4 Applicability for MOD-026-1 and MOD-027-1. NERC is focusing on standard requirements that have significant impacts on system reliability. Including smaller units without demonstrating their criticality to the system appears inconsistent with this philosophy. Verification for smaller units should only be required if technically justified by the Planning Coordinator as specified in 4.2.4 of MOD-026-1. The use of "sister" (essentially identical) units should be allowed by the standard (as is allowed in SERC's current MOD-025 procedure). Independent verification of essentialy identical units should not be required.

Organization	Yes or No	Question 4 Comment
Response: The GVSDT thanks you for your comment. The GVSDT at one point used direct language referencing the registry criteria but were advised by NERC to state it as it is currently shown because the compliance registry doesn't address ownership of synchronous condensers. If the registry criteria changes, then changes may be made to the standard. The intent of testing all units is to discover unintended differences or deficiencies with unit capabilities or control systems that can only be identified by testing all units, including sister units. The SDT believes that the applicability is different because MOD-026 and MOD-027 verify dynamic response, while MOD-025 verifies capability. The same basis does not apply.		
South Carolina Electric and Gas	No	The verification of sisters units on an alternating basis should be allowed by the standard.
Response: The GVSDT thanks you for your comment. The intent of testing all units is to discover unintended differences or deficiencies with unit capabilities or control systems that can only be identified by testing all units, including sister units.		
Associated Electric Cooperative, Inc.	No	The use of "sister" (essentially identical) units should be allowed by the standard (as is allowed in SERCs current MOD-025 regional criteria). Independent verification of essentially identical units should not be required.
Response: The GVSDT thanks you for your comment. The intent of testing all units is to discover unintended differences or deficiencies with unit capabilities or control systems that can only be identified by testing all units, including sister units.		
Tacoma Power	No	1) Gross unit nameplate is not an industry defined term. The size of unit required for verification for hydro units should be the FERC defined licensed hydro unit nameplate rating. 2) Aggregate gross nameplate plant/facility capacity for hydro units is not a defined term and may not be the combined unit capacities. It is common for hydro facilities with multiple units have increased head losses or other restrictions that restrict or limit plant capacity below the aggregate gross nameplate capacity. For determining gross aggregate hydro plants and units for verification it should be the FERC defined plant licensed capacity.
Response: The GVSDT thanks you for your comment. The terms, "gross unit nameplate" and "aggregate gross nameplate" are not used in the standard. The GVSDT has no basis to exclude any units included in the registration criteria from testing.		
BC Hydro	No	In principle, using compliance registry as a sole criteria for applicability of Reliability Standards removes technical evaluation and justification from the process. The value that technical experts participating in SDTs may add becomes limited, which ultimately does not benefit the industry.
Response: The GVSDT thanks you for your comment. The GVSDT agrees but has no basis to exclude any units included in the registration criteria		

Organization	Yes or No	Question 4 Comment
from testing.		
Northeast Utilities	No	Generally, only units larger 75 MVA are impactful. It is recommended making 75 MVA the reporting floor [regardless of connected voltage]. This is consistent with current draft BES definition being prepared by the BES SDT.
Response: The GVSDT thanks you for your comment. The GVSDT has no basis to exclude any units included in the registration criteria from testing. This standard may have to be revised if the registry criteria changes.		
Constellation Power Generation	No	Although CPG agrees with the approach of applying this standard to all generation facilities in the compliance registry, mimicking it in the standard is redundant and problematic. Should the compliance registry change, then this standard may include facilities not registered with NERC. Conversely, this standard could potentially exclude facilities in the registry should the compliance registry change.
Response: The GVSDT thanks you for your comment. The GVSDT at one point used direct language referencing the registry criteria but were advised by NERC to state it as it is currently shown because the compliance registry doesn't address ownership of synchronous condensers. This standard may have to be revised if the registry criteria changes.		
Consolidated Edison Co. of NY, Inc.	No	Generally, only units larger 75 MVA are impactful. It is recommended making 75 MVA the reporting floor [regardless of connected voltage]. This is consistent with current draft BES definition being prepared by BES SDT.
Response: The GVSDT thanks you for your comment. The GVSDT has no basis to exclude any units included in the registration criteria from testing. This standard may have to be revised if the registry criteria changes.		
Duke Energy	No	Obviously, all units which are critical to reliability should be included, but what is critical is dependent upon system configurations. The continent wide standard should specify the largest size units critical in an interconnection and then regional standards might tighten the number based on that region's need. The SERC region currently requires real & reactive verification only for units > 75 MVA (RFC uses 85 MVA). The use of "sister" (essentially identical) units should be allowed by the standard (as is allowed in SERC's current MOD-025 procedure). Independent verification of essentialy identical units should not be required. Blackstart units (4.2.3 of Section 4 above) should not be covered under the MOD standards. They are covered under the EOP standards (EOP-005-2).

Organization	Yes or No	Question 4 Comment
Response: The GVSDT thanks you for your comment. Any testing performed for Blackstart Resources under the EOP standards may be used to show compliance with the MOD-025 standard for similar requirements. Additional or separate testing is not required. The GVSDT also believes that a five-year testing frequency is reasonable for any unit. The intent of testing all units is to discover unintended differences or deficiencies with unit capabilities or control systems that can only be identified by testing all units, including sister units.		
Independent Electricity System Operator	No	The Applicability section is not clear enough to expect consistent application. When the facility that makes the connection at 100 kV or above is not owned by the Generator Owner (e.g. a Distribution Provider might own this facility) the present expression of the standard will lead to inconsistencies. Facilities with identical electrical characteristics may or may not be subject to this standard only because of the structure of the ownership of assets. To address this, we propose revising section 4.2 by removing the condition for interconnection at 100 kV and above and aligning with the standard's purpose:4.2.1 Individual generating unit or synchronous condenser greater than 20 MVA (gross nameplate rating) considered in BES reliability assessments.. 4.2.2 Generating plant/Facility greater than 75 MVA (gross aggregate nameplate rating) considered in BES reliability assessments.4.2.3 Blackstart units, regardless of size that are included in a Transmission Operator's restoration plan.
Response: The GVSDT thanks you for your comment. The GVSDT has revised the applicability to be consistent with NERC Compliance Registry Criteria and other standards being developed under this project: **For the purpose of this standard, the term, "applicable Facility" shall mean any one of the following:** **4.2.1 Individual generating unit greater than 20 MVA (gross nameplate rating) in a directly connected to the bulk power system.** **4.2.2 Synchronous condenser greater than 20 MVA (gross nameplate rating) directly connected to the bulk power system.** **4.2.3 Generating plant/Facility greater than 75 MVA (gross aggregate nameplate rating) directly connected to the bulk power system.**		
Indiana Municipal Power Agency	Yes	IMPA supports the SDT's decision to have the standard be applicable to the compliance registry.
Response: The GVSDT thanks you for your comment.		
Idaho Power-Power Production	Yes	Consistency with the compliance registry and the BES definition is important.

Organization	Yes or No	Question 4 Comment
Response: The GVSDT thanks you for your comment.		
FirstEnergy	Yes	We agree that this standard should be consistent with the NERC Compliance Registry.
Response: The GVSDT thanks you for your comment.		
Westar Energy	Yes	We propose that language be added to reference the Compliance Registry to ensure that as the Registry changes the appropriate applicability is followed.
Response: The GVSDT thanks you for your comment. The GVSDT at one point used direct language referencing the registry criteria, but were directed by NERC to state it as it is currently shown. If the registry criteria changes then changes may be made to the standard.		
SPP Reliability Standards Development Team	Yes	If the intent is that the team wants to follow the Compliance Registry then we would ask that there be direct language reference to the Registry. If this isn't done and the Registry changes as worded now the standard would be static to the numbers given. This team needs to get plugged into the BES DEF standard drafting team as there are discussions being held currently that could change the Registry criteria.
Response: The GVSDT thanks you for your comment. The GVSDT at one point used direct language referencing the registry criteria but were advised by NERC to state it as it is currently shown because the compliance registry doesn't address ownership of synchronous condensers. If the registry criteria changes, then changes may need to be made to the standard.		
Ingleside Cogeneration LP	Yes	These applicability criteria are consistent within the Regions that Ingleside Cogeneration has familiarity with (TRE, WECC, and SERC).
Response: The GVSDT thanks you for your comment.		
ISO New England	Yes	Yes, however the standard should not rewrite the Compliance Registry as attempted in section 4.2. The registry language of section IIIc.3 and IIIc.4 is more precise and differs from what is proposed in the standard. For instance, the registry's wording on Black Start generators applies to a blackstart unit material to and designated as part of a transmission operator entity's restoration plan. All that is needed is to have the standard applicable to Generator Owners and let the Registry dictate those who must register and comply.
Response: The GVSDT thanks you for your comment. The GVSDT at one point used direct language referencing the registry criteria but were advised by NERC to state it as it is currently shown because the compliance registry doesn't address ownership of synchronous condensers.		

Organization	Yes or No	Question 4 Comment
Manitoba Hydro	Yes	The Applicability of this standard should be to BES Generating Units and Facilities. Section 4.2 should not restate components of the proposed BES definition.
Response: The GVSDT thanks you for your comment. The GVSDT at one point used direct language referencing the registry criteria but were advised by NERC to state it as it is currently shown because the compliance registry doesn't address ownership of synchronous condensers.

5. The draft standard requires that the Reactive Power capability be verified at four points: Over-excited (lagging) and under-excited (leading) Reactive capability at (1) the rated Real Power capability and (2) expected minimum Real Power output. The SDT believes that this is consistent with the FERC directive in Order 693 at P1321, "Therefore, we adjust the proposal in the NOPR and direct the ERO to modify MOD-025-1 to require verification of Reactive Power capability at multiple points over a unit's operating range." Do you agree that the four points proposed by the SDT is adequate to provide a straight line approximation to a unit's Reactive Power capability over its actual operating range? If not, please explain.

Summary Consideration: A majority of stakeholders agreed that the four points proposed by the SDT are adequate to provide a straight-line approximation to a unit's Reactive Power capability over its actual operating range. Some stakeholders suggested testing less than four points (i.e. only Pmax, Qmax for nuclear units), while others suggested not testing at all. The SDT agrees that the four points proposed will provide an adequate approximation of the machine's capability and satisfy the directive in Order 693. For units that have environmental or other legally-bound restrictions, the standard does not require violating those restrictions. If a unit has no leading capability, then it should be reported with no leading capability. This statement was added as Note 4 of Attachment 1:

Note 4: The verification is intended to define the limits of the unit's capabilities. If a unit has no leading capability, then it should be reported with no leading capability, or the minimum lagging capability at which it can operate.

Organization	Yes or No	Question 5 Comment
LG&E and KU Energy		The addition of the lagging and leading at (2); the expected minimum Real Power output are new points to test from the existing version of MOD-025. This will eventually double the testing window (at a minimum)
Response: The GVSDT thanks you for your comment. The FERC Order 693 requires verification at multiple points, and the GVSDT believes that verification at a minimum of four points is necessary to approximate the capability curve.		
IRC Standards Review Committee (joint comments)	No	See comment to Q2. The planner should ask for the data that it needs to comply with NERC standards (nothing more and nothing less). There is no need for the requirement to get into the details. The Planning standards will force the Planner to ask for the data that it needs for its models. This approach limits the Planners from asking for data that they do not use in their Planning Models or that is not needed to comply

Organization	Yes or No	Question 5 Comment
		with a NERC standard. This approach also allows the Planner to tailor its requests to the Models and technologies that it has and needs.
Response: The GVSDT thanks you for your comment. See response to Question 2.		
SPP Reliability Standards Development Team	No	This is a non linear curve. Is the reason for using the 4 point method all that would fit into the model? We also have the concern that isn't addressed here and it is if the unit can't be tested at the time due to system conditions then you must wait until the system is able. We feel that the points should reflect what is usable.
Response: The GVSDT thanks you for your comment. The FERC Order 693 requires verification at multiple points, and the GVSDT believes that verification at a minimum of four points is necessary to approximate the capability curve. Although the GVSDT does not believe that engineering analysis alone is sufficient, it is envisioned that engineering analysis may be used to supplement operational data or staged testing. The following Note was added to Attachment 1 of the standard: **"While not required by the standard, it is desirable to perform engineering analysis to determine expected unit capabilities under less restrictive system conditions. Even though this analysis will not verify the complete MVAR capability curve, it provides a reasonable estimate of unit capability that the Transmission Planner can use for modeling."**		
Idaho Power-Power Production	No	No, we believe that the four points are not adequate to describe a unit's capability. FAC-008 and FAC-009 require us to have a normal and emergency rating and the WECC validation policy requires the verification of the unit's capability. Is this standard intended to replace those standards/policies? If so it was not clear in the project documentation. If not, we believe this standard to be redundant to our existing policies and procedures here in WECC.
Response: The GVSDT thanks you for your comment. MOD-025-2 is not intended to replace FAC-008 or FAC-009. The FAC standards relate to a Facility ratings methodology while MOD-025 is a verification of actual performance. It is possible that the required performance in this standard may satisfy the WECC validation policy.		
Santee Cooper	No	The current SERC Regional Criteria requires gross and net reactive capability be determined within the power factor range at which the generating equipment is normally expected to operate. We do not believe anything is gained by testing in power factor ranges where the unit is not expected to operate.
Response: The GVSDT thanks you for your comment. The GVSDT disagrees. The full reactive capability range must be known for planning purposes.		
Dominion	No	We believe that, if the Resource Planner or Transmission Planner desire use of any correction factor, other than ambient, they be allowed to request the GO or TO adjust for that (those) correction factor(s) but that

Organization	Yes or No	Question 5 Comment
		compliance with this standard be based solely upon the requirements contained within. If a RE desires to impose additional correction factor(s), it should file for a regional variance to this standard.
Response: The GVSDT thanks you for your comment. As now stated, the revised standard requires that sufficient data be taken to allow correction to conditions other than ambient, if requested. This requirement addresses one of the directives in FERC Order 693.		
FirstEnergy	No	As a TO, we rank the importance to the modeling effort as follows: (1) Pmax, Qmax; (2) Pmin, Qmin; (3)) Pmax, Qmin. We believe that the Pmin, Qmax is of little value to a Planning Engineer.
Response: The GVSDT thanks you for your comment. The FERC Order 693 requires verification at multiple points, and the GVSDT believes that verification at a minimum of four points is necessary to approximate the capability curve.		
NERC Staff	No	Reactive Power capability is not a linear function of Real Power. The reactive capability curve and minimum excitation limiter settings for each machine should be used to determine the expected gross reactive capability.
Response: The GVSDT thanks you for your comment. The GVSDT concurs that reactive capability is not a linear function of Real Power. However, MOD-025-2 is a performance-based standard which is to verify the Real and Reactive power capabilities of generators.		
Public Service Enterprise Group	No	For clarification, Attachment 1, paragraph 2.2 does not require Reactive Power capability verification for wind and photovoltaic at minimum Real Power output. It also appears that Nuclear Units are also exempt. “Nuclear Units” has the term “Units” capitalized, but it is not in the NERC Glossary and should probably be lower case. We suggest that R2.2 be redrafted as follows: “Verify Reactive Power capability of all generating units other than nuclear, wind and photovoltaic for maximum overexcited (lagging) and under-excited (leading) reactive capability at the minimum Real Power output at which they could normally be expected to operate. In addition, nuclear units should be exempted from under-excited Reactive Power verification at maximum Real Power capability because such verification may lead to concerns with unit stability and potential under-voltage conditions on internal nuclear plant safety buses. This would require a change in paragraph 2.1For other units, these points are acceptable.
Response: The GVSDT thanks you for your comment. The GVSDT believes that if a nuclear plant has under-excited capability, it should be tested within the unit’s capability and declared safety margins. The standard does not require challenging unit capabilities. The following statement was added to Note 1 of Attachment 1 for clarity, “Auxiliary bus voltage limits should be observed.”		
SERC Generation sub-committee	No	Although we agree that four points are sufficient to provide a straight line approximation over a unit's

Organization	Yes or No	Question 5 Comment
		operating range, we don't agree that four points are needed for baseload units. We strongly agree with the Commission's statement that "such a requirement for all generators may not be necessary." First, we believe 2.2, of Attachment 1 to the standard, should exempt all base load units (not just nuclear units) from verification of reactive capability at minimum real power output. There are other units that the industry should be able to exempt based on their normal operating modes. Examples are peaker CTs and units that have restrictions (environmental, run of the river, etc.) preventing operation at minimum load.Finally, for units where verification of multiple points are needed, the analytical approach to verification,discussed in our responses to Questions 10, 11, and 14, serves this purpose very well.This concern is addressed in Paragraph 1321 of the FERC Order which states: "...other than baseload units, most generating units rarely operate at full MW loading. It is unclear what reactive capability is available throughout a unit's real power (MW) operating range. Therefore, we believe a clearer standard would require a verification of MVAR capability throughout a unit's real power (MW) operating range. However, we share concern with several commenters that such a requirement for all generators may not be necessary." Also, The GS does not believe that verification for leading capability should be required where operational practices preclude operation in a leading mode.
Response: The GVSDT thanks you for your comment. The FERC Order 693 requires verification at multiple points, and the GVSDT believes that verification at a minimum of four points is necessary to approximate the capability curve. Analytical methods do not provide verification of equipment capability. The standard requires testing at the minimum Load that a unit is normally expected to operate. For units that have environmental or other legally-bound restrictions, the standard does not require violating those restrictions. If a unit has no leading capability, then it should be reported with no leading capability. This statement was added as Note 4 of Attachment 1: **Note 4: The verification is intended to define the limits of the unit's capabilities. If a unit has no leading capability, then it should be reported with no leading capability or the minimum lagging capability at which it can operate.**		
Southern Company	No	We agree that four points are sufficient to provide a straight line approximation over a unit's operating range. However, we strongly agree with the Commission's statement that "such a requirement for all generators may not be necessary." Paragraph 1321 of the FERC Order states, "...other than baseload units, most generating units rarely operate at full MW loading. It is unclear what reactive capability is available throughout a unit's real power (MW) operating range. Therefore, we believe a clearer standard would require a verification of MVAR capability throughout a unit's real power (MW) operating range. However, we share concern with several commenters that such a requirement for all generators may not be necessary." These statements indicate the Commission is seeking further guidance from the industry. Based on this, we have the following recommendations. First, we believe 2.2 of Attachment 1 to the standard should exempt all base load units, not just nuclear units, from verification of reactive capability throughout the full MW range. There are other units the industry should be able to justify exempting based on their normal operating modes.

Organization	Yes or No	Question 5 Comment
		Examples are peaker CTs and units that have restrictions (environmental, run of the river, etc.) that prevent operation at minimum load. Second, we suggest that an evaluation be made on a small subset of units that could then be used to respond to the question raised by FERC. Our experience indicates that a unit will typically be capable of delivering or absorbing a comparable amount of reactive power to/from the grid at minimum load when compared to full load. The industry as a whole does not need to perform the verification at multiple points on 100% of the units to respond to an open question from FERC. Third, for units where verification of multiple points are needed, the analytical approach to verification we discuss in our responses to Questions 10, 11, and 14 serves this purpose very well.
Response: The GVSDT thanks you for your comment. The drafting team believes that four test points represent the minimum number required to meet the FERC directive of testing multiple points throughout the Load range to approximate the capability curve. Nuclear units are exempted from Reactive Power testing at low Real Power levels to minimize risks associated with changing reactor power levels. These same risks are not present for other base Load units. Analytical methods do not provide verification of equipment capability. The standard requires testing at the minimum Load that a unit is normally expected to operate. For units that have environmental or other restrictions, the standard does not require violating those restrictions.		
Tennessee Valley Authority GO	No	Although we agree that four points are sufficient to provide a straight line approximation over a unit's operating range, we don't agree that four points are needed for baseload units. We strongly agree with the Commission's statement that "such a requirement for all generators may not be necessary."First, we believe 2.2, of Attachment 1 to the standard, should exempt all base load units (not just nuclear units) from verification of reactive capability at minimum real power output. There are other units that the industry should be able to exempt based on their normal operating modes. Examples are peaker CTs and units that have restrictions (environmental, run of the river, etc.) preventing operation at minimum load. Finally, for units where verification of multiple points are needed, the analytical approach to verification, discussed in our responses to Questions 10, 11, and 14, serves this purpose very well. This concern is addressed in Paragraph 1321 of the FERC Order which states:"...other than baseload units, most generating units rarely operate at full MW loading. It is unclear what reactive capability is available throughout a unit's real power (MW) operating range. Therefore, we believe a clearer standard would require a verification of MVAR capability throughout a unit's real power (MW) operating range. However, we share concern with several commenters that such a requirement for all generators may not be necessary."Also, We do not believe that verification for leading capability should be required where operational practices preclude operation in a leading mode.
Response: The GVSDT thanks you for your comment. The drafting team believes that four test points represent the minimum number required to meet the FERC directive of testing multiple points throughout the Load range to approximate the capability curve. Nuclear units are exempted from Reactive Power testing at low Real Power levels to minimize risks associated with changing reactor power levels. These same risks are not present for		

Organization	Yes or No	Question 5 Comment
other base Load units. Analytical methods do not provide verification of equipment capability. The standard requires testing at the minimum Load that a unit is normally expected to operate. For units that have environmental or other restrictions, the standard does not require violating those restrictions.		
Luminant Power	No	Luminant proposes the following: 1. At High Load - Maximum overexcitation and under-excitation testing shall be conducted at a minimum of 95% of real power output capability and achieve 90% or greater MVAR output based on the reactive capability curve or as limited by system conditions. 2. At Low Load - Maximum overexcitation and under-excitation testing shall be conducted in the output range between minimum stable load and minimum stable load plus 30%, and achieve 90% or greater MVAR output based on the reactive capability curve or as limited by system conditions. 3. Lead and lag tests can conducted independently.
Response: The GVSDT thanks you for your comment. The GVSDT believes that the Loads required for testing are safe and adequately described. Wording has been changed to better define tests derived from historical data in Requirements R1-R3 and Item 2 in Attachment 1. **Lead and lag tests can be conducted independently.**		
PacifiCorp	No	PacifiCorp believes that the four points proposed by the SDT are adequate with respect to thermal and hydro generation units; however, the proposed points do not adequately take operating conditions for wind generation facilities into consideration.
Response: The GVSDT thanks you for your comment. The GVSDT welcomes suggestions relative to testing wind generation facilities.		
Associated Electric Cooperative, Inc.	No	We don't agree that four points are needed for baseload units, since they are rarely expected to operate at or near Pmin. In addition to nuclear units, baseload units should be exempt from reactive capability verification at Pmin.
Response: The GVSDT thanks you for your comment. Nuclear units are exempted from Reactive Power testing at low Real Power levels to minimize risks associated with changing reactor power levels. These same risks are not present for other base Load units. Testing nuclear units at P min is not required by the standard.		
New York Independent System Operator	No	There is no value to performing the lagging testing at minimum real power loading and leading test at maximum power. The testing requirement should be changed to two test points. One test for an hour to

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 5 Comment</th></tr>
<tr><td></td><td></td><td>verify over-excited (lagging) capability at the real power level specified by the Transmission Operator or the Transmission Planner; a second test to verify under-excited capability (leading) at the real power level specified by the Transmission Operator or the Transmission Planner.</td></tr>
<tr><td colspan="3">Response: The GVSDT thanks you for your comment. The FERC Order 693 requires verification at multiple points, and the GVSDT believes that verification at a minimum of four points is necessary to approximate the capability curve.</td></tr>
<tr><td>Cowlitz County PUD</td><td>No</td><td>Cowlitz answers “no” in that the question does not address if the data is truly going to be used. The SDT should confer with Transmission Planners requesting specifically how they will implement such data and if it will result in better modeling results. Data collection that will not be used is wasted compliance effort. FERC also seems to be confused as to the purpose of the Standard when it states “[t]he capability of generators to produce reactive power is essential for real-time analysis” rather than system modeling and planning. Based on this, should the reactive capability data also be sent to the Balancing Authority? If the SDT has technical foundation to refute FERC’s directive then it should be communicated. The Standard can be written as FERC demands, but with a recommendation that the requirement be removed.</td></tr>
<tr><td colspan="3">Response: The GVSDT thanks you for your comment. The GVSDT has no technical foundation to refute the FERC directive in Paragraph 1321, which states:

“1321. We disagree with commenters that verifying generator reactive capability is a particularly difficult issue. The capability of generators to produce Reactive Power is essential for Real-time analysis and planning. The Reliability Standard addressing this issue requires a generator to verify Reactive capability only at the unit’s full MW Loading. However, other than base Load units, most generating units rarely operate at full MW Loading. It is unclear what Reactive capability is available throughout a unit’s Real Power (MW) operating range. Therefore, we believe a clearer standard would require a verification of MVAR capability throughout a unit’s Real Power (MW) operating range. However, we share concern with several commenters that such a requirement for all generators may not be necessary. Therefore, we adjust the proposal in the NOPR and direct the ERO to modify MOD-025-1 to require verification of reactive power capability at multiple points over a unit’s operating range.”

Regarding the Balancing Authority: As this is a long-term planning standard, it is envisioned that the TP receives the data and develops the appropriate models for use by other entities. The TP then hands these models off to entities that are concerned with the operations planning and Real-time Operations time horizons. Per the NERC Reliability Functional Model (VP, page 25), the Transmission Planner has the following relationships with other entities:

2. Collects information including:

c. Generator unit performance characteristics and capabilities from Generator Owners.

5. Coordinates the evaluation of BES expansion plans with Transmission Service Providers, Transmission Owners, Reliability Coordinators, Resource</td></tr>
</table>

Organization	Yes or No	Question 5 Comment
Planners, and other Transmission Planners. **6. Reports on and coordinates its BES expansion plan implementation with affected Planning Coordinators, Transmission Planners, Resource Planners, Transmission Service Providers, Transmission Owners, Transmission Operators and Reliability Assurers.**		
Exelon	No	Currently Attachment 1 states that nuclear units are excluded from performing Reactive Power verification at minimum Real Power output. This exclusion must be extended to include a statement that nuclear units are not required to perform under-excited (leading) reactive capability verification testing. Nuclear units do not perform under-excited (leading) reactive capability testing due to concerns with unit stability and potential under voltage conditions on internal nuclear plant safety buses that may challenge safe plant operations and could lead to a plant transient or shutdown in accordance with NRC operating license. Suggest the following revision to Attachment 1 as follows:2.2 Verify Reactive Power of all generating units other than wind and photovoltaic for maximum overexcited (lagging) and under-excited (leading) reactive capability at the minimum Real Power output at which they could normally be expected to operate. Nuclear Units are not required to perform under-excited (leading) reactive capability verification testing or Reactive Power verification at minimum Real Power output.
Response: The GVSDT thanks you for your comment. If a nuclear plant has under-excited capability, it should be tested within the unit's capability and declared safety margins. The standard does not require challenging unit capabilities. The following statement was added to Note 1 of Attachment 1 for clarity, "Auxiliary bus voltage limits should be observed."		
Georgia Transmission Corporation	No	Reactive capability cannot be determined, generally, without disturbances to the system. Long-term fault recorders could be installed at all generator high-side buses and verification of generation to any eventual disturbances could be used to get a better picture of the plants reactive power capability.
Response: The GVSDT thanks you for your comment. Engineering analysis is allowed and encouraged to supplement testing and gain a better picture of the plant's reactive power capability.		
Great River Energy	No	GRE doesn't agree with doing the under and over-excited limits at min. power levels. Mainly for baseload units, this is not representative of where the units run. Also, this would be costly when you are taking a baseload unit to min. load for the testing. There are also many unit specific conditions that exist that may prevent an unit from running at its true minimum load. If they want it at different points I think they should leave it up to the GO/GOP's to decide at what other load point they want to run the test.
Response: The GVSDT thanks you for your comment. The FERC Order 693 requires verification at multiple points, and the GVSDT believes that verification at a minimum of four points is necessary to approximate the capability curve. Low Load verification is required at the "minimum Real		

Organization	Yes or No	Question 5 Comment
Power output at which the unit is normally expected to operate.”		
BC Hydro	No	Technically, only verification at the maximu rated active power output has practical value since it is the most limiting operating condtion in terms of reactive power capability.Verifying reactive power capability at lower active power outputs is redundant because: 1. The capability will obviously be somewhat higher than at maximum active power output 2. Registration data normally include only Qmax and Qmin, which are determined at unit's rated active power output. 3. Reactive capability does not depend on unit's active power output as much as on other factors, such as system or station service voltagesD-curve is developed based on calculated data. The purpose of this should not be verification of the curve
Response: The GVSDT thanks you for your comment. The FERC Order 693 requires verification at multiple points, and the GVSDT believes that verification at a minimum of four points is necessary to approximate the capability curve.		
ISO New England	No	Performing testing for lagging capability at minimum real power output especially would require an inordinate amount of planning to ensure that transmission voltage levels in the local area are not exceeded. Testing requirements should be changed to two points, one for an hour to verify over-excited reactive capability at rated Real Power and one at minimum Real Power output to verify under-excited capability. Also the test of leading capability at minimum real power loading should be held for five minutes. These tests are adequate to verify critical characteristics of the generator for use in studies. The four point tests may be difficult to obtain given system configuration and operation.
Response: The GVSDT thanks you for your comment. The FERC Order 693 requires verification at multiple points, and the GVSDT believes that verification at a minimum of four points is necessary to approximate the capability curve. The GVSDT recognizes that limitations may inhibit being able to achieve the desired testing levels. Any limitations should be entered in Attachment 2, “Remarks”. The note states: “If the verification value did not reach the Thermal Capability Curve (D-Curve), describe the reason”. This could include transmission system limitations.		
Independent Electricity System Operator	No	One of the purposes of Project 2007-09 is to ensure that generator models accurately reflect the generator’s capabilities and operating characteristics. To achieve this, it is important that at least the minimum data requirements of entities that require these data are satisfied. This includes verifying the generating unit’s capability curve or at least that portion of the curve between its minimum and maximum real power capability. We therefore recommend including a new bullet 2.3 in MOD-025 Attachment 1 similar to bullet 2.1 that requires verification of Real and Reactive Power capability of all generating units at maximum over-excited

Organization	Yes or No	Question 5 Comment
		and under-excited reactive capability at maximum gross Real Power capability (PMAX) where this is different from the generating unit's rated gross Real Power capability. The additional data points provided by this measurement (i.e. Qmax and Qmin at PMAX) will allow for a more complete verification of the generating unit's capability curve. Footnote 1 of MOD-025 Attachment 1 seems to use "rated gross Real Power" and "maximum [gross] Real Power" interchangeably. In general these two ratings may be different. We suggest deleting the footnote.
Response: The GVSDT thanks you for your comment. The GVSDT disagrees that testing at values above Pmax is needed to approximate the Reactive capability. Testing at additional points, however, is not prevented by the standard. The footnote was deleted, as you suggested.		
Ameren	No	While the testing regimen for the generator owners should not be made unduly burdensome, the four point test, if used to provide a straight line approximation of the generator capability, could result in somewhat more conservative reactive power operating limits for other real power levels as compared to a generating unit's published capability curve. The accuracy of the straight line approximation would vary on a generator-by-generator basis.
Response: The GVSDT thanks you for your comment. While not required by the standard, it is desirable to perform engineering analysis to determine expected unit capabilities under less restrictive system voltage than encountered during the verification. Even though this analysis will not verify the complete MVAR capability curve, it provides a reasonable estimate of unit capability that the Transmission Planner can use for modeling		
Indeck Energy Services	No	We don't agree that four points are needed for baseload units. We strongly agree with the Commission's statement that "such a requirement for all generators may not be necessary." First, we believe 2.2, of Attachment 1 to the standard, should exempt all base load units (not just nuclear units) from verification of reactive capability at minimum real power output. There are other units that the industry should be able to exempt based on their normal operating modes. Examples are peaker CTs and units that have restrictions (environmental, run of the river, etc.) preventing operation at minimum load. This concern is addressed in Paragraph 1321 of the FERC Order which states: "...other than baseload units, most generating units rarely operate at full MW loading. It is unclear what reactive capability is available throughout a unit's real power (MW) operating range. Therefore, we believe a clearer standard would require a verification of MVAR capability throughout a unit's real power (MW) operating range. However, we share concern with several commenters that such a requirement for all generators may not be necessary." Also, we not believe that verification for leading capability should not be required where operational practices preclude operation in a leading mode. Finally, for units where verification of multiple points are needed to satisfy the FERC directive, we agree that 2 points are sufficient to verify the lagging capability and 2 points are sufficient to verify the leading capability

Organization	Yes or No	Question 5 Comment
		across the generator MW operating range. However, trying to represent that with a straight line approximation between the two points could eliminate a large portion of the available capability curve around rated pf when rated MW for the unit falls within the stator rating segment of the capability curve, especially when it approaches the stator limit (which can occur for some units).
Response: The GVSDT thanks you for your comment. The drafting team believes that four points represents the minimum number required to meet the FERC directive of multiple test points throughout the Load range to approximate the capability curve. Nuclear units are exempted from Reactive Power testing at low Real Power levels to minimize risks associated with changing reactor power levels. These same risks are not present for other base Load units. Analytical methods do not provide verification of equipment capability. The standard requires testing at the minimum Load that a unit is normally expected to operate. For units that have environmental or other restrictions, the standard does not require violating those restrictions.		
Oncor Electric Delivery Company LLC	No	Unit reactive capability is limited by many factors and cannot be estimated using a straight line approach, a region of reactive capability over various power levels using actual operating limits is more realistic.
Response: The GVSDT thanks you for your comment. The FERC Order 693 requires verification at multiple points, and the GVSDT believes that verification at a minimum of four points is necessary to approximate the capability curve and that this is a reasonable approximation. Additional testing, while not required, is allowed.		
Indiana Municipal Power Agency	No	IMPA believes that four point testing is excessive and that only two points need to be verified. Those two points would be over-excitged (lagging) and under-excited (leading) reactive capability at the rated Real Power capability only. The two points verified at the expected minimum Real Power output is excessive. Reactive power support happens when load is high and generating units are running at maximum Real Output capability.
Response: The GVSDT thanks you for your comment. The FERC Order 693 requires verification at multiple points, and the GVSDT believes that verification at a minimum of four points is necessary to approximate the capability curve.		
Chelan County PUD	Yes	It is adequate, but variation from testing at the extremes should be permitted due to conditions - in some applications it is difficult to go to full buck or boost without absorbine/providing the reactive power from another unit without impacting the voltage schedule. Should testing cause the voltage schedule to be violated (or worse an unacceptable voltage condition), what should govern? It is unreasonable to expect that every plant over 75MVA can go to these conditions and hold them for an hour.
Response: The GVSDT thanks you for your comment. While not required by the standard, it is desirable to perform engineering analysis to determine		

Organization	Yes or No	Question 5 Comment
expected unit capabilities under less restrictive system voltage than encountered during the verification. Even though this analysis will not verify the complete MVAR capability curve, it provides a reasonable estimate of unit capability that the Transmission Planner can use for modeling.		
Imperial Irrigation District (IID)	Yes	WE BELIEVE THAT FOUR POINTS IS SUBSTANTIAL INFORMATION FOR STRAIGHT LINE APPROXIMATION AS OVER-EXCITED (LAGGING) AND UNDER-EXCITED (LEADING) REACTIVE CAPABILITY AT RATED REAL POWER WOULD SOLELY BE A SUFFICIENT DATA FOR THIS PURPOSE.
Response: The GVSDT thanks you for your comment.		
PPL Generation	Yes	The proposed verification at multiple points over a unit's operating range appears to derive from a belief that the verification test results will follow the generator OEM's D-curve; and, owing to the abnormal voltages created by VAR testing and aux bus drop-out limitations; this will not be the case.
Response: The GVSDT thanks you for your comment. The FERC Order 693 requires verification at multiple points, and the GVSDT believes that verification at a minimum of four points is necessary to approximate the capability curve.		
SERC Dynamics Review Sub-committee	Yes	These 4 points should provide adequate testing of the generator. The DRS does not believe that verification for leading capability should be required where operational practices preclude operation in a leading mode.
Response: The GVSDT thanks you for your comment. The verification is intended to define the limits of the unit's capabilities. If a unit has no leading capability, then it should be reported with no leading capability or the minimum lagging capability at which it can operate. This has been added to Attachment 1, Note 4.		
Constellation Power Generation	Yes	CPG agrees that the points chosen would provide a sufficient approximation of a unit's capabilities. However, these capabilities will never match a generator's capability curve for a multitude of reasons, and as such, some verbiage should be included in the attachment under item 2 instead of as a note at the end of the document. Further, the limitations on the unit that may not allow the unit to perform to its capability curve are most likely designed into the control system as limiters or protection system components so as to not allow damage to the unit. These designed controls should not be "investigated for resolution" as stated in Note 1.
Response: The GVSDT thanks you for your comment. The standard doesn't require a unit to reach the capability curve value. The capability curve does not reflect all unit limitations that may exist. The limitation that is reached should be recorded on Attachment 2 in the remarks section. The limitations that you suggest are some of those expected to be identified with this standard. Item 2.1 has had the language "the generating unit's		

Organization	Yes or No	Question 5 Comment
normal (not emergency) expected maximum Real Power at the time of verification" inserted in the text rather than being included as a footnote. **The language in Attachment 1 Note 1 was changed to: "Could be further analyzed for resolution." If the limitation is by design, then no further investigation is necessary.**		
American Electric Power	Yes	The results of the test may not accurately reflect the VAR capability due to system conditions or alarm stopping the test and not reflect the actual generator limit in a real time scenario. This is discussed in Notes 1 and 2 of Attachment 1.
Response: The GVSDT thanks you for your comment.		
Ingleside Cogeneration LP	Yes	These operating points are more than sufficient to validate reactive capability in accordance with FERC's directive. However, Ingleside Cogeneration LP believes that it is sufficient and far less risky to perform the validation at the TOP's reactive capability schedule limits. In addition, there needs to be an allowance for known equipment limitations which prevent testing at the four test points. Similarly, unforeseen limitations which are determined during testing may prevent the validation at every extreme.
Response: The GVSDT thanks you for your comment. Note 1 of attachment 1 discusses limitations: **Note 1: Under some Transmission System, conditions, the data points obtained by the MVAR verification required by the standard will not duplicate the manufacturer supplied thermal capability curve (D-curve). However, the verification required by the standard, even when conducted under these transmission system conditions, may uncover applicable Facility limitations such as rotor thermal instability, improper tap settings, inaccurate AVR operation, etc. which could be further analyzed for resolution. Observe auxiliary bus voltage limits. The verified MVAR value obtained most likely will not be the value entered into the Transmission Planner's database; nor is it likely this value will agree with data required to be submitted by MOD-010.** **Any known equipment limitations should be entered in Attachment 2, "Remarks." The note states: "If the verification value did not reach the Thermal Capability Curve (D-Curve), describe the reason."**		
Duke Energy	Yes	We agree that four points are sufficient to provide a straight line approximation over a unit's operating range at points from Pmax and below, but additional consideration is needed for operation above Pmax. We don't agree that four points are needed for baseload units. We strongly agree with the Commission's statement that "such a requirement for all generators may not be necessary." The lagging capability curves have a break at rated pf. Trying to represent that with a single line with end point at Pmin and Pmax would eliminate a large portion of the available capability curve around rated pf. The leading capability might be more reasonably estimated by a linear assumption. Technically, nuclear units are base load plants as are some very large coal units and thus would not be expected to operate for any significant period of time at pmin, thus the term base

Organization	Yes or No	Question 5 Comment
		load is more appropriate than nuclear for excluding testing at Pmin First, we believe 2.2, of Attachment 1 to the standard, should exempt all base load units (not just nuclear units) from verification of reactive capability at minimum real power output. There are other units that the industry should be able to exempt based on their normal operating modes. Examples are peaker CTs and units that have restrictions (environmental, run of the river, etc.) preventing operation at minimum load.Finally, for units where verification of multiple points are needed, the analytical approach to verification,discussed in our responses to Questions 10, 11, and 14, serves this purpose very well.This concern is addressed in Paragraph 1321 of the FERC Order which states: "...other than baseload units, most generating units rarely operate at full MW loading. It is unclear what reactive capability is available throughout a unit's real power (MW) operating range. Therefore, we believe a clearer standard would require a verification of MVAR capability throughout a unit's real power (MW) operating range. However, we share concern with several commenters that such a requirement for all generators may not be necessary."
Response: The GVSDT thanks you for your comment. The FERC Order 693 requires verification at multiple points, and the GVSDT believes that verification at a minimum of four points is necessary to approximate the capability curve. Nuclear units are exempted from Reactive Power testing at low Real Power levels to minimize risks associated with changing reactor power levels. These same risks are not present for other base Load units.

6. Verification of over-excited reactive capability at rated Real Power Capability is required to be conducted over a minimum of one hour. Do you agree with the verification time? If not, please explain.

Summary Consideration: The overwhelming majority of stakeholders agree with the one-hour verification period. Several of the stakeholders who disagreed with the one-hour verification time suggested that we revise the verification time period to 15 minutes, 30 minutes, or two hours. The reliability goal of the one-hour verification is to ensure that temperatures on the generator are relatively stable and the verification reflects a capability that is sustainable. The GVSDT believes that the majority of generators will be sufficiently stable after one hour to meet the reliability objective of the standard. Some commenters suggested that one hour was not long enough to assure that temperatures have stabilized and that the unit capability is sustainable. The Standard has been modified in Attachment 1, 2.3 to say,

> "Conduct the maximum Real Power and overexcited Reactive Power verifications required in 2.1 for a minimum of one continuous hour."

Organization	Yes or No	Question 6 Comment
IRC Standards Review Committee (joint comments)	No	See comment to Q2. The planner should ask for the data that it needs to comply with NERC standards (nothing more and nothing less). There is no need for the requirement to get into the details. The Planning standards will force the Planner to ask for the data that it needs for its models. This approach limits the Planners from asking for data that they do not use in their Planning Models or that is not needed to comply with a NERC standard. This approach also allows the Planner to tailor its requests to the Models and technologies that it has and needs.
Response: The GVSDT thanks you for your comment. Please see response to Question 2.		
SPP Reliability Standards Development Team	No	Currently SPP has criteria that the testing period should be 15 minutes rather than the listed 1 hour. We have found that this time period is adequate.
Response: The GVSDT thanks you for your comment. The overwhelming majority of stakeholders agree with the one-hour verification period. The reliability goal of the one-hour verification is to ensure that temperatures on the generator are relatively stable and the verification reflects a capability that is sustainable. The GVSDT believes that the majority of generators will be sufficiently stable after one hour to meet the reliability objective of the		

Organization	Yes or No	Question 6 Comment
standard.		
Idaho Power-Power Production	No	No, if this is intended to verify an emergency reactive capability we believe 15 minutes is sufficient. If this is intended to verify a normal reactive capability then 1 hour is reasonable.
Response: The GVSDT thanks you for your comment. The overwhelming majority of stakeholders agree with the one-hour verification period. The reliability goal of the one-hour verification is to ensure that temperatures on the generator are relatively stable and the verification reflects a capability that is sustainable. The GVSDT believes that the majority of generators will be sufficiently stable after one hour to meet the reliability objective of the standard. The standard is aimed at verification of normal reactive capability.		
PPL Generation	No	The one-hour period appears to derive from D-curve (thermal limiting) expectations; and, as explained above, this will not be the case
Response: The GVSDT thanks you for your comment. The overwhelming majority of stakeholders agree with the one-hour verification period. The reliability goal of the one hour verification is to ensure that temperatures on the generator are relatively stable and the verification reflects a capability that is sustainable. The GVSDT believes that the majority of generators will be sufficiently stable after one hour to meet the reliability objective of the standard.		
NERC Staff	No	Often, on larger units, temperatures do not stabilize within one hour. It is important for this test to assure that temperatures have stabilized and that the unit capability is sustainable, so the overexcited reactive capability test should be conducted for a minimum of two hours or until the temperatures have stabilized.
Response: The GVSDT thanks you for your comment. The overwhelming majority of stakeholders agree with the one-hour verification period. The reliability goal of the one-hour verification is to ensure that temperatures on the generator are relatively stable and the verification reflects a capability that is sustainable. The GVSDT believes that the majority of generators will be sufficiently stable after one hour to meet the reliability objective of the standard. Attachment 1, 2.3 states: **"Conduct the rated Real Power and overexcited Reactive Power verifications required in 2.1 for a minimum of one continuous hour.** **It is up to the entity testing the unit to determine when the temperatures are stable."**		
Arizona Public Service Company	No	30 minutes are more than adequate. All components reach steady state temperatures within that time. There is no need to be there more than 30 minutes.
Response: The GVSDT thanks you for your comment. The overwhelming majority of stakeholders agree with the one-hour verification period. The reliability goal of the one-hour verification is to ensure that temperatures on the generator are relatively stable and the verification reflects a capability		

Organization	Yes or No	Question 6 Comment
that is sustainable. The GVSDT believes that the majority of generators will be sufficiently stable after one hour to meet the reliability objective of the standard.		
PacifiCorp	No	First, PacifiCorp believes that over-excited reactive capability at rated Real Power verification should be performed on the same basis as for under-excited reactive capability and over-excited reactive capability at expected minimum Real Power output - that such data should be recorded as soon as a limit is reached. Second, this does not adequately take operating conditions for wind facilities into consideration.
Response: The GVSDT thanks you for your comment. The GVSDT believes that a stabilization period is needed to assure that verified data is sustainable. The GVSDT also believes that the rated power lagging test is the most demanding so that extended operation at other test points would not be required. Item 2.1 was revised in Attachment 1 to provide better clarity around testing requirements for wind facilities. **"If verification of wind turbines or photovoltaic inverter Facility cannot be accomplished meeting the 90 percent threshold, the Generator Owner must document the reasons it was unable to meet the threshold and test to the full capability at the time of the test. The Generator Owner shall retest the Facility within six months of being able to reach the 90 percent threshold. Maintain as steady as practical Real and Reactive Power output during verifications."**		
Cowlitz County PUD	No	Cowlitz suggests that "rated" be replaced with "normal expected maximum" in requirement 2.1 and "maximum" in requirement 2.3; although the footnote makes the intent clear, there is no need to complicate the reading of the Attachment and effectively redefine the normal understanding of the word rating. As far as running the test at least one hour, this commenter is not sure how quickly a unit achieves thermal stability. Again, Cowlitz questions if the data will be used and its actual contribution to improved modeling and future planning.
Response: The GVSDT thanks you for your comment. The GVSDT agrees and has made the revision Attachment 1, Item 2.1 has had the language "the generating unit's normal (not emergency) expected maximum Real Power at the time of verification," inserted in the text rather than being included as a footnote. Attachment 1, item 2.3 was revised as suggested.		
Xcel Energy	No	Southwestern Power Pool testing criteria specifies a 15 minute hold point and WECC requires holding until the temperatures are stable, which has always been less than one hour. We believe one hour is excessively long, and instead recommend a 15 minute verification time.
Response: The GVSDT thanks you for your comment. The overwhelming majority of stakeholders agree with the one-hour verification period. The reliability goal of the one-hour verification is to ensure that temperatures on the generator are relatively stable and the verification reflects a capability that is sustainable. The GVSDT believes that the majority of generators will be sufficiently stable after one hour to meet the reliability objective of the standard. Some commenters suggested that one hour was not long enough to assure that temperatures have stabilized and that the unit capability is		

Organization	Yes or No	Question 6 Comment
sustainable. The Standard has been modified in Attachment 1, 2.3 to say: "Conduct the maximum Real Power and overexcited Reactive Power verifications required in 2.1 for a minimum of one continuous hour."		
Manitoba Hydro	No	To obtain more realistic rated real power and over-excited reactive power ratings, the minimum verification time should be 2 hours or until temperatures have stabilized. For under-excitation, the test duration should be 1 hour.
Response: The GVSDT thanks you for your comment. The overwhelming majority of stakeholders agree with the one-hour verification. The reliability goal of the one-hour verification is to ensure that temperatures on the generator are relatively stable and the verification reflects a capability that is sustainable. The GVSDT believes that the majority of generators will be sufficiently stable after one hour to meet the reliability objective of the standard.		
CPS Energy	No	30 minutes should be sufficient time to verify capability.
Response: The GVSDT thanks you for your comment. The overwhelming majority of stakeholders agree with the one-hour verification. The reliability goal of the one-hour verification is to ensure that temperatures on the generator are relatively stable and the verification reflects a capability that is sustainable. The GVSDT believes that the majority of generators will be sufficiently stable after one hour to meet the reliability objective of the standard.		
Gainesville Regional Utilities	No	We suggest 30 minutes. While it may take an hour to reach full stabilized temperatures the probability of being called to perform form greater than 30 minutes is remote.
Response: The GVSDT thanks you for your comment. The overwhelming majority of stakeholders agree with the one-hour verification period. The reliability goal of the one-hour verification is to ensure that temperatures on the generator are relatively stable and the verification reflects a capability that is sustainable. The GVSDT believes that the majority of generators will be sufficiently stable after one hour to meet the reliability objective of the standard.		
Chelan County PUD	No	What is the basis for an hour? It should be tested to demonstrate stability at that point and not trip. After that why stay at an extreme condition? If you are concerned about MVA verification that can be done at any value, certainly design output and power factor is a better point.
Response: The GVSDT thanks you for your comment. The reliability goal of the one-hour verification period is to ensure that temperatures on the generator are relatively stable and the verification reflects a capability that is sustainable. The GVSDT believes that the majority of generators will be sufficiently stable after one hour to meet the reliability objective of the standard.		

Organization	Yes or No	Question 6 Comment
Tacoma Power	No	Depending on the size of the unit and location in the transmission system operating the unit at full rated reactive capability with normal steady state transmission voltages may subject the plant and transmission system to a sustained overvoltage. The over-excitation limit should be verified in the same way the under-excitation limit is verified.
Response: The GVSDT thanks you for your comment. Operation beyond the capability of the equipment is not expected nor required. The GVSDT believes that a stabilization period is needed to assure that verified data is sustainable. The GVSDT also believes that the rated power lagging test is the most demanding so that extended operation at other test points would not be required.		
Austin Energy	No	The ERCOT required verification time is 15 minutes. Extending the verification time to one hour is burdensome with unclear benefit.
Response: The GVSDT thanks you for your comment. The overwhelming majority of stakeholders agree with the one-hour verification. The reliability goal of the one-hour verification is to ensure that temperatures on the generator are relatively stable and the verification reflects a capability that is sustainable. The GVSDT believes that the majority of generators will be sufficiently stable after one hour to meet the reliability objective of the standard.		
Ingleside Cogeneration LP	No	Ingleside agrees in principle that one hour is sufficient at this test point, but believes it should take place at the limit identified in the Transmission Operator's reactive capability schedule.
Response: The GVSDT thanks you for your comment. The requirement is intended to verify the D-Curve of the generator for planning studies, not Real-time operations.		
American Electric Power	Yes	This requirement is stated in Attachment 1, section 2.3.
Response: The GVSDT thanks you for your comment.		
ISO New England	Yes	Yes, the standard should also require a recording of generator vibration during the test and require that the Generator Owner report an increase in vibration over the test period indicating the presence of rotor shorted turns that would limit long term generator MVAR loading. One hour may be enough time to determine if rotor shorted turns are present as indicated by vibration but the vibration must be recorded. The reactive power output data recording should be at 5 minute intervals and use the average for the hour. Also testing leading capability at minimum real power loading should be held for five minutes.
Response: The GVSDT thanks you for your comment. The GVSDT believes that a one-hour period is sufficient for most units to be stable, regardless		

Organization	Yes or No	Question 6 Comment
of the reason. Although vibration is a potential indicator of problems such as thermal stability in the field, if it can be held to operable levels for an hour that is sufficient for planning purposes. The GVSDT believes that data recorded at the end of the test is sufficient for planning purposes.		
BC Hydro	Yes	It may be better to specify a particular rate of change of measured temperature determining that heating has stabilized instead of selecting an arbitrary time period.
Response: The GVSDT thanks you for your comment. The overwhelming majority of stakeholders agree with the one-hour verification. The reliability goal of the one hour verification is to ensure that temperatures on the generator are relatively stable and the verification reflects a capability that is sustainable. The GVSDT believes that the majority of generators will be sufficiently stable after one hour to meet the reliability objective of the standard.		
FirstEnergy	Yes	Although we are OK with the 1 hour interval, we are not convinced this will meet the reliability goals of the standard. Just being able to hit a specific reactive output is one thing, but that does not assure Reliability. Most large generators and large main transformers have only reached one, possibly two, thermal time constants within an hour timeframe There are many thermal problems that can be identified if the electrical equipment is permitted to be operated at high load levels over an extended period of time. It may be necessary to show that reactive output can be maintained over a longer period of time.
Response: The GVSDT thanks you for your comment. The overwhelming majority of stakeholders agree with the one-hour verification period. The reliability goal of the one-hour verification is to ensure that temperatures on the generator are relatively stable and the verification reflects a capability that is sustainable. The GVSDT believes that the majority of generators will be sufficiently stable after one hour to meet the reliability objective of the standard.		
Public Service Enterprise Group	Yes	The drafting team should provide the rationale for the one hour minimum for over-excited reactive capability.
Response: The GVSDT thanks you for your comment. The reliability goal of the one-hour verification period is to ensure that temperatures on the generator are relatively stable and the verification reflects a capability that is sustainable. The GVSDT believes that the majority of generators will be sufficiently stable after one hour to meet the reliability objective of the standard.		
SERC Generation sub-committee	Yes	Provided that the verification is accomplished through staged testing or through operational data review. This requirement would not apply if the verification is accomplished using an engineering analysis method (see this proposal in comments to Question 14).
Response: The GVSDT thanks you for your comment. The GVSDT believes this requirement would apply regardless of using a staged test or operational data.		

Organization	Yes or No	Question 6 Comment
Southern Company	Yes	Provided that the verification is accomplished through staged testing or through operational data review. This requirement would not apply if the verification is accomplished using an engineering analysis method (see this proposal in comments to Question 14).
Response: The GVSDT thanks you for your comment. The GVSDT believes this requirement would apply regardless of using a staged test or operational data. See response to Question 14.		
Associated Electric Cooperative, Inc.	Yes	Provided that the verification is accomplished through staged testing or through operational data review. This requirement would not apply if the verification is accomplished using an engineering analysis method.
Response: The GVSDT thanks you for your comment. The GVSDT believes this requirement would apply regardless of using a staged test or operational data.		
Duke Energy	Yes	Provided that the verification is accomplished through staged testing or through operational data review and a unit is capable of reaching the expected over excited capability, 1 hour should be adequate to determine if equipment temps that might limit capability are stabilized. This requirement would not apply if the verification is accomplished using an engineering analysis method (see this proposal in comments to Question 14).
Response: The GVSDT thanks you for your comment. The GVSDT believes this requirement would apply regardless of using a staged test or operational data. See response to Question 14.		
Exelon	Yes	The time of one hour as a minimum is reasonable; however, the reactive capability may not able to be tested at the rated Real Power Capability. It may not be feasible to perform both Real and Reactive tests at the same time. Considerations must be given for the generator reactive capability curve (RCC).
Response: The GVSDT thanks you for your comment. The standard has been revised to clarify that Real and Reactive Power testing may be done at different times (see Summary Response to question 1).

7. Verification of (1) under-excited Reactive capability at rated Real Power of the most recent gross verified Real Power capability reported, (2) under-excited Reactive capability at expected minimum Real Power output and (3) over-excited Reactive capability at expected minimum Real Power output are all to be recorded as soon as a limit is encountered. Do you agree that such data recorded as soon as a limit is encountered is appropriate for such verification? If not, please explain.

Summary Consideration: The majority of stakeholders agree that the data should be recorded as soon as a limit is reached. A few stakeholders suggested that a holding or settling time be added to make certain that a limit was reached. Several stakeholders suggested that minimum Load testing, minimum Load over-excited testing or under-excited testing of nuclear units was not needed or desirable. The following statement was added to Note 1 of Attachment 1 for clarity:

> "Auxiliary bus voltage limits should be observed."

Organization	Yes or No	Question 7 Comment
Consolidated Edison Co. of NY, Inc.	No	We recommend allowing the Transmission Operator (TOP) flexibility in determine the specific detailed nature of the reactive power tests performed in support its modeling. Regarding Part 2.1, in the NYISO, the maximum reactive power is tested at a real power level above 90% of maximum real power capability. The test was designed in this manner for a two reasons: (1) not to be a simultaneous test with 100% real power test and (2) to provide a reliable maximum reactive power test when the unit is stressed, but is still capable of providing reserve power. We recommend providing the TOP flexibility in this requirement by allowing reactive power to be tested above 90% of maximum real power capability. The NYISO Ancillary Services Manual also contemplates that GO's will test lagging and leading reactive power during time periods more appropriate to their use. On p. 28 and p. 34 the manual states: o Lagging MVAr capability testing will normally be performed during on-peak hours. The VSS Supplier must operate at maximum Lagging MVAr for at least one hour for the test to be acceptable. o The Leading MVAr testing will normally be performed during off-peak hours. The Leading MVAr test shall be scheduled with the corresponding TO, who will inform the NYISO. Ref: http://www.nyiso.com/public/webdocs/documents/manuals/operations/ancserv.pdf Presumably, under the NYISO tariff the leading and lagging Reactive Power tests would not be performed at

Organization	Yes or No	Question 7 Comment
		the same time or necessarily at the same "rated gross Real Power capability."ISO-NE also notes that maximum leading and lagging reactive power may not be at the same real power output level. o Points #4 and #9 in Figure #1, the two [lagging and leading] break points, do not necessarily correspond to the same MW output of the Generator. Ref: http://www.iso-ne.com/rules_proceds/operating/isone/op14/op14b_rto_final.pdf Proposed language change to MOD-025 Attachment 1: 2.1. Perform verification of Real and Reactive Power capability of all generating units at maximum over-excited (lagging) and under-excited (leading) reactive capability at rated gross Real Power capability1, or at the Real Power level stipulated by the Transmission Operator. ...
Response: The GVSDT thanks you for your comment. The GVSDT reviewed the language in the NYISO document, Table 3.1. The table uses terms UCAP and ICAP. The revised standard contains language in Item 2.1 of Attachment 1 that states the verification is to be performed at "the generating unit's normal (not emergency) expected maximum Real Power at the time of the verification." A test to satisfy MOD-025 would appear to meet the requirements for the NYISO, while also meeting the statement, "Extreme measures that might overstate a unit's Reactive capability must be avoided," in Section 3.6.2 of the NYISO document.		
Northeast Power Coordinating Council	No	Regarding Part 2.1, in the NYISO reactive power is tested at a real power level above 90% of maximum. The tariff was designed in this manner for a few reasons: (1) not to be simultaneous test with 100% real power test and (2) provide a reliable maximum reactive test when the unit is stressed, but is still capable of providing reserve power. Recommend providing some flexibility in this requirement by stating that reactive power can be tested above 90% of maximum real power.
Response: The GVSDT thanks you for your comment. The GVSDT reviewed the language in the NYISO document, Table 3.1. The table uses terms UCAP and ICAP. The revised standard contains language in Item 2.1 of Attachment 1 that states the verification is to be performed at "the generating unit's normal (not emergency) expected maximum Real Power at the time of the verification." A test to satisfy MOD-025 would appear to meet the requirements for the NYISO, while also meeting the statement, "Extreme measures that might overstate a unit's reactive capability must be avoided," in Section 3.6.2 of the NYISO document.		
Northeast Utilities	No	Regarding Part 2.1, in the NYISO reactive power is tested at a real power level above 90% of maximum. The tariff was designed in this manner for a few reasons: (1) not to be simultaneous test with 100% real power test and (2) provide a reliable maximum reactive test when the unit is stressed, but is still capable of providing reserve power. IRC Standards Review Committee (joint comments)	No	See comment to Q2. The planner should ask for the data that it needs to comply with NERC standards (nothing more and nothing less). There is no need for the requirement to get into the details. The Planning standards will force the Planner to ask for the data that it needs for its models. This approach limits the Planners from asking for data that they do not use in their Planning Models or that is not needed to comply with a NERC standard. This approach also allows the Planner to tailor its requests to the Models and technologies that it has and needs.
Response: The GVSDT thanks you for your comment. Please see response to question 2.		
SPP Reliability Standards Development Team	No	We would request that the time be a few minutes to make sure after a settling period that it was a limit that was encountered.
Response: The GVSDT thanks you for your comment. The GVSDT feels that the time needed to take data should be a sufficient settling period.		
Dominion	No	For items 2 and 3 see comments in question 5. We agree with item 1.
Response: The GVSDT thanks you for your comment. Please see response to question 5.		
Westar Energy	No	We suggest that the SDT considering adding clarifying language around "as soon as a limit is encountered." The current language is ambiguous.
Response: The GVSDT thanks you for your comment. The GVSDT believes the language is clear. We welcome suggested edits that you believe would provide the clarity that you seek.		
New York Independent System Operator	No	Testing requirements for reactive capability at minimum real power output should be removed. These tests are of no value and lead to system limit concerns. The testing requirement should be changed to two test points. One test for an hour to verify over-excited (lagging) capability at the real power level specified by the Transmission Operator or the Transmission Planner. A second test to verify under-excited capability (leading)

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 7 Comment</th></tr>
<tr><td></td><td></td><td>at the real power level specified by the Transmission Operator or the Transmission Planner.</td></tr>
<tr><td colspan="3">Response: The GVSDT thanks you for your comment. The FERC Order 693 requires verification at multiple points, and the GVSDT believes that verification at a minimum of four points is necessary to approximate the capability curve. Also, while not required by the standard, it is desirable to perform engineering analysis to determine expected unit capabilities under less restrictive system voltage than encountered during the verification. Even though this analysis will not verify the complete MVAR capability curve, it provides a reasonable estimate of unit capability that the Transmission Planner can use for modeling.</td></tr>
<tr><td>Cowlitz County PUD</td><td>No</td><td>Cowlitz at this time has insufficient information to formulate an opinion, but at the same time is skeptical of the reliability benefit being great enough to justify the cost of obtaining this data.</td></tr>
<tr><td colspan="3">Response: The GVSDT thanks you for your comment. The data us being collected as a result of a FERC directive in paragraph 1321 which states:

“1321. We disagree with commenters that verifying generator Reactive capability is a particularly difficult issue. The capability of generators to produce Reactive Power is essential for Real-time analysis and planning. The Reliability Standard addressing this issue requires a generator to verify Reactive capability only at the unit’s full MW Loading. However, other than base load units, most generating units rarely operate at full MW Loading. It is unclear what Reactive capability is available throughout a unit’s Real Power (MW) operating range. Therefore, we believe a clearer standard would require a verification of MVAR capability throughout a unit’s Real Power (MW) operating range. However, we share concern with several commenters that such a requirement for all generators may not be necessary. Therefore, we adjust the proposal in the NOPR and direct the ERO to modify MOD-025-1 to require verification of reactive power capability at multiple points over a unit’s operating range.</td></tr>
<tr><td>Ameren</td><td>No</td><td>(1) From transmission perspective: If a plant limit is encountered in the testing, and it is a hard limit not to be exceeded, then the capability at this limit should be recorded. If a limit is identified on the transmission system such that the testing cannot be completed, then the capability should be noted but this would not be a firm limit.

(2) From GO perspective : Our testing people won't know if the transmission system is causing the limit because they aren't allowed to "see" the transmission system. Second, they are not allowed to test at time of seasonal peak because their testing may jeopardize the availability of the unit and testing during the fall and spring will mean higher voltages and frequently some type of testing limit is reached. Engineering calculations and justification should be allowed. Finally, we thought the 20% "margin" was to allow for these unavoidable risk restraints on testing the units. If a plant limit is encountered in the testing, then the capability at this limit should be recorded. However, it is unclear how this data, and the 20% margin, should be used in the verification process. We request the SDT clarify how data readings within the 20% margin should be used to determine the Real and Reactive capabilities of a generator or plant.</td></tr>
</table>

Organization	Yes or No	Question 7 Comment
Response: The GVSDT thanks you for your comment. The GVSDT agrees that an entity should record data for a hard limit when the unit reaches the limit. While not required by the standard, it is desirable to perform engineering analysis to determine expected unit capabilities under less restrictive system voltages than those encountered during the verification. Even though this analysis will not verify the complete MVAR capability curve, it provides a reasonable estimate of unit capability that the Transmission Planner can use for modeling. Communication with the Transmission Operator is necessary when performing testing and system voltage limits would be part of that communication. The 20% margin was meant to be a permissive limit to accept operational data. The 20% value was removed and the wording of Item 2 in Attachment 1 has been modified in the standard based on industry feedback. 2. Perform verification with all auxiliary equipment needed for expected normal operation in service for both the Real Power and Reactive Power capability verification, and the automatic voltage regulator in service for the Reactive Power capability verification (see Note 3 if the automatic voltage regulator is not available). Operational data from within the two years prior to the verification date is acceptable for the verification, as long as it meets the criteria in 2.1 through 2.5 below and is at least 90 percent of a previously staged test that demonstrated at least 50% of the capability shown on the appropriate D-Curve. If the previously staged test was unduly restricted by unusual generation or equipment limitations(for example capacitor or reactor banks out of service), then the next verification shall be by another staged test, not operational data:		
Indeck Energy Services	No	Only if they are required for particular units.
Response: The GVSDT thanks you for your comment. The test points are required for all applicable units.		
Ingleside Cogeneration LP	No	Ingleside agrees in principle that a demonstration that the generator can reach these test points is sufficient, and reduces the risk to the equipment. However, the limits identified in the Transmission Operator's reactive capability schedule should be verified, not the generator's operational limits.
Response: The GVSDT thanks you for your comment. The intent of MOD-025 is to verify generator capability for long-term planning studies. Real-time issues with a Transmission Operators voltage schedule are not included in this standard.		
ISO New England	No	These types of tests should require remaining at the point for a length of time. Under-excited power verification at minimum power output for five minutes should be adequate. Testing requirements for over-excited reactive capability at minimum real power output and under-excited capability at maximum power should be removed. These tests lead to transmission system voltage concerns.
Response: The GVSDT thanks you for your comment. The GVSDT believes that the time required to take the data is sufficient for under-excited tests.		

Organization	Yes or No	Question 7 Comment
The FERC Order 693 requires verification at multiple points, and the GVSDT believes that verification at a minimum of four points is necessary to approximate the capability curve. Communication with the Transmission Operator is necessary when performing testing and system voltage limits would be part of that communication.		
Public Service Enterprise Group	Yes	This documents the system conditions and unit conditions when limits are reached.
Response: The GVSDT thanks you for your comment.		
Great River Energy		GRE would object to doing this at URGE because URGE is not our normal operating condition. The reactive power testing should be done at normal full load (normal operating conditions) to be representative of how much reactive power the unit can put out or absorb during normal running conditions. GRE doesn't agree with doing the under and over-excited limits at min. power levels. Mainly for baseload units, this is not representative of where the units run. Also, this would be costly when you are taking a baseload unit to min. load for the testing. There are also many unit specific conditions that exist that may prevent an unit from running at its true minimum load.
Response: The GVSDT thanks you for your comment. The FERC Order 693 requires verification at multiple points, and the GVSDT believes that verification at a minimum of four points is necessary to approximate the capability curve.		
GenOn Energy	Yes	The intent of the question is not well understood. The answer is complicated by the inability to replicate the system condition that will demand the unit operating limits, creating artificial lower limits under the test conditions.
Response: The GVSDT thanks you for your comment.		
SERC Generation sub-committee	Yes	But, we believe that there is little value to a minimum load, vars-out requirement. Also, it will be difficult to achieve since the system usually has minimum VAR output requirements when operating at minimum load. Experience has shown that a large unit cannot reach the full available lagging (many times) or leading (most times) reactive capability values due to voltage limitations. That does not mean that that capability is not available. This is exemplified by the testing of a large fossil unit below (attempted to include graphic).
Response: The GVSDT thanks you for your comment. The FERC Order 693 requires verification at multiple points, and the GVSDT believes that verification at a minimum of four points is necessary to approximate the capability curve. Planner can use for modeling.		
Tennessee Valley Authority GO	Yes	But, we believe that there is little value to a minimum load, vars-out requirement. Also, it will be difficult to achieve since the system usually has minimum VAR output requirements when operating at minimum load. Experience has shown that a large unit cannot reach the full available lagging (many times) or leading (most times) reactive capability values due to voltage limitations. That does not mean that that capability is not available.
Response: The GVSDT thanks you for your comment. The FERC Order 693 requires verification at multiple points, and the GVSDT believes that verification at a minimum of four points is necessary to approximate the capability curve. Also, while not required by the standard, it is desirable to perform engineering analysis to determine expected unit capabilities under less restrictive system voltage than encountered during the verification. Even though this analysis will not verify the complete MVAR capability curve, it provides a reasonable estimate of unit capability that the Transmission Planner can use for modeling.		
Southern Company	Yes	We believe that the minimum load, it will be difficult for a unit to produce Vars because the system usually has minimum VAR output requirements from generators when the generators are operating at minimum load. Therefore, we believe verification of Vars out at minimum load will not provide the data that transmission planning is seeking and, therefore, this requirement is not necessary. See our response to Question 5 for additional discussion on verification at minimum load.
Response: The GVSDT thanks you for your comment. The FERC Order 693 requires verification at multiple points, and the GVSDT believes that verification at a minimum of four points is necessary to approximate the capability curve. Also, while not required by the standard, it is desirable to perform engineering analysis to determine expected unit capabilities under less restrictive system voltage than encountered during the verification. Even though this analysis will not verify the complete MVAR capability curve, it provides a reasonable estimate of unit capability that the Transmission Planner can use for modeling.		
Associated Electric Cooperative, Inc.	Yes	We believe that there is little value to a minimum load, vars-out requirement. Also, it will be difficult to achieve since the system usually has minimum VAR requirements when operating at low system load. Experience has shown that a large unit cannot reach the full available lagging (many times) or leading (most times) reactive capability values due to voltage limitations. That does not mean that that capability is not available.
Response: The GVSDT thanks you for your comment. Organization	Yes or No	Question 7 Comment
Planner can use for modeling.		
Duke Energy	Yes	We believe that there is little value to a minimum load, vars-out requirement. Also, it will be difficult to achieve since the system usually has minimum VAR output requirements when operating at minimum load. Experience has shown that a large unit cannot reach the full available lagging (many times) or leading (most times) reactive capability values due to voltage limitations. That does not mean that that capability is not available. This is exemplified by the testing of a large fossil unit (Graphic has been provided to the SDT). There needs to be standards on how model values are selected, such as, o The lagging capabilitiy values should be based on 90% of gross generator capability at minimum normal Hydrogen pressure minus aux system loads and xfmr losses o The leading capability values being modeled should be based on (UEL limiter setpoints as documented by PRC-19 coordination is probably appropriate).
Response: The GVSDT thanks you for your comment. The FERC Order 693 requires verification at multiple points, and the GVSDT believes that verification at a minimum of four points is necessary to approximate the capability curve. Also, while not required by the standard, it is desirable to perform engineering analysis to determine expected unit capabilities under less restrictive system voltage than encountered during the verification. Even though this analysis will not verify the complete MVAR capability curve, it provides a reasonable estimate of unit capability that the Transmission Planner can use for modeling.		
Exelon	Yes	Recording the test data as soon as a limit is encountered is reasonable; however, the reactive capability may not able to be tested at the rated Real Power Capability. It may not be feasible to perform both Real and Reactive tests at the same time. Considerations must be given for the reactive limits given by the plant specific generator reactive capability curve (RCC) at the attainable real power output. Currently Attachment 1 states that nuclear units are excluded from performing Reactive Power verification at minimum Real Power output. This exclusion must be extended to include a statement that nuclear units are not required to perform under-excited (leading) reactive capability verification testing. Nuclear units do not perform under-excited (leading) reactive capability testing due to concerns with unit stability and potential under voltage conditions on internal nuclear plant safety buses that may challenge safe plant operations and could lead to a plant transient or shutdown in accordance with NRC operating license. Suggest the following revision to Attachment 1 as follows:2.2 Verify Reactive Power of all generating units other than wind and photovoltaic for maximum overexcited (lagging) and under-excited (leading) reactive capability at the minimum Real Power output at which they could normally be expected to operate. Nuclear Units are not required to perform under-excited (leading) reactive capability verification testing or Reactive Power verification at minimum Real Power output.

Organization	Yes or No	Question 7 Comment
Response: The GVSDT thanks you for your comment. Language has been added to make it clear that Real and Reactive Power tests are not required to be performed at the same time. The GVSDT feels that if a nuclear plant has under-excited capability it should be tested within the unit's capability and declared safety margins. The standard does not require challenging unit capabilities. The following statement was added to Note 1 of Attachment 1 for clarity, "Auxiliary bus voltage limits should be observed."		
Luminant Power	Yes	See Luminant comments to Question #5 regarding operating ranges for testing.
Response: The GVSDT thanks you for your comment. Please see response to question 5.		
BC Hydro	Yes	Only verification of (1) has practical significance; (2) and (3) are redundant. Please see Comment 5.
Response: The GVSDT thanks you for your comment. Please see response to question 5.		
American Electric Power	Yes	This is stated in Attachment 1, section 2.4. A clarification could be in order to relate the recording of the time when the limit is reached to the requirement that the test be conducted over a one hour interval. For example, if a limit is reached in 15 minutes, is the verification test completed or is the expectation that the unit is held at that level for the balance of the one hour test window. Also, it is curious why this question excludes the condition of over-excited reactive capability at the rated gross real power per Attachment 1, section 2.1.
Response: The GVSDT thanks you for your comment. The intent, as stated, is that the Reactive Power lagging test at rated Real Power and the Real Power test be held for one hour; once that level is attained, to allow the unit to stabilize before taking data. All other reactive power tests need only be held long enough to take data.

8. Synchronous condensers are also reactive resources that may be important to reliability, but they are not generators. The SDT proposes that synchronous condensers be verified under MOD-025-2. Do you feel that this is appropriate?

Summary Consideration: There was overwhelming stakeholder support for verifying synchronous condensers as a Reactive resource under MOD-025-2. Some stakeholders suggested that consideration be given under this or a different standard for verification of other Reactive resources.

The SDT added the following sentence to the first paragraph of Attachment 1 in response to a stakeholder comment: "If a unit is operated in synchronous condenser mode as well as generation mode, the unit should be verified in both modes."

Organization	Yes or No	Question 8 Comment
Ingleside Cogeneration LP	No	There is a significant body of work underway defining the extent of the Bulk Electric System, which this proposal bypasses. This determination should rest with the project team responsible for that effort.
Response: The GVSDT thanks you for your comment. The GVSDT has sufficient expertise to recommend synchronous condensers be included under the verification requirements of MOD-025 to help ensure the reliability of the BES.		
Indeck Energy Services	No	They are owned and registered differently.
Response: The GVSDT thanks you for your comment. Synchronous condensers are not currently included in the compliance registry. The GVSDT has sufficient expertise to recommend synchronous condensers be included under the verification requirements of MOD-025 and, hence, the compliance registry, to help ensure the reliability of the BES.		
Oncor Electric Delivery Company LLC	No	Oncor does not believe that there is a reliability based need for the verification of synchronous condensers under this standard
Response: The GVSDT thanks you for your comment. The GVSDT disagrees and has included Reactive verification for synchronous condensers.		
Southern Company	No	

Organization	Yes or No	Question 8 Comment
Imperial Irrigation District (IID)	Yes	THERE ARE NO SYNCHRONOUS CONDENSERS INSTALLED AND IN SERVICE WITHIN IID FACILITY.
Response: The GVSDT thanks you for your comment.		
Pepco Holdings Inc Affiliates	Yes	However, based on the requirements and measures identified in the standard it is unclear why the standard was made applicable to Transmission Owners; unless the standard is intended to only apply to Transmission Owners that own synchronous condensers. If that is the case, Section A- 4.1.2 should be re-written as follows: "Transmission Owner that owns a synchronous condenser." This qualification is consistent with other PRC standards (PRC-010, PRC-015, PRC-023, etc.) where applicability to a specific sub-set of Transmission Owners is clearly defined.
Response: The GVSDT thanks you for your comment. The standard applies to TOs that may own synchronous condensers, and this is reflected in Section 4.1.2, as suggested..		
FirstEnergy	Yes	Yes, we believe they should be verified because they are the same type of dynamic, voltage independent, source of reactive power as is a real power generator. We also believe that they certainly are generators, generators of reactive power. In fact, they are identical in function, design and equipment as a real power generator, minus the prime mover. A synchronous condenser, like its sister the real power generator, can be continuously adjusted for the desired output and contains equipment that must be properly adjusted to provide the desired range of reactive output.
Response: The GVSDT thanks you for your comment. The GVSDT concurs with your comments.		
SERC Dynamics Review Sub-committee	Yes	Synchronous condensers supply reactive power to the grid. Therefore, the Transmission Planner needs to know a verified capability for the device.
Response: The GVSDT thanks you for your comment.		
NERC Staff	Yes	Although the penetration of synchronous condensers in North America is low, in most cases they are applied to address a reliability need, making it necessary to have accurate models of these devices for system studies. Although other devices may be outside the scope of this standard, accurate models are similarly necessary for devices such as static var compensators (SVCs) and static compensators (STATCOMs).
Response: The GVSDT thanks you for your comment. Synchronous condensers are synchronous machines, so the GVSDT feels they should be included with other synchronous machines. Solid state devices are significantly different, and the GVSDT believes that a separate SAR should be		

Organization	Yes or No	Question 8 Comment
drafted to cover these devices.		
Manitoba Hydro	Yes	To cover all configurations, the standard should also include and stipulate that synchronous machines that operate as generators at some times and as synchronous condensers at other times must perform a reactive capability test in each operating mode. This may be covered in Applicability 4.2.1 however the current wording should be modified to make this clear.
Response: The GVSDT thanks you for your comment. The following sentence was added to the beginning of Attachment 1: **"If a unit is operated in synchronous condenser mode as well as generation mode, the unit should be verified in both modes."**		
Independent Electricity System Operator	Yes	The standard should also be applicable to static var compensators and similar equipment used in reliability assessments of the BES.
Response: The GVSDT thanks you for your comment. Synchronous condensers are synchronous machines so the GVSDT feels they should be included with other synchronous machines. Solid state devices are significantly different, and the GVSDT believes that a separate SAR should be drafted to cover these devices.		
ISO New England	Yes	Yes, but as written the standard is not clear as to how the testing is to be performed for a synchronous condenser.
Response: The GVSDT thanks you for your comment. The following was added to the beginning of Attachment 1: **"For synchronous condensers, the verification should be performed as specified below with the exception of the Real Power Capability testing."**		
Cowlitz County PUD		Cowlitz does not own such equipment and therefore must defer to those that do. Cowlitz will consider the comments of others in the future.
Response: The GVSDT thanks you for your comment.

9. The SDT proposes that the size of synchronous condensers to be verified be limited to those greater than 50 MVA. Do you feel that this size criterion for synchronous condenser verification is appropriate?

Summary Consideration: There was an error in the comment form for this question. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit. While some commenters suggested values higher than 20 MVA, technical justification was not provided for a value exceeding the generator registration criterion of 20 MVA.

Organization	Yes or No	Question 9 Comment
IRC Standards Review Committee (joint comments)	No	There is no technical justification provided to support the 50 MVA criterion. Absent this, we propose to use the 20 MVA for generators as a general criterion for synchronous condensers as well.
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit.		
Dominion	No	First, we would like to state that we did not see the 50 MVA threshold in the posted version of this standard. And, if we had, we would not have agreed. If 20 MVA is the appropriate threshold for a generator, it is appropriate for a synchronous condenser.
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit.		
SERC Planning Standards Subcommittee	No	We recommend a limit of 20 MVA since these may be in remote areas where reactive capability is critical.
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit.		

Organization	Yes or No	Question 9 Comment
Southern Company	No	This MVA size does not agree with that found in the Applicability section 4.2.1 (20 MVA). As previously stated, we feel that the size of an individual unit that is significant in the Eastern Interconnection is 100 MVA.
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit.		
Tennessee Valley Authority GO	No	It is noted that this criteria is not consistent with the criteria for generators or with 4.2.1 of the draft standard.
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit.		
SERC Dynamics Review Sub-committee	No	A 50 MVA criteria for synchronous condensers is not in the standard. The standard says 20 MVA. However, a criteria of 75 MVA would be a more reasonable number. Units smaller than 75 MVA will have little impact to the reliability of the grid.
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit.		
NERC Staff	No	Section 4.2.1 indicates the standard is applicable to synchronous condensers greater than 20 MVA. We agree that the standard should be applicable to synchronous condensers greater than 20 MVA rather than 50 MVA.
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit.		
SERC Generation sub-committee	No	It is noted that this criteria is not consistent with the criteria for generators or with 4.2.1 of the draft standard.
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit.		
Associated Electric Cooperative, Inc.	No	It is noted that this criteria is not consistent with the criteria for generators or with 4.2.1 of the draft standard.
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit.		

Organization	Yes or No	Question 9 Comment
New York Independent System Operator	No	100 MVA is a more appropriate limit.
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit.		
Independent Electricity System Operator	No	There is no technical justification provided to support the 50 MVA criterion. Absent this, we propose to use the 20 MVA for generators as a general criterion for synchronous condensers as well.
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit.		
Ameren	No	The size of synchronous condensers to be verified should be consistent with generator sizes which need to be verified. Testing for units less than 75 MVA should not be required.
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit.		
Oncor Electric Delivery Company LLC	No	Oncor does not believe that there is a reliability based need for the verification of synchronous condensers under this standard therefore we believe this criterion is not applicable to this standard.
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit. Reactive output of synchronous condensers directly impacts the reliability of the BES.		
Georgia Transmission Corporation	No	20 MVA seems more consistent with the reasoning in question 4.
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit.		
Ingleside Cogeneration LP	No	There is a significant body of work underway defining the extent of the Bulk Electric System, which this proposal bypasses. This determination should rest with the project team responsible for that effort.

Organization	Yes or No	Question 9 Comment
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit.		
Wisconsin Public Service Corp	No	Synchronous condensers are specifically for local area voltage regulation purposes. Units between the sizes of 20MVA to 50MVA could be significant to an area's dynamic performance under contingencies.
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit.		
ISO New England	No	There is no technical justification supporting the 50 MVA criterion. Absent this, we propose to use the Compliance Registry criteria for generators of 20 MVA as a general criterion for data being verified for synchronous condensers over 20 MVA as well.
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit.		
Manitoba Hydro	No	The 50MVA criteria in question 9 does not appear in the draft standard (only in the implementation plan). If the question is valid and 50MVA is not a typo, it is not clear why the size of applicable synchronous condensers should be different from that of synchronous generators. Also 50 MVA seems like an arbitrary number with no basis. MH proposes that the applicable MVA rating of synchronous generators and synchronous condensers be identical. This eliminates confusion associated with units capable of operating in either mode.
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit.		
Indeck Energy Services	No	
Public Service Enterprise Group		A 50 MVA minimum size for synchronous condensers was not found in the proposed standard - see paragraph 4.2.1 which has a 20 MVA minimum. Whether the limit was intended to be 50 MVA or the 20 MVA limit stated in the draft, the SDT should provide a justification of basis for that MVA threshold. The impact that such smaller units would have on the BES is not substantial enough to justify requiring their inclusion in this standard.
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included		

Organization	Yes or No	Question 9 Comment
a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit.		
Cowlitz County PUD		Cowlitz does not own such equipment and therefore must defer to those that do. Cowlitz will consider the comments of others in the future.
Response: The GVSDT thanks you for your comment.		
BC Hydro		Not clear why would verification be required for generating units over 20 MVA while for SCs the threshold is over 50 MVA, especially having in mind that SCs are specifically used to provide reactive support
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit.		
Xcel Energy	Yes	There is a discrepancy between this question and the size limit in the draft standard (20 MVA). We believe 50 MVA is the better value.
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit.		
Westar Energy	Yes	We agree with the 50 MVA limit, however the standard does not currently address this limit.
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit.		
Imperial Irrigation District (IID)	Yes	THERE ARE NO SYNCHRONOUS CONDENSERS INSTALLED AND IN SERVICE WITHIN IID FACILITY.
Response: The GVSDT thanks you for your comment.		
Pepco Holdings Inc Affiliates	Yes	Question 9 mentions that a threshold was proposed by the SDT for synchronous generators greater than, or equal to, 50MVA. However, the existing language in Section A- 4.2.1 of the standard makes it applicable to both individual generating units and synchronous condensers greater than 20MVA. The 50MVA threshold for synchronous condensers seems reasonable, so if this was the intent then the language in the standard should be revised.
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included		

Organization	Yes or No	Question 9 Comment
a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit.		
SPP Reliability Standards Development Team	Yes	We agree with the 50 MVA limit but would request that it be included in the actual standard.
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit.		
FirstEnergy	Yes	The applicability section does not mention the 50 MVA threshold.
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit.		
American Electric Power	Yes	The current draft of the standard in section 4.2.1 proposes that the size of synchronous condensers to be verified be limited to those greater than 20 MVA, not 50MVA as stated in this question. Regardless, either limit would be acceptable.
Response: The GVSDT thanks you for your comment. There was an error in the comment form for this question. The question should have included a 20 MVA limit, rather than 50 MVA. Many stakeholders suggested including the 20 MVA limit.

10. Either operational data or staged testing is allowed by the standard for verification. Do you agree that these two methods of verification are acceptable? If not, please explain.

Summary Consideration: Most stakeholders agree that either operational data or staged testing should be allowed for verification.

Organization	Yes or No	Question 10 Comment
SERC Generation sub-committee	No	As the draft is currently written, these two methods are understood to be allowed. However, we believe a third alternative, engineering analysis, is needed in order for GOs to be able to verify generating unit reactive capabilities that are suitable for transmission system planning studies (See our Comment 2 under Question 14 for additional discussion on the verification methods.). It is proposed that Requirement R1.1 be re-written as follows: "Verify the Real and Reactive Power capability of its generating units and shall verify the Reactive Power capability of its synchronous condenser units in accordance with either Attachment 1 (staged testing or operational data) or by a new Attachment 3 (addressing engineering analysis)." The SERC GS could provide a template for this. Requirement R1.2 could then be qualified to be limited to reporting the results from staged testing or the use of operational data, and a new R1.3 could be inserted to require suitable reporting of the results from an engineering analysis. The time horizon of the two requirements in this standard are Long-Term Planning. MOD-025-2 does not have to focus solely upon operational testing to determine capabilities used for planning entity models. It is noted that TOP-002-2a R13 now requires the GOP to perform real and reactive capability testing at the request of the BA or TOP. The test can be specified if determined to be necessary by the BA or TOP.
Response: The GVSDT thanks you for your comment. It is envisioned that engineering analysis may be used to supplement operational data or staged testing. The GVSDT does not believe that engineering analysis alone is sufficient. Attachment 1, Section 2 of the proposed standard states: **"Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90 percent of a previously staged test that demonstrated at least 50 percent of the capability shown on the associated D-Curve."** **And Note 2 in Attachment 1 states:**		

Organization	Yes or No	Question 10 Comment
Note 2: "While not required by the standard, it is desirable to perform engineering analysis to determine expected applicable Facility capabilities under less restrictive system voltages than those encountered during the verification. Even though this analysis will not verify the complete MVAR capability curve, it provides a reasonable estimate of applicable Facility capability that the Transmission Planner can use for modeling." TOP-002-2a, R13 is proposed for retirement by the RTOSDT (Project 2007-03).		
Southern Company	No	As the draft is currently written, these two methods are understood to be allowed. However, we believe a third alternative, engineering analysis, is needed in order for GOs to be able to verify generating unit reactive capabilities that are suitable for transmission system planning studies (See our Comment 2 under Question 14 for additional discussion on the verification methods.). Reliance on data from testing or operations alone will result in understated reactive capabilities for planning purposes. To provide these alternative methods of establishing P&Q capabilities for each applicable facility, it is proposed that Requirement R1.1 be re-written as follows: "Verify the Real and Reactive Power capability of its generating units and shall verify the Reactive Power capability of its synchronous condenser units in accordance with either Attachment 1 (staged testing or operational data) or Attachment 3 (by engineering analysis)." Requirement R1.2 could then be qualified to be limited to reporting the results from staged testing or the use of operational data, and a new R1.3 could be inserted to require suitable reporting of the results from an engineering analysis. The time horizon of the two requirements in this standard are Long-Term Planning. MOD-025-2 does not have to focus solely upon operational testing to determine capabilities used for planning entity models. It is noted that TOP-002-2a R13 now requires the GOP to perform real and reactive capability testing at the request of the BA or TOP. The test can be specified if determined to be necessary by the BA or TOP.
Response: The GVSDT thanks you for your comment. It is envisioned that engineering analysis may be used to supplement operational data or staged testing. The GVSDT does not believe that engineering analysis alone is sufficient. Attachment 1, Section 2 of the proposed standard states: **"Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90 percent of a previously staged test that demonstrated at least 50 percent of the capability shown on the associated D-Curve."** **And Note 2 in attachment 1 states:** **Note 2: "While not required by the standard, it is desirable to perform engineering analysis to determine expected applicable Facility capabilities under less restrictive system voltages than those encountered during the verification. Even though this analysis will not verify the complete MVAR capability curve, it provides a reasonable estimate of applicable Facility capability that the Transmission Planner can use for modeling."**		

Organization	Yes or No	Question 10 Comment
TOP-002-2a, R13 is proposed for retirement by the RTOSDT (Project 2007-03).		
Tennessee Valley Authority GO	No	As the draft is currently written, these two methods are understood to be allowed. However, we believe a third alternative, engineering analysis, is needed in order for GOs to be able to verify generating unit reactive capabilities that are suitable for transmission system planning studies. It is proposed that Requirement R1.1 be re-written as follows: "Verify the Real and Reactive Power capability of its generating units and shall verify the Reactive Power capability of its synchronous condenser units in accordance with either Attachment 1 (staged testing or operational data) or by a new Attachment 3 (addressing engineering analysis)." Associated Electric Cooperative, Inc.	No	As the draft is currently written, these two methods are understood to be allowed. However, we believe a third alternative, engineering analysis, is needed in order for GOs to be able to verify more appropriate generating unit reactive capabilities that are needed to ensure that planning entities have accurate generator data when assessing BES reliability. MOD-025-2 should not focus solely upon operational testing to

Organization	Yes or No	Question 10 Comment
		determine capabilities used for planning models, because experience has shown that testing does not provide appropriate reactive power capabilities. It is noted that TOP-002-2a R13 now requires the GOP to perform real and reactive capability testing at the request of the BA or TOP. The test can be specified if determined to be necessary by the BA or TOP.
Response: The GVSDT thanks you for your comment. It is envisioned that engineering analysis may be used to supplement operational data or staged testing. The GVSDT does not believe that engineering analysis alone is sufficient. Attachment 1, Section 2 of the proposed standard states: **"Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90 percent of a previously staged test that demonstrated at least 50 percent of the capability shown on the associated D-Curve."** **And Note 2 in attachment 1 states:** **Note 2: "While not required by the standard, it is desirable to perform engineering analysis to determine expected applicable Facility capabilities under less restrictive system voltages than those encountered during the verification. Even though this analysis will not verify the complete MVAR capability curve, it provides a reasonable estimate of applicable Facility capability that the Transmission Planner can use for modeling."** **TOP-002-2a, R13 is proposed for retirement by the RTOSDT (Project 2007-03).**		
Duke Energy	No	As the draft is currently written, these two methods are understood to be allowed, but experience has shown may not be able to fully validate the available capabilities. We believe engineering analysis could be used in order for GOs to be able to verify generating unit reactive capabilities that are suitable for transmission system planning studies. The answer may be to test or operate as far as you can based on system voltage and then evaluate margin to unit thermal limits (Generator, Bus, GSUs, etc) and determine if you could reasonably have reached full capability if system conditions warranted the need.
Response: The GVSDT thanks you for your comment. It is envisioned that engineering analysis may be used to supplement operational data or staged testing. The GVSDT does not believe that engineering analysis alone is sufficient. Attachment 1, Section 2 of the proposed standard states: **"Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90 percent of a previously staged test that demonstrated at least 50 percent of the capability shown on the associated D-Curve."** **And Note 2 in attachment 1 states:** **Note 2: "While not required by the standard, it is desirable to perform engineering analysis to determine expected applicable Facility capabilities under less restrictive system voltages than those encountered during the verification. Even though this analysis will not verify the complete MVAR capability curve, it provides a reasonable estimate of applicable Facility capability that the Transmission Planner can use for modeling."**

<tr><td>Pepco Holdings Inc Affiliates</td><td>Yes</td><td>“Staged” vs “operational” verification should be defined. In Attachment 1, are sections 2 and 5.2 consistent? That is should the % value be the same?</td></tr>
</table>

Organization	Yes or No	Question 10 Comment
Response: The GVSDT thanks you for your comment. A staged test is simply one that is scheduled for purposes of verification whereas an operational verification includes historical performance records. Section 2 was revised to, "At least 90 percent of a previously staged test that demonstrated at least 50 percent of the capability shown on the associated D-Curve". This makes Section 2 and 5.2 consistent. The percentage in Section 2 refers to the data that is acceptable to be used for verification for operational data where the percentage in 5.2 is the criterion for the level of change in a Facility capability that triggers the need to perform another verification. The GVSDT felt that the percentages chosen were appropriate for the intended purpose. The wording in Section 2 was revised to clarify intent.		
Cowlitz County PUD	Yes	Operational data will always be the preferred method of obtaining verification; however Cowlitz can't see how this would be possible for obtaining the reactive capabilities as prescribed. This will require costly and burdensome staged testing.
Response: The GVSDT thanks you for your comment. In order to obtain the data required by the standard, staged testing may be required. It is believed that staged testing can be scheduled at the required Load levels along with other plant operations (e.g. startup/shutdown, high Load, etc.) and since verification is required only once every five years (in most cases), the effort is not considered to be costly or burdensome.		
Ingleside Cogeneration LP	Yes	There is no reason to preclude the use of actual operations data in validation exercises.
Response: The GVSDT thanks you for your comment.

11. If operational data is utilized, the standard requires the verification be within 20 percent of the expected value. Do you agree with the 20 percent requirement? If not, please explain.

Summary Consideration: Many of the comments indicated that the proposed language in the standard on this point was confusing so the GVSDT has revised the language to better clarify intent. Several commenters indicated the 20percent tolerance value was too high, while others thought this value was too restrictive. The revised wording specifies the percentage selection criterion is applied to "the last reported capability." Attachment 1, Item 2 was revised to include:

Operational data from within the two years prior to the verification date is acceptable for the verification of either the Real Power or the Reactive Power capability, as long as that operational data meets the criteria in 2.1 through 2.5 below and is at least 90 percent of a previously staged test that demonstrated at least 50percent of the capability shown on the associated D-Curve.

The GVSDT believes this change will alleviate commenter concerns. The GVSDT disagrees with commenters suggesting operational data restrictions should not be included.

Organization	Yes or No	Question 11 Comment
IRC Standards Review Committee (joint comments)	No	We have difficulty interpreting the 20% in Item 2 of Attachment 1, which says: "Operational data from within the year prior to the verification date is acceptable for the verification as long as IT (emphasis added) meets the criteria in 2.1 through 2.5 below and is within 20% of the expected value:" We interpret that the "IT" refers to the operational data. As such, we do not understand the "within 20% of the expected value". Does it mean the generator's real power output during the period from which operational data was collected must be within 20% of the generators' declared or name plate capability, or what? We need clarification, and suggest a revision to this Item 2 to provide the clarity. As written, we are unable to comment on the acceptability of the 20%.

Response: The GVSDT thanks you for your comment. Based on comments and further review, the GVSDT has revised the sentence in Section 2 to state:

"Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90percent of a previously staged test that demonstrated at least 50percent of the capability shown on the appropriate Dee-Curve. If the previously staged test was unduly restricted by unusual generation or equipment limitations (for example capacitor or reactor banks out

Organization	Yes or No	Question 11 Comment
of service), then the next verification shall be by another staged test, not operational data.” **The intent of this statement is that an entity may use operational data in lieu of a staged test if the operational data is at least 90percent of the last reported verified capability.**		
Pepco Holdings Inc Affiliates	No	20% “appears” to be a large variance. The DT should explain the justification for 20%. 5% or 10% would seem more reasonable, especially for large units.
Response: The GVSDT thanks you for your comment. Based on comments and further review, the GVSDT has revised the sentence in Section 2 to state: **“Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90percent of a previously staged test that demonstrated at least 50percent of the capability shown on the appropriate Dee-Curve. If the previously staged test was unduly restricted by unusual generation or equipment limitations (for example capacitor or reactor banks out of service), then the next verification shall be by another staged test, not operational data.”** **The intent of this statement is that an entity may use operational data in lieu of a staged test if the operational data is at least 90percent of the last reported verified capability.**		
SPP Reliability Standards Development Team	No	We feel that 20% is too great a buffer for this data and would suggest that the number reflect a buffer of 10% or less. We feel like having a buffer that is too high would cause entities to not use testing verification and would use the operational data verification. We also feel that this verification should be as accurate as possible to reflect the system in planning.
Response: The GVSDT thanks you for your comment. Based on comments and further review, the GVSDT has revised the sentence in Section 2 to state: **“Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90percent of a previously staged test that demonstrated at least 50percent of the capability shown on the appropriate Dee-Curve. SERC Planning Standards Subcommittee	No	The 20 % requirement is too restrictive. Any operational data should be allowed to be used if it is accompanied by engineering analysis which calculates appropriate expected limits. This will be more useful to the Transmission Planner than a value from operational data within 20% which does not give the appropriate

Organization	Yes or No	Question 11 Comment
		expected limit.
Response: The GVSDT thanks you for your comment. Based on comments and further review, the GVSDT has revised the sentence in Section 2 to state: **"Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90percent of a previously staged test that demonstrated at least 50percent of the capability shown on the appropriate Dee-Curve. If the previously staged test was unduly restricted by unusual generation or equipment limitations (for example capacitor or reactor banks out of service), then the next verification shall be by another staged test, not operational data."** **The intent of this statement is that an entity may use operational data in lieu of a staged test if the operational data is at least 90percent of the last reported verified capability.**		
Idaho Power-Power Production	No	What is the technical basis for the 20%? It seems high.
Response: The GVSDT thanks you for your comment. Based on comments and further review, the GVSDT has revised the sentence in Section 2 to state: **"Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90percent of a previously staged test that demonstrated at least 50percent of the capability shown on the appropriate Dee-Curve. If the previously staged test was unduly restricted by unusual generation or equipment limitations (for example capacitor or reactor banks out of service), then the next verification shall be by another staged test, not operational data."** **The intent of this statement is that an entity may use operational data in lieu of a staged test if the operational data is at least 90percent of the last reported verified capability.**		
Santee Cooper	No	First of all "expected value" is not defined. Second any expected value based solely on nameplate data is subject to great variation based on the system the generator is connected to and should not be used to draw conclusions of satisfactory or unsatisfactory test results.
Response: The GVSDT thanks you for your comment. Based on comments and further review, the GVSDT has revised the sentence in Section 2 to state: **"Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90percent of a previously staged test that demonstrated at least 50percent of the capability shown on the appropriate Dee-Curve. Organization	Yes or No	Question 11 Comment
reported verified capability. The phrase, "expected value" is not used in the revised standard.		
PPL Generation	Yes	Note however that the expectation, as discussed above, is (for certain PPL Generation Registered Entities' units) derived from the aux bus limits, not the D-curve.
Response: The GVSDT thanks you for your comment.		
Dominion	No	If the question was meant to ask whether we agree with the sentence that reads" Operational data from within the year prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is within 20% of the expected value:" (Attachment 1, @2) then we respond affirmatively. However, we do not agree that a verification MUST be within 20%. It is possible that a physical change to either the asset being verified or the system it is interconnected with may result in its inability to perform to within 20%. If this is true, then we could agree that any such variance must be accompanied by an explanation as to why the verification did not fall with the 20% 'boundary'. There should be no requirement for percent of expected value.
Response: The GVSDT thanks you for your comment. You are correct with regard to the intent of the sentence. The intent of this standard is to verify the capability of a generator or synchronous condenser. A staged verification or operational data may be used for the verifications required by MOD-025. Based on comments and further review, the GVSDT has revised the sentence in Section 2 to state: **"Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90percent of a previously staged test that demonstrated at least 50percent of the capability shown on the appropriate Dee-Curve. If the previously staged test was unduly restricted by unusual generation or equipment limitations (for example capacitor or reactor banks out of service), then the next verification shall be by another staged test, not operational data."** **If a physical change occurs to an asset the verification should be based on the assets demonstrated capability with that change accounted for.**		
FirstEnergy	No	If the generating unit is capable of reaching 20% of the "expected value", than why should verification be concluded at that point? (We could potentially be missing out on fully realizing the potential of a reactive resource by pre-maturely ending the verification. A very important dimension of this verification (that was touched on in the Standard) is the recognition of equipment conditions or voltage regulator settings that could be improved when a staged test is performed. It is difficult if not impossible to capture equipment shortcomings or limitations which can be very useful to improving operations when verifying through the use of Operational data. Also, we need clarification regarding what would be considered "within 20% of expected value" if your leading reactive limit was 0 MVAR (unity)?
Response: The GVSDT thanks you for your comment. Based on comments and further review, the GVSDT has revised the sentence in Section 2 to		

Organization	Yes or No	Question 11 Comment
state: **“Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90% of a previously staged test that demonstrated at least 50percent of the capability shown on the appropriate Dee-Curve. If the previously staged test was unduly restricted by unusual generation or equipment limitations (for example capacitor or reactor banks out of service), then the next verification shall be by another staged test, not operational data.”** **The intent of this statement is that an entity may use operational data in lieu of a staged test if the operational data is at least 90percent of the last reported verified capability. This change is not intended to limit the scope of effort performed during a staged test. This change only establishes acceptance criteria for using operational data for verification in lieu of performing a staged test.**		
SERC Dynamics Review Sub-committee	No	The 20 % requirement is too restrictive. Any operational data should be allowed to be used if it is accompanied by engineering analysis which calculates appropriate expected limits. This will be more useful to the Transmission Planner than a value from operational data within 20% which does not give the appropriate expected limit.
Response: The GVSDT thanks you for your comment. Based on comments and further review, the GVSDT has revised the sentence in Section 2 to state: **“Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90percent of a previously staged test that demonstrated at least 50percent of the capability shown on the appropriate Dee-Curve. If the previously staged test was unduly restricted by unusual generation or equipment limitations (for example capacitor or reactor banks out of service), then the next verification shall be by another staged test, not operational data.”** **The intent of this statement is that an entity may use operational data in lieu of a staged test if the operational data is at least 90percent of the last reported verified capability. The intent of this statement is to allow an entity to use operational data in lieu of performing a staged test if the operational data is at least 90percent of the last reported verified capability.**		
NERC Staff	No	We agree the standard should provide flexibility to the Generator Owner; however, the need for flexibility must be balanced against the need for valid models for system studies. Accuracy must be at least as stringent as required for market dispatch. When operational data cannot be verified within 5% of the expected value, an entity should be required to provide data based on staged testing.
Response: The GVSDT thanks you for your comment. Based on comments and further review, the GVSDT has revised the sentence in Section 2 to state: **“Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90percent of a previously staged test that demonstrated at least 50percent of the capability shown on the appropriate Dee-**		

Organization	Yes or No	Question 11 Comment
Curve. If the previously staged test was unduly restricted by unusual generation or equipment limitations (for example capacitor or reactor banks out of service), then the next verification shall be by another staged test, not operational data." **The intent of this statement is that an entity may use operational data in lieu of a staged test if the operational data is at least 90percent of the last reported verified capability. The operational data would always have been preceded by a staged test to demonstrate the unit/Facility capability. The allowance for operational data that is at least 90percent of a prior staged test with reasonable results will allow for a reduced burden on the GO or TO. The GVSDT disagrees that verification within 5percent of an expected value should require staged testing in this case because the expected value is mostly dependent on the system conditions at the time of the test rather than the unit's/facilities capabilities. If the unit/Facility cannot reach the revised criteria mentioned above, another staged test would then be required.**		
Public Service Enterprise Group	No	Attachment 1 is unclear as to the implementation of the 20% requirement. Paragraph 2 states "Operational data from within the year prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is within 20% of the expected value:" As written, it appears that the 20% only applies to operational data "within the year prior to the verification date." Does the 20% apply also to staged tests? If not, why not? Paragraph 5.2 in Attachment 1, regarding operational tests, is also relevant: "If data for different points is recorded on different days, the Generator Owner shall designate one of the dates as the verification date, and report that date as the verification date on MOD-025- Attachment 2 for periodicity purposes." Is the SDT proposing to comingle operational data from one-year prior to the verification date as long as it is within 20% of the expected value? If so, what value would be reported - the test data that may be up to 20% higher or lower than the expected value or the expected value?
Response: The GVSDT thanks you for your comment. Based on comments and further review, the GVSDT has revised the sentence in Section 2 to state: **"Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90percent of a previously staged test that demonstrated at least 50percent of the capability shown on the appropriate Dee-Curve. If the previously staged test was unduly restricted by unusual generation or equipment limitations (for example capacitor or reactor banks out of service), then the next verification shall be by another staged test, not operational data."** **The intent of this statement is that an entity may use operational data in lieu of a staged test if the operational data is at least 90percent of the last reported verified capability.**		
SERC Generation sub-committee	No	Since the "expected value" is not clearly identified, it is not possible to determine if 20% is an appropriate value. Furthermore, if the "expected value" is the "D-curve" for lagging Vars, we believe this is not a realistic expectation since operational data for most generating units does not approach 80% of the "D curve" value in

Organization	Yes or No	Question 11 Comment
		normal operating conditions (or even in staged testing based on our experience). A recent survey of the SERC region has shown that only 34% of 85 generators surveyed performing staged Q production tests could reach 80% of their D curve lagging Q capability. The same survey showed that only 19% of 32 generators surveyed performing staged Q absorption tests could reach 80% of their under excitation limit (UEL) characteristic setting. Therefore, the "within 20% of the expected value" requirement should be deleted. If an engineering analysis (which uses operational data for analytical model confirmation) is allowed as an alternative verification method, the 20% tolerance given above is not needed. Reference comment 2 under Question 14 for additional discussion on the verification methods.Any operational data should be allowed if accompanied by engineering analysis that calculates appropriate expected limits. This will be more useful to the Transmission Planner than a value from operational data within 20% which does not give the appropriate expected limit.
Response: The GVSDT thanks you for your comment. The phrase, "expected value" is not used in the revised standard. **Based on comments and further review, the GVSDT has revised the sentence in Section 2 to state:** **"Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90percent of a previously staged test that demonstrated at least 50percent of the capability shown on the appropriate Dee-Curve. Ameren	No	While the 20% margin is appropriate and appreciated, it is unclear if verifying the output of a generator at 80% of real rated output will satisfy regulator rating requirements at the time of seasonal peak. Thus, from the user of this data (e.g. planners), this % is too great. From the generator owner and testing personnel , this % makes sense and seems appropriate. We would suggest the SDT provide basis for this % and a guidance how it should be used for all conditions.
Response: The GVSDT thanks you for your comment. Based on comments and further review, the GVSDT has revised the sentence in Section 2 to state: **"Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90percent of a previously staged test that demonstrated at least 50percent of the capability shown on the appropriate Dee-Curve. If the previously staged test was unduly restricted by unusual generation or equipment limitations (for example capacitor or reactor banks out of service), then the next verification shall be by another staged test, not operational data."** **The intent of this statement is that an entity may use operational data in lieu of a staged test if the operational data is at least 90percent of the last reported verified capability. The GVSDT has added a note to Attachment 1 to allow for and encourage engineering analysis to provide a more reasonable estimate of unit capabilities in cases where system conditions will not allow the unit to demonstrate its full capability. The GVSDT does not believe that engineering analysis alone is sufficient and therefore testing is still required to show that limitations do not exist that would not be identified with engineering analysis such as a thermally sensitive field or an inaccurate limiter in the voltage regulator.** **Note 2: While not required by the standard, it is desirable to perform engineering analysis to determine expected applicable Facility capabilities**		

Organization	Yes or No	Question 11 Comment
under less restrictive system voltages than those encountered during the verification. Even though this analysis will not verify the complete MVAR capability curve, it provides a reasonable estimate of applicable Facility capability that the Transmission Planner can use for modeling.		
Indeck Energy Services	No	The point is that the rating should be changed to the value tested. If a unit can't reach it, it's not a rating.
Response: The GVSDT thanks you for your comment. Based on comments and further review, the GVSDT has revised the sentence in Section 2 to state: **"Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90percent of a previously staged test that demonstrated at least 50percent of the capability shown on the appropriate Dee-Curve. If the previously staged test was unduly restricted by unusual generation or equipment limitations (for example capacitor or reactor banks out of service), then the next verification shall be by another staged test, not operational data."** **The intent of this statement is that an entity may use operational data in lieu of a staged test if the operational data is at least 90percent of the last reported verified capability. The proposed standard allows engineering analysis to obtain the best possible results for use in modeling.**		
Oncor Electric Delivery Company LLC	No	Any operational varation from expected should be explained by the Generator Owner and a solution to provide full capability be presented.
Response: The GVSDT thanks you for your comment. This change only establishes acceptance criteria for using operational data for verification in lieu of performing a staged test. The reason for the variation must be included in the remarks section of Attachment #2 if a limitation is reached during verification testing.		
Georgia Transmission Corporation	No	The data should be accepted as is unless the data is meaningless.
Response: The GVSDT thanks you for your comment. Based on comments and further review, the GVSDT has revised the sentence in Section 2 to state: **"Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90percent of a previously staged test that demonstrated at least 50percent of the capability shown on the appropriate Dee-Curve. If the previously staged test was unduly restricted by unusual generation or equipment limitations (for example capacitor or reactor banks out of service), then the next verification shall be by another staged test, not operational data."** **The intent of this statement is that an entity may use operational data in lieu of a staged test if the operational data is at least 90percent of the last reported verified capability.**		

Organization	Yes or No	Question 11 Comment
Austin Energy	No	This requires a guarantee to an expected performance that may be impacted by a particular operational problem during the test (high cooling water or ambient temperatures, etc). The test results should be accepted as is and logged as the new generator capability until such time as it is retested later with better results.
Response: The GVSDT thanks you for your comment. The phrase, "expected value" is not used in the revised standard. Based on comments and further review, the GVSDT has revised the sentence in Section 2 to state: **"Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90percent of a previously staged test that demonstrated at least 50percent of the capability shown on the appropriate Dee-Curve. If the previously staged test was unduly restricted by unusual generation or equipment limitations (for example capacitor or reactor banks out of service), then the next verification shall be by another staged test, not operational data."** **The intent of this statement is that an entity may use operational data in lieu of a staged test if the operational data is at least 90percent of the last reported verified capability. The reason for a variation must be included in the remarks section of Attachment #2 if a limitation is reached during verification testing.**		
BC Hydro	No	Such a wide margin seems to defeat the purpose of verifications. If such margin is technically acceptable to planners, the question is why even requiring verifications, especially for smaller units. It is hard to immagine that actual capability (active or reactive) of generating units/facilities would ever be lower than 80% of declared.
Response: The GVSDT thanks you for your comment. Based on comments and further review, the GVSDT has revised the sentence in Section 2 to state: **"Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90percent of a previously staged test that demonstrated at least 50percent of the capability shown on the appropriate Dee-Curve. If the previously staged test was unduly restricted by unusual generation or equipment limitations (for example capacitor or reactor banks out of service), then the next verification shall be by another staged test, not operational data."** **The intent of this statement is that an entity may use operational data in lieu of a staged test if the operational data is at least 90percent of the last reported verified capability.**		
American Electric Power	No	System conditions greatly affect the expected reactive power values as stated in Attachment 1, Notes 1 and 2. While 20% appears reasonable for the real power verification, there needs to be flexibility as to this value for reactive power, given that system conditions are not constant.

Organization	Yes or No	Question 11 Comment
Response: The GVSDT thanks you for your comment. Based on comments and further review, the GVSDT has revised the sentence in Section 2 to state: **"Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90percent of a previously staged test that demonstrated at least 50percent of the capability shown on the appropriate Dee-Curve. If the previously staged test was unduly restricted by unusual generation or equipment limitations (for example capacitor or reactor banks out of service), then the next verification shall be by another staged test, not operational data."** **The intent of this statement is that an entity may use operational data in lieu of a staged test if the operational data is at least 90percent of the last reported verified capability. Please note this statement specifies the acceptance criteria required for performing verification using operational data. If acceptable operational data cannot be obtained, then staged testing is required.**		
Ingleside Cogeneration LP	No	The real and reactive capacities should be validated to be within 20% of expectation at the limits identified in the Transmission Operator's reactive capability schedule, not the generator's operational limits.
Response: The GVSDT thanks you for your comment. Based on comments and further review, the GVSDT has revised the sentence in Section 2 to state: **"Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90percent of a previously staged test that demonstrated at least 50percent of the capability shown on the appropriate Dee-Curve. If the previously staged test was unduly restricted by unusual generation or equipment limitations (for example capacitor or reactor banks out of service), then the next verification shall be by another staged test, not operational data."** **The intent of this statement is that an entity may use operational data in lieu of a staged test if the operational data is at least 90percent of the last reported verified capability. The SDT disagrees that the verification should be against the TOP's reactive capability schedule since the data collected is for use in long-term planning studies, not for Real-time operations.**		
ISO New England	No	As we interpret the language, we do not agree with the 20% requirement. In the assessments performed in our area our goal is to use data that is much more accurate than what appears to be required under the standard. Allowing verification to be up to 20% inaccurate may result in inaccurate system assessments, potentially leading to overlooking potential system problems or to unnecessary system investment to address system concerns which are not really present. This value should be changed to a maximum of 5%.
Response: The GVSDT thanks you for your comment. Based on comments and further review, the GVSDT has revised the sentence in Section 2 to state: **"Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90percent of a previously staged test that demonstrated at least 50percent of the capability shown on the appropriate Dee-**		

Organization	Yes or No	Question 11 Comment
Curve. If the previously staged test was unduly restricted by unusual generation or equipment limitations (for example capacitor or reactor banks out of service), then the next verification shall be by another staged test, not operational data." **The intent of this statement is that an entity may use operational data in lieu of a staged test if the operational data is at least 90percent of the last reported verified capability. The operational data would always have been preceded by a staged test to demonstrate the unit/Facility capability. The allowance for operational data that is at least 90percent of a prior staged test with reasonable results will allow for a reduced burden on the GO or TO. The GVSDT disagrees that verification within 5percent of an expected value should require staged testing in this case because the expected value is mostly dependent on the system conditions at the time of the test, rather than the unit's/Facilities capabilities. If the unit/Facility cannot reach the revised criteria mentioned above, another staged test would then be required.**		
Duke Energy	No	We have model validation requirements but no definitions to what we are needing to validate to. The "expected value" is not clearly defined, so it is not possible to determine if 20% of this value is appropriate. Furthermore, if the "expected value" is the "D curve" for lagging Vars, we believe this is not a realistic expectation since operational data for most generating units does not approach 80% of the "D curve" value in normal operating conditions (or even in staged testing based on our experience). A recent survey of the SERC region has shown that only 34% of 85 generators surveyed performing staged Q production tests could reach 80% of their D curve lagging Q capability. The same survey showed that only 19% of 32 generators surveyed performing staged Q absorption tests could reach 80% of their underexcitation limit (UEL) characteristic setting. Therefore, the "within 20% of the expected value" requirement should be deleted. If an engineering analysis (which uses operational data for analytical model confirmation) is allowed as an alternative verification method, the 20% tolerance given above is not needed. Reference our response to Question #10.
Response: The GVSDT thanks you for your comment. The phrase, "expected value" is not used in the revised standard. Based on comments and further review, the GVSDT has revised the sentence in Section 2 to state: **"Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90percent of a previously staged test that demonstrated at least 50percent of the capability shown on the appropriate Dee-Curve. If the previously staged test was unduly restricted by unusual generation or equipment limitations (for example capacitor or reactor banks out of service), then the next verification shall be by another staged test, not operational data."** **The intent of this statement is that an entity may use operational data in lieu of a staged test if the operational data is at least 90percent of the last reported verified capability. Please note this statement specifies operational data acceptance criterion and does not apply to staged testing.**		
Lincoln Electric System	No	The definition of "expected value" needs to be more clearly defined as it is somewhat unclear. The verification should probably be within at least 5percent of the expected output of the generating unit for a given ambient temperature, rather than 20% as stated in this draft. For a simple-cycle gas turbine the real

Organization	Yes or No	Question 11 Comment
		power output for the verification test would in most cases be greater than what it would be for summer peak conditions due to the higher generator output that typically occurs with these units as the turbine inlet temperature decreases. It is usually desirable to test the unit with the same conditions that the unit will be most needed. For summer peaking utilities this would be with reasonably high ambient conditions. When only recording real power data it is usually not that difficult to recordthe data in the summer when the units are already operating to serve the load. The coordination to record reactive power data at this time may be more difficult.
Response: The GVSDT thanks you for your comment. The phrase, "expected value" is not used in the revised standard. Based on comments and further review the GVSDT has revised the sentence in Section 2 to state: **"Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90percent of a previously staged test that demonstrated at least 50percent of the capability shown on the appropriate Dee-Curve. If the previously staged test was unduly restricted by unusual generation or equipment limitations (for example capacitor or reactor banks out of service), then the next verification shall be by another staged test, not operational data."** **The intent of this statement is that an entity may use operational data in lieu of a staged test if the operational data is at least 90percent of the last reported verified capability. The proposed standard allows the use of operational data as an option when verifying units. If acceptable operational data cannot be obtained, then staged testing is required.**		
Independent Electricity System Operator	No	We have difficulty interpreting the 20% in Item 2 of Attachment 1, which says: "Operational data from within the year prior to the verification date is acceptable for the verification as long as IT (emphasis added) meets the criteria in 2.1 through 2.5 below and is within 20% of the expected value:"We interpret that the "IT" refers to the operational data. As such, we do not understand the "within 20% of the expected value". Does it mean the generator's real power output during the period from which operational data was collected must be within 20% of the generator's declared or name plate capability, or what? We need clarification, and suggest a revision to this Item 2 to provide the clarity.As written, we are unable to comment on the acceptability of the 20%.
Response: The GVSDT thanks you for your comment. The phrase, "expected value" is not used in the revised standard. Based on comments and further review, the GVSDT has revised the sentence in Section 2 to state: **"Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90percent of a previously staged test that demonstrated at least 50percent of the capability shown on the appropriate Dee-Curve. If the previously staged test was unduly restricted by unusual generation or equipment limitations (for example capacitor or reactor banks out of service), then the next verification shall be by another staged test, not operational data."** **The intent of this statement is that an entity may use operational data in lieu of a staged test if the operational data is at least 90percent of the last**		

Organization	Yes or No	Question 11 Comment
reported verified capability.		
percentpercentpercent		
Chelan County PUD		For hydro, 20% of min and max reactive may be difficult to achieve. Salient pole machines have much greater lattitude than thermal, but system and bus conditions dictate if it is possible. Allowance should be made for realities in these cases. Again, what will dictate - voltage schedule or testing requirements?
Response: The GVSDT thanks you for your comment. Based on comments and further review, the GVSDT has revised the sentence in Section 2 to state: **"Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90percent of a previously staged test that demonstrated at least 50percent of the capability shown on the appropriate Dee-Curve. If the previously staged test was unduly restricted by unusual generation or equipment limitations (for example capacitor or reactor banks out of service), then the next verification shall be by another staged test, not operational data."** **The intent of this statement is that an entity may use operational data in lieu of a staged test if the operational data is at least 90percent of the last reported verified capability. The reason for the variation must be included in the remarks section of Attachment #2 if a limitation is reached during verification testing.**

Response: The GVSDT thanks you for your comment.		

12. Are you aware of any regional variances that would be required for this standard?

Summary Consideration: Commenters have identified regional variances currently in effect, as required by MOD-024 and MOD-025. It is anticipated that these regional standards will be retired once MOD-025-2 is approved. Language provided by Relaibility*First* staff has been added to the Implementation plan concerning the Reliability*First* standards:

"It is the intent of Reliability*First* to perform a review of both the MOD-024-RFC-01 and MOD-025-RFC-01 standards upon NERC Board of Trustees approval of the associated NERC MOD-025-2 standard. The purpose of the review would be to ensure that any duplicative requirements or any requirements which are less restrictive or do not add additional detail will be considered for retirement. The steps outlined in the Reliability*First* Reliability Standards Development Procedure will be followed for any such revisions or retirements."

Organization	Yes or No	Question 12 Comment
SPP Reliability Standards Development Team	Yes	If the testing time is 1 hour as written then we have a variance of the SPP criteria of 15 minutes, but if the team decides to change that time limit then we wouldn't and our answer would change to no.
Response: The GVSDT thanks you for your comment. The reliability goal of the one-hour verification period is to ensure that generator temperature is stable and the verification demonstrates a sustainable capability. The GVSDT believes one hour is sufficient for the generator to reach thermal stability during testing for confirming the reliability objective of this standard. If MOD-025-2 is approved as proposed, then the SPP regional criteria will need to be revised. The continent-wide standard takes precedence over regional criteria. When this standard is approved, members of SPP will need to comply with the continent-wide standard. SPP could request a regional variance if SPP has technical justification to support the need for a 15-minute test period that is based on a physical difference in the bulk power system.		
Westar Energy	Yes	The SPP Criteria requires that the testing period should be 15 minutes rather than the 1 hour listed in the standard.
Response: The GVSDT thanks you for your comment. The reliability goal of the one-hour verification period is to ensure that generator temperature is stable and the verification demonstrates a sustainable capability. The GVSDT believes one hour is sufficient for the generator to reach thermal stability during testing for confirming the reliability objective of this standard. If MOD-025-2 is approved as proposed, then the SPP regional standard will need to be revised. The continent-wide standard takes precedence over regional criteria. When this standard is approved, members of SPP will need to comply with the continent-wide standard. SPP could request a regional variance if SPP has technical justification to support the need for a 15-minute test period that is based on a physical difference in the bulk power system.		

Organization	Yes or No	Question 12 Comment
Indeck Energy Services	Yes	The temperature adjustment probably varies by region. There is no basis in the ROP for members on one region to vote on requirements for another region. There are nationwide standards or regional standards. The SDT can't have it both ways.
Response: The GVSDT thanks you for your comment. Within a continent-wide standard, a requirement can include alternative performance based on different Facility characteristics, different regions, or different interconnections. (See INT-006-3 for an example.)		
Oncor Electric Delivery Company LLC	Yes	Oncor also recommends that consideration be given to a regional variance in that the information required of the Generator Owner as specified in R1 should be provided to the Planning Authority in the ERCOT region and not the Transmission Planner. This would align with current protocols, operating guide and planning guide as it relates to resource testing.
Response: The GVSDT thanks you for your comment. Oncor could sponsor a regional variance if its Region has technical justification to support the need for a variance based on a physical difference in the BES.		
Exelon	Yes	It is strongly suggested that the SDT review each existing Generator Real and Reactive Power Capability Regional Standard (or other guidance) currently in place for best practices and potential conflicts. As stated in responses to questions 5, 7, 13, and 14 nuclear units do not perform under-excited (leading) reactive capability testing due to concerns with unit stability and potential under voltage conditions on internal nuclear plant safety buses that may challenge safe plant operations and could lead to a plant transient or shutdown in accordance with NRC operating license. Exelon Nuclear is a member of and has 17 nuclear units in two Regions (ReliabilityFirst and SERC). RFC Regional Standard MOD-025-RFC-01, "Verification and Data Reporting of Generator Gross and Net Reactive Power Capability," currently has a specific exclusion that "Under-excited (leading) Reactive Power capability verification is not required of nuclear units." SERC Regional Criteria, "Verification of Generator Real and Reactive Power Capability," has the following statement regarding nuclear units, " (t)he capabilities of nuclear units will be determined taking into consideration the fuel management program of the unit and any restrictions imposed by regulatory agencies.
Response: The GVSDT thanks you for your comment. RFC has informed the GVSDT that: **It is the intent of Reliability*First* to perform a review of both the MOD-024-RFC-01 and MOD-025-RFC-01 standards once the NERC Board of Trustees approves the NERC MOD-025-2 standard. The purpose of this review is to ensure redundant and less restrictive requirements are either revised or considered for retirement from the RFC standards in accordance with the Reliability*First* Reliability Standards Development Procedure.** **Nuclear units are not required to perform Reactive Power verification at minimum Real Power output.**		

Organization	Yes or No	Question 12 Comment
Ingleside Cogeneration LP	Yes	TRE, WECC, and SERC have similar but slightly different requirements. It is Ingleside's expectation that these regions would align their processes to MOD-025-2 when it takes effect.
Response: The GVSDT thanks you for your comment.		
Duke Energy	Yes	There have historically been regional differences in unit criticality size.
Response: The GVSDT thanks you for your comment.		
Luminant Power	Yes	
New York Independent System Operator	No	In the NPCC region Directory 9 and 10 were written to meet the original obligations of MOD-024 and MOD-025. These directories are more specific or more stringent than MOD-025-2.
Response: The GVSDT thanks you for your comment. The original MOD-024 and MOD-025 standards required entities to do verification as directed by the regional entities. In response to a FERC directive, the revised standard now specifies requirements that apply to all entities as a continent-wide standard. If a region determines a technical variation is required, then the region can propose a variance in accordance with the Standard Processes Manual. FERC has indicated that it will generally accept regional variances that address performance not addressed in a continent-wide standard, and technically-justified performance that is more stringent than the performance in the continent-wide standard.		
American Electric Power	No	With respect to reactive power, AEP is not aware of any regional variances that would be required for this standard.
Response: The GVSDT thanks you for your comment.

13. Are you aware of any conflicts between the proposed standard and any regulatory function, rule, order, tariff, rate schedule, legislative requirement, or agreement?

Summary Consideration: Major conflicts were not reported between the proposed standard and any regulatory function, rule, order, tariff, rate schedule, legislative requirement, or agreement.

Organization	Yes or No	Question 13 Comment
PPL Generation	Yes	Ref. the inputs made above, there should be just one VAR test, with a single set of results going to all parties.
Response: The GVSDT thanks you for your comment. The standard requires the GO and TO to provide the information to the TP. As this is a long-term planning standard, it is envisioned that the TP receives the data and develops the appropriate models for use by other entities. The TP then hands these models off to entities that are concerned with the operations planning and Real-time operations time horizons. Per the NERC Reliability Functional Model (V5, Page 25), the Transmission Planner has the following relationships with other entities : **2. Collects information including:** **c. Generator unit performance characteristics and capabilities from Generator Owners.** **5. Coordinates the evaluation of BES expansion plans with Transmission Service Providers, Transmission Owners, Reliability Coordinators, Resource Planners, and other Transmission Planners.** **6. Reports on and coordinates its BES expansion plan implementation with affected Planning Coordinators, Transmission Planners, Resource Planners, Transmission Service Providers, Transmission Owners, Transmission Operators and Reliability Assurers.**		
FirstEnergy	Yes	Regional Entities such as RFC currently have Real and Reactive standards in place for its members and will need to evaluate the need to keep their standard or revise it to remove any inconsistencies that may exist. One inconsistency is the periodicity of verification for real power.
Response: The GVSDT thanks you for your comment. RFC has informed the GVSDT that: **It is the intent of Reliability*First* to perform a review of both the MOD-024-RFC-01 and MOD-025-RFC-01 standards once the NERC Board of Trustees approves the NERC MOD-025-2 standard. The purpose of this review is to ensure redundant and less restrictive requirements are either revised or**		

Organization	Yes or No	Question 13 Comment
considered for retirement from the RFC standards in accordance with the Reliability First Reliability Standards Development Procedure.		
Exelon	Yes	Nuclear units do not perform under-excited (leading) reactive capability testing due to concerns with unit stability and potential under voltage conditions on internal nuclear plant safety buses that may challenge safe plant operations and could lead to a plant transient or shutdown in accordance with NRC operating license. Performance of reactive capability tests cannot challenge nuclear plant NRC licensee Technical Specification voltage limit requirements.
Response: The GVSDT thanks you for your comment. Item 2.2 in Attachment 1 states: "Verify Reactive Power of all generating units, other than wind and photovoltaic, for maximum over-excited (lagging) and under-excited (leading) Reactive capability at the minimum Real Power output at which they are normally expected to operate. Nuclear units are not required to perform Reactive Power verification at minimum Real Power output."		
Ameren	Yes	There may be a conflict with MISO Module E as it relates to duration of the testing, e.g. one hour versus longer than hour duration.
Response: The GVSDT thanks you for your comment. If the MISO duration is longer, then there will not be any issue with meeting the one-hour requirement in MOD-025.		
Oncor Electric Delivery Company LLC	Yes	In the ERCOT Region, resource testing and most all communications regarding unit performance is facilitated by the Independent System Operator who is the Planning Authority. This is consistent with current, ERCOT protocols, operating guide and planning guide.
Response: The GVSDT thanks you for your comment. MOD-025 requires the GO to provide information to the Transmission Planner. As envisioned, if the Planning Coordinator (Authority) needs the information provided, the Transmission Planner will provide per the relationships in the functional model.		
Austin Energy	Yes	See the response to Question 6.
Manitoba Hydro	Yes	A number of Canadian Entities have the BES defined within their provincial legislation. This may introduce differences between the elements that are included in the BES (and elements that are therefore applicable to this standard) according to provincial legislation and the NERC definition. As well, since Canadian Entities are not under FERC jurisdiction, the effective date of this standard may differ for Canadian entities and entities under FERC jurisdiction.
Response: The GVSDT thanks you for your comment. Entities are responsible for verifying only those units applicable under the Facilities section of		

Organization	Yes or No	Question 13 Comment
this standard. The GVSDT is aware that Canadian entities may have a different Implementation plan since they are not FERC jurisdictional.		
Chelan County PUD		Voltage schedule requirements may conflict.
Response: The GVSDT thanks you for your comment. The GVSDT cannot respond fully to this comment without more information.		
Idaho Power-Power Production	No	No conflict, but as stated before, it seems to be redundant with FAC-008, FAC-009 and the existing WECC validation policy.
Response: The GVSDT thanks you for your comment. Please see response to earlier comment.		
American Electric Power	No	AEP is not aware of any conflicts between the proposed standard and any regulatory function, rule, order, tariff, rate schedule, legislative requirement, or agreement.
Response: The GVSDT thanks you for your comment.		
ISO New England	No	The obligations set by this Standard are less stringent for Generator Owners/Operators than those contained in ISO-NE's Tariff. In addition, FERC's Standard Generation Interconnection Rules make clear that material changes to generation facilities (which would include changes to reactive power capabilities) must be reported to the Transmission Service Provider prior to the change being made. The Standard Drafting Team should consider whether language is appropriate to make clear that the Standard is not meant to displace obligations to report reactive power capabilities already contained in Transmission Service Providers' tariffs.
Response: The GVSDT thanks you for your comment. The standard is designed to be a verification of capability for long-term planning studies and have no interaction with any tariffs.

Response: The GVSDT thanks you for your comment.		

14. Do you have any other questions or concerns with the proposed standard that have not been addressed? If yes, please provide a reference to the section, requirement, or subrequirement that you believe should be changed, added ,or deleted and the rationale for your proposal.

Summary Consideration: A number of commenters suggested revisions for clarity that were accepted by the GVSDT. Minor changes were made to the standard to incorporate many of those suggestions. Language was added to recommend that the AVR be in automatic control while conducting reactive capability testing, but that Reactive capability testing must be done even if the AVR is not available.

The following language was also added to allow flexibility if 90percent of the generation is not available when testing wind turbines or photovoltaic inverters.

If verification of wind turbines or photovoltaic inverter Facility cannot be accomplished meeting the 90 percent threshold, the Generator Owner must document the reasons it was unable to meet the threshold and test to the full capability at the time of the test. The Generator Owner shall retest the Facility within six months of being able to reach the 90 percent threshold. percent

Organization	Yes or No	Question 14 Comment
Associated Electric Cooperative, Inc.	Yes	1) We agree with the stated purpose of this standard however we don't believe that this standard, as written, meets the intent related to reactive capabilities. We have already spent significant time, effort and money to perform reactive capability testing, and the test results provide little value toward establishing appropriate capabilities for planning purposes. Additionally, this testing puts our equipment and the BES at risk. It appears that this standard will make us repeat this effort with additional requirements for reactive capability testing at Pmin. 2) This requirement will require units that normally do not run or have a very low capacity factor to be verified. Please add a provision for excluding these requirements for units that do not regularly run, similar to other NERC standard exemption requirements. 3) The standard needs to allow the inclusion of engineering analysis to supplement or replace testing when appropriate (see comments to question #10). 4) Instead of the periodic requirements, there needs to be a change based validation requirement. If a plant is materially changed (such as significant equipment changes or performance degradation), there needs to be a new validation done. 5) In R1.2 and R2.2, the phrase "same information" is used, while in M1 and M2 the phrase "equivalent

Organization	Yes or No	Question 14 Comment
		information" is used - we suggest changing R1.2 and R2.2. to match the M1 and M2. 6) Specifying Normal Operating H2 pressure in Attachment 1, section 2.5 may not produce the desired maximum Q cap results - consider changing "normal operating " to "maximum sustainable (within design limits)" 7) In Attachment 1, section 2.2, we suggest changing "they could normally be expected to operate" to "they are normally expected to operate". 8) We suggest revising Requirements R1.3 and R2.3 to read: "Submit the capability information to its TP within 90 calendar days of completion of the verification." to clarify these requirements and to make them consistent. We also believe 90 days will create an undue hardship for GOs who own a large number of generators and believe this requirement should allow for additional time when authorized by the TP or PC. 9) The first paragraph of the Compliance Data Retention Section D 1.2 is difficult to understand. Please simplify using multiple sentences, if possible. 10) In the VSL table for R1 and R2, we suggest changing the phrasing "from the date the data was recorded" to "from the verification date" each time it is used (7 times). 11) In the VSL table for R1, both the first and fourth items are not needed in the list of the four items which make up the OR statement. It is sufficient to measure if the data is more than 30 days late to be categorized as Severe. 12) In the VSL table for R2, we suggest replacing the second item in the list of the two items which make up the OR statement to match the corresponding item in R1 relative to the tardiness of the submission to the TP greater than 30 days late (> 120 days total). 13) Revise attachment 1 section 5.1 and 5.2 to change “last more than 6 months” to “last more than 1 year,” to align with the typical long-term planning horizon. 14) Note that the standard is only applicable to the GO/GOP, but needs involvement from the TO/TP/TOP to adequately complete a validation. Thus the standard needs to address the responsibilities of those entities for it to adequately address the issue of model validation. It is noted that MOD-11which is supposed to clarify modeling data requirements has not yet been completed and approved. Yet MOD-25 is requiring verification of this data. It is also recognized that generator verification methods are producing results that are not being directly used in the models (due to various operating or system limitations). As a result, it is not clear that MOD-025 is achieving the reliability purpose intended. 15) This standard establishes a periodic generator testing regime which, when implemented on a large number if generators, creates a continuous state of testing across the BES. We question if this approach

Organization	Yes or No	Question 14 Comment
		really improves the reliability of the BES. The use of normal operational data, supplemented by analysis, represents a better approach for most generators.

Response: The GVSDT thanks you for your comment.

(1) Response: Since system conditions can be a limiting factor, no test can assure that the rated values of the excitation equipment and generator will be reached during a test. The GVSDT believes that testing as close as possible to the Pmax and Qmax point will identify most issues with equipment, and the reliability purpose will be achieved. Through Order 693, the FERC has required testing at other points in order to help define the entire performance curve for the unit. This data verification is a result of a FERC directive in paragraph 1321 which states:

1321. We disagree with commenters that verifying generator reactive capability is a particularly difficult issue. The capability of generators to produce reactive power is essential for Real-time analysis and planning. The Reliability Standard addressing this issue requires a generator to verify reactive capability only at the unit's full MW Loading. However, other than baseLoad units, most generating units rarely operate at full MW Loading. It is unclear what reactive capability is available throughout a unit's Real Power (MW) operating range. Therefore, we believe a clearer standard would require a verification of MVAR capability throughout a unit's Real Power (MW) operating range. However, we share concern with several commenters that such a requirement for all generators may not be necessary. Therefore, we adjust the proposal in the NOPR and direct the ERO to modify MOD-025-1 to require verification of reactive power capability at multiple points over a unit's operating range.

(2) Response: The standard only requires testing once every 5 years. Operating a low capacity factor unit for 1 hour every five years should not be a burden.

(3) Response: Engineering analysis is allowed to supplement operating data as specified in Note 2 of Attachment 1.

(4) Response: The GVSDT agrees that material changes should require verification, and the standard calls for this specifically in item 2 of Attachment 1, "Periodicity for conducting a new verification". The GVSDT further believes that even if changes do not occur, verification is performed at least every five years to assure that equipment can still reliably function.

(5) **Response: The GVSDT agrees and has modified the standard to use the same wording in both the measures and requirements.**

(6) **Response: The intent is to capture the normal operating condition and not to increase hydrogen pressure or make other alteration just for testing.**

(7) **Response: The GVSDT has changed the standard to clarify this point. The phrase, "could normally be expected" was changed to "are normally expected."**

(8) **Response: The GVSDT believes that 90 days provides sufficient time and is not a hardship.**

(9) **Response: This is standard language. The GVSDT believes language is clear.**

(10) **Response: The GVSDT has modified the standard's VSLs for clarity by changing "date data was recorded" to "date of verification".**

Organization	Yes or No	Question 14 Comment
(11 **Response: The GVSDT believes that all the items in the "or" statement are needed to characterize a possible severe violation level. VSLs should identify a wide range of possible noncompliance.** (12) **Response: The GVSDT believes that all the items in the "or" statement are needed to characterize a possible severe violation level.** (13) **Response: The GVSDT believes that the 6 month time frame specified is appropriate.** (14) **Response: Since system conditions can be a limiting factor, no test can assure that the rated values of the excitation equipment and generator will be reached during a test. The GVSDT believes that testing as close as possible to the Pmax and Qmax point will identify most issues with equipment, and the reliability purpose will be achieved. Through Order 693, the FERC has required testing at other points in order to help define the entire performance curve for the unit. Please advise if the commenter has specific suggestions on how to better achieve this reliability purpose. Note that the intent of MOD-025 is to verify the accuracy of specific data used in long-range planning, not Real-time operations. While MOD-011 was not approved by FERC, it is effective in some Canadian Provinces and in the United States, FERC advised that entities "should" comply with MOD-011. (From Order 693: In the interim, compliance with MOD-011-0 should continue on a voluntary basis, and the Commission considers compliance with the Reliability Standard to be a matter of good utility practice.)** (15) **Response: Normal operational data is allowed by the standard.**		
SERC Generation sub-committee	Yes	1) This requirement will require units that normally do not run or have a very low capacity factor to be verified. Please add a provision for excluding these requirements for units that do not regularly run, similar to other NERC standard exemption requirements. 2) The standard needs to allow the inclusion of engineering analysis (with operational data) to supplement or replace testing when appropriate (see comments to question #10). It is noteworthy that the original NERC Board Approved version of this standard states in requirement R1.3 that acceptable methods for reactive capability verification "include use of commissioning data, performance tracking, engineering analysis, testing, etc." This represents the "allowance to use of all the tools in the toolbox" approach which is appropriate when no single tool is sufficient to accomplish the stated reliability objectives, consistent with the FERC Acceptance Criteria of a Reliability Standard (reference Paragraphs 321, 324, 328, 332). This approach is reflected in the SERC regional procedure for MOD-025-1 which was developed by a joint transmission-generation task force. 3) The 5 year test interval should be changed to a 10 year interval since there is a provision for re-verification with an associated 10% system change. 4) In R1.2 and R2.2, the phrase "same information" is used, while in M1 and M2 the phrase "equivalent information" is used - we suggest changing R1.2 and R2.2. to match the M1 and M2.

Organization	Yes or No	Question 14 Comment
		5) Specifying Normal Operating H2 pressure in Attachment 1, section 2.5 may not produce the desired maximum Q cap results - consider changing "normal operating " to "maximum sustainable (within design limits)" 6) In Attachment 1, section 2.2, we suggest changing "they could normally be expected to operate" to "they are normally expected to operate". 7) We suggest revising Requirements R1.3 and R2.3 to read: "Submit the capability information to its TP within 90 calendar days of completion of the verification." to clarify these requirements and to make them consistent. We also believe 90 days will create an undue hardship for GOs who own a large number of generators and thus we also request that this requirement be revised to allow additional time when authorized by the TP or PC. 8) The first paragraph of the Compliance Data Retention Section D 1.2 is difficult to understand. Please simplify using multiple sentences, if possible. 9) In the VSL table for R1 and R2, we suggest changing the phrasing "from the date the data was recorded" to "from the verification date" each time it is used (7 times). 10) In the VSL table for R1, both the first and fourth items are not needed in the list of the four items which make up the OR statement. It is sufficient to measure if the data is more than 30 days late to be categorized as Severe. 11) In the VSL table for R2, we suggest replacing the second item in the list of the two items which make up the OR statement to match the corresponding item in R1 relative to the tardiness of the submission to the TP greater than 30 days late (> 120 days total). 12) Revise attachment 1 section 5.1 and 5.2 to change “last more than 6 months” to “last more than 1 year,” to align with the typical long-term planning horizon. 13) It is noted that MOD-11which is supposed to clarify modeling data requirements has not yet been completed and approved. Yet MOD-25 is requiring verification of this data. It is also recognized that generator verification methods are producing results that are not being directly used in the models (due to various operating or system limitations) .As a result, it is not clear that MOD-025 is achieving the reliability purpose intended. 14) This standard establishes a periodic generator testing regime which, when implemented on a large number of generators, creates a continuous state of testing across the BES. We question if this approach really improves the reliability of the BES. The use of normal operational data, supplemented by analysis, represents a better approach to verify reactive capability for most generators. Targeted testing can then be

Organization	Yes or No	Question 14 Comment
		used on a limited basis.

Response: The GVSDT thanks you for your comment.

(1) **Response: The standard only requires testing once every five years. Operating a low capacity factor unit for one hour every five years should not be a burden.**

(2) **Response: The GVSDT believes that engineering analysis alone does not provide verification of equipment.**

(3) **Response: The five- year interval was chosen to ensure that equipment degradation or inadvertent or unknown changes would be identified.**

(4) **Response: The GVSDT agrees and has modified the standard to use the same wording in both the measures and requirements.**

(5) **Response: The intent of the standard is to capture the normal operating capability.**

(6) **Response: The GVSDT agrees and has modified the standard as suggested. The phrase, "could normally be expected" was changed to "are normally expected."**

(7) **Response: The GVSDT has modified the language to improve clarity. The GVSDT believes the 90-day time period specified is sufficient for submitting data**.

(8) **Response: This is standard language. The GVSDT believes language is clear.**

(9) **Response: The GVSDT has modified the standard's VSLs for clarity by changing "date data was recorded" to "date of verification."**

(10) **Response: The GVSDT believes that all the items in the "or" statement are needed to characterize a possible severe violation level. VSLs should identify a wide range of possible noncompliance.**

(11) **Response: The GVSDT believes that all the items in the "or" statement are needed to characterize a possible severe violation level.**

(12) **Response: The GVSDT believes that the six- month time frame specified is appropriate given most Transmission Planners run simulations annually. Extending the time period to one year increases the likelihood that the changes discovered may not exist when performing the next simulation.**

(13) **Response: Since system conditions can be a limiting factor, no test can assure that the rated values of the excitation equipment and generator will be reached during a test. The GVSDT believes that testing as close as possible to the Pmax and Qmax point will identify most issues with equipment, and the reliability purpose will be achieved. Through Order 693, the FERC has required testing at other points in order to help define the entire performance curve for the unit. Organization	Yes or No	Question 14 Comment
and the reliability purpose will be achieved. Through Order 693, the FERC has required testing at other points in order to help define the entire performance curve for the unit. Please advise if the commenter has specific suggestions on how to better achieve this reliability purpose. Note that the intent of MOD-025 is to verify the accuracy of specific data used in long-range planning, not Real-time operations. While MOD-011 was not approved by FERC, it is effective in some Canadian Provinces and in the United States. FERC advised that entities "should" comply with MOD-011. (From Order 693: In the interim, compliance with MOD-011-0 should continue on a voluntary basis, and the Commission considers compliance with the Reliability Standard to be a matter of good utility practice.) (12) **Response: Normal operational data is allowed by the standard.**		
Southern Company	Yes	1) This requirement will require units that normally do not run or have a very low capacity factor to be run for testing. Please consider a provision for excluding these requirements for units that do not regularly run unless verification using engineering analysis is allowed. 2) Each of the methods of verification proposed have merits and deficiencies. For staged testing, there exists the risk of tripping a unit during testing. System conditions which allow for the maximum reactive power output production/absorption are extreme system voltage conditions - precisely where it is undesirable to perform such testing or trip a unit. Staged testing or verification using operational data during normal system voltage conditions will result in reactive limits constrained by system conditions (not representative of the actual unit capabilities for extreme voltage conditions when the reserve Var capabilities are needed most). Staged testing may, however, reveal unknown thermal or mechanical problems which, while are good to know, are maintenance related and are not the primary objective of the standard which is verification of reactive capability for use in planning models (Long Term Planning Horizon). But, if system constraints during staged testing do not permit a unit to reach the reactive limits the unit could reach during extreme system voltage conditions, one could argue the results of the test are inconclusive in terms of meeting the reliability objective of the standard. Our experience has shown that unit reactive limits for extreme voltage conditions (when the reserve Var capabilities are needed most) can best be determined using engineering analysis. It is noteworthy that the original NERC Board Approved version of this standard states in requirement R1.3 that acceptable methods for reactive capability verification "include use of commissioning data, performance tracking, engineering analysis, testing, etc." This represents the "allowance to use of all the tools in the toolbox" approach which is appropriate when no single tool is sufficient to accomplish the stated reliability objectives, consistent with the FERC Acceptance Criteria of a Reliability Standard (reference Paragraphs 321, 324, 328, 332). This approach is reflected in the SERC Regional Criteria for MOD-025-1 which was developed by a joint transmission-generation task force. 3) The test interval and new unit test requirement described in Attachment 1, part 5 should be included in the

Organization	Yes or No	Question 14 Comment
		main standard requirement section rather than in the staged test details. However, we believe re-verification every 5 years is too frequent. We agree that re-verification is appropriate for significant changes that impact the real or reactive capability by more than 10%, but we question the six month criteria. For the Long Term Planning Horizon, one year would be more appropriate. 4) In R1.2 and R2.2 the phrase "same information" is used, while in M1 and M2 the phrase "equivalent information" is used - we suggest changing R1.2 and R2.2. to match the M1 and M2. 5) Specifying Normal Operating H2 pressure in Attachment 1, section 2.5 may not produce the desired maximum Q cap results - consider changing "normal operating " to "maximum sustainable (within design limits)" 6) In Attachment 1, section 2.2, we suggest changing "they could normally be expected to operate" to "they are normally expected to operate". 7) We suggest revising Requirements R1.3 and R2.3 to read: "Submit the capability information to its TP within 90 calendar days of completion of the verification." to clarify these requirements and to make them consistent. We also believe 90 days will create an undue hardship for GOs who own a large number of generators and believe this requirement should allow for additional time when authorized by the TP or PC. 8) The first paragraph of the Compliance Data Retention Section D 1.2 is difficult to understand. Please simplify using multiple sentences, if possible. 9) In the VSL table for R1 and R2, we suggest changing the phrasing "from the date the data was recorded" to "from the verification date" each time it is used (7 times). 10) In the VSL table for R1, both the first and fourth items are not needed in the list of the four items which make up the OR statement. It is sufficient to measure if the data is more than 30 days late to be categorized as Severe. In the VSL table for R2, we suggest replacing the second item in the list of the two items which make up the OR statement to match the corresponding item in R1 relative to the tardiness of the submission to the TP (> 30 days late)

Response: The GVSDT thanks you for your comment.

(1) **Response: The standard only requires testing once every five years. Operating a low capacity factor unit one hour every five years should not be a burden.**

(2) **Response: Since system conditions can be a limiting factor, no test can assure that the rated values of the excitation equipment and generator will be reached during a test. The GVSDT believes that testing as close as possible to the Pmax and Qmax point will identify most issues with equipment,**

Organization	Yes or No	Question 14 Comment
and the reliability purpose will be achieved. Through Order 693, the FERC has required testing at other points in order to help define the entire performance curve for the unit. Engineering analysis alone does not verify the functionality or health of equipment and thus cannot serve as a verification method. Please advise if the commenter has specific suggestions on how to better achieve this reliability purpose. (3) **Response: Guidance was received from NERC on how to develop an attachment referenced by requirements. The attachment contains procedural elements needed for satisfying the requirements. The requirements require verification of performance and timely reporting of data to the Transmission Planner. The GVSDT believes that the six-month timeframe specified is appropriate.** (4) **Response: The GVSDT agrees and has modified the standard to use the same wording in both the measures and requirements.** (5) **Response: The intent is to capture the normal operating condition and not to increase hydrogen pressure or make other alteration just for testing.** (6) **Response: The GVSDT has changed the standard to clarify this point. The GVSDT believes language is clear.** (9) **Response: The GVSDT has modified the standard’s VSLs for clarity by changing “date data was recorded” to “date of verification.”** (10) **Response: The GVSDT believes that all the items in the “or” statement are needed to characterize a possible severe violation level. VSLs should identify a wide range of possible noncompliance.** **(11) Response: The GVSDT believes that all the items in the “or” statement are needed to characterize a possible severe violation level.**		
Duke Energy	Yes	1) This requirement will require units that normally do not run or have a very low capacity factor to be verified. Please add a provision for excluding these requirements for units that do not regularly run, similar to other NERC standard exemption requirements. 2) MVAR validation issues should be combined with generation FAC-8 issues to eliminate confusion that these separate standards have caused. 3) Specifying Normal Operating H2 pressure in Attachment 1, section 2.5 may not produce the desired maximum Q cap results - consider changing "normal operating " to "maximum sustainable (within design limits)" 4) We suggest revising Requirements R1.3 and R2.3. Data should be submitted to the TP at the next annual update provided on MOD-010 model data. 5) Revise attachment 1 section 5.1 and 5.2 to change “last more than 6 months” to “last more than 1 year,” to align with the typical long-term planning horizon. 6) It is noted that MOD-11 which is supposed to clarify modeling data requirements has not yet been

Organization	Yes or No	Question 14 Comment
		completed and approved. Yet MOD-25 is requiring verification of this data. It is also recognized that generator verification methods are producing results that are not being directly used in the models (due to various operating or system limitations). As a result, it is not clear that MOD-025 is achieving the reliability purpose intended. 7) Since GO/GOPs do not always model electrical systems, nor participate in interconnected system models groups such as the Master Model Working Group (MMWG), there probably needs to be a guide that clearly identifies the steps a GO/GOP needs to take to maintain models up to date. The NATF and EPRI/NAGF is considering a collaboration to do so.
Response: The GVSDT thanks you for your comment. (1) **Response: The standard only requires testing once every five years. Operating a low capacity factor unit one hour every five years should not be a burden.** (2) **Response: FAC-008 deals with Facility ratings methodology whereas MOD-025 is concerned with verification of those ratings. THE GVSDT is unsure of the confusion that is indicated.** (3) **Response: The intent is to capture the normal operating condition and not to increase hydrogen pressure or make other alteration just for testing.** (4) **Response: The MOD-025 standard requires the data to be submitted within 90 days after verification. This time period may or may not correspond with MOD-010 data submission requirements.** (5) **Response: The GVSDT believes that the six month timeframe specified is appropriate.** (6) **Response: Since system conditions can be a limiting factor, no test can assure that the rated values of the excitation equipment and generator will be reached during a test. The GVSDT believes that testing as close as possible to the Pmax and Qmax point will identify most issues with equipment, and the reliability purpose will be achieved. Through Order 693, the FERC has required testing at other points in order to help define the entire performance curve for the unit. Please advise if the commenter has specific suggestions on how to better achieve this reliability purpose. While MOD-011 was not approved by FERC, it is effective in some Canadian Provinces and in the United States. FERC advised that entities "should" comply with MOD-011. (From Order 693: In the interim, compliance with MOD-011-0 should continue on a voluntary basis, and the Commission considers compliance with the Reliability Standard to be a matter of good utility practice.)** (7) **Response: The creation of the guide suggested is outside the scope of the project SAR. The commenter may consider submitting a SAR for this issue.**		
Ameren	Yes	(1)If a demonstrated value is less than the corresponding expected value, then the generator owner should be required to provide calculated values for reactive capability in addition to the demonstrated values (this should be included in R1). Without this, the data is useless to the Transmission Owners for system modeling use.

Organization	Yes or No	Question 14 Comment
		(2) There may be different usage of the term 'point of interconnection" in the industry. We suggest the SDT to consider proposing a formal definition of this term. (3) We understand the 20% and 10% variances allowed in the draft are for testing purposes. However, it's unclear how they should be used. For example, are they relative to the results at time of seasonal peak, or just maximum output at the time of testing? (4) Notes 1 and 2 should be Requirements. It is difficult to determine how compliance with footnotes will be audited. (5) Engineering judgment should be clearly allowed when meter data (for example no meter at the high side of a GSU), auxiliary data, etc. is not available as required in Attachment 1. (6) Sister Unit exemptions should be allowed for generators that are essentially identical and operated in an identical fashion.
Response: The GVSDT thanks you for your comment. (1) **Response: Calculated values do not provide verification of equipment capability.** (2) **Response: The GVSDT believes that the diagram in Attachment 2 clearly identifies the intent of the term "point of Interconnection."** (3) **Response: The GVSDT has revised the language for clarity. The revised standard, Attachment 1, step 2 states:** **"Operational data from within the two years prior to the verification date is acceptable for the verification as long as it meets the criteria in 2.1 through 2.5 below and is at least 90percent of a previously staged test that demonstrated at least 50percent of the capability shown on the appropriate Dee-Curve. If the previously staged test was unduly restricted by unusual generation or equipment limitations (for example capacitor or reactor banks out of service), then the next verification shall be by another staged test, not operational data."** (4) **Response: Notes 1 and 2 are informational and do not contain actions that are auditable. Note 2 specifically states that it is not required by the standard.** (5) **Response: The standard allows engineering analysis if metering does not exist at a particular location.** (6) **Response: The standard requires verification only once every five years. The GVSDT believes to maintain reliability every unit should be verified once every five years.**		
SERC Dynamics Review Sub-committee	Yes	The VSL for R2 is missing a needed component. The Severe category needs to include the following: "The Transmission Owner verified and recorded the Real and Reactive Power capability of its applicable synchronous condenser, but submitted the data to its Transmission Planner more than 120 calendar days from the date the data was recorded."

Organization	Yes or No	Question 14 Comment
		GO's should be required to provide expected values for reactive capability in addition to the demonstrated values (this should be included in R1). Without this, the data is useless to the Transmission Planners. Item 3.4 in Attachment 1 refers to Transmission Owner. It should say Transmission Planner to match Requirements 1 & 2. Only one verification is needed for sister (identical) units. The standard currently requires verification for all units.
Response: The GVSDT thanks you for your comment. (1) **Response: A synchronous condenser does not have Real Power capability.** (2) **Response: Engineering analysis is allowed. Expected values are not required because the GVSDT does not believe the results constitute verification.** (3) **Response: This has been revised to Transmission Planner.** (4) **Response: The standard requires verification only once every five years. The GVSDT believes to maintain reliability every unit should be verified once every five years.**		
IRC Standards Review Committee (joint comments)	Yes	The proposed MOD-025-2 standard appears to violate many conventions, such as: o The use of Attachments for mandating requirements o The combinations of different actions in the same requirement o The mandating of specific formats
Response: The GVSDT thanks you for your comment. **(1) Response: The requirement would be cumbersome without including the attachment. The use of the attachment improves requirement clarity and is supported by NERC's standards staff.** **(2) Response: Requirement R1 has been split into separate requirements to resolve this concern.** **(3) Response: The standard calls for data to be submitted and a sample form is provided for reference. The GVSDT has included the information necessary for meeting the reliability objective of the standard. Entities can use their own form for submitting data and this is clear in the revised standard**		
Pepco Holdings Inc Affiliates	Yes	Should Attachment 1 Sec 5 be added to the standard list of requirements instead of part of the attachment? It

Organization	Yes or No	Question 14 Comment
		appears that this section is more than just additional details on verification and reporting. In the project background information it is stated “. If regions have generating units that are connected at under 100 kV that are important to the reliability of the system due to some local consideration, then the region has the authority to require that those units be verified if they so choose.” This capability should be noted directly in the standard.
Response: The GVSDT thanks you for your comment. **(1) Response: The requirement states that verification is performed in accordance with the procedure listed in Attachment 1. The GVSDT believes the attachment contains procedural elements needed for satisfying the requirements. The requirements require verification performance and timely reporting of data to the Transmission Planner.** **(2) Response: This is a part of the delegation agreements and the NERC Rules of Procedure.**		
Midwest Reliability Organization's NERC Standards Review Forum (NSRF)	Yes	Please consider the following comments: 1. Attachment 1, Item 2 - Add the adjective “gross” to the Real Power and Reactive Power reference for added clarity and to assure awareness that the verification is for “gross”, rather than “net” values. 2. Attachment 1, Item 2 - Modify the wording of “with all auxiliary equipment needed for expected normal operation” to “with all auxiliary and voltage regulation equipment, such as reactive power compensation, needed for expected normal operation and voltage regulation” to assure that any reactive power compensation equipment (e.g. capacitor banks, SVCs, STATCOMs) are not overlooked and omitted from the verification data. This added text is particularly needed for wind generation situations. 3. Attachment 1, Item 2 - We would prefer the acceptable verification with operational data to be 10%, rather than 20%. 4. Attachment 1, Item 2 - Expand the text of “expected value” to “expected maximum gross Real and Reactive Power Generator capability values” to add more clarity. 5. Attachment 1, Item 2.1 - Add the adjective “gross” to the Real Power and Reactive Power reference for added clarity and to assure awareness that the verification is for “gross”, rather than “net” values. 6. Attachment 1, Item 2.1 - Replace the wording “at rated gross Real Power capability” with “at the generating unit’s normal expected maximum Real Power capability” and drop the footnote reference. 7. Attachment 1, Item 2.2 - Add the adjective “gross” to the Real Power and Reactive Power references for added clarity and to assure awareness that the verification is for “gross”, rather than “net” values.

Organization	Yes or No	Question 14 Comment
		8. Attachment 1, Item 2.4 - We think that both "2.1 and 2.2" should be referenced for the over-excited data. If this is incorrect, then please explain why 2.1 should be omitted. 9. Attachment 1, Item 2.6 - Add an Item 2.6 of "Record the generator step up (GSU) transformer losses if the verification measurements are taken from the high side of the GSU transformer". This addition will help avoid the omission of the GSU transformer reactive power losses when calculating the gross generation power capabilities when high side measurements were taken. We are aware that this oversight has already occurred several times. [Add Point "F" (pointing to the generator step up transformer) to the Verification Information Reporting Form in Attachment 2 to accommodate and remind the Generator Owner or Transmission Owner to record these losses, when it is needed.] 10. Attachment 1, Item 3.4 - Correct the functional entity reference from "Transmission Owner" to "Transmission Planner". Revise the wording to allow the Generator Owner or Transmission Owner to report, "The ambient air temperature and/or ambient water temperature at the end of the verification period". [Require that the 'basis' ambient air temperature and/or ambient water temperature associated with the reported gross generator Real Power capabilities be stated on the Verification Information Reporting Form along with a correction factor if any, to allow the Transmission Planner to correct the Real Power capability to different ambient temperatures, if needed.] 11. Attachment 1, Item 3.7 - Add an Item 3.7 of "The GSU transformer losses if the verification measurements were taken from the high side of the GSU transformer." This addition will help avoid the omission of the GSU transformer reactive power losses when calculating the gross generation power capabilities when high side measurements are taken". 12. Attachment 1, Item 5.3 - Add revise the wording, "within one year of their commercial operation" to "within one year of their commercial operation or as scheduled by the applicable Transmission Planner" to allow the exception of an earlier or later due date when it may be appropriate and agreed to be the affected Transmission Planner. 13. Attachment 2, Item A - Add a note that the individual unit values should be reported separately whenever the verification measurements were taken at the individual unit. In most cases, the individual units are modeled separately (including compound units) in the power flow cases and the loss of individual units are simulated in system planning assessments. So, if the verification data was collected in a manner that would allow individual unit power capability verification, then the reporting form should not direct the Generator Owner or Transmission Owner to mask this information. 14. Attachment 2, Item F - As noted above, add a Point "F" (pointing to the generator step up transformer) to the Verification Information Reporting Form to refer to the GSU transformer losses. Also add a Point "F" row to the data table with entries that indicate to provide the GSU transformer MW and MVAR losses

Organization	Yes or No	Question 14 Comment
		when the verification data was based on measurements that were taken from the high side of the GSU transformer. Otherwise, GOs and TOs that base verification values on measurements from the high side of the GSU transformer may forget to make the proper correction when they calculate the gross values for Point "A", as others have historically done. The scope of this standard does not include the verification of high voltage power flow controllers that are connected to the transmission system at 100 kV or above. We propose that a Standard Authorization Request (SAR) be created to address the power capability verification gap that is not being filled with this standard. The test form has remarks space for reactive limit constraints but not for real power constraints. 15. Attachment 1 , #2, the use of the word "all" auxiliary equipment is unnecessary and is over reaching, the Requirement is for expected normal operation. Recommend deleting "all" from this sentence. 16. Attachment 1, # 2.1, should the SDT give an alternate threshold if "90%" could not be achieved during the testing window?

Response: The GVSDT thanks you for your comment.

(1) Response: The Attachment 2 form makes the data requirement clear. Other values are recorded in addition to gross values.

(2) Response: The GVSDT believes the current verbiage, "with all auxiliary equipment" is sufficient to address this concern. The capacitor banks, SVCs, and STATCOMs are not part of this standard. The GVSDT recognizes these are important reactive resources and has suggested a SAR be created to address them.

(3) Response: The GVSDT has modified the Attachment to use 10percent of the last staged test rather than 20percent.

(4) Response: The GVSDT has removed the "expected value" phrase. The sentence now reads "…is at least 90percent of a previously staged test where a voltage limitation was reached"

(5) Response: The Attachment 2 form makes the data requirement clear. Other values are recorded in addition to gross values.

(6) Response: The GVSDT concurs and has revised the language as suggested.

(7) Response: The Attachment 2 form makes the data requirement clear. Other values are recorded in addition to gross values.

(8) Response: Item 2.1 was omitted from the over-excited case in Item 2.4 because it is covered in Item 2.3.

(9) Response: The GVSDT concurs and has revised the language as suggested and added a section to Attachment 2 for recording the value.

(10) Response: The GVSDT has corrected the reference to indicate the Generator Owner as the entity to record the ambient conditions in case there is a need to perform a correction... The GVSDT has also revised the ambient condition correction language.

(11) Response: The GVSDT concurs and has made the revision suggested.

Organization	Yes or No	Question 14 Comment
(12) Response: The GVSDT believes this suggestion adds ambiguity to the standard and may create compliance issues. The one-year requirement will be retained. **(13) Response: The GVSDT concurs and has made the revision suggested.** **(14) Response: A section was added to Attachment 2 for recording the value for the GSU losses. The commenter is encouraged to submit a SAR to address the remainder of this comment. The remarks space can be used to document either Real or Reactive power constraints.** **(15) Response: The GVSDT disagrees and has retained the word "all."** **(16) Response: The GVSDT has added the following verbiage to Attachment 1, Item 2.1 to address this concern:** **"If verification of wind turbines or photovoltaic inverter Facility cannot be accomplished meeting the 90 percent threshold, the Generator Owner must document the reasons it was unable to meet the threshold and test to the full capability at the time of the test. The Generator Owner shall retest the Facility within six months of being able to reach the ninety percent threshold."** **If a Facility has an issue that affects the output by 10percent for more than six months, the Facility is to be re-rated per Item 5.1 in Attachment 1.**		
SPP Reliability Standards Development Team	Yes	VSLS for R2 there is an extra applicable in the chart. Would suggest removing.
Response: The GVSDT thanks you for your comment. The chart has been corrected.		
SERC Planning Standards Subcommittee	Yes	If the demonstrated value is less than the expected value, then the GO's should be required to provide calculated values for reactive capability in addition to the demonstrated values (this should be included in R1). Without this, the data is useless to the Transmission Planners. "The comments expressed herein represent a consensus of the views of the above-named members of the SERC EC Planning Standards Subcommittee only and should not be construed as the position of SERC Reliability Corporation, its board, or its officers"
Response: The GVSDT thanks you for your comment. The GVSDT believes that calculations do not provide verification that a unit or Facility can reach the specified operating point.		
Idaho Power-Power Production	Yes	1. The language in the Applicability Section 4.2.1, implies that the standard applies to only synchronous condensers in generating facilities. Please clarify. 2. As stated before, we believe that FAC-008 and FAC-009 specify our generator have a normal and emergency rating. The standards should use similar language in requiring validation of capability.

Organization	Yes or No	Question 14 Comment
		However, our regional policy required by MOD-010, specifies validation of the generator reactive capability, thus we believe this standard is redundant and not needed. That is unless MOD-010 is going to be retired. 3. Note 1 in Attachment 1 states that the data point may not match the manufacturer capability curve or the verified values for the MOD-010 standard. We question what the point of this standard is if not to validate. Note 1 mentions other items that might be discovered during the validation required by this standard, but we believe those benefits are achieved by our existing validation policy.
Response: The GVSDT thanks you for your comment. **(1) Response: The GVSDT has revised 4.2.1 to state:** "Individual generating unit greater than 20 MVA (gross nameplate rating) in a generating Facility or synchronous condenser greater than 20 MVA (gross nameplate rating) connected at the point of Interconnection at 100 kV or above." **(2) Response: The GVSDT is not aware of any effort to retire MOD-010. MOD-025 requires verification of Real and Reactive power capability of a unit or synchronous condenser. The verification is performed for normal capability, not emergency capability. FAC-008 and FAC-009 specify a methodology for developing Facility ratings whereas MOD-010 pertains to data and equipment characteristics, not validation requirements. The standards do not duplicate requirements.** **(3) Response: The GVSDT believes that reactive power limitations originating inside the generating station (e.g., hydrogen pressure, thermally sensitive generator, voltage regulator settings, excitation problems, etc.) need to be verified by testing. MOD-025 is a verification standard. Note 1 addresses the possibility that a unit may not be able to reach the D-curve value because of limitations outside owner control. MOD-010 is not a verification standard.**		
Santee Cooper	Yes	Attachment 1 Item 1 requires testing of units that are 20 MVA and above to be tested a second time if they are tested as part of the aggregate.
Response: The GVSDT thanks you for your comment. The GVSDT disagrees with your assertion. Units rated greater than 20 MVA are individually verified. Units 20 MVA or less can be verified individually or in aggregate. Item 1 states: "For units of 20 MVA or less that are part of a plant greater than 75 MVA in aggregate, record data either on an individual unit basis or as a group. Perform verification individually for every generating unit greater than 20 MVA (gross nameplate rating)."		
PPL Generation	Yes	PPL offers the following comments on Attachment 1:

Organization	Yes or No	Question 14 Comment
		1. Att. 1, para. 2: Change the final sentence to end, "within 20% of the expected real and reactive power values."Reason: Clarification Att.1, footnote to para. 2.1: Change "normal expected maximum" to "normal," and "at the time of the verification" to "for the ambient conditions during the verification."Reason: Clarification. The normal output of a unit is often not its (emergency) maximum generation, and the word "ambient" works better than "time." 2. Att. 1, para. 2.1, 1st sentence: Change "at rated gross Real Power capability" to "within 20% of the Real Power capability."Reason: Clarification, see the comment above to para. 2. Also, the terms capability and rating have different meanings. 3. Att. 1, para. 2.1, last sentence: Change "possible" to "practical" 4. Att. 1, para. 2.2: Change exception in 1st sentence to "other than wind, photovoltaic and peaking (capacity factor < 10%)."Reason: Given that peaking units typically operate only during periods of maximum demand, it can be difficult to establish a realistic min power expectation, this exercise would add little or no value, and such testing would be unnecessarily economically burdensome. 5. Att.1, para. 2.3: Add at end, "for baseload units. Values for peaking units (<10% capacity factor) may be recorded as soon as they are reached. Reason: The dispatch volatility of peaking units can make a one-hour hold-period unnecessarily economically burdensome. 6. Att. 1, para. 2.5: Add at end, "if attainable. Otherwise a 10% variation is acceptable. Reason: Hydrogen pressure can vary, and minor disturbances should not disqualify an otherwise-acceptable test. 7. Att. 1, para. 3.2: Clarification is needed. Is the standard saying that a special-for-test voltage schedule should be established with the RTO? 8. Att. 1, para. 3.3: Add at the end, "one or the other of these values may be calculated, if metering is not present at both locations."Reason: Same concept as para. 4.1. 9. Att. 1, Note 1, 1st sentence: Add at the end, "or unit auxiliary system voltage limits or facility operational practices." Make the same change also for "transmission system conditions" in the third sentence. Reason: VAR testing involves creating abnormal voltages at the generator terminals and in the feeds to auxiliary equipment. Drop-out of aux motors can constitute the practical test limit. It is appropriate to apply safety margins in this respect (ref. facility operational practices), lest units be at risk of tripping in the course of conducting a reliability test. 10. Att. 1, Note 2: Clarification is needed regarding the less-restrictive conditions being referred-to. 11. Att. 1, para 3.4: Replace "and a correction factor...if needed" with "and, if requested, correction to other ambient conditions."Reason: Correction often involves more than a simple multiplication factor, especially

Organization	Yes or No	Question 14 Comment
		when using a thermodynamic computer model for this purpose. This exercise includes truncating corrections to lower ambients for GSU and generator limits, if necessary. 12. General: The generator OEM D-curve constitutes a rating, not a capability, and is applicable only at rated voltage. VAR testing involves identifying a capability at abnormal voltages, and is thus likely to rarely if ever match the D-curve. 13. General: Where the RTO has an effective VAR testing program in place (as is the case for PJM) the results should be acceptable as-is for NERC compliance purposes, lest there be created two different tests, resulting in reporting of two different reactive capabilities to two different entities.

Response: The GVSDT thanks you for your comment.

(1) Response: The GVSDT has revised the sentence to state: "Operational data from within the two years prior to the verification date is acceptable for the verification of either the Real Power or the Reactive Power capability as long as that operational data meets the criteria in 2.1 through 2.5 below and is at least 90 percent of a previously staged test that demonstrated at least 50percent of the capability shown on the associated D-Curve. percent

(2) Response: The GVSDT has removed the footnote and revised the sentence based on other stakeholder comments:

2.1. Verify Real Power capability, Reactive Power capability over-excited (lagging) and Reactive Power capability under-excited (leading) of all applicable Facilities at the applicable Facilities' normal (not emergency) expected maximum Real Power at the time of the verifications.

(3) Response: See responses above.

(4) Response: We concur with adding wind and photovoltaic and have made the revision suggested. We do not concur with providing the exception to other units as the standard applies to applicable Facilities that meet registration criteria. Item 2.2 also contains the phrase, "minimum Real Power output at which they are normally expected to operate." If a peaking unit only operates at maximum output, then this is how the unit should be verified.

(5) Response: The GVSDT does not have evidence that exempting these additional units will not adversely impact reliability. The verification is only required to be performed for one hour every five years. The GVSDT does not believe this is an economically burdensome requirement.

(6) Response: Paragraph 2.5 does not specify a pressure or bandwidth. It is expected that verification will be performed at the normal pressure. In other words, at the pressure the unit usually operates.

(7) Response: The standard does not specify a special voltage schedule. Item 3.2 only states to record the voltage during the test. This voltage value may be the normal voltage schedule.

(8) Response: The GVSDT concurs and has revised item 3.3 by adding: "If only one of these values is metered, the other may be calculated."

Organization	Yes or No	Question 14 Comment
(9) Response: The standard does not require testing to exceed voltage limitations and risk equipment damage or jeopardize reliability. **(10) Response: The GVSDT has added the following phrase to the end of the sentence in Note 2: "Than those encountered during the verification," and changed "conditions" to "voltages" to provide clarity. The sentence now states:** **"While not required by the standard, it is desirable to perform engineering analysis to determine expected unit capabilities under less restrictive system voltages than those encountered during the verification."** **(11) Response: The verbiage of item 3.4 is designed to address the FERC Order 693 directive to provide this information. This language has been revised for clarity.** **(12) Response: The standard doesn't require a unit to reach the D-curve value. The D-curve does not reflect all unit limitations that may exist.** **(13) Response: If the requirements of the PJM standard satisfy the requirements of the NERC MOD-025-2 standard, then additional testing should not be necessary.**		
Dominion	Yes	Test form needs to be improved. Provide the form in format that can be electronically completed by the user.
Response: The GVSDT thanks you for your comment. The form was developed as an example. The commenter can develop an electronic form, if desired.		
FirstEnergy	Yes	Regarding Notes 1 & 2 in the standard: Generally we have found that reactive power limitations that originate inside the generating station (hydrogen pressure, thermally sensitive generator, voltage regulator settings, and excitation problems) usually cannot be overcome through engineering analysis on the part of the transmission planning engineer. These types of conditions can only be addressed by the GO. On the other hand, Generator Terminal Voltage limits, or Transmission System voltage Limits can be eliminated using engineering analysis to simulate a more stressed system. Attachment 1, R2 - Assuming there are no transmission system related limitations, how close does the test value for VARs have to come from the expected value to be considered "verified"? Attachment 1, R2.2 - Nuclear units should be exempt from having to test leading VAR capability as this would challenge the plant's licensing limits for safety bus minimum voltage. MOD-025-RFC-01 currently allows this exemption for nuclear plants. Attachment 1, NOTE 1 - For clarity, nuclear plant safety bus voltage limits should mentioned as a reason why D-Curve values may not be met during a test.
Response: The GVSDT thanks you for your comment.		

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 14 Comment</th></tr>
<tr><td colspan="3">(1) Response: The GVSDT agrees.
(2) Response: The goal of the requirement is to verify the actual Reactive Power capability of the unit, and not necessarily confirm a predetermined capability.
(3) Response: If a nuclear plant has under-excited capability it should be tested within the unit's capability and declared safety margins.
(4) Response: Note 1 has been revised for clarity, and the following sentence was added to Note 1:
"Auxiliary bus voltage limits should be observed"</td></tr>
<tr><td>NERC Staff</td><td>Yes</td><td>The violation risk factors associated with Requirements R1 and R2 should be at least medium. Use of invalid models resulting from violation of these standards can produce erroneous results and adversely affect assumptions of the electrical state or capability of the bulk electric system, or the ability to effectively control or restore the bulk electric system, particularly under emergency, abnormal, or restorative conditions. This can result in operating beyond the true stability limits of the system. The models validated by application of this standard are used in both the long-term planning and the operations planning horizon. The time horizon for Requirements R1 and R2 should include the operations planning horizon. The SDT should consider use of the word "verification" versus "validation" and assure that the term used in this standard is consistent with other standards.</td></tr>
<tr><td colspan="3">Response: The GVSDT thanks you for your comment. The GVSDT agrees and has modified the standard accordingly (VRF's are now Medium)</td></tr>
<tr><td>Public Service Enterprise Group</td><td>Yes</td><td>We have listed several concerns and questions below:
a. We believe that Reactive Power capability at minimum Real Power output needs to be verified when a unit is installed and only verified thereafter when the generator itself is modified. Performing such tests will be difficult to run due to system voltage limitations at minimum Real Power generator output. This would require a modification or Attachment 1, paragraph 2.2, and paragraph 5.
b. For the VSL's for requirement R2, the last paragraph of a Severe VSL should be modified as follows: "The TO verified and recorded the Reactive Power capability of its applicable synchronous condenser, but submitted the data to its Transmission Planner more than 120 calendar days from the date the data was recorded."
c. The comments below reference Attachment 1.
i. Paragraph 2 and its subparts would be more easily understandable if companion tables were provided that summarized the information. At last two tables would be helpful - one for traditional</td></tr>
</table>

Organization	Yes or No	Question 14 Comment
		dispatchable resources and one for variable resources. ii. In paragraph 3, whether the verification is staged or operational should be provided. iii. In paragraph 3.2, the requirement to supply the voltage schedule provided by the Transmission Operator would not appear to be applicable for a staged test. Trying to test Reactive Power limits while maintaining a prescribed voltage schedule in not practical.
Response: The GVSDT thanks you for your comment. **(1) Response: The standard allows the GO to test until a system limitation is met. This is the point that should be noted in the "remarks" section of Attachment 2 for the verification data. Equipment ages with use and needs to be re-verified periodically. The GVSDT has determined that testing every 5 years is required to maintain reliability. This comes directly from the previous version of the "fill-in-the-blank" standard. It also matches up well to the PRC-019 proposed standard. Although the two standards are separate it is anticipated that PRC-019 would be done before MOD-025. The MW testing portion of the standard is based on stakeholder consensus in previous posting of the SAR and draft standards. It was anticipated that the MW testing could be completed with little effort while doing MVAR testing.** **(2) Response: The wording in the VSLs has been corrected. However, based on comments from other stakeholders, the timing element was modified so that it is linked to the date of the test rather than the date of the recording.** **(3) Response: The GVSDT tried to develop companion tables but determined that it made the document harder to understand and did not add it to the Attachment. It was also viewed as being prescriptive. Paragraph 3 was revised per your suggestion and two check boxes were added to Attachment 2 for "Staged Test" and "Operational Data". Please see Attachment 2. It is recognized that a larger voltage schedule deviation is required to perform this task and this task should be coordinated with your TOP.**		
Arizona Public Service Company	Yes	The proposed VSL levels are spaced 10 days apart. For a test which is done once in a 5 year, it is unnecessarily restrictive. The minimum spacing between the VSLs should be 90 days. Reporting results 90 days late or even a 180 days late does not cause any concern for a planning horizon study. This data is only needed for such studies and such cases are typically updated annually. The real power verification tests are unnecessary and do not add any value. The peaking unit with less than 5% capacity factor should be exempt.
Response: The GVSDT thanks you for your comment. The GVSDT believes the VSL time frame specified is reasonable and is in alignment with NERC's VSL guidelines. **The FERC Order 693 requires verification of Real Power capability. The GVSDT does not have evidence that exempting the peaking units will not**		

Organization	Yes or No	Question 14 Comment
adversely impact reliability. **Because the verification is only required to be performed for one hour every five years the GVSDT does not believe this is a burdensome requirement.**		
Lakeland Electric	Yes	In the VSL table for Requirement R2, the word “applicable” appears twice in a row in the “Lower VSL” and “Moderate VSL” columns. Propose striking one instance of the word.
Response: The GVSDT thanks you for your comment. The error has been corrected.		
PacifiCorp	Yes	Section 4.2 of proposed Standard MOD-025-2 contemplates the inclusion of large wind farms within the scope of the proposed standard, as it is applicable to generating units above individual and aggregate nameplate rating thresholds (as the commentary seems to indicate is intended). The specific requirements for verifying Real and Reactive Power capabilities, however, do not make any allowance for operating differences of wind generation units. If wind generating resources are to be included within the scope of this proposed standard, then the standard should include express allowances for verification methodologies that are applicable to wind generating units.
Response: The GVSDT thanks you for your comment. The GVSDT believes the standard provides sufficient flexibility for wind farms. The GVSDT does not understand the ‘operating differences’ concern. Further explanation is needed before the GVSDT can provide a response.		
South Carolina Electric and Gas	Yes	If the demonstrated value is less than the expected value, then the GO's should be required to provide calculated values for reactive capability in addition to the demonstrated values (this should be included in R1). Without this, the data is useless to the Transmission Planners.
Response: The GVSDT thanks you for your comment. Engineering analysis is allowed. Expected values are not required because the GVSDT does not believe results obtained constitute verification.		
New York Independent System Operator	Yes	1. Effective Dates: How is this to be implemented? GOs may have units in multiple control areas. TOs may be in multiple areas. This seems impossible to track and may leave some areas without any verification for 5 years after the standard has been approved. The Planning Coordinator should be given the discretion to require and approve a test schedule within its area.

Organization	Yes or No	Question 14 Comment
		Additional NYISO Comments not addressed above for MOD-25-2 Under A. Introduction 2. Section 4 - Transmission Planner should be added under Functional Entities 3. Section 5.1.1 through 5.1.5 and 5.2.1 through 5.2.5 - These requirements should clarify that the Transmission owner requirement is for units that the Transmission owner owns and not for the generators in the Transmission Owners area. Under B. Requirements 4. Section 1.3 - The requirement should either be up to 225 days after the test or 60 days after the end of the test period. Attachment 1 - Verification of Generator Real and Reactive Power Capability 5. Section 1 - There should be some provision for allowing the verification results from small, electrically identical units at the same location to apply to other units in the group. 6. Section 2.1 - It is not practical to determine reactive power at rated gross Real Power capability. The requirement that ninety percent of wind turbines or photovoltaic inverters be online during verification of reactive power should be removed. 7. Section 2.2 - This verification is not needed. 8. Section 2.4 - Please clarify the definition of “limit”. 9. Section 3.2 - Please clarify the definition of “voltage schedule”. 10. Section 3.3 - This data is not needed. 11. o Section 3.4 - Ambient air temperature is not needed for reactive power test results. It is only necessary for certain generators in Real Power tests (combined cycle, combustion and turbine).

Organization	Yes or No	Question 14 Comment
		12. Section 4 - The diagram is not needed. 13. Section 4.1 - For the NYISO, Real Power verifications are conservatively measured as Net output, so no auxiliary loads are required to be reported. Attachment 2 14. Attachment 2 requires an unnecessary level of detail for “Data Type” to be recorded and collected; only gross MVAR, auxiliary reactive power and Net MW readings are required. 15. o What is meant by “MVAR values were adjusted to rate generator voltage”?

Response: The GVSDT thanks you for your comment.

(1) Response: The GVSDT believes the GO/TO, as applicable, is responsible to coordinate verification of all units with its TOP within the verification period identified in the standard. The Implementation Plan calls for various percentages of assets to be verified in each year over the phase-in period.

(2) Response: The TP is not responsible for any of the standard requirements and, therefore, is not listed in the Applicability Section. However, data is submitted to the TP.

(3) Response: The GVSDT believes the wording is clear.

(4) Response: The requirement has been modified for clarity.

(5) Response: The standard requires verification only once every five years. The GVSDT believes to maintain reliability every unit should be verified once every five years.

(6) Response: The GVSDT believes verification of Reactive Power at normal expected maximum Real Power is necessary for reliability. Section 2.1 has been modified to state:

> **”If verification of wind turbines or photovoltaic inverter Facility cannot be accomplished meeting the 90 percent threshold, the Generator Owner must document the reasons it was unable to meet the threshold and test to the full capability at the time of the test. The Generator Owner shall retest the Facility within six months of being able to reach the 90 percent threshold.”**

(7) Response: The FERC Order 693 requires verification at multiple points, and the GVSDT believes verification of four points is necessary to approximate the capability curve.

(8) Response: A limit is the point, edge, or line beyond which something cannot or may not proceed. Examples include the thermal capability curve,

Organization	Yes or No	Question 14 Comment
aux bus voltage limit, voltage regulator limiter, or vibration limit. **(9) Response: Refer to VAR-001-1, Requirement 4.** **(10) Response: The GVSDT respectfully disagrees. This information is relevant for Transmission Planners to run accurate and reliable studies.** **(11) Response: Section 3.4 has been revised to include additional correction factor considerations so the GO must determine which ambient conditions need to be recorded for use as a correction factor for Real Power.** **(12) Response: The diagram was added for clarity.** **(13) Response: The GVSDT believes most generators do not meter net power. The standard allows for approximating auxiliary Load if an entity only meters the net power.** **(14) Response: The GVSDT believes most generators do not meter net power. The standard allows for approximating auxiliary Load if an entity only meters the net power.** **(15) Response: Many modern voltage regulators automatically adjust the under-excited limit to account for low bus voltage. A correction may be necessary to determine the limit for rated voltage.**		
Cowlitz County PUD	Yes	As already stated, Cowlitz questions the reliability benefit of the extensive reactive capability requirements and is currently consulting with Transmission Planners if such extensive data will actually be beneficial in their modeling efforts. It may be better to require data that must be verified though staged testing only after request by the Transmission Planner with a reasonable time frame to obtain the data.
Response: The GVSDT thanks you for your comment. Please refer to the previous response. The FERC Order 693 requires verification of Reactive capability at multiple points, and the GVSDT believes that verification at a minimum of four points is necessary to approximate the capability curve.		
Xcel Energy	Yes	It is not clear in the standard if a separate load flow report (Attachment 1) is required for each point of verification, or only for the maximum load, maximum lagging reactive point. Please clarify in the standard.
Response: The GVSDT thanks you for your comment. The GVSDT anticipates that each test point would require a separate Attachment 2 report to be completed.		
Lakeland Electric	Yes	Under the section B. requirements R1, 1.1; it refers us to “attachment - 1” . Under attachment - 1, item 2 - 2.1 it states the following:

Organization	Yes or No	Question 14 Comment
		o Perform verification of real and reactive power capability of all generating units at maximum over excited (lagging) and under-excited (leading) reactive capability at gross real power capability. We would like to propose adding “or to the documented limiting factor of the equipment (generator, voltage regulator, transformer, transmission etc.)”. We want to avoid having to test to the min and max of the capability curve if there is some other limiting factor we can document.
Response: The GVSDT thanks you for your comment. The standard doesn’t require a unit to reach the capability curve value. The capability curve does not reflect all unit limitations that may exist. The limitation that is reached should be recorded on Attachment 2 in the remarks section.		
Exelon	Yes	Nuclear units do not perform under-excited (leading) reactive capability testing due to concerns with unit stability and potential under voltage conditions on internal nuclear plant safety buses that may challenge safe plant operations and could lead to a plant transient or shutdown in accordance with NRC operating license. Performance of reactive capability tests cannot challenge nuclear plant NRC licensee Technical Specification voltage limit requirements. Exelon strongly suggests that the SDT coordinate this revised Standard with the Nuclear Regulatory Commission (NRC) to preclude any challenges to the licensing basis of any of the nuclear generating facilities. Suggest that all exceptions to test performance criteria be pulled forward into body of the Standard. Additional comments for MOD-025-2 Attachment 1 o Step 2.3 - remove reference to "rated real power" - the reactive power test is conducted as a stand alone test using the attainable real power (which is generally governed by ambient conditions at the time of the test). o Step 2.4 - remove reference to "over-excited reactive capability" - the over-excited test is conducted for a minimum of 1 hour o Step 3.4 - remove reference to "correction factor: - this applies to correcting MW as part of the MOD-024 test. Reactive power is tested at the attainable MWe.
Response: The GVSDT thanks you for your comment. **(1) Response: If a nuclear plant has under-excited capability it should be tested within the unit’s capability and declared safety margins. The standard does not require challenging unit capabilities. The following statement was added to Note 1 of Attachment 1 for clarity, “Auxiliary bus voltage limits should be observed”.**		

Organization	Yes or No	Question 14 Comment
(2) Response: The GVSDT has added language to Attachment 1, Section 2.1 to clarify the required full Load test points. **(3) Response: Refer to Attachment 1, Section 2.3. The one-hour over-excited reactive capability test is performed only for the rated Real Power capability test. Step 2.4 refers to verification at minimum Real Power capability.** **(4) Response: The GVSDT modified the language in Attachment 1, Section, 3.4 for clarity and “correction factor” was removed.**		
Georgia Transmission Corporation	Yes	Regarding reactive capability, the SDT has recognized that this standard will not meet the purpose “To ensure that planning entities have accurate generator Real and Reactive Power capability data when assessing Bulk Electric System (BES) reliability.” Should the standard and/or purpose be adjusted to where they match? Reactive capability cannot be determined, generally, without disturbances to the system. Long-term fault recorders could be installed at all generator high-side buses and verification of generation to any eventual disturbances could be used to get a better picture of the plants reactive power capability. R1.3 is unclear we propose: Submit the recorded data to its Transmission Planner within 90 calendar days of the date the data is recorded.
Response: The GVSDT thanks you for your comment. **(1) Response: The goal of this standard is to model steady state capability of generators and synchronous condensers. Therefore, the standard requirements meet the stated purpose.** **(2) Response: Requirement R1, Part 1.3 has been revised for clarity and the revised language is:** **“1.3. Submit to its Transmission Planner within 90 calendar days of either the date the data is recorded for a staged test or the date the data is selected for verification using historical operational data.”**		
Wisconsin Electric	Yes	Attachment 1, 2.1 and 2.2: It would be more reasonable to allow for some small variation in real power level around the rated gross real power output and minimum real power outputs, perhaps within +/- 5 percent of these values. This would allow for variability in coal conditions, system voltages, etc. Also, the requirement in 2.1 for 90 percent of wind turbines online may be impractical in many cases. A lower value such as 75 percent may be more reasonable.
Response: The GVSDT thanks you for your comment. Reference Attachment 1, 2.1. Some drift in Load is expected and language was added to account for less than 90 percent of wind turbines being on line.		
Great River Energy	Yes	Please see comments submitted by the MRO NSRF for question #14

Organization	Yes or No	Question 14 Comment
Response: Please see response to above question.		
Constellation Power Generation	Yes	CPG is concerned with the general wording of Attachment 1 as the verbiage is not auditable. For example, Item 2.1 states "Maintain as steady as possible Real and Reactive Power output during verification." The term "steady as possible" is extremely subjective and open to a multitude of interpretations. From a technical perspective, item 3.3 is not auditable because it is assuming that the voltages and the high and low side of the GSU are metered. This is usually not the case. A statement allowing for an entity to report on the requested metered points based on their configuration and allowing for some points to not be answered would be preferable. Likewise, Attachment 2 would require a similar statement.
Response: The GVSDT thanks you for your comment. **(1) Response: The GVSDT has revised Attachment 1, 2.1 for clarity. The revised language states:** "Maintain as steady as practical Real and Reactive Power output during verifications (i.e. make no purposeful Load changes and do not have the unit in automatic Load control)." (2) **Response: The GVSDT has revised Attachment 1, 3.3 for clarity. It is anticipated that some non- metered values would need to be calculated.**		
ISO New England	Yes	1. Effective Dates: This proposal is not well explained and very well may not work. Some concerns that arise: (a) For those GOs that have units in multiple control areas, are they supposed to apply the Implementation Plan for their entire fleet or for their fleet on a per Region basis? This same issue can apply to TOs which may be in multiple areas. This seems impossible to track and may leave some areas without any verification for 5 years after the standard has been approved. The Transmission Operator should be given the discretion to require and approve a test schedule within its area. (b) For those GOs with only one or two facilities in a region, how will the 5-year implementation plan work? Will the GO with one facility in a region have 5 years to implement (i.e., the 100% rule would not "kick" in until 5 years out, or will the GO with one facility in a region have only 1 year to implement (since 20% of 1 unit would arguably capture the unit). 2. R1.2 and 2.2 All entities should use the same submittal form. Please delete the option for a Generator Owner to develop its own form. 3. R1.3... 90 days is too long for reporting data. Recommend 30 days for providing verification data.

Organization	Yes or No	Question 14 Comment
		4. VSL for R2 should mirror VSL for R1. Specifically R2 doesn't mention submitting >120 days as R1 does. 5. Attachment 1: 1. specify that the AVR must be in service and in automatic controlling voltage if required by the TOP 6. 2. If AVR is not required by the TOP, does the unit still have to test? Under the VAR-001 standard an entity may be exempted by the Transmission Operator from having a functional AVR. Under such an exemption the need for testing should not be required. 7. Attachment 2: move the check boxes to the top so that that someone looking at form knows immediately what type of audit was performed. 8. o There should be VSLs in regards to going more than 66 months between verifications. 9. o Periodicity should be captured in Requirements, not in the Attachment 10. If each test is done on different days, does each test have its own verification date? 11. Please clarify what footnote 1 of Attachment 1 is intended to describe with "normal" with respect to the unit's normal expected maximum Real Power at the time of the verification. 12. o Attachment 1, Section 2.1 states that during wind turbine and photovoltaic verification, 90% must be on line. This should read "with AT LEAST ninety percent of the..."

Response: The GVSDT thanks you for your comment.

(1) Response: The GVSDT believes the GO/TO, as applicable, is responsible to coordinate verification of all units with their TOP(s) within the verification period identified in the standard. The Implementation Plan calls for various percentages of assets to be verified in each year over the phase-in period.

(2) Response: The GVSDT created a sample form, Attachment 2. This form should be modified for each unit.

(3) Response: Because this data is for the long-term planning horizon, the GVSDT believes the timeframe specified is appropriate.

(4) Response: The VSLs have been revised and now include a Severe VSL as proposed for Requirement R2 (R3 in the revised standard).

Organization	Yes or No	Question 14 Comment
(5) Response: Voltage control mode is required by VAR-001. **(6) Response: Attachment 1, 2 states the voltage regulator must in automatic mode for the Reactive Power capability test. If automatic control is not available and is not expected to be available any time soon, the test should be conducted but with caution relative to the generator limits.** **(7) Response: The GVSDT liked the suggestion and has made the change.** **(8) Response: The severe VSL applies in this situation.** **(9) Response: The GVSDT believes the current format is clear. The attachments are an extension of the requirements.** **(10) Response: Yes.** **(11) Response: If a generator goes to full output (not emergency output), that would be considered "normal." This is most likely the declared output of this unit.** **(12) Response: The GVSDT agrees and has modified attachment language to use the proposed, "at least 90 percent".**		
Independent Electricity System Operator	Yes	1. In our previous comments, we raised a concern over the detailed requirements in Attachment 1 which in our view are overly prescriptive. Specifically, the requirements listed in Item 3 of Attachment 1 are too detailed, and some of the items listed in 3.1 to 3.6 are not needed or relevant to the provision of verified data for modeling or BES reliability assessment, but they create unnecessary administrative burden. For example, what would be the use of voltage at the high side of the generator step-up and/or system interconnection transformer(s) and the tap settings of these transformers in the application of the recorded real and reactive capabilities to modeling and reliability assessments? And what would be the required actions if the voltage levels and/or the transformer tap setting in the load flow model or in real time are different from the reported values? Imposing the reporting requirement without a clear statement of the intended use, with justification, is unnecessary and should be dropped. Further, we request clarification regarding the phrase "at the end of the verification period" in 3.1 and 3.3? Does it mean the time when the verification test ends, i.e. at the end of the 1-hour period referred to in Attachment 1, bullet 2.3? 2. If the verification is provided by operational data, what would constitute "the end of the verification period"? 3. We believe Attachment 1 needs only to specify the sustainability (Items 1 and 2) and the periodicity (Item 5). We also respectfully disagree with the SDT's response to our previous comments on Attachment 1. The SDT's view that (excerpt from Comment Report) "The SDT believes that attachment one does not contain requirements but provides clarity to the Requirements of the Standard." is incorrect since it is clearly indicated in Requirement 1.1 to "Verify the Real and Reactive Power capability of its generating units and shall verify the Reactive Power capability of its synchronous condenser units in accordance with

Organization	Yes or No	Question 14 Comment
		Attachment 1."According to the general rule for NERC standards, an attachment is a part of the standard that must be complied with, and hence any items contained in an attachment are mandatory requirements. With that understanding and with the way Attachment 1 is included in Requirement 1.1 that the items in Attachment 1 are not there for clarity but are requirements that must be complied with, we urge the SDT to remove the entire Item 3 from Attachment 1 as the information required in that item does not add to the intended use of the verified data. 4. We do not have the same concern over Attachment 2 since it is made clear in Requirement 2.2 and in the Attachment itself that use of other forms is acceptable and hence use of the diagram is not mandatory. In Attachment 1, step 2.4 seems to be inconsistent. For the over-excited check, record should be taken at min. and max. real power output (i.e. it should state... data required in 2.1 and 2.2.)The table in Attachment 2 should be improved to match data to be recorded in Attachment 1 (i.e. there should be two columns for MVAR to record lagging and leading reactive power for a given MW). 5. MOD-025 Attachment 1 bullets 2.1 and 2.2 should stipulate that Generator Owners and Transmission Owners conduct verification at generator terminal voltages as close as possible to rated terminal voltage. Finally, the standard should use SI units (e.g. active power not real power, Mvar not MVAR).

Response:

Response: The GVSDT thanks you for your comments. The GVSDT believes that the data requested in Attachment 1, Paragraph 3 reflects the data needed to properly verify the unit/Facility. Most of this data was included in the FERC Directives.

(1) Response: Yes, "at the end of the verification period" means at the end of the one-hour period referred to in Attachment 1, Section 2.3.

(2) Response: For operational data, "the end of the verification period" would be the end of the one hour test, the whole hour of which should be recorded.

(3) Response: The GVSDT agrees that items contained in the attachments are mandatory. The GVSDT also believes that the data required in Attachment 1, Section 3 is necessary for meaningful evaluation of Real Power capability or Reactive Power capability.

(4) Response: Attachment 1, Section 2.4 refers to when the data should be taken, i.e., the data can be taken immediately for the low load over-excited and any under-excited tests. The full load over-excited test is run for one hour and is included in Attachment 1, Section 2.3.

(5) Response: The GVSDT thanks you for your comments. The GVSDT feels that allowing a full range of voltage, within equipment limitations and allowed by the TOP would provide a more reasonable expectation of demonstrating the unit/Facility capability over a greater portion of the D-Curve. Testing "as close as possible" to generator terminal voltage would be too subjective and not allow adequate range on many units. The GVSDT believes that the use of Real and Reactive power is appropriate for this standard. The term "MVAR" has been revised to "Mvar" throughout the

Organization	Yes or No	Question 14 Comment
standard.		
Indeck Energy Services	Yes	For a plant with fewer than 5 units, implementation should be at the point that the unit finally satisfies the requirement, stated differently, a single unit station would comply at the 5 year point, not at the 1 year point. Why should multiple unit plants be given more time than single unit plants. If having the units done in 5 years meets the BPS reliability need, then it should apply this alternative way. If BPS reliability needs compliance in 1 year, then all should comply.
Response: The GVSDT thanks you for your comment. The implementation is phased in over five years because testing all units in the same year would be impractical. Since the requirement requires testing only once every five years, it is reasonable to space unit testing.		
Indiana Municipal Power Agency	Yes	IMPA believes that the first sentence of requirement 2.1. does not read correctly in the sense that it is requiring the verification of Real Power Capability at maximum over-excited and under-excited reactive capability at rated gross Real Power Capability. This sentence would make sense if Real was removed at the beginning of the sentence and read "Perform verification of Reactive Power capability of all generating...". Requirement 2.2 covers real power testing requirements. Since Real power needs to be removed from 2.1 then requirement 2.3 needs to have the requirement 2.2 added to it to cover the Real power testing time.
Response: The GVSDT thanks you for your comment. The language of Attachment 1, Section 2.1 has been revised for clarity. The revised language is shown below: **"2.1. Perform verification of Real Power capability, Reactive Power capability over-excited (lagging) and Reactive Power capability under-excited (leading) of all generating units at the generating unit's normal (not emergency) expected maximum Real Power at the time of the verifications. Verify variable generating units, such as wind, solar, and run of river hydro, at the maximum Real Power output the variable resource can provide at the time of the verification. Perform verification of reactive capability of wind turbines and photovoltaic inverters with at least 90 percent of the wind turbines or photovoltaic inverters at a site on line. If verification of wind turbines or photovoltaic inverter Facility cannot be accomplished meeting the 90 percent threshold, the Generator Owner must document the reasons it was unable to meet the threshold and test to the full capability at the time of the test. The Generator Owner shall retest the Facility within six months of being able to reach the 90 percent threshold. Maintain as steady as practical Real and Reactive Power output during verifications."**		
Los Angeles Department of Water and Power	Yes	MOD-025 Attachment 1 Sec. 2.1During normal operations, it is typical to have many wind and solar units not working due to equipment malfunctions such as faults. How will failures that prevent the testing of 90% of equipment integrate with the standard? MOD-025 Attachment 1 Sec. 4Will As-Built Project Drawings suffice for the requirement? The development of

Organization	Yes or No	Question 14 Comment
		new one-line diagrams for a simplified version could have a significant impact because it will require the support of drafting resources which might not be available potentially delaying the submittals of Models and Data Reports. The requirement of directional arrows for Reactive Power Flows can be superimposed on the As-Built drawings. MOD-025 Attachment 1, Sec. 5From a user's perspective, it would be useful to get some language from the ERO that quantifies and qualifies what type of control system conditions would trigger the need for a new model and data verification, and also to have access to a comprehensive sample of a model and data verification test plan. This would allow the user to better manage its compliance implementation phase.
Response: The GVSDT thanks you for your comment. **(1) Response: The language of Attachment 1, Section 2.1 has been revised to allow flexibility.** **(2) Response: See the example in Attachment 2. A very simple drawing is suggested and should not require significant resources to create. If your existing one-line drawings have the information required they may be used as a basis for this standard.** **(3) Response: Attachment 1, Section 5 refers to any change that would affect the Real Power or Reactive Power capability of the unit and makes no distinction between control system changes or limitations from other equipment that would alter the last verified capability by more than 10 percent and would last for more than six months. Some examples triggering retesting would include GSU replacements, excitation system change outs (replacements, upgrades or parameter changes), turbine rotor replacements, turbine control system change outs (replacements, upgrades or parameter changes). Basically, any change that would be expected to have an effect on the capability.**

Consideration of Comments on Generator Verification (MOD-027-1) — Project 2007-09

The Generator Verification Drafting Team thanks all commenters who submitted comments on the First Posting of MOD-027-1, Verification of Models and Data for Turbine/Governor and Load Control or Active Power/Frequency Control Functions (Project 2007-09). These standards were posted for a 30-day public comment period from June 15, 2011 through July 15, 2011. The stakeholders were asked to provide feedback on the standards through a special Electronic Comment Form. There were 65 sets of comments, including comments from approximately 182 different people from approximately 95 companies representing 9 of the 10 Industry Segments as shown in the table on the following pages.

http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President of Standards and Training, Herb Schrayshuen, at 404-446-2563 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

Summary Consideration:

The GVSDT expanded the applicability of MOD-027-1 to include plants/facilities comprised of multiple small units such as variable energy resource plants/facilities. Stakeholders were asked whether they were aware of other generation configurations or types that should be covered in the Applicability. The vast majority of industry agrees that all of generation configurations or types that should be included in the Applicability section are specified in the current draft of the standard. A few minority comments were received suggesting that the Applicability section proposed should either be expanded or reduced. The SDT believes industry supports the current draft of the proposed applicability.

The GVSDT did not propose a Requirement in MOD-027-1 where the Planning Coordinator can request a review of a turbine/governor and load control or active power/frequency control system model for a unit not specified in the standard Applicability section. This was discussed in relation to the proposed MOD-026-1 where a Planning Coordinator may request information on an excitation control system model for a technically justified unit. The GVSDT does not believe that it is likely that the turbine/governor and load control or active power/frequency control system will contribute to a stability limit, and governor response is not consistent from one frequency excursion event to the next. Stakeholders were asked if they agreed with this approach. The majority of industry comments support the GVSDT proposal not to include a Requirement allowing the Planning Coordinator to request a model review for a unit not specified in the standard Applicability section. There is minority opinion suggesting that such a Requirement should be developed; with some commenters also questioning the basis for the Applicability section and the capacity factor philosophy. Most of the minority comments were received from one Reliability Region and as such the GVSDT suggests that region should consider developing a

[1] The appeals process is in the Standard Processes Manual:
http://www.nerc.com/files/Appendix_3A_Standard_Processes_Manual_Rev%201_20110825.pdf

Regional Standard containing a more stringent Applicability. The Planning Coordinator can still request a model review however, the review is not mandatory under the standard requirements.

Based on industry comments received, the following modifications to the proposed standard have been made by the GVSDT:

1) Corrections of various typos in the body of the standard, the VSLs, and in Attachment 1

2) Extended the time to comply with Requirement 1 from 30 to 90 days

3) Modified Attachment 1 (Periodicity Table) to address units which are always base loaded (by definition a base loaded unit is considered verified).

4) Modified Attachment 1 (Periodicity Table) to clarify establishing the Initial Ten Year Unit Verification Period Start Date

5) Reduced the maximum time allowed between capture of an event and completing model verification from two years to one year.

6) Referenced the NERC GADS document for references to capacity factor in the draft standard.

7) Included partial load rejection as a potential test to obtain a recording of the equipment response to be used in model verification.

Index to Questions, Comments, and Responses

1. The Applicability section of MOD-027 standard is expanded to include plants/facilities comprised of multiple small units such as variable energy resource plants/facilities. Are you aware of other generation configurations/types that should be covered in the Applicability? 14
2. Because it is not likely that the turbine/governor and load control or active power/frequency control system will contribute to a stability limit, and because governor response is not consistent from one frequency excursion event to the next, the SDT is not proposing a Requirement in MOD-027-1 where the Planning Coordinator can request a review of a turbine/governor and load control or active power/frequency control system model for a unit not specified in the standard Applicability section. Do you agree with the proposal to not include a Requirement in MOD-027-1 where the Planning Coordinator can request a review of a turbine/governor and load control or active power/frequency control system model for a unit not specified in the standard Applicability section? 22
3. The SDT discussed if MOD-027-1 should also include verification of excitation control systems of synchronous condensers. Synchronous condensers are not currently addressed in the NERC Registry Criteria. Synchronous condensers are not mentioned in the Generation Verification SAR. On an MVA capacity basis, the penetration of synchronous condensers in North America is extremely low. It is common for Transmission Owners to be the owners of synchronous condensers. As such, the peer review draft requirements would not make sense. Therefore, the team decided that a more appropriate strategy would be to include synchronous condensers with other transmission system dynamic reactive devices (such as SVCs, STATCOMs, etc.) in a separate SAR. Do you agree with the proposal to not include the verification of synchronous condensers in MOD-027-1? 31
4. Are you aware of any regional variances that would be required as a result of MOD-027-1? If yes, please identify the regional variance. 38
5. Are you aware of any conflicts between the proposed MOD-027-1 and any regulatory function, rule, order, tariff, rate schedule, legislative requirement, or agreement? 44
6. Do you have any other questions or concerns with the proposed standards that have not been addressed? If yes, please explain 51

1. **The Applicability section of MOD-027 standard is expanded to include plants/facilities comprised of multiple small units such as variable energy resource plants/facilities. Are you aware of other generation configurations/types that should be covered in the Applicability?**

Summary Consideration: The vast majority of industry agrees that all generation configurations/types that should be included in the Applicability section are specified in the current draft of the standard. There was some confusion regarding the treatment of small units at plants. The SDT in response revised the Applicability to include plants greater than X MVA that have units with ratings less than 20 MVA (X is 100 for Eastern and Qubec, 75 for WECC, and 75 for ERCOT). The SDT believes that this revised applicability Section language is clearer while at the same time it still captures the appropriate units and plants for model verification (i.e., greater than 80% of interconnected VER plants for each Interconnection). A few minority comments were received suggesting that the Applicability section proposed should either be expanded or reduced. The SDT believes industry supports the current draft of the Applicability section proposed.

Organization	Yes or No	Question 1 Comment
SPP Reliability Standards Development Team	No	By setting the MVA rating at 100MVA in section 4.2.1 for single units aren't you excluding units? It is then mentioned in the bullet below that units below 20MVA are included but as an aggregate if the site is over 100MVA. We aren't clear how this is expanding the standard. The other standards in this group refer to the limits used in the Compliance Registry. Should this be consistent with those?
Response: Thank you for your comment. The SDT believes it is unnecessary to require all units in the compliance registry to have verified models. However, it is useful to have verified models for at least 80% of the connected MVA in the interconnection and as such the SDT has specified in the Applicability section gross nameplate rating size requirements for each interconnection for achieving this threshold. Given the increasing importance of renewable generation plants comprised of several small units, the SDT also proposes requiring verification of these plants and has added language to the Applicability section to capture this intent. Also, the SDT revised the Applicability to include plants greater than X MVA that have units with ratings less than 20 MVA (X is 100 for Eastern and Quebec, 75 for WECC, and 75 for ERCOT). Note that "X" is 100 for the Eastern and Quebec Interconnections, 75 for WECC and ERCOT. The SDT believes that this revised applicability Section language is clearer while at the same time capturing the appropriate units and plants for model verification (i.e., greater than 80% of interconnected VER plants for each Interconnection).		
SERC Planning Standards Subcommittee		
Idaho Power-Power Production	Yes	We believe Black Start units, regardless of size, should be considered in this standard.
Response: Thank you for your comment. Turbine/Governor and Load Control or Active Power/Frequency Control models are less important for a black start unit emergency power source because these units are not typically modeled in planning studies. When needed, these units are started in asynchronous mode to power black start unit auxiliaries and are not configured to control grid frequency.		
Santee Cooper		
PPL Generation	No	
Dominion	No	
FirstEnergy	No	

Organization	Yes or No	Question 1 Comment
SERC Dynamics Review Sub-committee	No	The DRS agrees that the intended generating units would be covered by reasonable interpretation of the applicability section 4.2. However, the DRS recommends that footnote 3 be changed to read “The common transmission voltage level bus (i.e. 100 kV or greater) to which the step up transformer(s) is connected.” This more clearly includes “step up” transformers for some types of variable energy plants which may not be “generator step up” transformers.
Response: Thank you for your comment. The SDT agrees and has removed the footnote and revised the applicability for clarity.		
NERC Staff	No	We are not aware of other units types at this time, but the applicability should be written broadly enough to not preclude applicability to other types of resources that may be connected in the future.
Response: Thank you for your comment. The SDT believes that the Applicability section is technology neutral.		
Public Service Enterprise Group	No	
SERC Generation sub-committee		
ACES Power Members	No	
Arizona Public Service Company	Yes	
Westar Energy	No	We suggest for consistency with the other standards in this project that this standard also reference the limits used in the Compliance Registry.
Response: Thank you for your comment. The SDT believes it is unnecessary to require all units in the compliance registry to have verified models. However, it is useful to have verified models for at least 80% of the connected MVA in the interconnection and as such the SDT has specified in the Applicability section gross nameplate rating size requirements for each interconnection for achieving this threshold.		
Southern Company	No	1) We are not convinced that wind plants need to be included at all due to a) the uncertainty of the wind availability during a frequency excursion and b) the transient nature of any contribution that the a wind turbine may be able to provide to correct or affect the frequency excursion. It is believed that the time

Organization	Yes or No	Question 1 Comment
		frame of the frequency excursion will far exceed the wind turbine's ability to sustain a correcting action. 2) It is our opinion that a 20MVA machine is too small to be able to significantly impact a frequency perturbation. A technical basis for including units as small as 20MVA in all regions needs to be provided. NERC is focusing on standard requirements that have significant impacts on system reliability, and including units this small seems to be inconsistent with this philosophy.
Response: Thank you for your comment. The SDT has added another row to Attachment 1 (the Periodicity Table) defining requirement exceptions for units that cannot control frequency such as a significant number of wind plants. For the Eastern Interconnection, 20 MVA rated units only have to be verified if they are part of a plant that is 100 MVA or greater. The SDT believes that 100 MVA plants in the Eastern Interconnection are significant. Also, the unit Applicability for this standard is already a subset of the Compliance Registry.

Constellation Power Generation	No	No. CPG believes that the use of capacity factor, a variable data point, in the applicability of a standard is too problematic. Capacity factor is a market a function that is dependent on many variables outside of reliability and therefore does not belong in a reliability standard. CPG is also unsure as to how the SDT arrived at the MVA thresholds in each of the Interconnections, and is requesting that a technical justification of those thresholds be submitted along with the response of comments.
Response: Thank you for your comment. The 5% capacity factor exemption was selected to achieve a balance between the cost and benefits. The SDT believes that there are a limited number of units greater than 100 MVA with a capacity factor of less than 5%. Also, units with a capacity factor of less than 5% are excluded from model verification however other standards still require that the data be supplied. The SDT believes it is not necessary to require all units in the compliance registry to have models verified. The SDT also believes that the applicability section thresholds specified will result in substantial accuracy improvement to the governor models and associated Reliability based limits determined by dynamic simulations, while not unduly mandating costly and time consuming verification efforts. As a basis, the SDT recognized that the governor models and model data are already collected through the processes identified in MOD-012 and MOD-013. These models and data should, with few exceptions, already result in a quality dynamics database. However, as confirmed through the Field Test initiated by the Phase III-IV SDT, performing the activities specified in the draft standard is expected to result in an improvement of the accuracy of the governor models used in dynamic simulations. Utilizing engineering judgment, based in part on recent entity experiences in verifying governor models, the SDT is proposing to require verification of governor models associated with 80% or greater of the connected MVA per Interconnection. Therefore, specific MVA thresholds which the SDT believes corresponds to 80% of connected MVA or greater for each Interconnection are proposed. Given the increasing importance of renewable generation plants comprised of several small units, the SDT also proposes requiring verification of these plants and has added language to the Applicability section to capture this intent. Please note the calculation of capacity factor is specified in Appendix F of the GADS Data Reporting Instructions on the NERC website.

Organization	Yes or No	Question 1 Comment
ISO New England	Yes	Generators sized well over 100 MVA with a capacity factor under 5% are numerous in our area of the Eastern Interconnection. These older large generators with a capacity factor below 5% will have a significant impact on electric system performance during stressed conditions with high loads. These generators must not be excluded from the verification requirement. Generators sized under 100 MVA may also be important, what is the justification for the cutoff from the verification requirement at 100 MVA? This applicability criteria in this standard should be the same as the Compliance Registry requirements.
Response: Thank you for your comment. The 5% capacity factor exemption was selected to achieve a balance between the cost and benefits. The SDT believes that there are a limited number of units greater than 100 MVA with a capacity factor of less than 5%. Also, units with a capacity factor of less than 5% are excluded from model verification however other standards still require that the data be supplied. The SDT believes it is not necessary to require all units in the compliance registry to have models verified. The SDT also believes that the applicability section thresholds specified will result in substantial accuracy improvement to the governor models and associated Reliability based limits determined by dynamic simulations, while not unduly mandating costly and time consuming verification efforts. As a basis, the SDT recognized that the governor models and model data are already collected through the processes identified in MOD-012 and MOD-013. These models and data should, with few exceptions, already result in a quality dynamics database. However, as confirmed through the Field Test initiated by the Phase III-IV SDT, performing the activities specified in the draft standard is expected to result in an improvement of the accuracy of the governor models used in dynamic simulations. Utilizing engineering judgment, based in part on recent entity experiences in verifying governor models, the SDT is proposing to require verification of governor models associated with 80% or greater of the connected MVA per Interconnection. Therefore, specific MVA thresholds which the SDT believes corresponds to 80% of connected MVA or greater for each Interconnection are proposed. Given the increasing importance of renewable generation plants comprised of several small units, the SDT also proposes requiring verification of these plants and has added language to the Applicability section to capture this intent.

that cannot control frequency, which includes a significant number of wind plants.		
Lincoln Electric System		
CPS Energy		
Independent Electricity System Operator	No	No, we are not aware of any, but the Applicability Section of the draft standard does not contain specific references to variable energy resource plants/facilities. It only covers generating units and plants of certain sizes for the three (and Quebec) Interconnections without any specificity on generator types. Was it an oversight or did the SDT suggest that the “generating units” suffice to generally include all types of energy resources?
Response: Thank you for your comment. The SDT is developing a technology neutral standard that covers all current and future technologies.		
Gainesville Regional Utilities	No

Los Angeles Department of Water and Power		LADWP does not have a position on this question at this time.
Chelan County PUD	No	

2. Because it is not likely that the turbine/governor and load control or active power/frequency control system will contribute to a stability limit, and because governor response is not consistent from one frequency excursion event to the next, the SDT is not proposing a Requirement in MOD-027-1 where the Planning Coordinator can request a review of a turbine/governor and load control or active power/frequency control system model for a unit not specified in the standard Applicability section.

Do you agree with the proposal to not include a Requirement in MOD-027-1 where the Planning Coordinator can request a review of a turbine/governor and load control or active power/frequency control system model for a unit not specified in the standard Applicability section?

Summary Consideration: The majority of industry comments support the SDT proposal not to include a Requirement allowing the Planning Coordinator to request a model review for a unit not specified in the standard Applicability section. There is minority opinion suggesting that such a Requirement should be developed; with some commenters also questioning the basis for the Applicability section and the capacity factor philosophy. Most of the minority comments were received from one Reliability Region and as such that region should consider developing a Regional standard containing a more stringent Applicability. The Planning Coordinator can still request a model review however the review is not mandatory by standard requirements.

Organization	Yes or No	Question 2 Comment
LG&E and KU Energy		
Northeast Power Coordinating Council	No	A Planning Coordinator should be able to request a review of turbine/governor and load control or active power/frequency control system model even though response is not consistent from one frequency excursion event to the next from any unit connected to the power system. If not being listed in the Applicability section is an issue, then the wording should be changed in the Applicability section so as not to preclude the Planning Coordinator from collecting necessary data.
Response: Thank you for your comment. The majority of industry comments support the SDT proposal not to include a Requirement allowing the Planning Coordinator to request a model review for a unit not specified in the standard Applicability section. Governor response is not consistent from one frequency excursion event to the next for several reasons, such as the operating condition of the plant, ambient temperature, the number of coal pulverizes on line, the pre-contingency MW output of the unit, etc. Therefore, the SDT does not believe it is appropriate to include such a Requirement in MOD-027-1. The Planning Coordinator can still request a model review however the review is not mandatory by standard requirements.		

Organization	Yes or No	Question 2 Comment
Imperial Irrigation District (IID)	Yes	
IRC Standards Review Committee (joint comments)		
Pepco Holdings Inc Affiliates		
NERC System Protection and Control Subcommittee		
Midwest Reliability Organization's NERC Standards Review Forum (NSRF)	Yes	We agree with this proposal as being in line with our overall concern that model verification requirements should be based on cost efficiency and practicality. Facilities outside of the Applicability Section are already judged to be of minimal significance in dynamic impact, and are also typically of vintages and origins whose modeling data and parameters are difficult or impossible to obtain. For facilities of minor dynamic impact in a locality, typical or surrogate model data would serve the simulation purposes the vast majority of times.
Response: Thank you for your comment. The SDT agrees and believes that it has implemented this philosophy in the draft of the standard.

SERC Dynamics Review Sub-committee	Yes	
NERC Staff	No	The standard should include a requirement that provides the Planning Coordinator the ability to request a review of any turbine/governor and load control or active power/frequency control system model for a unit not specified in the standard Applicability section. Accurate turbine-governor models can be critical to valid underfrequency load shedding assessments and other studies requiring accurate frequency response. This is particularly important for large units that operate infrequently, but are committed for critical operating conditions such as peak load or other times of capacity deficiency.
Response: Thank you for your comment. The majority of industry comments support the SDT proposal not to include a Requirement allowing the Planning Coordinator to request a model review for a unit not specified in the standard Applicability section. Governor response is not consistent from one frequency excursion event to the next for several reasons, such as the operating condition of the plant, ambient temperature, the number of coal pulverizes on line, the pre-contingency MW output of the unit, etc. Therefore, the SDT does not believe it is appropriate to include such a Requirement in MOD-027-1. The Planning Coordinator can still request a model review however the review is not mandatory by standard requirements. Also, studies in support of the FR SDT effort show that governor response to a frequency excursion is a more critical concern during off peak operations when low capacity factor units are not expected to be committed. The reason for this is that during peak periods, there is inherently more inertia that helps mitigate the severity and duration of the generation – load mismatch.

American Electric Power	Yes	
Ingleside Cogeneration LP	Yes	MOD-027-1 already takes Ingleside Cogeneration LP out of its comfort zone by requiring the ownership and validation of interconnected system performance simulations. This is normally a Transmission Planner or Transmission Operator function, not a Generator Owner. Although we understand the benefit of modeling validations, it is appropriate to begin with only the most critical facilities. If anything, we believe the applicability criteria should be consistent with those generation facilities which have DME installed as required by their Regional Entity. This is a reasonable, in-place means to identify those generators which are important to BES frequency response - and have already the recording equipment needed to validate performance.
Response: Thank you for your comment. It is undesirable to link this standard with the DME standard development. Also, the DME standard applies to fault recorders and PMU equipment. Lower resolution data is adequate for this verification. We agree that if DME is already in place, then it should be simpler to capture the required data for verification. The applicability section requires verification of units larger than the threshold gross nameplate rating size specified for each interconnection and is intended to emphasize the importance of modeling critical units.		
Wisconsin Public Service Corp	Yes	We agree with this proposal as being in line with our overall concern that model verification requirements

Organization	Yes or No	Question 2 Comment
		should be based on cost efficiency and practicality. Facilities outside of the Applicability Section are already judged to be of minimal significance in dynamic impact, and are also typically of vintages and origins whose modeling data and parameters are difficult or impossible to obtain. Response: Thank you for your comment.		
GE Energy		
ISO New England	No	NERC is largely concerned with the declining frequency response of the Eastern Interconnection and this proposal seems completely at odds with that concern. The Planning Coordinator (or Transmission Planner) should definitely be allowed to request verification of selected governors. In addition to generators that have governor effect overridden by outer control loops (Distributed Control System, DCS) there may be a dead band within the governor. The Transmission Planner must be able to request verification of selected governor models that may fall outside of the standard. The question mentions Planning Coordinator but the standard itself is applicable to the Transmission Planner.
Response: Thank you for your comment. The majority of industry comments support the SDT proposal not to include a Requirement allowing the Planning Coordinator to request a model review for a unit not specified in the standard Applicability section. Governor response is not consistent from one frequency excursion event to the next for several reasons, such as the operating condition of the plant, ambient temperature, the number of coal pulverizes on line, the pre-contingency MW output of the unit, etc. Therefore, the SDT does not believe it is appropriate to include such a Requirement in MOD-027-1. Both the Planning Coordinator and the Transmission Planner can still request a model review however the review is not mandatory by standard requirements. **It is true that the Planning Coordinator is not an applicable FME in the standard since the Planning Coordinator is not assigned responsibility for any of the Requirements.** **The SDT recognizes that modeling improvements are needed in the Eastern Interconnection to correctly represent the frequency response. This standard will require verification of the frequency response model for at least 80% of the interconnection MVA, which will result in improved modeling. The purpose of the standard is to improve the modeling of the frequency response. Other standards are responsible for improving the frequency response.**

Independent Electricity System Operator	No	We do not agree with this approach. Currently, the applicability threshold of nameplate rating greater that 100MVA is too high. The combined performance of many units smaller than the threshold identified in the applicability section will have a material effect on the system frequency response. Even if the standard leads to the provision of useable model to the Transmission Planner for the applicable generating units, without sufficient good models, it might not be possible to meet the goals of accurately represent generating unit active power response to system frequency variations and predicting system frequency response to contingencies.We repeat the concern we expressed in our comments to MOD-025-2 related to the applicability criteria “connected at the point of interconnection at greater than 100 kV.” This condition will lead to the exclusion of units that are material in dynamic simulations and to which the applicability should extend.Also, we wonder whether the inclusion of Planning Coordinator in the question is a typo or the standard is missing the Planning Coordinator as an applicable entity. Please clarify.

Response: Thank you for your comment. The majority of industry comments support the SDT proposal not to include a Requirement allowing the Planning Coordinator to request a model review for a unit not specified in the standard Applicability section. Governor response is not consistent from one frequency excursion event to the next for several reasons, such as the operating condition of the plant, ambient temperature, the number of coal pulverizes on line, the pre-contingency MW output of the unit, etc. Therefore, the SDT does not believe it is appropriate to include such a Requirement in MOD-027-1. Both the Planning Coordinator and the Transmission Planner can still request a model review however the review is not mandatory by standard requirements.

The SDT recognizes that modeling improvements are needed in the Eastern Interconnection to correctly represent the frequency response. This standard will require verification of the frequency response model for at least 80% of the interconnection MVA, which will result in improved modeling. The purpose

Organization	Yes or No	Question 2 Comment
of the standard is to improve the modeling of the frequency response. Other standards are responsible for improving the frequency response. It is true that the Planning Coordinator is not an applicable FME in the standard since the Planning Coordinator is not assigned responsibility for any of the Requirements.

3. The SDT discussed if MOD-027-1 should also include verification of excitation control systems of synchronous condensers. Synchronous condensers are not currently addressed in the NERC Registry Criteria. Synchronous condensers are not mentioned in the Generation Verification SAR. On an MVA capacity basis, the penetration of synchronous condensers in North America is extremely low. It is common for Transmission Owners to be the owners of synchronous condensers. As such, the peer review draft requirements would not make sense. Therefore, the team decided that a more appropriate strategy would be to include synchronous condensers with other transmission system dynamic reactive devices (such as SVCs, STATCOMs, etc.) in a separate SAR.

Do you agree with the proposal to not include the verification of synchronous condensers in MOD-027-1?

Summary Consideration: This question was not intended to be on the Comment Form. The SDT recognizes that synchronous condensers do not contain frequency control elements and regrets the administrative error.

Indeck Energy Services	Yes	The standard as drafted contains regional standards (ERCOT vs WECC). The ROP doesn't permit members of one region to vote on regional requirements for other regions. Regional standards will be required to implement regional differences.
Response: Thank you for your comment. The SDT believes that it has accounted for units that are critical to the control of frequency by establishing interconnection specific MVA thresholds corresponding to 80% or greater of the installed MVA generation capacity. Even though the MVA threshold is different for each Interconnection, the penetration of connected MVA is essentially the same. It should be recognized that a Regional standard also have to comply with the requirements of a National standard.		
Oncor Electric Delivery Company LLC	Yes	Oncor is in general agreement of the standards however, Oncor believes that the Transmission Planner in the ERCOT Region is not the appropriate receiving entity of test verification data from the Generator Owner. Oncor believes that a regional variance should be given strong consideration such that the Planning Authority would be the receiving entity of all testing data from the Generator Owner. This would align with current ERCOT protocols, operating guide and planning guide at it relates to resource testing and verification.
Response: Thank you for your comment. The SDT believes that it is appropriate to make the Transmission Planner responsible. The Transmission Planner can delegate work as appropriate.		
Indiana Municipal Power Agency		
Los Angeles Department of Water and Power		LADWP does not have a position on this question at this time.

6. Do you have any other questions or concerns with the proposed standards that have not been addressed? If yes, please explain.

Summary Consideration: Based in part on industry comments received to this question, the following modifications to the proposed standard have been made by the SDT. (note: some of these issues and listed modifications are addressed by other consideration of comments questions):

1) Corrections of various typos in the body of the standard, the VSLs, and in Attachment 1
2) Extended the time to comply with Requirement 1 from 30 to 90 days
3) Modified Attachment 1 (Periodicity Table) to address units which are always base loaded (by definition a base loaded unit is considered verified).
4) Modified Attachment 1 (Periodicity Table) to clarify establishing the Initial Ten Year Unit Verification Period Start Date
5) Reduced the maximum time allowed between capture of an event and completing model verification from two years to one year.
6) Referenced the NERC GADS document for references to capacity factor in the draft standard.
7) Included partial load rejection as a potential test to obtain a recording of the equipment response to be used in model verification.

Organization	Yes or No	Question 6 Comment
LG&E and KU Energy		
Northeast Power Coordinating Council	Yes	In the Applicability Section, why the differences between the Eastern Interconnection/Quebec and WECC in generating unit and plant sizes specified?
Response: Thank you for your comment. The SDT believes that the proposed applicability thresholds will result in substantial accuracy improvement to the governor models and associated Reliability based limits determined by dynamic simulations, while not unduly mandating costly and time consuming verification efforts. As a basis, the SDT recognized that the governor models and model data are already collected through the processes identified in MOD-012 and MOD-013. These models and data should, with few exceptions, already result in a quality dynamics database. However, as confirmed through the		

Organization	Yes or No	Question 6 Comment
Field Test initiated by the Phase III-IV SDT, performing the activities specified in the draft standard is expected to result in an improvement of the accuracy of the governor models used in dynamic simulations. Utilizing engineering judgment, based in part on recent entity experiences in verifying governor models, the SDT is proposing to require verification of governor models associated with 80% or greater of the connected MVA per Interconnection. Given the increasing importance of renewable generation plants comprised of several small units, the SDT also proposes requiring verification of these plants and has added language to the Applicability section to capture this intent.		
Imperial Irrigation District (IID)	Yes	IT WOULD BE EFFECTIVE IF SDT WOULD CONSIDER PROVIDING A DETAILED EXAMPLE OF DYNAMIC MODELS, GRAPHS, AND INFORMATION REQUIRED AS PART OF THIS STANDARD.
Response: Thank you for your comment. This standard is not a guideline for developing model parameters. The standard describes what should be done and specifically is not perscriptive. The SDT recognizes expertise is needed to perform model verification for specific types of equipment.		
IRC Standards Review Committee (joint comments)		
Pepco Holdings Inc Affiliates		
NERC System Protection and Control Subcommittee		
Midwest Reliability Organization's NERC Standards Review Forum (NSRF)	Yes	Please consider the following comments:Footnote 2 - Include the explanation that “average capacity factor is the average of all the unit or plant output values compared to the gross nameplate rating value”, since historically some have asked how this factor is defined and calculated”.Requirement R3, bullet 2 - Append wording like, “such as a model is unusable by the Transmission Planner, dubious model type, abnormal model parameter values, and unusual simulation results” to the text, “technical concerns with the verification documentation”. Attachment 1, Row 6 (New or Existing Generator Unit) -Replace “Excitation control system model” with “Turbine/governor and load control or active/frequency control system model”. Comments: We have a number of questions and concerns as follows: o While the Standard uses the word “verified” and “verification” loosely, it is not precisely clear what a GO would have to do to satisfy the verification requirements in R2. Would each of the Time Constants, Forward and/or Feedback Gains, Dead-

Organization	Yes or No	Question 6 Comment
		band Excitation Limits, Saturation Characteristics, etc. to be determined separately each on its own? Or are these parameters taken as a whole so long as their combined effect produces a response characteristic in a simulation that matches the recorded test response during an off-line step-input test? o The response of a unit is dependent on the instantaneous conditions of the external system to which it is connected at the time of the disturbance, in addition to the inherent response characteristics as built. This may result in the modeling parameters derived based on on-line frequency/Load excursion test not being unique. o If a simulation study results in response characteristics that does not match an on-line step input test response, can the GO arbitrarily adjust one or more of the model parametric values to produce a matching response, and send the Transmission Planner these adjusted values as the model data? We have concern about whether this Standard is cost efficient to the industry. The transient stability dynamic modeling for turbine/governor was developed under the assumption of limited bandwidth validity and approximations. The other equipment models in the simulation, e.g. generators, excitation controls, SVCs, HVDC Converters, boiler/burner controls, etc. are all approximations without any correlated degree of accuracies in comparison to each other. On the other hand, the verification efforts are expected to cost quite a bit to GOs, especially for older units whose vendors/manufacturers may not even be in existence any more.
Response: Thank you for your comment. In response to this and other industry comments, the SDT has referenced the capacity factor calculation specified in Appendix F of the GADS Data Reporting Instructions on the NERC website. **Regarding the rest of your comments, the SDT offers the following response:** **The SDT constructed text language to ensure the Transmission Planner can address any technical concern with the Generator Owner. Since the Generator Owner is responsible for the model, the Generator Owner can respond that the technical concern raised is unfounded.** **The SDT regrets the Attachment 1 typographical error and will correct.** **The turbine/governor and load control or active power/frequency control response is a characteristic of the generator equipment, not the external system. The intent is that the Generator Owner should strive to match the predicted response of the complete model with the actual response recorded. Verification of individual parameters should not be the emphasis of the model verification effort.**		

Organization	Yes or No	Question 6 Comment
It is true that modifying a parameter will alter the predicted response of the model however, an individual parameter should not be assigned an incorrect value for the sake of verifying the model. Ideally, model parameters should be altered to more accurately reflect the physical characteristic represented. However, based on actual experience in the WECC region, the ultimate goal of the verification process is to sufficiently refine model parameters to consistently approximate equipment response to a frequency excursion. The SDT recognizes expertise is required to perform model verification and this is the reason why the model verification periodicity proposed is a 10 year cycle. **Especially considering that the units contained in the Applicability is a subset of the NERC Compliance Registry, the SDT believes that the drafted standard is cost efficient to the industry. As a basis, the SDT recognized that the governor models and model data are already collected through the processes identified in MOD-012 and MOD-013. These models and data should, with few exceptions, already result in a quality dynamics database. However, as confirmed through the Field Test initiated by the Phase III-IV SDT, performing the activities specified in the draft standard is expected to result in improved accuracy of the governor model used in dynamic simulation. Utilizing engineering judgment, based in part on recent entity experience with verifying governor models, the SDT is proposing to require verification of governor models associated with 80% or greater of the connected MVA in each Interconnection. Given the increasing importance of renewable generation plants comprised of several small units, the SDT also proposes requiring verification of these plants and has added language to the Applicability section to capture this intent.**		
SPP Reliability Standards Development Team	Yes	In the VSLS for R2 there is a “no” that needs to be deleted. In VSLS for R2 and R4 there is a footnote referenced on page 2 of the draft standard so it shouldn’t be included here as well.
Response: Thank you for your comment. The SDT believes that it has made the corrections you noted. Please review the current draft of the standard to make sure your concern was addressed.		
SERC Planning Standards Subcommittee		
Idaho Power-Power Production		WECC has an existing model validation policy that is well defined and established. This project documentation does not specifically state that MOD-012 and MOD-013 would be retired. If not, this policy would be redundant with the existing WECC policy.
Response: Thank you for your comment. MOD-027 is a verification requirement. MOD-012 and MOD-013 are data submittal requirements. There are no plans to retire MOD-012 and MOD-013.		
Santee Cooper		

Organization	Yes or No	Question 6 Comment
PPL Generation	Yes	PPL Generation suggests the following changes:1. Increase the capacity factor threshold identified in the Applicability Section from the current 5% to 10%. Otherwise, ambient monitoring may be required for an excessively long period.2. Allow the use of OEM-provided governor models and, if adequate, existing models to satisfy the requirement in R2. OEM models can have equivalent-or-better validity than on-line testing.3. Define what response is expected to be documented for Requirement 2.1.1 (as pertaining to a time-frame of 30 seconds or less, and to sudden frequency dips, not step-increases). Units have an immediate response (e.g. opening the control valves) and a long-term response (e.g. ramping-up the coal feed). Governors (the subject of this standard) deal only with the former category. Ambient monitoring should eventually provide a frequency-dip event to analyze, but the same is not true for opposite-direction events.4. Should the recorded response in Requirement 2.1.1 be the predicted response? It appears that the on-line response and the recorded response are the same thing.5. In Requirement 2.1.1, clarify under what circumstances a lack of response constitutes suitable verification, e.g. experiencing a frequency drop for units running valves-wide-open or CTGs at baseload firing temperature.

Response: Thank you for your comment. Q1: The SDT believes that the 5% capacity factor threshold functions to establish a balance between verifying modeling information for units that play an important role in the reliability of the BES and units that report information which is not verified because they are seldom online and have a relatively diminished reliability role. While it is true that units that have a capacity factor that is marginally greater than 5% could result in a long ambient monitoring period before capturing a response suitable for model verification, the SDT believes that it is better to wait for a suitable event as opposed to requiring a on-line staged test that Generator Owners are not comfortable performing and even argue is not an accurate test. However, in part due to recognizing that relatively low capacity factor units (though greater than 5%), the SDT has added to the standard the ability of the Generator Owner to perform a partial load rejection test. As with the reference change test, the partial load rejection test is an optional strategy. The Generator Owner can choose to wait on an ambient event when the unit is in a mode that is expected to be able to respond to the frequency excursion. Also, as noted in an added footnote in the current draft of the standard, differences between the control mode tested and the final simulation model must be identified, particularly when analyzing load rejection data. Most controls change gains or have a set point runback which takes effect when the breaker opens. Load or set point controls will also not be in effect once the breaker opens. Some method of accounting for these differences must be presented if the final model is not validated from on load data under the normal operating conditions under which the model is expected to apply

Q2: OEM models are not verified and do not capture potential load control or MW setpoint functions.

Q3: Please reference modification of 2.1.1 that clarifies the SDT intent of comparing predicted model response to actual equipment response. The SDT did not specify the timeframe for model verification, instead leaving it to the expert performing model verification to establish. The standard is constructed such that either an over frequency or under frequency event is allowed to be used for model verification. The SDT believes the industry understands that model

Organization	Yes or No	Question 6 Comment
validity during normal stability studies is less than 30 seconds. **Q4 The SDT has modified Requirement 2.1.1 in response to your comment.** **Q5: The SDT has modified Attachment 1 (Periodicity Table) to address units which are always base loaded (by definition a base loaded unit is considered verified).**		
Dominion	Yes	While we understand that a significant portion of the industry supports the 5% capacity factor threshold, we believe that this term is subject to different uses by various entities and parties, particularly biased as to whether one is discussing capacity or energy. We suggest that, for the purpose of this standard, capacity factor be described as defined by NERC GADS.Please elaborate on Requirement 2.1.5. Also, we believe that “Load Control” and “AGC” are the same.R3, the third bullet, we suggest that “did not match the recorded response for three or more transmission system events be changed to “did not approximate the recorded response for three or more transmission system events “We believe there needs to be an exception allowed if a frequency event does not occur in 10 years.What is “staged test” mentioned on Attachment 1? Also Attachment 1 is very confusing and should be rewritten.
Response: Thank you for your comment. The SDT has incorporated your suggestion and updated footnote 2 by referring to the NERC GADS definition (Attachment F). **Load Control and AGC are not the same. Load Control is a plant control also known as MW control. AGC is a Balancing Authority level control.** **The SDT incorporated your recommendation for R3.** **Based on this and others comments, the SDT realized there was an omission in Attachment 1 (the Periodicity Table). Attachment 1 has been revised to make it clear that if a unit is not in a control mode with MW output responsive to a frequency excursion during the 10 year verification cycle, then the entity can continue to wait for this scenario to occur.** **The “staged test” mentioned in Attachment 1 is the “on-line frequency reference change” test referenced in 2.1.1. The SDT has made several corrections and modifications to Attachment 1 in an attempt to make the document easier to understand, including clarifying the Initial Ten Year Unit Verification Period. Also, the SDT has added to the standard the ability of the Generator Owner to perform a partial load rejection test. As with the reference change test, the partial load rejection test is an optional strategy. The Generator Owner can always wait for a frequency excursion to occur when the unit is in a mode that it would be expected to govern. Please review the revised version and provide additional feedback during the next posting.**		
FirstEnergy	Yes	As a result of the 2010 NERC Generator Governor Survey, it became clear that many nuclear units (and I

Organization	Yes or No	Question 6 Comment
		believe all of the BWR units) do not respond to changes grid frequency because their governors are controlling steam pressure. The standard should have a specific exclusion for nuclear generating units which have governors that operate to control steam pressure and which do not respond to grid frequency deviations. This is consistent with the Eastern Interconnection Reliability Assessment Group (ERAG) Multi-Regional Modeling Working Group Procedure Manual version 5, May 6, 2010 which states in Appendix II, Section B Dynamic Modeling Requirements, Paragraph 2b) that "Turbine-governor representation shall be omitted for units that do not regulate frequency such as base load nuclear units, pumped storage units...". For those nuclear units that are able to respond to overfrequency events there is a possibility that a response to a system transient may not be seen during a ten year period. Since responding to an overfrequency event will result in a drop in unit load and a corresponding change in reactivity, the governor control dead band, which is set to minimize the possibility of a spurious reactivity change, could be large enough to ignore an event that meets the frequency excursion threshold (for example a 0.1 Hz dead band would ride through on a 0.07 Hz excursion). Likewise a nuclear unit would not perform a frequency reference change input test with the unit on-line because of the resulting change in reactivity. Would injecting a frequency signal to the EHC during off-line calibration and noting the response be acceptable?
Response: Thank you for your comment. The SDT has added an additional row to Attachment 1 (the Periodicity Table) which specifies units that do not operate in a control mode, except during normal start up and shut down, that would result in a turbine/governor and load control or active power/frequency control mode response (such as valves wide open or base loaded) are not required to be verified. The SDT believes this modification will preclude nuclear units from having to perform model verification; and instead show compliance with the Requirement by maintaining documentation explaining the unit's operating mode.		
SERC Dynamics Review Sub-committee	Yes	For Requirement R1, the SERC DRS recommends that the time be changed from 30 calendar days to 90 calendar days. Relative to the time allowed for accomplishing other requirements, there is no benefit for only allowing 30 days for requirement R1. 90 days would allow for more communications between the requesting Generator Owner, the providing Transmission Planner and other entities (such as the software vendor or turbine manufacturer) to coordinate obtaining the necessary items listed in requirement R1. Additionally, 90 days would be consistent with the "more than 90 days" VSL level for this requirement.Relative to R3, bullet three, this covers the situation where predicted response does not match recorded response for three or more events. We suggest this be one or more events because significant events are so rare in the eastern interconnection.Relative to the VSL for R2, the first paragraph in the "Severe column" has confusing words "failed to provide the verified models no more than 90 days late." We

Organization	Yes or No	Question 6 Comment
		recommend changing the words to "provided more than 90 days late".In multiple locations in Attachment 1, 730 days seems to be an excessive amount of time from capturing an event to sending documentation to the TP. We recommend a period of 180 days.In two places in Attachment 1, excitation control system is referred to. Shouldn't this be turbine/ governor control system?
Response: Thank you for your comment. The SDT corrected the discrepancy between R1 and the R1 Lower VSL by changing R1 language to read "within 90 calendar days". The SDT believes that the 0.05 hertz frequency deviation for the Eastern Interconnection will be exceeded often enough to verify consistent unit equipment response to frequency excursions. As an example, in October 2010, there were 12 Eastern Interconnection frequency excursions that exceeded 0.05 hertz. Based on this and other comments, the "Severe" VSL language for R2 has been revised. The SDT decided to modify periodicity to indicate that from the date of the last recorded frequency excursion response, the Generator Owner has one year to verify the model. It is expected that the Generator Owner will collect several frequency excursion responses however, the standard only requires model verification within one year of the frequency excursion collected for compliance within the 10 year timeframe. The Attachment 1 copy and paste errors with references to "excitation control systems" have been corrected.		
NERC Staff	Yes	It is not possible to accurately model system frequency response with valid models for only 80% of the installed system capacity. System frequency perturbations are experienced by and responded to by all frequency responsive generators, regardless of interconnection voltage. The standard should be applicable to all units greater than 20 MVA and all plants greater than 75 MVA regardless of interconnection voltage. Per SDT estimates, this will assure accurate modeling for approximately 95% of installed capacity. The interconnection voltage is not relevant to frequency response and should not be a condition for applicability. We also disagree with the exemption for units with <5% capacity factor for the past three years. Some large, less efficient units may only run during peak load conditions giving them lower capacity factors. However, those will also be the units loaded at lower levels, making them the units with head-room to respond, thereby making them critical to frequency response during those conditions. They may be of a lower priority in the implementation plan.The violation risk factors associated with Requirements R1 through R5 should be at least medium. Use of invalid models resulting from violation of these standards can produce erroneous results and adversely affect assumptions of the electrical state or capability of the bulk electric system, or the ability to effectively control or restore the bulk electric system, particularly under emergency, abnormal, or restorative conditions. This can result in operating beyond the true stability limits

Organization	Yes or No	Question 6 Comment
		of the system.The models validated by application of this standard are used in both the long-term planning and the operations planning horizon. The time horizon for Requirements R1 through R5 should include the operations planning horizon.In Requirement R2, part 2.1.1, it appears the comparison should be between recorded response and simulated modeled response rather than between on-line response and recorded response. Further clarification is necessary.In Requirement R4, when the turbine/governor and load control or active power/frequency control system are modified as part of a planned project, the Generator Owner should be required to provide a revised model prior to placing the revised equipment back in service.In Requirement R5, part 5.2, the reference to negligible transients is not measurable. We recommend modifying this to ". . . results in a response that varies less than the numerical stability of the program used for the simulation."In Requirement R5, part 5.3, the introductory phrase "For an otherwise stable simulation" is not necessary and a potential source of confusion. We recommend deleting this phrase and starting the sentence with "A disturbance simulation results in . . ."The SDT should consider use of the word "verification" versus "validation" and assure that the term used in this standard is consistent with other standards.Validation of models only every 10 years is far too long a period. Models should be calibrated as often as possible, preferably with every significant system frequency disturbance. Experience in the WECC region has shown that validation by observation against system events yields more accurate model performance than relying on a single staged test because the events provide for a wide variety of system conditions for the comparison. The background material suggests that more frequent validation against frequency events is impractical because of the scarcity of events. That is incorrect; there are several frequency events each year in all of the interconnections where frequency deviates beyond the short-term trigger limits set forth by the Resources Subcommittee, which indicate that generators should have exceeded the traditional deadband of Â±36 mHz and responded. The initial completion of validation for all applicable units should be within 5 years, not 10 years. The 10 year time is excessive.Validation or calibration after a measured system event should occur within 6 to 9 months of the event, not 2 years. Experience in the WECC regions shows this to be sufficient and achievable.

Response: Although the standard does not require verification of modeled frequency response for all units/plants smaller than the MVA nameplate rating thresholds listed in the Applicability section, it is expected that provided models are accurate.

The SDT believes that requiring verification of small size MVA units and units with a small (< 5%) capacity factor is not practical and would deplete the industry's limited verification capability for very little reliability benefit as concluded from the field testing involving 4 regions (WECC, SERC, ERCOT, and the FRCC) initiated by the Phase III-IV SDT and completed July 2007. Units with low capacity factors would seldom be running during significant frequency

Organization	Yes or No	Question 6 Comment
events, and measurements of ambient response data needed for verification would be unavailable because the units were likely not running. With regard to the interconnection voltage identified, the standard does not deviate from the NERC registration requirement. The SDT believes that the 10 year period provides is adequate for both initial verification and re-verification given that the standard also specifies re-verification when equipment changes are made that would affect the units' frequency response. The SDT believes that the lower VRF is appropriate because the model is suppose to be accurate even if the model is not verified. The verification merely provides assurance that the model is accurate. Violation of these requirements are not expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system, which is consistent with the low risk level guideline established. As a comparison, MOD-10 and MOD-12 requirements specify providing a complete set of data for all entity facilities and/or generators. This typically will involve dozens if not hundreds of generators whereas MOD-027 requirements only specify providing data for a single generator unit. Because model verification act ivies typically take months if not years to perform, the time horizon of “Long Term Planning” is appropriate. The SDT thanks you for the comment regarding requirement R2 subpart 2.1.1. The standard has been corrected to require comparison between modeled and measured response. The SDT agrees that models should be revised when equipment is changed. The requirement for providing accurate models is specified by MOD-012. Verification cannot occur until after the revised equipment is in service. There is no known industry practice to take into account the numerical stability of the program. Also, it is left up to the judgment of the expert reviewing the study results to determine if the transients are negligible. Utilizing a stable simulation is necessary to determine if the model will adversely impact the robustness of dynamic modeling to be performed. If an unstable simulation is used as basis, then there is no way to determine additional negative response of the model that is being assessed for useability. The SDT agrees that the term verification is a better term for the requirements of this standard than validation. The standard as currently drafted uses the term verification, not validation. Also, the SDT does recognize that there are several frequency events each year which results in frequency deviations that would exceed traditional deadband settings. It was not the intention of the SDT to suggest otherwise. However, a unit must be both on-line and in a proper operating state so that meaningful MW response recordings can be collected. Regarding the 2 year time frame for validation after a measured system event is recorded, Attachment 1 has been revised to provide only a 1 year period after the event is recorded. This time period provides the Generator Owner time to be notified of the event and assess the impact. The SDT intent was to recognize that it would be a challenge in some Interconnections for a suitable frequency excursion to occur with the unit in a responsive operating state. Based on industry responses to both MOD-027 and MOD-026 postings, the SDT believes that the majority of industry agrees the proposed 10 year periodicity		

Organization	Yes or No	Question 6 Comment
verification cycle is appropriate.		
Public Service Enterprise Group	Yes	Nuclear units are often prohibited by their NRC licenses from having their governors engaged for frequency response. Since the Purpose of the standard is to "accurately represent generator unit real power response to system frequency," nuclear units with the restriction described above will have no response. These units should be explicitly exempted from the standard in the Applicability section.
Response: The SDT has added an additional row to Attachment 1 (the Periodicity Table) which specifies units that do not operate in a control mode, except during normal start up and shut down, that would result in a turbine/governor and load control or active power/frequency control mode response (such as valves wide open or base loaded) are not required to be verified. The SDT believes this modification will preclude nuclear units from having to perform model verification; and instead show compliance with the Requirement by maintaining documentation explaining the unit's operating mode.		
SERC Generation sub-committee		
ACES Power Members		
Arizona Public Service Company	No	30 minutes are more than adequate. All components reach steady state temperatures within that time. There is no need to be there more than 30 minutes.
Response: Thank you for your comment. The SDT believes this comment was intended for another standard.		
Westar Energy	No	
Southern Company	Yes	1) Requirement 2.1.1 requires a comparison of the on-line response to the recorded response. The comparison needs to be between the on-line recorded response and the model simulated response. 2) The VSL table for R1 has time frames that don't match the Requirement R1 30 calendar day time frame. 3) The first paragraph of the Severe VSL for R2 needs to be split into two parts to form an additional OR statement which reads: "The GO failed to provide its verified model(s)" OR "The GO provided the verified model(s) more than 90 calendar days late to its TP in accordance with the periodicity timeframe specificed in MOD-027 Attachment 1." 4) The second paragraph of the Severe VSL for R3 is not grammatically correct and does not match the Requirement R3. Please consider changing it to read: "The GO's written response failed to contain one of the following: the technical basis for maintaining the current model, a list of future

Organization	Yes or No	Question 6 Comment
		model changes, or a plan to perform another model verification." 5) For the Lower, Moderate, and Higher VSLs for R5, please consider placing "including a technical description if the model is not useable" within parenthesis to aide in understanding the measure. 6) For the second paragraph of the Severe VSL for R5, please consider rephrasing to read: "The TP provided a written response without including confirmation of all specified model criteria listed in R5, parts 5.1 through 5.3." 7) In Requirement R4, it is unclear how an entity could revise model data without performing a model verification - (the requirement is written to either revise model data or plan to perform model verification) 8) Attachment 1 contains multiple copy/paste errors (from MOD-026) and was difficult to constructively comment on due to these. Those items that need correcting include: 8a) The "Facility" column entries need to better describe the conditions that are being detailed in the "Condition" column. Can some additional words better describe the each row? [for example, the row 2 could have the title 1-existing unit, no sister unit exceptions; row 3 could have the title 2-existing unit, sister unit exception applies, etc.] 8b) The use of "exceptions" in the Draft 1, row 2 is not defined and it is unclear what exceptions may apply. 8c) Can the third AND element of the Condition described in row 2 be written more simply by beginning "While the unit is operating in a frequency responsive mode and is subjected to at least one BES frequency excursion as specified in Criteria 1 above." This change could be used in multiple entries of this table to simply the reading and understanding. 8d) For row 3 (with exceptions row), we suggest eliminating the requirement for the same physical location being true for allow "sisterhood" - an entity is likely to own multiple units at different physical locations which are identical. 8e) Row 5 contains "new excitation control system equipment" - shouldn't this be "new governor/load control equipment"? 8f) Row 7 contains "Excitation control system model" rather than "Gov/Load control model"

Response: Thank you for your comment. 1) The SDT revised Requirement 2.1.1.

2) Based on this and other comments, the SDT lengthened the R1 time frame to 90 days to match the time frame in the associated VSL.

3) The SDT revised Severe VSL language for R2.

4) The SDT agrees the incorrect grammar and has incorporated language similar to what you suggested.

5) The SDT agrees and has incorporated suggested language.

6) The SDT agrees and has incorporated suggested language.

7) In most instances, verification of the model will be required instead of revising model data. An instance where revising model data can suffice is if MW set

Organization	Yes or No	Question 6 Comment
point control is implemented instead of droop control. **8) For 8a) and 8b) NERC has discouraged the use of the term "sister unit" and other folksy terms therefore the SDT believes current language is sufficient. For 8c) The SDT incorporated suggested language. For 8d) The SDT believes that the proxy unit philosophy should be limited to units at the same physical location to improve the likelihood of a legitimate inspection walkdown of equipment and settings is performed by the same individual ensuring that the units are actually "proxy " units. For 8e and 8f) The SDT regrets the copy and paste errors and has corrected them.**		
Tennessee Valley Authority GO	Yes	It is our opinion that a 20MVA machine is too small to be able to significantly impact a frequency excursion. A technical basis for including units as small as 20MVA in all regions needs to be provided. NERC is focusing on standard requirements that have significant impacts on system reliability, and including units this small seems to be inconsistent with this philosophy. 2)
Response: . Thank you for your comment. For the Eastern Interconnection, 20 MVA rated units only have to be verified if they are part of a plant that is 100 MVA or greater. The SDT believes that 100 MVA plants in the Eastern Interconnection are significant. Also, 20 MVA plants are included in the NERC Registry Criteria.		
Luminant Power	No	
Lakeland Electric		
Salt River Project	No	
PacifiCorp	Yes	Section 4.2 of proposed Standard MOD-027-1 provides that units or plants with an average capacity factor greater than 5% over the last three calendar years, that also meet other characteristics, will be considered "applicable units." However, the term "capacity factor" is not defined in proposed Standard MOD-027-1. Proposed Standard MOD-026-1, on the other hand, uses the term "Capacity Factor," suggesting it is a defined term but without an accompanying definition in the NERC Glossary of Terms or otherwise. PacifiCorp believes that the Standards Drafting Teams should make the use of the term "capacity factor" consistent across all proposed standards and define the term as necessary for additional clarity.
Response: Thank you for your comment. The SDT has addressed your suggestion and updated footnote 2 by referring to the NERC GADS definition of capacity factor, in both MOD-026 and MOD-027.		

Organization	Yes or No	Question 6 Comment
South Carolina Electric and Gas	Yes	How are sister units to be handled? Do they all need to be tested individually. Also, are all the units counted individually when calculating the percent of units in the implementation schedule?
Response: Thank you for your comment. Attachment 1 has been revised for clarity regarding the requirement as it pertains to equivalent (sister) units. In determining the percentage of fleet generating units satisfying verification requirements for each implementation schedule effective date specified, all equivalent units are counted as verified if Attachment 1 conditions specified for equivalent units are satisfied.		
APS		being intentionally left blank (no answer to be provided)
Associated Electric Cooperative, Inc.	Yes	1) Item 2.1.1 should be reworded: ".......model verification activities including the on-line RECORDED response compared to the MODEL'S SIMULATED response....."2) It is anticipated that many GO/GOP's may not have industry experience with modeling concepts and model verification techniques. It may be beneficial to provide an appendix for reference that basically describes the anticipated mechanics of how the verification is performed. This may help provide consistency for the verification process.
Response: Thank you for your comment. Requirement R2 subpart 2.1.1 language has been revised. The standard describes what should be done and specifically is not prescriptive. The SDT recognizes expertise is needed to perform model verification for specific types of equipment. Prior to developing the standard SAR, several entities in 4 NERC Regions field tested the concept and demonstrated that verification is practical. Also note that there is an extensive Reference section (Section G) listing several technical papers that address modeling techniques.		
Dynegy Inc.	Yes	1) In R2.1.1 it is not clear if the “recorded” response refers to the model response. Consider rewording this requirement to make clear the meaning of “recorded”. 2.) Attachment 1 seems to give two options for periodicity of verifying the model frequency control functions for existing generators. One option is to record data for a BES frequency excursion during a ten year calendar period. A second option is to record such data after the ten year period if a suitable BES frequency excursion does not occur. Does this mean existing generators can wait indefinitely for a suitable frequency excursion to verify the model response?
Response: Thank you for your comment. The wording in R2 subpart 2.1.1 has been revised. **2) Given the importance of verifying the model based upon actual performance while synchronized to the system, the standard is written to allow ample time for the generator to experience a suitable frequency excursion with the unit on-line and responsive. This means that a GO can wait longer than 10 years for a suitable frequency excursion with the unit on-line and in a mode that it is expected to governor. Also, within the 10 year recurring window, optional**		

Organization	Yes or No	Question 6 Comment
staged tests can be conducted (reference change test or partial load rejection test) in lieu of monitoring for an acceptable ambient event. Since industry has expressed concern, Attachment 1 has been revised to make clear generating units normally operated as a base loaded unit or with valves wide open do not need to be verified. Instead, a statement describing the units operating condition is sufficient for compliance with the requirement. Also, other elements of Attachment 1 have been revised for clarity, including establishing the Initial Ten Year Unit Verification Period.		
New York Independent System Operator		
Tri-State Generation and Transmission, In.	No	
Cowlitz County PUD	No	
Xcel Energy	No	
Lakeland Electric		
Exelon	Yes	Exelon strongly suggests that the SDT coordinate this revised Standard with the Nuclear Regulatory Commission (NRC) to preclude any challenges to the licensing basis of any of the nuclear generating facilities.The proposed NERC Standard MOD-027-1 should have a specific exclusion for nuclear generating units which have governors that operate to control steam pressure and which do not respond to grid frequency deviations. As detailed in a memorandum from Jesus (Nano) Sierrra (FERC) to John Odom (ERAG Management Committee Chair), "Follow-up on the Provision of Primary Frequency Response by Nuclear Units in the ERAG-MMWG Dynamic Models," dated April 27, 2011, most all generating units do not respond to frequency deviations; however, there are some nuclear unit designs that do have limited response to under frequency conditions. It is important to note that even if a nuclear unit' s governor design does have limited response to grid frequency deviations, the nuclear unit is administratively restricted by their respective NRC operating license requirements to 100% thermal power. It is not clear from the proposed Standard MOD-027-1 or the Implementation Plan the SDT intended implementation timeline for the first verification period. That is, when must Requirement R2 be completed for the first 25% of the Generator Owner's applicable units? The second 25%? Etc. It is confusing when

Organization	Yes or No	Question 6 Comment
		considering the wording in Section A.5, "Effective Date:" combined with the wording in Attachment 1, Criteria 2 of the Standard. In addition, the Implementation Plan does not provide any further guidance.Is the intent that the staggered percentage implementation provides the start time for the generating units to complete R2 within a following ten year period? This would allow the applicable units to modify/install recording equipment and then set T=0 to then start the ten year staggered verification period.ORIs the intent to short cycle the initial verification period during implementation based on the percentage of units and then set up a ten year staggered verification period thereafter?
Response: Thank you for your comment. The SDT has added an additional row to Attachment 1 (the Periodicity Table) which specifies units that do not operate in a control mode, except during normal start up and shut down, that would result in a turbine/governor and load control or active power/frequency control mode response (such as valves wide open or base loaded) are not required to be verified. The SDT believes this modification will preclude nuclear units from having to perform model verification; and instead show compliance with the Requirement by maintaining documentation explaining the unit's operating mode **Regarding the rest of your comment, Attachment 1 has been revised for clarity and to better reflect the intent of the Implementation Plan. Attachment 1 Criteria 2 has been revised to incorporate the Implementation Plan 9-year transition period schedule including guidance for compliance.**		
American Wind Energy Association	No	
Tacoma Power	No	
Georgia Transmission Corporation	Yes	Have software manufacturers agreed to provide their models as described in R1?
Response: Thank you for your comment. Yes, the major software manufacturers have agreed to provide their models as described in R1. No later than by the effective date of the standard, software manufacturers' model information can be obtained from them by entering into the agreements they require.		
Austin Energy	Yes	Since dynamic data for old units is often not available, the SDT may consider allowing the use of typical or generic modeling parameters for these units.
Response: Thank you for your comment. If the unit is covered by the proposed Applicability of the draft standard, then the model can still be verified in		

Organization	Yes or No	Question 6 Comment
accordance with the Requirements specified. This is true even if existing dynamic data for an older unit (submitted per the submission Requirements of MOD-012 and MOD-013) is typical or generic data.		
Wisconsin Electric	Yes	It is not clear how this standard would be applied to wind generators. They should perhaps be specifically exempted from these requirements.
Response: Thank you for your comment. Some wind equipment have controls that can respond to a frequency excursion. For wind equipment that does not possess this capability, the SDT has added another row to Attachment 1 (the Periodicity Table) defining requirement exceptions for units that cannot control frequency. For these units compliance with the Requirement is shown by maintaining documentation explaining the unit's operating limitations.		
Great River Energy		
BC Hydro	Yes	The standard apparently favours ambient monitoring as a verification method. While this method has certain advantages over methods traditionally used to verify response of turbine-governors (off-line and on-line step tests), it should be well understood that its implemention is associated with additional costs and difficulties. The question is how would GOs make use of ambient monitoring data to verify the models? GOs are responsible only for equipment models and would not normally have overall system models which are necessary to evaluate the results of ambient monitoring. That puts the focus back on traditional approaches.
Response: Thank you for your comment. Software tools are available for use to record response at the generator terminals (or highside of the GSU) for model verification. The response of the modeled generator to the applied signal can be used to demonstrate that model performance matches measured performance. Overall system model verification is not required to verify the individual generator model.		
Northeast Utilities	Yes	In the Applicability Section, why the differences between the Eastern Interconnection/Quebec and WECC in generating unit and plant sizes specified?
Response: Thank you for your comment. The SDT also believes that the applicability section thresholds specified will result in substantial accuracy improvement to the governor models and associated Reliability based limits determined by dynamic simulations, while not unduly mandating costly and time consuming verification efforts. As a basis, the SDT recognized that the governor models and model data are already collected through the processes identified in MOD-012 and MOD-013. These models and data should, with few exceptions, already result in a quality dynamics database. However, as confirmed through the Field Test initiated by the Phase III-IV SDT, performing the activities specified in the draft standard is expected to result in an improvement of the accuracy of the governor models used in dynamic simulations. Utilizing engineering judgment, based in part on recent entity		

Organization	Yes or No	Question 6 Comment
experiences in verifying governor models, the SDT is proposing to require verification of governor models associated with 80% or greater of the connected MVA per Interconnection. Therefore, specific MVA thresholds which the SDT believes corresponds to 80% of connected MVA or greater for each Interconnection are proposed. Given the increasing importance of renewable generation plants comprised of several small units, the SDT also proposes requiring verification of these plants and has added language to the Applicability section to capture this intent.		
Constellation Power Generation	Yes	CPG is unsure as to what Requirement 2.1.1 is actually requiring. Please explain the difference between an on-line response to a frequency excursion vs. a recorded response. This sub requirement seems to be implying that each GO has the necessary equipment to capture an on line or recorded response. Is it the intent of the drafting team to force GOs to install equipment in order to comply with R2.1.1 along with the conditions found in Attachment 1? CPG would also like clarification on Requirement 2.1.5. Outer loop controls don't affect the governor control (frequency loop). Lastly, CPG would like the SDT to describe how a GO will know that a frequency excursion event occurred on the BES if their facility was unaffected and the facility did not have equipment sensitive enough to measure within .15 Hz.
Response: Thanks for your comment. The language of Requirement R2 subpart 2.1.1 has been revised. The equipment required to capture an on-line frequency response is relatively simple. Experience indicates the MW signal sent to a PI recording systems is adequate if the time resolution is set to two seconds or better. The effects of outer loop controls are important to understand to properly capture the frequency response of the unit. The SDT understands that a list of suitable frequency disturbances will be compiled by other NERC initiatives and made available to industry.		
Consolidated Edison Co. of NY, Inc.	Yes	In the Applicability Section, why the differences between the Eastern Interconnection/Quebec and WECC in generating unit and plant sizes specified?
Response: Thank you for your comment. The SDT also believes that the applicability section thresholds specified will result in substantial accuracy improvement to the governor models and associated Reliability based limits determined by dynamic simulations, while not unduly mandating costly and time consuming verification efforts. As a basis, the SDT recognized that the governor models and model data are already collected through the processes identified in MOD-012 and MOD-013. These models and data should, with few exceptions, already result in a quality dynamics database. However, as confirmed through the Field Test initiated by the Phase III-IV SDT, performing the activities specified in the draft standard is expected to result in an improvement of the accuracy of the governor models used in dynamic simulations. Utilizing engineering judgment, based in part on recent entity experiences in verifying governor models, the SDT is proposing to require verification of governor models associated with 80% or greater of the connected MVA per Interconnection. Therefore, specific MVA thresholds which the SDT believes corresponds to 80% of connected MVA or greater for each Interconnection are proposed. Given the increasing importance of renewable generation plants comprised of several small units, the SDT also proposes		

Organization	Yes or No	Question 6 Comment
requiring verification of these plants and has added language to the Applicability section to capture this intent.		
American Electric Power	Yes	Standard models may not be available for wind units and wind facilities (which appear to be within scope of 4.2), particularly aggregate reactive and frequency response controls. As a result, it might be difficult to obtain and provide such information.
Response: Thank you for your comment. Some wind equipment have controls that can respond to a frequency excursion for which non-proprietary models exist. For wind equipment that does not possess this capability, the SDT has added another row to Attachment 1 (the Periodicity Table) defining requirement exceptions for units that cannot control frequency. For these units compliance with the Requirement is shown by maintaining documentation explaining the unit's operating limitations.		
Ingleside Cogeneration LP	Yes	Like many Generator Owners, Ingleside Cogeneration LP has limited experience with transmission system modeling and scenario planning. Although in general we have a good working relationship with our Transmission Planner, MOD-027-1 may border on exchanging information which either entity may consider to be proprietary. In addition, the extra costs required to deploy recording equipment and to engage external experts to assist with frequency response planning are not budgeted. With this in mind, a priority deployment may be more appropriate - where the most critical facilities in each Region are evaluated first.
Response: Thank you for your comment. The information referenced by this standard needs to be shared between the Generator Owner and Transmission Owner to facilitate essential study work. The implementation plan provides sufficient time for budget planning. Specifically, the proposed phased implementation plan has effective dates of 3, 5, 7 and 9 years after appropriate regulatory approval.		
Wisconsin Public Service Corp	Yes	We have a number of questions and concerns as follows: o While the Standard uses the word "verified" and "verification" loosely, it is not precisely clear what a GO would have to do to satisfy the verification requirements in R2. Would each of the Time Constants, Forward and/or Feedback Gains, Dead-band Excitation Limits, Saturation Characteristics, etc. to be determined separately each on its own? Or are these parameters taken as a whole so long as their combined effect produces a response characteristic in a simulation that matches the recorded test response during an off-line step-input test? o The response of a unit is dependent on the instantaneous conditions of the external system to which it is connected at the time of the disturbance, in addition to the inherent response characteristics as built. This may result in the modeling parameters derived based on on-line frequency/Load excursion test not being unique. o If a simulation study results in response characteristics that does not match an on-line step input test response,

Organization	Yes or No	Question 6 Comment
		can the GO arbitrarily adjust one or more of the model parametric values to produce a matching response, and send the Transmission Planner these adjusted values as the model data? o We have concern about whether this Standard is cost efficient to the industry. The transient stability dynamic modeling for turbine/governor was developed under the assumption of limited bandwidth validity and approximations. The other equipment models in the simulation, e.g. generators, excitation controls, SVCs, HVDC Converters, boiler/burner controls, etc. are all approximations without any correlated degree of accuracies in comparison to each other. On the other hand, the verification efforts are expected to cost quite a bit to GOs, especially for older units whose vendors/manufacturers may not even be in existence any more.

Response: Thank you for your comment. The turbine/governor and load control or active power/frequency control response is a characteristic of the generator equipment, not the external system. The intent is that the Generator Owner should strive to match the predicted response of the complete model with the actual response recorded. Verification of individual parameters should not be the emphasis of the model verification effort. Also note an off-line step test is not allowed to be performed per the current draft language of the standard. The SDT is requiring either a) an on-line step in frequency reference test or b) ambient measurements for a naturally occurring frequency deviation – both of which ensure the effect of MW setpoint control is captured – or c) a partial load rejection test with the requirement that differences between the differences any modes that are disabled as soon as the generator breaker is opened (such as load or set point control).

It is true that modifying a parameter will alter the predicted response of the model however, an individual parameter should not be assigned an incorrect value for the sake of verifying the model. Ideally, model parameters should be altered to more accurately reflect the physical characteristic represented. However, based on actual experience in the WECC region, the ultimate goal of the verification process is to sufficiently refine model parameters to consistently approximate equipment response to a frequency excursion. The SDT recognizes expertise is required to perform model verification and this is the reason why the model verification periodicity proposed is a 10 year cycle.

Especially considering that the units contained in the Applicability is a subset of the NERC Compliance Registry, the SDT believes that the drafted standard is cost efficient to the industry. As a basis, the SDT recognized that the governor models and model data are already collected through the processes identified in MOD-012 and MOD-013. These models and data should, with few exceptions, already result in a quality dynamics database. However, as confirmed through the Field Test initiated by the Phase III-IV SDT, performing the activities specified in the draft standard is expected to result in improved accuracy of the governor model used in dynamic simulation. Utilizing engineering judgment, based in part on recent entity experience with verifying governor models, the SDT is proposing to require verification of governor models associated with 80% or greater of the connected MVA in each Interconnection. Given the increasing importance of renewable generation plants comprised of several small units, the SDT also proposes requiring verification of these plants and has added language to the Applicability section to capture this intent.

Organization	Yes or No	Question 6 Comment
GE Energy	Yes	The second bullet, in part B “Requirements,” section R1, page 4: The word “library” should be removed from the phrase “system model library block diagrams,” since not all wind manufacturers have standard library models.
Response: Thank you for your comment. The SDT believes that the word “library” is appropriate in this context. User defined models can still be utilized for verification to the extent that the Transmission Planner is willing to accept them.		
ISO New England	Yes	In requirement R2.1.1 what is meant by frequency excursion/reference change?This standard must require that all models provided are non-proprietary, otherwise a major reason (NERC MMG) for model collection will be undermined. This will prevent coordination of studies across regions which may undermine reliability.We are not sure if we have the correct version of draft MOD-027-1. In the “Differences also exist between MOD-026-1 and MOD-027-1” Section of this Comment Form, there are several mentions of Requirement R1 Part 1.x which we are unable to find in the draft standard. For example, Requirement R1 Part 1.2.1 in (5), R1 Part 1.3 in (6), R1 Part 1.4 in (7), and R1 Parts 1.1, 1.3, 1.4 in the “Compliance Elements for MOD-027-1” Section. Also, the referenced MOD-026-1 does not have the parts mentioned in this Comment Form. Is the background provided in this comment form incorrect, or are the posted versions of MOD-026 and MOD-027 out of date?In requirement R5.3: It stipulates as a criterion that a disturbance simulation results in the turbine/governor and Load control or active power/frequency control model exhibiting positive damping. We do not agree with the condition that the simulate must exhibits positive damping. Even with an accurate turbine/governor and Load control or active power/frequency control model, system damping is affected by a many other dynamic performance contributors such as other generators, system topology, power flow levels, voltage levels, excitation system and power system stabilizer settings, etc. In short, having an accurate turbine/governor and Load control or active power/frequency control model does not necessary guarantee or equate to positive damping.
Response: Thank you for your comments. The SDT agrees with your comment that it is important for the model to be non-proprietary. This is why the standard requires each Generator Owner provide data for models that are acceptable to the Transmission Provider. The SDT apologizes for comment form errors discovered. The requirement for positive damping mandates the Generator Owner provide a response if an otherwise acceptable simulation is negatively damped after introducing a new model. This requirement recognizes the fact that equipment must be positively damped during actual operation, so negative damping occurring during simulation would indicate incorrect modeling. Initialization errors and oscillations during steady state conditions would also be an indication of model deficiencies. Each of these tests are components of an established industry practice for assuring model integrity.		

Organization	Yes or No	Question 6 Comment
GenOn Energy		
Manitoba Hydro	Yes	-MH disagrees with the SDT's assumption that the majority of turbine/governor and load control functions will be verified through ambient monitoring. If both turbine/governor and load control functions as well as excitation control functions are to be
Response: Thank you for your comment. Unfortunately part of the comment provided is missing. The SDT believes ambient monitoring is the preferred method for verifying turbine/governor and load control function models. Staged tests do not always capture the effects of load controllers and control modes. However, this standard does permit the optional utilization of stage tests (both on-line reference change and partial load rejections, though the impacts of any wrap around control modes not captured during the staged test have to be considered). The SDT has constructed the standard such that a Generator Owner can wait for a suitable event, even if it takes longer than 10 years when the unit is in a mode that is expected to govern, as opposed to requiring a on-line staged test that a significant number of Generator Owners are not comfortable performing and/or based on the vintage of equipment, do not have the capability of performing.		
Duke Energy	Yes	1) Requirement 2.1.1 requires a comparison of the on-line response to the recorded response. The comparison needs to be between the on-line recorded response and the model simulated response. 2) The VSL table for R1 has time frames that don't match the Requirement R1 30 calendar day time frame. 3) The first paragraph of the Severe VSL for R2 needs to be split into two parts to form an additional OR statement which reads: "The GO failed to provide its verified model(s)" OR "The GO provided the verified model(s) more than 90 calendar days late to its TP in accordance with the periodicity timeframe specificed in MOD-027 Attachment 1." 4) The second paragraph of the Severe VSL for R3 is not grammatically correct and does not match the Requirement R3. Please consider changing it to read: "The GO's written response failed to contain one of the following: the technical basis for maintaining the current model, a list of future model changes, or a plan to perform another model verification." 5) For the Lower, Moderate, and Higher VSLs for R5, please consider placing "including a technical description if the model is not useable" within parenthesis to aide in understanding the measure. 6) For the second paragraph of the Severe VSL for R5, please consider rephrasing to read: "The TP provided a written response without including confirmation of all specified model criteria listed in R5, parts 5.1 through 5.3." 7) Attachment 1 contains multiple copy/paste errors (from MOD-026) and was difficult to constructively comment on due to these. 8) The frequency response of a generation unit is intrinsically connected to the Pmax values used in various system models (old MOD-24). These 2 validation efforts should be connected and the following modeling

Organization	Yes or No	Question 6 Comment
		parameters defined and addressed:Pmax o The continuous operating limit o The ultimate max emergency output. o Should there consider weather conditions (summer or winter, etc.). o PMAX associated with Transient stability - is it the same as for LF o Is this on the order of 105% or 110% or ??% of normal max loading A graphic illustrating this point has been provided to the SDT.
Response: Thank you for your comment. 1) The SDT revised Requirement 2.1.1. 2) Based on this and other comments, the SDT lengthened the R1 time frame to 90 days to match the time frame in the associated VSL. 3) The SDT revised Severe VSL language for R2. 4) The SDT agrees the incorrect grammar and has incorporated language similar to what you suggested. 5) The SDT agrees and has incorporated suggested language. 6) The SDT agrees and has incorporated suggested language. 7)) The SDT regrets the copy and paste errors and has corrected them. 8) The SDT recognizes that to obtain the correct frequency response, the frequency control model needs to limit the modeled response when units are base loaded or operated with valves wide open. The industry is working on resolving this issue and the SDT believes that the proposed MOD-027 provides an appropriate framework. Attachment 1 has been revised to allow owners of units/plants to provide a statement describing control limitation for units that do not provide frequency response as evidence of compliance with the requirement. The SDT did not receive a graphic. However, the SDT can say that loadflow based Pmax is not the same as the dynamic model maximum power.		
Lincoln Electric System	Yes	Under the Applicability Section, 4.2 Facilities, the “applicable units” are stated to have an average capacity factor greater than 5% over the last three calendar years and that the “majority of industry agreed with the standard MOD-026-1 5% capacity factor threshold” (Background Information: “Standard MOD-027-1” - #3). LES is concerned that the industry builds power flow models for future summer peak conditions, and therefore, LES is not convinced that the capacity factor threshold of less than 5% is a good indication of what units are on-line in these future models. Therefore, the goal for verification of the dynamic models associated with 80% or greater of the connected MVA per Interconnection may not be achieved. LES believes that a check (i.e., survey) of the ERAG MMWG models would be a good indication of whether or not the capacity factor threshold satisfies this objective.

Organization	Yes or No	Question 6 Comment
Response: Thank you for your comment. The SDT believes that the 5% capacity factor threshold functions to establish a balance between verifying modeling information for units that play an important role in the reliability of the BES and units that report information which is not verified because they are seldom online and have a relatively diminished reliability role. While it is true that units that have a capacity factor that is marginally greater than 5% could result in a long ambient monitoring period before capturing a response suitable for model verification, the SDT believes that it is better to wait for a suitable event as opposed to requiring a on-line staged test that Generator Owners are not comfortable performing and even argue is not an accurate test. Finally, by its inherent nature, an expected summer peak load ERAG MMWG case will include many on-line low capacity factor units. However, the SDT recognized that the governor models and model data for all generators in the ERAG MMWG case are already collected through the processes identified in MOD-012 and MOD-013. These models and data should, with few exceptions, already result in a quality dynamics database. However, as confirmed through the Field Test initiated by the Phase III-IV SDT, performing the activities specified in the draft standard for 80% or greater of units making up the total interconnected MVA is expected to result in an improvement of the accuracy of the governor models used in dynamic simulations.		
CPS Energy		
Independent Electricity System Operator	Yes	We do not agree with some of the requirements.i. R1: Standards should stipulate the “what’s” not the “how’s”. To avoid the perception that the requirement is prescribing the “how”, we suggest simplifying the language of Requirement R1 by replacing “Instruction on how to obtain” with “Instructions for obtaining”.Further, are all three bullets meant to be complied with or are they listed as options? We understand that the general rule for NERC standards is that those items that must be complied with are labeled as parts (e.g. 1.1, 1.2, etc.) while those that are options or examples that do not need to be complied with are placed in bullets. Please verify this with the Director of Standards Process.ii. R2.1: The phrase “models acceptable to its Transmission Planner” begs the question on what is deemed acceptable and what if the GO disagrees with the TP’s determination. To address the two issues, we suggest adding a requirement for the TP to specify the models (or change the second bullet in R1 to achieve this), and change the wording in R2.1 to “in accordance with the models specified by the TP (or referencing the requirement part that contains the specification). Another possibility would be to remove this phrase altogether since the Transmission Planner would in any case have to declare the model “useable” pursuant to Requirement R5.iii. R5.3: It stipulates as a criterion that a disturbance simulation results in the turbine/governor and Load control or active power/frequency control model exhibiting positive damping. We do not agree with the condition that the simulate must exhibits positive damping. Even with an accurate turbine/governor and Load control or active power/frequency control model, system damping is affected by many other dynamic performance contributors such as other generators, system topology, power flow levels, voltage levels,

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 6 Comment</th></tr>
<tr><td></td><td></td><td>excitation system and power system stabilizer settings, etc. In short, having an accurate turbine/governor and Load control or active power/frequency control model does not necessary guarantee or equate to positive damping. Similar arguments may also apply to R5.1 and R5.2, i.e., that having an accurate model does not necessarily mean that the modeling data can be initialized without errors, and a no-disturbance simulation always results in negligible transients. We suggest the SDT to revise the determination criteria, based solely on the models specified by the TP, the data provided by the GO meeting the specified model requirements, and the tracking of actual performance, where applicable.iv. We decide not to comment on the Measures and other compliance elements at this time in view of the comments, above.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. Requirement 1 does describe the “what” and avoids being prescriptive. Upon request, the Transmission Planner provides requested information to the Generator Operator. Items that the Generator Owner can request from the Transmission Planner are stated in requirement 1 (refer to the bulleted items). The Transmission Planner is only required to provide the items if requested to do so and as such the standard language and format is correct.

Since the Transmission Planner is the user of the model, submitted models must be acceptable to the transmission planner to be useful. The first bullet under requirement R1 does require the Transmission Planner to provide instructions on how to obtain the list of acceptable models.

The requirement for positive damping mandates the Generator Owner provide a response if an otherwise acceptable simulation is negatively damped after introducing a new model. This requirement recognizes the fact that equipment must be positively damped during actual operation, so negative damping occurring during simulation would indicate incorrect modeling. Initialization errors and oscillations during steady state conditions would also be an indication of model deficiencies. Each of these tests are an established industry practice for assuring model integrity.</td></tr>
<tr><td>Gainesville Regional Utilities</td><td>No</td><td></td></tr>
<tr><td>Ameren</td><td>Yes</td><td>(1) There may be different usage of the term 'point of interconnection" in the industry. We suggest the SDT to consider proposing a formal definition of this term. (2) R4 of the Draft references footnote 5. It appears this footnote is overly broad and requires editing to precisely identify equipment systems that can truly impact system reliability. This footnote should be edited so it becomes either a new Requirement or a new set of sub-requirements. No other systems should be included.</td></tr>
<tr><td colspan="3">Response: Thank you for your comment. 1) The standard has been revised for clarity regarding the meaning for the “point of interconnection.” The SDT believes a formal definition is not needed since the point of interconnection is described in the standard.</td></tr>
</table>

Organization	Yes or No	Question 6 Comment
2) In the development of Footnote 5, the SDT strove to cover all reasonable examples that might result in the alteration of equipment response. However, the requirement leaves the responsibility for determining what alters equipment response to the Generator Owner.		
Indeck Energy Services	Yes	This standard imposes significant costs on generators and requires them to, in many cases unless they are also a transmission company, to hire consultants to conduct the verification. There is no evidence that unverified model data for units smaller than the level of the NERC Reportable Disturbance for the control area will have any impact on BPS reliability.
Response: Thank you for your comment. This standard has been vetted including SAR development and field testing. Industry believes that this standard is needed. The STD recognizes there are costs associated with compliance and has proposed a standard applicability limited to the most critical units/plant listed in the compliance registry criteria.		
Oncor Electric Delivery Company LLC	No

END OF REPORT

Consideration of Comments on Generator Verification (PRC-019-1)—Project 2007-09

The Generator Verification drafting team thanks all commenters who submitted comments on the first posting of PRC-019-1, Coordination of Generating Unit/Facility Voltage Regulating Controls with Generating Unit/Facility Capabilities and Protection (Project 2007-09). These standards were posted for a 30-day public comment period from June 15, 2011 through July 15, 2011. The stakeholders were asked to provide feedback on the standards through a special electronic comment form. There were 65 sets of comments, including comments from approximately 182 different people from approximately 95 companies representing 9 of the 10 industry segments, as shown in the table on the following pages.

http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President of Standards and Training, Herb Schrayshuen, at 404-446-2563, or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

Summary Consideration:

The GVSDT posted PRC-019-1 for a 30 day formal comment period from June 15-July 15, 2011. The majority of stakeholders agreed with the proposed standard and provided some comments for revisions to the standard. The Applicability to Transmission Owners was clarified to include only those that own synchronous condenser(s) ad follows:

4.1.2 Transmission Owner that owns synchronous condenser(s)

The GVSDT asked stakeholders if they believed that the proposed PRC-019-1 standard was written to be "technology neutral" such that it can be used for all forms of generation connected to the BES. The vast majority of stakeholders believe that the standard is technology neutral. Several stakeholders that expressed concerns commented that the standard may not work for photovoltaic or wind technologies. The GVSDT agrees that while some of the standard elements might not apply to all technologies, most elements and the example diagrams (in general) would apply to all technologies.

One stakeholder recognized that the SSSL calculation plot used in the example diagrams is based on a fixed field current, which would require the excitation system to be in Manual Mode. The GVSDT, having previously considered this and knowing the excitation system to typically be in Auto Mode per VAR-002, provided the following response: The calculation of the SSSL based on a fixed field current value is a typical industry practice and provides a conservative number to be used for coordination purposes without making calculations overly complex.

The GVSDT asked stakeholders if they agreed with the applicability to synchronous condensers. The question contained a limit of ≥50 MVA while the standard contained ≥20

[1] The appeals process is in the Standard Processes Manual:
http://www.nerc.com/files/Appendix_3A_Standard_Processes_Manual_Rev%201_20110825.pdf

MVA. The GVSDT intended for ≥20 MVA to be the correct number. Many stakeholders pointed out this discrepancy and agreed with the ≥20 MVA threshold. The GVSDT will ask this question again in the next posting.

Some stakeholders suggested higher MVA limits for units applicable to this standard. The GVSDT based the applicability criteria on the current Compliance Registry Criteria and the current posted draft of the BES definition, both of which currently set the applicability threshold at 20 MVA for individual units. The SDT felt that there was not sufficient technical justification to set the applicability requirement at a value that differs from the Compliance Registry Criteria and the BES definition.

Constellation Power pointed out that repeating the Compliance Registry Criteria within the standard is not wise since the standard must be changed if the Compliance Registry Criteria changes. The SDT agrees with this logic but felt it was necessary to include the appropriate Compliance Registry Criteria within the standard because the standard also applies to synchronous condensers, which are not explicitly mentioned in the Compliance Registry Criteria. If the Compliance Registry Criteria language for generating units was not included in the standard the standard could be interpreted to apply only to synchronous condensers and not to generators.

Stakeholders were asked if they thought that variable static reactive sources that are not located at generating facilities should be included in the standard. The vast majority of stakeholders did not see a reliability need for including variable static reactive sources that are not located at generating facilities. This equipment is normally protected for internal failures and do not have similar equipment protection such as synchronous generators using generator field limiters and over- and under-excitation protection. The SDT has determined that variable static reactive resources not located at generating facilities are outside the scope of this project. For these reasons, including static reactive resources not located at a generating facility are not part of this standard.

The majority of stakeholders agreed with the Purpose Statement of PRC-019-1. The GVSDT revised the Purpose Statement of the standard for clarity based on stakeholder comments. The revised Purpose Statement is:

> To improve the reliability of the Bulk Electric System by ensuring coordination of generating unit/facility or synchronous condenser voltage regulating controls and limit functions with generator capabilities and protection system settings.

The proposed effective dates provide a “phased-in” approach to establishing compliance with this standard to provide adequate time for entities to include all applicable units/facilities. The majority of stakeholders agreed with the phased in approach. Stakeholders pointed out that, for jurisdictions where regulatory approval is not required, the 100% completion item was missing. The GVSDT added item 5.2.5:

> 5.2.5 By the first day of the first calendar quarter, five calendar years following Board of Trustees approval each Generator Owner and Transmission Owner shall have verified 100 percent of its applicable units.

Stakeholders were asked about Section G of the standard which provides examples of how the coordination can be demonstrated. The majority of stakeholders agreed with the information provide and several stakeholders made suggestion for clarifying language. Specific changes were made to Section G of the standard based on comments received. These changes included:

1. The example diagrams added that they are drawn at nominal voltage and frequency.

2. The formula for calculating the radius of the SSSL was corrected.

3. The items “under-excited limiters or minimum excitation limiters” and “over-excited limiters or maximum excitation limiters” have been placed in the bulleted list of the standard.

4. The SDT changed “protective” to “protection” within the standard to be consistent with Section G.

5. The SDT added a reference document for use in calculation of SSSL.

Several commentators were concerned that Section G has a method for illustrating coordination of AVR limiter/protection functions with other protection systems. The SDT agrees that there are numerous ways of demonstrating coordination and does not prescribe any particular method. Any protective function that is enabled should be evaluated for proper coordination.

The SDT reviewed the requests to remove the distance relay and volts/hertz relay elements from the standard. It is the belief that these two elements remain in the document since a) the distance element should illustrate coordination with field forcing controls of the AVR, and b) the volts per hertz function can operate with the unit on-line under certain operating conditions.

Index to Questions, Comments, and Responses

1. Do you agree that the standard, as written, is "technology neutral," such that it can be used for all forms of generation connected to the BES? If you do not agree, please state your reasons and suggest alternatives to make the standard technology neutral in the Comment area. 15

2. The SDT applied the requirements of this standard to the functional entities Generator Owner, and Transmission Owners that own synchronous condensers rated equal to or greater than 50 MVA. The standard applies to generating units/Facilities that meet the Compliance Registry criteria and to synchronous condensers rated 50 MVA and greater. Do you agree with this Applicability? If not, please provide an alternative and supporting information in the Comment section. 22

3. As currently drafted, this standard applies to synchronous generators, synchronous condensers, and variable static Reactive resources located at asynchronous generating Facilities (e.g., wind and solar sites). Do you see a reliability need for including variable static Reactive resources (e.g., static VAr compensators) that are not located at generating sites in this standard? Please explain your answer in the comments block. 33

4. The SDT revised the Purpose of the standard in accordance with the SAR, "To improve the reliability of the Bulk Electric System by preventing tripping of generating units/Facilities due to miscoordination of generating unit/Facility voltage regulating controls, and limit functions with generator capabilities and Protection System settings." Do you agree with the revised Purpose of the standard? If not, please provide suggested language changes in the Comment section. 44

5. The proposed effective dates provide a "phased-in" approach to establishing compliance with this standard to provide adequate time for entities to include all applicable units/Facilities. Do you agree with the proposed implementation schedule? If not, please provide an alternative implementation schedule, approach, and supporting information in the comments. 52

6. Do you agree that the evidence, documents, and functions listed in Section G are sufficient for giving the Generator Owner/Transmission Owner examples of how the coordination can be demonstrated? If not, please provide suggested language changes to the Measure and supporting information in the Comment section. 61

7. Do you agree with the data retention language listed in the Compliance section of the draft standard? If not, please comment and provide alternative data retention language. 69

8. Are you aware of the need for any regional variances to this standard? If yes, please explain in the comment section. 78

9. Do you have any other questions or concerns with the proposed standard that have not been addressed? If yes, please explain in the Comment section. 84

END OF REPORT 101

The Industry Segments are:

1 — Transmission Owners
2 — RTOs, ISOs
3 — Load-Serving Entities
4 — Transmission-dependent Utilities
5 — Electric Generators
6 — Electricity Brokers, Aggregators, and Marketers
7 — Large Electricity End Users
8 — Small Electricity End Users
9 — Federal, State, Provincial Regulatory, or other Government Entities
10 — Regional Reliability Organizations, Regional Entities

1. Do you agree that the standard, as written, is "technology neutral," such that it can be used for all forms of generation connected to the BES? If you do not agree, please state your reasons and suggest alternatives to make the standard technology neutral in the Comment area.

Summary Consideration: The majority consensus of the stakeholders was "yes," the standard is technology neutral. Several of the "no" responders commented that the standard may not work for photovoltaic or wind technologies. The SDT agrees that while some of the standard elements might not apply to all technologies, most elements and the example diagrams (in general) would apply to all technologies.

One stakeholder recognized that the SSSL calculation plot used in the example diagrams is based on a fixed field current, which would require the excitation system to be in manual mode. The SDT, having previously considered this and knowing the excitation system to typically be in auto mode per VAR-002, provided the following; the calculation of the SSSL based on a fixed-field current value is a typical industry practice and provides a conservative number to be used for coordination purposes without making calculations overly complex.

Organization	Yes or No	Question 1 Comment
LG&E and KU Energy		
Northeast Power Coordinating Council	No	This draft standard appears to have been written from a traditional steam or combustion turbine generator perspective. It may not work for a photovoltaic or wind generator installation.
Response: Thank you for your comment. The SDT received input from owners and operators of wind and solar Facilities, as well as an OEM involved with these technologies. The examples provided contain some elements that may not apply to all technologies; though the diagrams, in general, would apply to all technologies.

Cowlitz County PUD		Cowlitz has no opinion.
Xcel Energy	Yes	
Lakeland Electric		
Exelon	No	The SDT needs to evaluate the requirements related to the Steady State Stability Limit (SSSL). Specifically, Section G (top of page 7) states "(F)or the coordination required by this standard, the Steady State Stability Limit (SSSL) is the limit to synchronous stability in the under-excited region with fixed field current." This conflicts with Requirement R1.1.1 that states "... assuming normal AVR control loop and system steady state operating conditions. Currently the two statements are in conflict with one another in that one requires a "fixed" field current (i.e., AVR in "manual") and the other requires "normal operation" (i.e., AVR in "automatic").The SDT needs to allow for automatic mode for AVR to accommodate those Generators that have redundant automatic channels as is the case for newer digital AVRs. This will allow the owner to use AVRs automatic mode when plotting SSSL.
Response: Thank you for your comment. The SDT agrees that the generators must normally operate in AVR mode. The calculation of the SSSL, based on a fixed-field current value, is a typical industry practice and provides a conservative number to be used for coordination purposes without making calculations overly complex. The SSSL is an element that applies only to synchronous generating units. It would not necessarily apply to wind or solar facilities.		
American Wind Energy	Yes	

Organization	Yes or No	Question 1 Comment
Association		
Tacoma Power	Yes	None
Georgia Transmission Corporation		
Austin Energy	Yes	
Wisconsin Electric	Yes	
Great River Energy		
BC Hydro	Yes	
Northeast Utilities	No	This draft standard appears to have been written from a traditional steam or combustion turbine generator perspective. It may not work for a photovoltaic or wind generator installation.
Response: Thank you for your comment. The SDT received input from owners and operators of wind and solar Facilities, as well as an OEM involved with these technologies. The examples provided contain some elements that may not apply to all technologies; though the diagrams, in general, would apply to all technologies.		
Constellation Power Generation	No	Although CPG agrees with the approach of applying this standard to all generation facilities in the compliance registry, mimicking it in the standard is redundant and problematic. Should the compliance registry change, then this standard may include facilities not registered with NERC. Conversely, this standard could potentially exclude facilities in the registry should the compliance registry change.
Response: Thank you for your comment. Because this standard includes equipment that is not specifically listed in the Registry criteria (synchronous condensers), the SDT feels it is necessary to explicitly list the generating equipment included in the criteria. If the Registry criteria are revised in the future, this standard may have to be revised as well.		
Consolidated Edison Co. of	No	This draft standard appears to have been written from a traditional steam or combustion

Organization	Yes or No	Question 1 Comment
NY, Inc.		turbine generator perspective. It may not work for a photovoltaic or wind generator installation.
Response: Thank you for your comment. The SDT received input from owners and operators of wind and solar Facilities, as well as an OEM involved with these technologies. The examples provided contain some elements that may not apply to all technologies; though the diagrams, in general, would apply to all technologies.		
American Electric Power	Yes	Though we agree that the standard as written is "technology neutral", its apparent neutrality might well be impacted by the definition of BES which is currently being revised. This topic might need to be revisited once the revised definition of BES has been approved.
Response: Thank you for your comment. If the definition of the BES is revised in the future, this standard may have to be revised as well.		
Ingleside Cogeneration LP	Yes	Ingleside Cogeneration LP's gas and steam turbine units use voltage limiting and protection system technologies which are clearly referenced under PRC-019-1.
Response: Thank you for your comment.

2. **The SDT applied the requirements of this standard to the functional entities Generator Owner, and Transmission Owners that own synchronous condensers rated equal to or greater than 50 MVA. The standard applies to generating units/Facilities that meet the Compliance Registry criteria and to synchronous condensers rated 50 MVA and greater. Do you agree with this Applicability? If not, please provide an alternative and supporting information in the Comment section.**

Summary Consideration: The majority of stakeholders agreed with the applicability of the standard.

Several stakeholders noted that the posted question mistakenly stated that the proposed standard applied synchronous condensers rated equal to or greater than 50 MVA, rather than the correct value of equal to or greater than 20 MVA. Four of the "no" votes were based on disagreeing with the 50 MVA threshold, and preferring the (correct) 20 MVA threshold.

A few stakeholders recommended applying the standard to units that are larger than 75 MVA, and pointed out that this is the threshold used in the current draft definition of the BES. Three more stakeholders also recommended a higher threshold. The SDT based the applicability criteria on the current Compliance Registry criteria and the current posted draft of the BES definition, both of which currently set the applicability threshold at 20 MVA for individual units. The SDT felt that there was not sufficient technical justification to set the applicability requirement at a value that differs from the Compliance Registry criteria and the BES definition. If the Compliance Registry criteria and/or the BES definition changes in the future, it is likely that the applicability for this standard should be changed as well.

Constellation Power pointed out that repeating the Compliance Registry criteria within the standard is not wise since the standard must be changed if the Compliance Registry criteria changes. The SDT agrees with this logic, but felt it was necessary to include the appropriate Compliance Registry criteria within the standard because the standard also applies to synchronous condensers, which are not explicitly mentioned in the Compliance Registry criteria. If the Compliance Registry criteria language for generating units was not included in the standard, the standard could be interpreted to apply only to synchronous condensers, and not to generators.

A couple of stakeholders stated that the standard should not apply to synchronous condensers because they are not included in the Compliance Registry. The SDT feels, as do many other stakeholders, that, for reliability reasons, this standard needs to apply to synchronous condensers, and it is appropriate to list equipment that is not in the Registry criteria.

Organization	Yes or No	Question 2 Comment
LG&E and KU Energy		
Northeast Power Coordinating Council	No	Generally only units larger 75 MVA are impactful. Recommend making 75 MVA the reporting floor [regardless of connected voltage]. This is consistent with the current draft BES definition being prepared by BES SDT.
Response: Thank you for your comment. The proposed draft of the BES definition that is posted on the NERC website includes individual units of 20 MVA and greater, not 75 MVA. If the draft changes in the future, this standard and others may need to be revised.		
Imperial Irrigation District (IID)	Yes	
IRC Standards Review Committee (joint comments)		
Pepco Holdings Inc Affiliates	Yes	Question #2 mentions that a threshold was chosen by the SDT for synchronous generators greater than, or equal to, 50MVA. However, the existing language in Section A- 4.2.1 of the standard makes it applicable to both individual generating units and synchronous condensers greater than 20MVA. The 50MVA threshold for synchronous condensers seems reasonable, so if this was the intent then the language in the standard should be revised.
Response: Thank you for your comment. The question on this form mistakenly used the value of 50 MVA. Although synchronous condensers are not mentioned in the Registry criteria, the SDT feels that the 20 MVA value more nearly matches the value for individual generating units.		
NERC System Protection and Control Subcommittee	No	The SPCS notes that the posted standard references synchronous condensers rated 20 MVA in Applicability section 4.2.1. The SPCS agrees with the 20 MVA threshold in the posted standard.
Response: Thank you for your comment. The question on this form mistakenly used the value of 50 MVA.		
Midwest Reliability Organization's NERC Standards Review Forum (NSRF)	Yes	

Organization	Yes or No	Question 2 Comment
SPP Reliability Standards Development Team	Yes	This question refers to the applicability of the standard yet doesn't reflect the wording in this question. In the standard the applicability for synchronous condensers is 20 MVA due to it being lumped with single units. This needs to be broken out in the applicability section of the standard.
Response: Thank you for your comment. The question on this form mistakenly used the value of 50 MVA. Although synchronous condensers are not mentioned in the Registry criteria, the SDT feels that the 20 MVA value more nearly matches the value for individual generating units.		
SERC Planning Standards Subcommittee		
Idaho Power-Power Production	Yes	
Santee Cooper		
PPL Generation	No	See item 1 in Question 9 Response.
Dominion	Yes	
FirstEnergy	Yes	Although we agree with the applicability, the standard that was posted does not mention the 50 MVA threshold.
Response: Thank you for your comment. The question on this form mistakenly used the value of 50 MVA. Although synchronous condensers are not mentioned in the Registry criteria, the SDT feels that the 20 MVA value more nearly matches the value for individual generating units.		
SERC Dynamics Review Sub-committee		
NERC Staff	No	The posted standard references synchronous condensers rated 20 MVA in Applicability section 4.2.1. We agree with the 20 MVA threshold in the posted standard.
Response: Thank you for your comment. The question on this form mistakenly used the value of 50 MVA.		

Organization	Yes or No	Question 2 Comment
Public Service Enterprise Group	No	The question and the standard contradict each other. The standard states that it applies to “synchronous condensers > 20 MVA” not “rated > 50 MVA.We do not agree with the threshold MVA applicability for generators. Field testing and industry history do not warrant the need for such a low MVA threshold. We suggest that the threshold be for larger units (rated > 500 MVA) that have the ability to significantly impact BES reliability. The resources required to apply this standard to smaller units compares to the benefits to the BES and the GO are generally not justified in most regions. However, it can be argued that smaller units can have a significant impact on the BES, especially in weak systems. Therefore, we recommend that an inclusion criteria be developed that would require units in such regions to be included.
Response: Thank you for your comment. The SDT based the applicability of the standard on the Registry criteria, and does not have sufficient technological justification to deviate from those values.		
SERC Generation sub-committee		
ACES Power Members	Yes	
Arizona Public Service Company	Yes	
Westar Energy	Yes	In the standard the applicability for synchronous condensers is > 20 MVA for an individual unit. Additional language should be added to the standard to address the applicability for generating units/facilities.
Response: Thank you for your comment. The SDT believes that Section 4.2.1 does address the applicability for generating units/Facilities.		
Southern Company	No	We feel that this standard is not applicable for solar facilities. For other facilities, we recommend that only units > 75MVA be included. If the significant aggregated plant MVA size is > 75 MVA, then an individual unit included as significant should also be 75 MVA. Consider the case where a 21 MVA machine would be included in the scope, yet a 'five unit, 15 MVA each' plant (totaling 75 MVA) would be excluded. A 20MVA machine today can not impact the system like it could have 20 years ago. A technical basis for including units as small as 20MVA

Organization	Yes or No	Question 2 Comment
		in all regions needs to be provided. NERC is focusing on standard requirements that have significant impacts on system reliability, and including units less than 75MVA seems to be inconsistent with this philosophy. We do acknowledge that in some areas of the BES, some units â ‰ ¤ 75MVA may be identified by a transmission entity as critical for BES reliability. Thus, the standard could include requirements applicable to such units where identified by a tranmission entity as critical for BES reliability.
Response: Thank you for your comment. Miscoordination between inverter capabilities and protection would apply to solar facilities. The SDT based the applicability of the standard on the Registry criteria, and does not have sufficient technological justification to deviate from those values.

<tr><th>Organization</th><th>Yes or No</th><th>Question 2 Comment</th></tr>
<tr><td>Tri-State Generation and Transmission, In.</td><td>Yes</td><td>The standard seems to indicate 20mva instead of the stated 50mva.</td></tr>
<tr><td colspan="3">Response: Thank you for your comment. The question on this form mistakenly used the value of 50 MVA.</td></tr>
<tr><td>Cowlitz County PUD</td><td>No</td><td>The Compliance Registry Criteria was hastily put together without proper reliability justification. The end result has created a registration process that assumes reliability impact where there is none, and allows exemptions where reliability impact does exist. Cowlitz believes in a protective backbone approach to reliability, the bulk power system (BPS) as a whole need not be completely protected in order to assure its reliability. There exists a core “backbone” subset from the BPS which must be protected; this is known as the Bulk Electric System (BES) and is currently undergoing revision in Project 2010-17. Once this project is complete, it may be necessary to revise the Compliance Registry Criteria to clearly identify entities as users of the BES who must participate in BES protective standard compliance activities. In other words, the Compliance Registry objective should be to identify all entities who must participate in the protection of the BES to assure reliability of the BPS, not identify elements of the BES. Using the Compliance Registry Criteria’s generator MVA name plate ratings to assign applicability of the Standard is questionable. Cowlitz can find no reliability justification; it appears to be completely arbitrary. If models are currently accurate it should be a simple process to verify the size of generation that can be ignored. Further, the unit versus plant MVA criteria is illogical. If the BES can withstand the loss of a 75 MVA plant, then logically it will withstand the loss of a 20 MVA unit. Cowlitz believes that after the appropriate study is completed, the applicability line should be somewhere in the range of a verified nominal plant or unit output of 100 to 200 MVA. Last of all, applicability should be assigned to BES generation when it has been defined.</td></tr>
<tr><td colspan="3">Response: Thank you for your comment. The question on this form mistakenly used the value of 50 MVA. Although synchronous condensers are not mentioned in the Registry criteria, the SDT feels that the 20 MVA value more nearly matches the value for individual generating units. The GVSDT is not attempting to justify the NERC registration criteria through this standard. We are simply using it as the basis for Facility applicability.</td></tr>
<tr><td>Xcel Energy</td><td>Yes</td><td>There is a discrepancy between the question and the 20 MVA size limit for synchronous condensers in the draft standard. We believe 50 MVA is the better value.</td></tr>
<tr><td colspan="3">Response: Thank you for your comment. The question on this form mistakenly used the value of 50 MVA. Although synchronous condensers are not</td></tr>

mentioned in the Registry criteria, the SDT feels that the 20 MVA value more nearly matches the value for individual generating units.		
Lakeland Electric		
Exelon		
American Wind Energy Association	Yes	
Tacoma Power		
Georgia Transmission Corporation		
Austin Energy	Yes	
Wisconsin Electric	Yes	
Great River Energy		
BC Hydro		
Northeast Utilities	No	Generally only units larger 75 MVA are impactful. Recommend making 75 MVA the reporting floor [regardless of connected voltage]. This is consistent with the current draft BES definition being prepared by BES SDT.
Response: Thank you for your comment. The proposed draft of the BES definition that is posted on the NERC website includes individual units of 20 MVA and greater, not 75 MVA. If the draft changes in the future, this standard and others may need to be revised.		
Constellation Power Generation	No	Although CPG agrees with the approach of applying this standard to all generation facilities in the compliance registry, mimicking it in the standard is redundant and problematic. Should the compliance registry change, then this standard may include facilities not registered with NERC. Conversely, this standard could potentially exclude facilities in the registry should the

Organization	Yes or No	Question 2 Comment
		compliance registry change.
Response: Thank you for your comment. The question on this form mistakenly used the value of 50 MVA. Although synchronous condensers are not mentioned in the Registry criteria, the SDT feels that the 20 MVA value more nearly matches the value for individual generating units.		
Consolidated Edison Co. of NY, Inc.	No	Generally only units larger than 75 MVA are impactful. Recommend making 75 MVA the reporting floor [regardless of connected voltage]. This is consistent with the current draft BES definition being prepared by the BES SDT.
Response: Thank you for your comment. The proposed draft of the BES definition that is posted on the NERC website includes individual units of 20 MVA and greater, not 75 MVA. If the draft changes in the future, this standard and others may need to be revised.		
American Electric Power	No	It needs to be explicitly stated whether or not a Transmission Owner is held under R1 if they do not own synchronous condensers. This might be achieved by adding additional language to 4.1.2 stating that the standard applies to those who own facilities as specified in 4.2.Usage of the words “coordinate” and “coordination” seems ambiguous, and might be open to interpretation. In other standards these words are often used to describe communication between NERC functions rather than ensuring that necessary and sufficient settings exist among equipment types to permit them to operate in a pre-determined sequence.The threshold of 50MVA is not mentioned in the draft standard. Rather, 4.2.1 specifies a threshold of 20MVA.It appears the term “synchronous condenser” has been omitted from R1. Suggest using "Each Generator Owner and Transmission Owner with applicable Facilities shall coordinate its generating unit, generating Facility, or synchronous condenser voltage regulating system controls, including limiters and protection functions with the generating unit and Facility or synchronous condenser capabilities and protective system settings; to include as applicable".
Response: Thank you for your comment. The Applicability section of the draft standard has been changed to explicitly show that the standard only applies to TOs that own synchronous condensers. The concept of “coordination,” as applied to protective relays, limiters, and equipment capabilities, is commonly understood in the industry as meaning their desired sequence of operation. The value of 50 MVA was mistakenly used in the question on this form. The SDT agrees with your suggested wording revision to R1. The SDT also agrees that the Application section needed to be clarified for TOs, and has modified Section 4.1.2 to state that the standard only applies to TOs that own synchronous condensers.		
Ingleside Cogeneration LP	No	PRC-019-1 is appropriate for generating units and facilities identified under the compliance registry criteria. Since synchronous condensers are not part of those criteria, they should be

Organization	Yes or No	Question 2 Comment
		not be considered applicable to any NERC standard at this time. There is a project team presently modifying the definition of the Bulk Electric System - this determination should rest with them.
Response: Thank you for your comment. For reliability reasons, this standard needs to apply to synchronous condensers, and it is appropriate to list equipment that is not in the Registry criteria. Many elements of the Bulk Electric System are not specifically named in the Registry criteria or definition of the BES. For example, PRC-005 deals with Protection Systems, which are not specifically named in the BES definition or the Registry criteria.		
Wisconsin Public Service Corp		
GE Energy		
ISO New England	Yes	Yes, however the standard should not rewrite the Compliance Registry as attempted. The registry language of section IIIc.3 and IIIc.4 is more precise and differs from what is proposed in the standard. For instance, the registry's wording on Black Start generators applies to a blackstart unit material to and designated as part of a transmission operator entity's restoration plan. If the NERC standards become effective for non-material 9 MVA black start units those units will likely drop out of the program. All that is needed is to have the standard applicable to Generator Owners and let the Registry dictate those who must register and comply.
Response: Thank you for your comment. The SDT agrees to use the wording in the current version of the Registry criteria. Because this standard includes equipment that is not specifically listed in the Registry criteria (synchronous condensers), the SDT feels it is necessary to explicitly list the generating equipment included in the Criteria. If the Registry criteria are revised in the future, this standard may have to be revised as well.		
GenOn Energy		
Manitoba Hydro	No	The 50MVA criteria in question 2 does not appear in the draft standard. If the question is valid and 50MVA is not a typo, it is not clear why the size of applicable synchronous condensers should be different from that of synchronous generators. Also 50 MVA seems like an arbitrary number with no basis. MH proposes that the applicable MVA rating of synchronous generators and synchronous condensers be identical. This eliminates confusion associated with units capable of operating in either mode.

Organization	Yes or No	Question 2 Comment
Response: Thank you for your comment. The question on this form mistakenly used the value of 50 MVA.		
Duke Energy	No	We feel that this standard is not applicable for solar facilities or induction type generators used in some wind farms. Several different exemption criteria are specified in the various GVSDT standards. We understand the distinction made for MOD-26/27 (100MVA) from the MOD-25 criteria (75MVA). The standard likely should be consistent with one or the other, rather than having a 3rd criteria (50MVA). For this standard, we recommend that only units > 75MVA be included. If the significant aggregated plant MVA size is > 75 MVA, then an individual unit included as significant should also be 75 MVA. Consider the case where a 21 MVA machine would be included in the scope, yet a 'five unit, 15 MVA each' plant (totaling 75 MVA) would be excluded. A 20MVA machine today can not impact the system like it could have 20 years ago. A technical basis for including units as small as 20MVA in all regions needs to be provided. NERC is focusing on standard requirements that have significant impacts on system reliability, and including units less than 75MVA seems to be inconsistent with this philosophy. We do acknowledge that in some areas of the BES, some units â‰¤ 75MVA may be identified by a transmission entity as critical for BES reliability. Regional criteria are allowed to address these concerns to make requirements applicable to such units identified as critical for BES reliability in that region.
Response: Thank you for your comment. Miscoordination between inverter capabilities and protection would apply to solar Facilities. The SDT based the applicability of the standard on the Registry criteria, and does not have sufficient technological justification to deviate from those values.		
Lincoln Electric System		
CPS Energy		
Independent Electricity System Operator	No	There is no technical justification provided to support the 50 MVA criterion. Absent this, we propose to use the 20 MVA for generators as a general criterion for synchronous condensers as well.
Response: Thank you for your comment. The question on this form mistakenly used the value of 50 MVA.		
Gainesville Regional Utilities	Yes	

Organization	Yes or No	Question 2 Comment
Ameren	Yes	
Indeck Energy Services	No	Not sync condensers
Response: Thank you for your comment. The SDT believes that synchronous condensers are as important a Reactive resource as synchronous generators and should be included as applicable equipment in this standard.		
Oncor Electric Delivery Company LLC	Yes	
Indiana Municipal Power Agency	Yes	IMPA supports the application of the standard to generating units/facilities that meet the compliance registry criteria and to synchronous condensers rated 50MVA and greater.
Response: Thank you for your comment. The question on this form mistakenly used the value of 50 MVA. Although synchronous condensers are not mentioned in the Registry criteria, the SDT feels that the 20 MVA value more nearly matches the value for individual generating units.		
Los Angeles Department of Water and Power		LADWP does not have a position on this question at this time.
Chelan County PUD	Yes	

3. **As currently drafted, this standard applies to synchronous generators, synchronous condensers, and variable static Reactive resources located at asynchronous generating Facilities (e.g., wind and solar sites). Do you see a reliability need for including variable static Reactive resources (e.g., static VAr compensators) that are not located at generating sites in this standard? Please explain your answer in the comments block.**

Summary Consideration: —The majority of stakeholders did not see a reliability need for including variable static Reactive sources that are not located at generating Facilities. This equipment is normally protected for internal failures and do not have similar equipment protection, such as synchronous generators using generator field limiters and over- and under-excitation protection. The SDT has determined that variable static Reactive resources not located at generating Facilities are outside the scope of this project. For these reasons, the drafting team has not included static Reactive resources not located at a generating Facility.

Organization	Yes or No	Question 3 Comment
LG&E and KU Energy		
Northeast Power Coordinating Council	Yes	Only units larger 75 MVA are generally impactful. We recommend making 75 MVA the reporting floor [regardless of connected voltage].Coordination will be needed. Static VAR Compensators are typically self protected by the vendor. As long as the interface point (transformer) is properly and redundantly protected and the Static VAR Compensator safely shuts down for internal faults or out of spec operation, there should be minimal need for coordination with transmission system protection. However, this issue would have to be researched with the vendor of the equipment. Coordination with the Transmission Operator will have to be reviewed for pre and post protection system operation conditions.
Response: Thank you for your comment. The standard applies to voltage control resources at generating Facilities, regardless of their design. The SDT has determined that variable static Reactive resources not located at generating Facilities are not within the scope of this standard.		
Imperial Irrigation District (IID)	No	These devices are covered already under the VAR standards.
Response: Thank you for your comment.		

Organization	Yes or No	Question 3 Comment
IRC Standards Review Committee (joint comments)		
Pepco Holdings Inc Affiliates	No	Question #3 indicated that as currently drafted the standard applies to variable static reactive resources located at asynchronous generating facilities (e.g. wind and solar sites). This is either specifically mentioned, or inferred, within the language of the June 15, 2011 Draft 2 standard. Regarding the question of a reliability need for including variable static reactive resources (e.g. static Var compensators) that are not located at generating sites in this standard, the answer is no. We see no need to make the standard applicable to Static Var Compensators (SVC's), whether they are located at generating sites, or remote from generating sites. An SVC is merely a thyristor switched / controlled capacitor or reactor. Maximum and minimum output is controlled by the firing controls to the thyristor, and is limited by the size of the installed shunt capacitor / reactor banks. When the thyristor is switched off there is no output. As the firing angle is increased toward the full on position the reactive output is increased until the full value of the shunt capacitor bank, or reactor bank, is reached. Protective devices and settings on the shunt capacitor bank and reactor bank within the SVC are typical of those employed on fixed banks. The control system merely provides a means to adjust the output between zero and full bank rating. As in the case of fixed banks, SVC protective devices are set assuming the full bank is in service. Therefore, if fixed shunt reactive banks are not subject to the standard, which they should not be, then SVC's should not be either. Synchronous machines, however, are a different story entirely. The quantity of reactive power produced by, or drawn into, the machine is a function of the machine field current. In an under-excited condition the unit may loose synchronism, or trip via loss of field protection, unless the voltage regulator (min. excitation limiter) is properly set and coordinated with the machine's capability and protective devices. Similarly, excessive Var output and / or terminal overvoltage caused by over-excitation of the field can result in equipment damage, or unit tripping, unless the voltage regulator is properly set and coordinated with the machine's capability and protective devices.
Response: Thank you for your detailed comment. While SVC's located at the bus of a variable energy resource would not coordinate with the individual generating equipment, the internal coordination between the current limiters and the protection of the SVC can be verified.		
NERC System Protection and	Yes	Devices such as Static Var Compensators and STATCOMs have equipment limitations, control

Organization	Yes or No	Question 3 Comment
Control Subcommittee		systems, and protections that must be coordinated to assure system reliability. The reliability impact of unnecessarily tripping reactive support from a variable static resource is similar to tripping reactive support from a generator or synchronous condenser.
Response: Thank you for your comment. The standard applies to voltage control resources at generating Facilities, regardless of their design. The SDT has determined that variable static Reactive resources not located at generating Facilities are not within the scope of this standard.		
Midwest Reliability Organization's NERC Standards Review Forum (NSRF)	No	
SPP Reliability Standards Development Team	Yes	We weren't able to locate the variable static reactive resources located at asynchronous generating facilities (e.g. wind and solar sites) within the standard as the question suggests. We feel like variable static reactive resources (e.g. static VAr compensators) that are not located at generating sites should have been included but would request that the team provide a limit on the size of these types of facilities. Our team isn't sure what a cutoff number would be, but would ask that the drafting team investigate this issue to come up with an appropriate number.
Response: Thank you for your comment. The standard describes "generating Facility voltage regulating controls." This equipment could include static Reactive resources (typically at asynchronous Facilities, such as wind or solar). The SDT has determined that variable static Reactive resources not located at generating Facilities are not within the scope of this standard.		
SERC Planning Standards Subcommittee		
Idaho Power-Power Production		
Santee Cooper		
PPL Generation	No	

Organization	Yes or No	Question 3 Comment
Dominion	No	
FirstEnergy	No	
SERC Dynamics Review Sub-committee		
NERC Staff	Yes	Devices such as static var compensators (SVCs) and static compensators (STATCOMs) have equipment limitations, control systems, and protections that must be coordinated to assure system reliability. The reliability impact of unnecessarily tripping reactive support from a variable static resource is similar to tripping reactive support from a generator or synchronous condenser.Also, the standard must remain neutral as to the type of reactive resource, allowing for other technologies such as storage and demand-side regulation through electronically coupled loads that are relied upon for reliability purposes in the same vain as other reactive sources cited.
Response: Thank you for your comment. The standard applies to voltage control resources at generating Facilities, regardless of their design. The SDT has determined that variable static Reactive resources not located at generating Facilities are not within the scope of this standard.		
Public Service Enterprise Group	No	First, the inclusion of "variable static reactive resources located at asynchronous generating facilities (e.g. wind and solar sites)" was not noted in the standard. Second, we do not believe that including other static reactive resources that are not located at generating sites would materially impact reliability
Response: Thank you for your comment. The standard describes "generating Facility voltage regulating controls.. This equipment could include static Reactive resources (typically at asynchronous Facilities, such as wind or solar). The SDT has determined that variable static Reactive resources not located at generating Facilities are not within the scope of this standard.		
SERC Generation sub-committee		
ACES Power Members	No	It is not clear how this standard is applicable to variable static reactive resources located at asynchronous generating facilities. They do not appear in applicability section.

Organization	Yes or No	Question 3 Comment
Response: Thank you for your comment. The standard describes "generating Facility voltage regulating controls." This equipment could include static Reactive resources (typically at asynchronous Facilities such as wind or solar). The SDT has determined that variable static Reactive resources not located at generating Facilities are not within the scope of this standard.		
Arizona Public Service Company	No	
Westar Energy	Yes	Currently the requirements do not address variable static reactive resources located at asynchronous generating facilities as the question states. If the intent is for the standard to apply to variable static reactive resources located at asynchronous generating facilities, we propose language be added to the standard to address these resources. Yes, we do see a reliability need for including variable static reactive resources (e.g. static VAr compensators) that are not located at generating sites. We propose that language be included to address the limit on the size of these types of facilities.
Response: Thank you for your comment. The standard describes "generating Facility voltage regulating controls." This equipment could include static Reactive resources (typically at asynchronous Facilities such as wind or solar). The SDT has determined that variable static Reactive resources not located at generating Facilities are not within the scope of this standard. The standard applies to voltage control resources at generating Facilities, regardless of their design. The SDT has determined that variable static Reactive resources not located at generating Facilities are not within the scope of this standard.

Associated Electric Cooperative, Inc.		
Dynegy Inc.		
New York Independent System Operator		
Tri-State Generation and Transmission, In.	No	The standard name indicates it applies to generating sites.
Response: Thank you for your comment.		
Cowlitz County PUD	Yes	But not at the 20/75 MVA name plate criteria. First the applicability should be tied to expected maximum MVA output. Second, the MVA basis should be established from a modeling study. Ultimately, the applicability should only include plants that are members of the BES once this has been defined.
Response: Thank you for your comment. The standard applies to voltage control resources at generating Facilities, regardless of their design. The SDT has determined that variable static Reactive resources not located at generating Facilities are not within the scope of this standard.		
Xcel Energy	No	These units are not tested under the proposed MOD-025-2, so should not be included in PRC-019-1.
Response: Thank you for your comment.		
Lakeland Electric		

Organization	Yes or No	Question 3 Comment
Exelon	No	Exelon does not see a reliability need to include static reactive resources in PRC-019. The standard as written is applicable to voltage regulating controls and limit functions with generator capabilities and protection system settings which is generator specific. Adding static reactive resources would require unnecessary additional guidance to be included in the standard. The maintenance and coordination of relays related to static reactive resources is currently covered in PRC-005 and modeling and studies are included in the MOD standard.
Response: Thank you for your comment.		
American Wind Energy Association	No	
Tacoma Power	No	Even if the variable devices or their impact is well defined, such as "Devices within 2 buses and that can affect the transmission system voltage plus or minus 5% or greater", including this requirement for variable static reactive sources could involve a wide scope of devices and potentially many owners and operators for very little improvement in reliability.
Response: Thank you for your comment.		
Georgia Transmission Corporation		
Austin Energy		
Wisconsin Electric	No	The primary applicability should be to rotating synchronous machines which must have their protection settings and excitation controls properly coordinated with the machine capability. It is not clear how this can be applied to wind generators.
Response: Thank you for your comment. The standard describes "generating Facility voltage regulating controls." This equipment could include static Reactive resources (typically at asynchronous Facilities such as wind or solar). The SDT agrees that static Reactive resources not at generating Facilities should not be within the scope of this standard.		
Great River Energy		

Organization	Yes or No	Question 3 Comment
BC Hydro	No	
Northeast Utilities	Yes	Only units larger 75 MVA are generally impactful. We recommend making 75 MVA the reporting floor [regardless of connected voltage].Coordination will be needed. Static VAR Compensators are typically self protected by the vendor. As long as the interface point (transformer) is properly and redundantly protected and the Static VAR Compensator safely shuts down for internal faults or out of spec operation, there should be minimal need for coordination with transmission system protection. However, this issue would have to be researched with the vendor of the equipment. Coordination with the Transmission Operator will have to be reviewed for pre and post protection system operation conditions.
Response: Thank you for your comment. The standard applies to voltage control resources at generating Facilities, regardless of their design. The SDT has determined that variable static Reactive resources not located at generating Facilities are not within the scope of this standard.		
Constellation Power Generation	No	
Consolidated Edison Co. of NY, Inc.	Yes	Only units larger 75 MVA are generally impactful. We recommend making 75 MVA the reporting floor [regardless of connected voltage].Coordination will be needed. Static VAR Compensators are typically self protected by the vendor. As long as the interface point (transformer) is properly and redundantly protected and the Static VAR Compensator safely shuts down for internal faults or out of spec operation, there should be minimal need for coordination with transmission system protection. However, this issue would have to be researched with the vendor of the equipment. Coordination with the Transmission Operator will have to be reviewed for pre and post protection system operation conditions.
Response: Thank you for your comment. The standard applies to voltage control resources at generating Facilities, regardless of their design. The SDT has determined that variable static Reactive resources not located at generating Facilities are not within the scope of this standard.		
American Electric Power	No	AEP sees no benefit to the reliability of the BES in adding to this standard the controls associated with static reactive resources.
Response: Thank you for your comment.		

Organization	Yes or No	Question 3 Comment
Ingleside Cogeneration LP	No	Ingleside Cogeneration LP is hesitant to require validation of components which have not been clearly identified as a reliability imperative under either the revised definition of the BES or CIP-002-4's bright-line criteria.
Wisconsin Public Service Corp		
GE Energy		
ISO New England		
GenOn Energy		
Manitoba Hydro	No	Static VAr compensators do not belong in a generation standard.
Response: Thank you for your comment. The standard describes "generating Facility voltage regulating controls." This equipment could include static Reactive resources (typically at asynchronous Facilities such as wind or solar). The SDT agrees that static Reactive resources not at generating Facilities should not be within the scope of this standard.		
Duke Energy	No	See the purpose of the standard. It's not clear why a generation protection/control coordination requirement would be applicable to non-generation resources, other than maybe synchronous condensors.
Response: Thank you for your comment. The standard describes "generating Facility voltage regulating controls." This equipment could include static Reactive resources (typically at asynchronous Facilities such as wind or solar).		
Lincoln Electric System		
CPS Energy		
Independent Electricity System Operator	No	The SVCs serve quite different purpose and react to system conditions quite differently compared to their generator/synchronous condenser counterparts. Further, SVCs do not "trip", per se, they vary their reactive outputs including going to and crossing 0 MVar and hence some

Organization	Yes or No	Question 3 Comment
		of the interactions between the device and its protection systems in the case of generators/synchronous condensers are not applicable to SVCs.
Response: Thank you for your detailed comment.		
Gainesville Regional Utilities	No	
Ameren	Yes	Question should be directed at transmission planners. I would believe the static VAr compensators are required for system voltage support, similar to synchronous condenser or generation.
Response: Thank you for your comment. The standard applies to voltage control resources at generating Facilities, regardless of their design. The SDT has determined that variable static Reactive resources not located at generating Facilities are not within the scope of this standard.		
Indeck Energy Services	No	Not registered
Response: Thank you for your comment.		
Oncor Electric Delivery Company LLC	No	Oncor does not believe that there is a reliability need for including dynamic or static reactive resources (e.g. static VAr compensators) that are not located at generating sites in this standard.
Response: Thank you for your comment.		
Indiana Municipal Power Agency		
Los Angeles Department of Water and Power		LADWP does not have a position on this question at this time.
Chelan County PUD	Yes	If there is a reliabiity need for synch-condensors and generators, why not SVCs for similar minimum capacity? don't they similarly impact system reliability?
Response: Thank you for your comment. The standard applies to voltage control resources at generating Facilities, regardless of their design. The		

Organization	Yes or No	Question 3 Comment
SDT has determined that variable static Reactive resources not located at generating Facilities are not within the scope of this standard.		

4. The SDT revised the Purpose of the standard in accordance with the SAR, "To improve the reliability of the Bulk Electric System by preventing tripping of generating units/Facilities due to miscoordination of generating unit/Facility voltage regulating controls, and limit functions with generator capabilities and Protection System settings."

Do you agree with the revised Purpose of the standard? If not, please provide suggested language changes in the Comment section.

Summary Consideration: The vast majority of stakeholders agreed with the revised Purpose of the standard. Topics of concern among those not in agreement included the following (# of stakeholders expressing the concern listed in parenthesis):

- **Concern that existing language limits the standard only to traditional rotating machinery.**
- **Concern that "capability" was inconsistently used.**
- **Concern that units less than 50 MVA are too small to include.**
- **Dislike "prevent tripping," suggest "reduce the potential for tripping."**
- **Concern that PRC-001 should include this standard's scope.**
- **Dislike the use of "Protection System settings."**
- **Concern that Purpose over reaches the purpose and intention of the SAR.**

The drafting team made minor changes to the Purpose in response to the concerns and suggestions provided by the stakeholders. The proposed Purpose is:

To verify coordination of generating unit Facility or synchronous condenser voltage regulating controls, limit functions, equipment capabilities and Protection System settings.

Organization	Yes or No	Question 4 Comment
LG&E and KU Energy		
Northeast Power Coordinating Council	No	Modify the wording to reflect all 'real and reactive power sources,' not limiting it exclusively to traditional rotating machinery.

Organization	Yes or No	Question 4 Comment
Response: Thank you for your comment. The SDT does not agree with the expansion in scope that would result from the suggested change in wording. For example, this would include all transmission capacitor banks on the BES. The scope of this standard is not limited to traditional rotating machinery, but also applies to all generating Facilities, including asynchronous Facilities such as wind and solar.		
Imperial Irrigation District (IID)	Yes	
IRC Standards Review Committee (joint comments)		Does this SDT really believe a standard will "prevent" trippings due to mis-coordination?
Response: Thank you for your comment. The SDT agrees with your concern, and has changed the wording to that suggested by the Independent Electricity System Operator.

Georgia Transmission Corporation		
Austin Energy	Yes	
Wisconsin Electric	No	Replace the phrase "...preventing tripping..." with "...reducing the potential for tripping..."
Response: Thank you for your comment. The SDT agrees with your concern, and has changed the wording to that suggested by the Independent Electricity System Operator.		
Great River Energy		
BC Hydro	Yes	
Northeast Utilities	No	Modify the wording to reflect all 'real and reactive power sources,' not limiting it exclusively to traditional rotating machinery.
Response: Thank you for your comment. The SDT does not agree with the expansion in scope that would result from the suggested change in wording. For example, this would include all transmission capacitor banks on the BES. The scope of this standard is not limited to traditional rotating machinery, but also applies to all generating Facilities, including asynchronous Facilities such as wind and solar.		
Constellation Power Generation	No	Although CPG believes that the purpose of this standard is valid and accurate, it closely resembles the purpose of PRC-001 and therefore the requirements drafted in PRC-19 should be rolled into a revision of PRC-1.

Organization	Yes or No	Question 4 Comment
Response: Thank you for your comment. The PRC-001 SDT could propose retiring PRC-019-1 as part of their process if they include the content of PRC-019 in their standard.		
Consolidated Edison Co. of NY, Inc.	No	Modify the wording to reflect all 'real and reactive power sources,' not limiting it exclusively to traditional rotating machinery.
Response: Thank you for your comment. The SDT does not agree with the expansion in scope that would result from the suggested change in wording. For example, this would include all transmission capacitor banks on the BES. The scope of this standard is not limited to traditional rotating machinery, but also applies to all generating Facilities, including asynchronous Facilities such as wind and solar.		
American Electric Power	No	We are concerned by the inclusion of "protection system settings" in how it might differ from, or be confused with, the NERC defined term Protection System. The term "generator capabilities" should be removed from the purpose statement (as well as the requirements), as it is general enough of a term to make proving compliance difficult.
Response: Thank you for your comment. The "Protection System settings" are the settings used in the Protection System. For the purpose of this standard, some of the functions of the Generator Protection System may be among those that need to coordinate with limiters and equipment capabilities. The SDT feels it is appropriate to consider both "Protection System settings" and "generator capabilities." Documentation of "generator capabilities" are usually provided by the OEM, but may be modified by the Generator Owner for specific conditions.		
Ingleside Cogeneration LP	Yes	
Wisconsin Public Service Corp		
GE Energy		
ISO New England		
GenOn Energy	No	Disagree strongly: It is overreach to make this a generator protection standard; the standard is not comprehensive enough to take on that task. As a result, the SDT has overstated the purpose and intent of this standard. Simple is better and appropriate. Purpose: To improve reliability through coordination of generator protection systems with unit/facility voltage

Organization	Yes or No	Question 4 Comment
		regulating limiter functions and protection.
Response: Thank you for your comment. The SDT agrees with your concern, and has changed the wording to that suggested by the Independent Electricity System Operator.		
Manitoba Hydro	Yes	
Duke Energy	Yes	
Lincoln Electric System		
CPS Energy		
Independent Electricity System Operator	Yes	We do not have any real issues with the purpose statement; however, we offer an alternative to add a bit more positive spin (as opposed to preventing tripping):To improve the reliability of the Bulk Electric System by ensuring proper coordination of generating unit/facility voltage regulating controls and limit functions with generator capabilities and protection system settings.
Response: Thank you for your comment. The SDT agrees, and has revised the language based on your proposed wording for the Purpose statement.		
Gainesville Regional Utilities	Yes	
Ameren	Yes	
Indeck Energy Services	No	There is no evidence that this needs to be done to any unit less than the NERC Reportable Disturbance level for the control area.
Response: Thank you for your comment. The SDT based the applicability of the standard on the Registry criteria, and does not have sufficient technological justification to deviate from those values.		
Oncor Electric Delivery Company LLC	Yes	

Organization	Yes or No	Question 4 Comment
Indiana Municipal Power Agency	Yes	
Los Angeles Department of Water and Power		LADWP does not have a position on this question at this time.
Chelan County PUD	Yes	

5. The proposed effective dates provide a "phased-in" approach to establishing compliance with this standard to provide adequate time for entities to include all applicable units/Facilities. Do you agree with the proposed implementation schedule? If not, please provide an alternative implementation schedule, approach, and supporting information in the comments.

Summary Consideration: A majority of stakeholders agreed with the proposed phased-in approach outlined in the implementation schedule. Topics of concern among those not in agreement included the following:

- **Concern that Applicability Section 5.2.5 is missing.**
- **Suggestion that the first 20 percent be due in two years vs. one year.**
- **Concern over M1 previous test evidence requirements.**
- **Conflicting information between the standard effective date section and the implementation plan schedule.**
- **Recommendation to match MOD-026 implementation plan.**
- **Misunderstanding of one unit vs. multiple unit plant application.**

The standard drafting team made the following changes in response to the comments received:

- **The Applicability Section 5.2.5 was added, as suggested.**
- **The effective date in the Implementation Plan has been corrected to match that shown in the Applicability section of the standard.**
- **Measure M1 was modified to address the previous test evidence requirements, and now reads:**

M1. Each Generator Owner and Transmission Owner will have evidence, such as example evidence provided in PRC-019 Section G, to show that its applicable Facility voltage regulating system controls and Protection System functions are coordinated with the applicable Facility capabilities and Protection System settings as specified in Requirement R1. As applicable, this may include the following:

- **In service excitation system and voltage regulating system control, limiters and protection functions**
- **In-service generator or synchronous condenser protection system settings**
- **Generator or synchronous condenser capabilities, or**
- **Steady state stability limit.**

The coordination should include 1) verifying the in-service limiters are set to operate before the protection and the protection is set to operate before conditions cause damage to equipment assuming normal AVR

control loop and system steady state operating conditions, and 2) verifying the desired settings are applied to the in-service equipment.

The SDT did not adopt the recommendation to verify the initial 20 percent of applicable units within two years instead of one year of the effective date because it is desired to align the Implementation Plan of this standard to match the MOD-025-2 Implementation Plan. The SDT believes the elements of this standard should be performed as a precursor to performing Reactive power capability testing, specified by MOD-025-2.

LG&E and KU Energy		
Northeast Power Coordinating Council	Yes	
Imperial Irrigation District (IID)	Yes	
IRC Standards Review Committee (joint comments)		
Pepco Holdings Inc Affiliates	Yes	
NERC System Protection and Control Subcommittee	Yes	
Midwest Reliability Organization's NERC Standards Review Forum (NSRF)	No	It appears that Item 5.2.5 in the Applicability section is missing. We propose adding, "5.2.5 By the first day of the first Calendar quarter, five calendar years following Board of Trustee approval each Generator Owner and Transmission Owner shall have verified 100% of its applicable units".
Response: Thank you for your comment. The SDT has corrected this oversight.		
SPP Reliability Standards	No	The team would like to move out the initial 20% to 2 years and add a year to the following phases as well i.e 40% 3 years 60% 4 years etc. 5.2.5 seems to be missing from the standard

Organization	Yes or No	Question 5 Comment
Development Team		which doesn't include a bullet for 100% for those who need Board approval.
Response: Thank you for your comment. The SDT believes the five-year phase-in plan is appropriate. This corresponds to the phase-in period of MOD-025-2. The SDT has corrected the oversight concerning Section 5.2.5, and has corrected the Effective Date for the first 20 percent of applicable units in the Implementation Plan.		
SERC Planning Standards Subcommittee		
Idaho Power-Power Production	Yes	
Santee Cooper		
PPL Generation	Yes	
Dominion	No	The effective date implementation schedules contained in the standard and the associated Implementation Plan do not agree. Specifically, the standard indicates one year following regulatory and/or Board of Trustee approval where as the Implementation Plan indicates two year. Additionally, the standard at Step 5.2 does not include a sub-step for 100% of applicable units.
Response: Thank you for your comment. The SDT has corrected the oversight concerning Section 5.2.5, and has corrected the Effective Date for the first 20 percent of applicable units in the Implementation Plan.		
FirstEnergy	Yes	
SERC Dynamics Review Sub-committee		
NERC Staff	No	As written, the standard only addresses 80% compliance on generation and reactive sources that are not subject to regulatory approval. It appears that a section 5.2.5, similar to section 5.1.5, is missing from the Effective Dates section.

Organization	Yes or No	Question 5 Comment
Response: Thank you for your comment. The SDT has corrected the oversight concerning Section 5.2.5.		
Public Service Enterprise Group	Yes	
SERC Generation sub-committee		
ACES Power Members		
Arizona Public Service Company	Yes	
Westar Energy	No	We would recommend the following implementation schedule:20% - 2 years after regulatory approval40% - 3 years after regulatory approval60% - 4 years after regulatory approval80% - 5 years after regulatory approval100% - 6 years after regulatory approval
Response: Thank you for your comment. The SDT believes the five-year phase-in plan is appropriate. This corresponds to the phase-in period of MOD-025-2. The SDT has corrected the oversight concerning Section 5.2.5, and has corrected the Effective Date for the first 20 percent of application units in the Implementation Plan.		
Southern Company	Yes	
Tennessee Valley Authority GO	Yes	
Luminant Power	Yes	In requirement R5.2 - there should be a sub-requirement R5.2.5 for 100% compliance at five calendar years?
Response: Thank you for your comment. The SDT has corrected the oversight concerning Section 5.2.5.		
Lakeland Electric		

Organization	Yes or No	Question 5 Comment
Salt River Project	Yes	
PacifiCorp	No	Measure M1 in proposed Standard PRC-019-1 requires current evidence to satisfy the coordination requirements of Requirement R1, Section 1.1, plus one previous dated set of evidence demonstrating the latest coordination review has been performed within the intervals prescribed in Requirement R1, Section 1.2. The latter category of evidence may not be available immediately upon the effective date of this proposed standard. The implementation plan should clarify how this Measure will be addressed during the phased-in implementation schedule.
Response: Thank you for your comment. The SDT agrees, and Measure M1 has been changed to address your concern.		
South Carolina Electric and Gas	No	There seems to be a mistake on the Implementation Plan versus the Standard. The implementation plan states two years for the first 20% of applicable units and the standard states one year. Please clarify this inconsistency.
Response: Thank you for your comment. The SDT has corrected the Effective Date for the first 20 percent of applicable units in the Implementation Plan.		
APS		being intentionally left blank (no answer to be provided)
Associated Electric Cooperative, Inc.	Yes	
Dynegy Inc.	No	Some of the requested data will reside in places not familiar to smaller entities and may require the use of consultants. The SDT may want to consider giving 2 years until the first 20% compliance level is reached because it will take time to set up a program.
Response: Thank you for your comment. The SDT believes the five-year phase-in plan is appropriate. This corresponds to the phase-in period of MOD-025-2.		
New York Independent System Operator		

Organization	Yes or No	Question 5 Comment
Tri-State Generation and Transmission, In.	Yes	
Cowlitz County PUD	Yes	For Cowlitz, this would be acceptable. However, Cowlitz only owns a few generation plants. We must defer to those who own many plants.
Response: Thank you for your comment.		
Xcel Energy	Yes	
Lakeland Electric		
Exelon	No	There is a conflict with the implementation periods stated within the body of Standard PRC-019-1 and the associated Implementation Plan. PRC-019-1 Section 5 Effective Date Step 5.1.1 states "(b)y the first day of the first calendar quarter, one year following applicable regulatory approval ... " [emphasis added]; however, the Implementation Plan states the Effective Date is "(t)he first day of the first calendar quarter two years following applicable regulatory approval ... " [emphasis added].Exelon requests that the implementation period be 2 years following regulatory approval. Nuclear generating stations have refueling outage schedule windows of approximately 18 months or 24 months (based on reactor type). An implementation period of 2 years will allow for any modifications to existing equipment be completed during a refueling outage.
Response: Thank you for your comment. The conflict between the Implementation Plan and the body of the standard has been corrected. The SDT does not believe the requirement to have 20 percent of applicable units compliant within the first year is an undue burden. For the example noted, the unit could be verified with the last 20 percent of Exelon's fleet, which gives over four years to comply with the standard.		
American Wind Energy Association	Yes	
Tacoma Power	Yes	None
Georgia Transmission		

Organization	Yes or No	Question 5 Comment

Austin Energy	Yes	
Wisconsin Electric	Yes	
Great River Energy		
BC Hydro	Yes	
Northeast Utilities	Yes	
Constellation Power Generation	Yes	
Consolidated Edison Co. of NY, Inc.	Yes	
American Electric Power	No	In light of the many other changes to standards currently proposed, and their implementations, AEP would suggest an additional year to the proposed implementation schedule to ensure a successful adaptation to PRC-019-1.The effective date for the 20% compliance milestone is inconsistent between the draft standard and the implementation plan, with one document allowing one year for compliance and the other allowing two years.
Response: Thank you for your comment. The SDT believes the five-year phase-in plan is appropriate. This corresponds to the phase-in period of MOD-025-2. The SDT has corrected the oversight concerning Section 5.2.5, and has corrected the Effective Date for the first 20 percent of applicable units in the Implementation Plan.		
Ingleside Cogeneration LP	Yes	The five year phased-in validation of settings is sufficient for Ingleside Cogeneration LP.
Response: Thank you for your comment.		
Wisconsin Public Service		

Organization	Yes or No	Question 5 Comment
Corp		
GE Energy		
ISO New England		
GenOn Energy	Yes	
Manitoba Hydro	No	-MH recommends that the effective dates for this standard be identical to MOD-026. This will allow entities to schedule all work and required outages simultaneously.
Response: Thank you for your comment. The SDT believes the elements of this standard should be performed as a precursor to performing Reactive power capability testing, as specified in MOD-025-2. The Implementation Plan is designed to match that of MOD-025-2.		
Duke Energy	Yes	
Lincoln Electric System		
CPS Energy		
Independent Electricity System Operator		
Gainesville Regional Utilities	Yes	
Ameren	Yes	Yes, only if settings need to be verified. No if testing needs to be done to verify settings.
Response: Thank you for your comment. The standard does not require testing. It only requires that the settings that are used for determining coordination have been verified to be the settings that are in service.		
Indeck Energy Services	No	For a plant with fewer than 5 units, implementation should be at the point that the unit finally satisfies the requirement, stated differently, a single unit station would comply at the 5 year point, not at the 1 year point. Why should multiple unit plants be given more time than single

Organization	Yes or No	Question 5 Comment
		unit plants. If having the units done in 5 years meets the BPS reliability need, then it should apply this alternative way. If BPS reliability needs compliance in 1 year, then all should comply.
Response: Thank you for your comment. The implementation plan is based on an entity's total number of applicable units, not the number of units installed at a plant. An entity that owns only one unit would have to be in compliance after one year, not five.		
Oncor Electric Delivery Company LLC	Yes	
Indiana Municipal Power Agency	Yes	
Los Angeles Department of Water and Power		LADWP does not have a position on this question at this time.
Chelan County PUD	Yes	

6. **Do you agree that the evidence, documents, and functions listed in Section G are sufficient for giving the Generator Owner/Transmission Owner examples of how the coordination can be demonstrated? If not, please provide suggested language changes to the Measure and supporting information in the Comment section.**

Summary Consideration: Specific changes were made to Section G of the standard based on comments received. These changes include:

1. **Providing example diagrams using nominal voltage and frequency as basis.**
2. **Correcting the SSSL radius calculation.**
3. **Information previously listed in the "under-excited limiters or minimum excitation limiters" and the "over-excited limiters or maximum excitation limiters" section has been combined into a bulleted list section.**
4. **The SDT changed "protective" to "protection" within the standard to be consistent with Section G.**
5. **The SDT added another reference document for use in calculation of SSSL.**

Several commentators were concerned that Section G prescribed a method for illustrating coordination of AVR limiter/protection functions with other Protection Systems. The SDT agrees there are several ways of demonstrating coordination, and does not prescribe a particular method. Any protective function that is enabled should be evaluated for proper coordination.

The SDT considered the request to remove distance relay and volts/hertz relay elements from the standard. The SDT believes these elements should remain in the standard because (a) the distance element should illustrate coordination with field forcing controls of the AVR, and (b) the volts per hertz function can operate with the unit on-line under certain operating conditions.

LG&E and KU Energy		
Northeast Power	Yes	

Organization	Yes or No	Question 6 Comment
Coordinating Council		
Imperial Irrigation District (IID)	Yes	
IRC Standards Review Committee (joint comments)		
Pepco Holdings Inc Affiliates		
NERC System Protection and Control Subcommittee	No	The diagrams need to incorporate the permissible voltage and frequency ranges. For example, the P-Q diagram probably is based on 1 pu voltage and frequency.
Response: Thank you for your comment. The SDT has revised example diagrams using nominal voltage and frequency as basis.		
Midwest Reliability Organization's NERC Standards Review Forum (NSRF)	Yes	
SPP Reliability Standards Development Team	Yes	While the team agrees with this evidence, some of the older units in the system may not have this information readily available.
Response: Thank you for your comment.		
SERC Planning Standards Subcommittee		
Idaho Power-Power Production	No	We believe that the tutorial like language in Section G is not appropriate for a standard. There is an abundance of material available describing the coordination of generator protection equipment, such as textbooks, IEEE tutorials and even NERC tutorials. We believe referencing the documents could be appropriate and helpful. Even though the diagrams are listed as examples, we believe they might be interpreted a recipe to be followed.

Organization	Yes or No	Question 6 Comment
Response: Thank you for your comment. The SDT believes Section G provides applicable entities information on how compliance may be demonstrated without prescribing how to accomplish compliance. Entities may demonstrate compliance in ways other than those offered as examples in Section G.		
Santee Cooper		
PPL Generation	No	
Dominion	Yes	
FirstEnergy		At the moment we do not have comments on the proposed measures. We will review the proposed measures on the next draft and provide out input.
Response: The SDT will respond when comments are provided.		
SERC Dynamics Review Sub-committee		
NERC Staff	No	The diagrams need to incorporate the permissible voltage and frequency ranges. For example, the P-Q diagram probably is based on 1 pu voltage and frequency.Further, Section G should address the system concerns described in Table 2 of the SPCS Technical Reference Document “Power Plant and Transmission System Protection Coordination,” for the generator protection functions that must be coordinated.
Response: Thank you for your comment. The SDT has revised the example diagrams using nominal voltage and frequency as basis. The SPCS Technical Reference Document addresses issues regarding generator and system protection coordination that are beyond the scope of PRC-019-1. At the same time, some of the coordination required in PRC-019-1 is not covered by the SPCS document. For example, the Loss of Field (40) function in Table 2 does not discuss coordination with the under-excitation limiter nor the steady-state stability limit.		
Public Service Enterprise Group	Yes	
SERC Generation sub-

committee		
ACES Power Members	Yes	
Arizona Public Service Company	No	30 minutes are more than adequate. All components reach steady state temperatures within that time. There is no need to be there more than 30 minutes.
Response: Thank you for your comment. We believe this comment refers to a different standard – probably MOD-025-2.		
Westar Energy	Yes	Examples for older units, where the information in the current examples are not readily available, could be included.
Response: Thank you for your comment. The examples provided in Section G are representative of both older units and newer units. Entities may demonstrate compliance in ways other than those offered as examples in Section G.		
Southern Company	Yes	
Tennessee Valley Authority GO	Yes	
Luminant Power	No	This item needs to coordinate with PRC-001 (System protection Coordination) and the future PRC-023-1 (generator loadability) standard currently under development. Section G indicates a distance relay (21) but does not indicate any timers that would be coordinated with the transmission provider. Propose removing this protective relay from Attachment 2.
Response: Thank you for your comment. The SDT believes the distance function (21) may need to be coordinated with excitation limiters and equipment capabilities, and should be evaluated if it is applied to a generating Facility. Coordination of that protective function with the transmission system is addressed by PRC-001 and PRC-023, as mentioned.

Cowlitz County PUD	Yes	Cowlitz needs to confer with its consultant to form a more informed opinion. However, it appears to be reasonable.
Response: Thank you for your comment.		
Xcel Energy	Yes	
Lakeland Electric		
Exelon	No	In addition to the methodology listed, a provision should be allowed to use an alternative acceptable methodology that meets the intent of the Standard such as a methodology that uses impedance locus for loss of field for settings for the loss of field relays.Attachment G second formula is incorrect and should be corrected as follows:R = V2 g/2*(1/Xs+1/Xd) (Divide by 2)
Response: Thank you for your comment. The methodology listed in the example is not all-inclusive. The wording in Section G specifically states		

Organization	Yes or No	Question 6 Comment
"…the evidence of coordination associated with Requirement R1 may be in the form of …" The SDT has corrected the error in the formula for R.		
American Wind Energy Association	Yes	
Tacoma Power	Yes	None
Georgia Transmission Corporation		
Austin Energy	Yes	
Wisconsin Electric	No	The following should be added to the list in Section G:1. under-excited limiters or minimum excitation limiters 2. over-excited limiters or maximum excitation limiters.
Response: Thank you for your comment. While all of the items identified were contained in the posted standard, the SDT has revised the standard by moving the example items to be considered for coordination from the list section referenced into a bulleted list section.		
Great River Energy		
BC Hydro	Yes	
Northeast Utilities	Yes	
Constellation Power Generation	No	CPG believes that engineering documents detailing the coordination of the these components should be sufficient in lieu of coordination plots requiring software that is not commonly used by generators.
Response: Thank you for your comments. The SDT agrees there are several ways of demonstrating coordination, and does not prescribe a particular method.		
Consolidated Edison Co. of NY, Inc.	Yes	

Organization	Yes or No	Question 6 Comment
American Electric Power	No	There appear to be inconsistencies between the standard and appendix G. the standard uses the term “protective system settings” and “protection system settings” while the appendix uses the term “protection function”.
Response: Thank you for your comment. The SDT has changed “protective” to “protection” within the standard.		
Ingleside Cogeneration LP	No	Ingleside Cogeneration LP agrees with the concept of establishing a mode of operation that allows voltage regulators and limiters the first opportunity to deal with a voltage transient well before the corresponding Protection Systems are activated. However, we are concerned that protective relay settings must be always set in accordance with the Steady State Stability Limit (SSSL) as defined by NERC. There may be factors that are more limiting which require more sensitive settings - which should be acceptable if demonstrated on a P-Q, R-X or similar graph.
Response: Thank you for your comment. The standard does not prescribe that the protective relay settings must always be set in accordance with the SSSL. The SDT agrees that there may be limiting factors requiring more sensitive Protection System settings than required by the SSSL. Setting Protection Systems to the most limiting factor is acceptable.

Ameren	No	(1)Volts per hertz and stator overvoltage protection are more applicable during unit start-up, not running conditions, where the system maintains the voltage and frequency. These should be eliminated. (2) The standard needs to be clear on what relay elements need to be included if enabled. (3) The standard needs to be clear on how to plot the diagrams to incorporate operating voltage. For example the generation is most stable while maintaining maximum permissible voltage and producing the most VAr's possible. Therefore should the plot be at maximum voltage of 1.05pu. (4) It would be helpful to have some reference for where the development of the Steady State Stability Limit equations in the draft standard could be found. None could be found on the NERC website. We are concerned that the method proposed for calculating steady state stability limits does not include sufficient conservatism.
Response: Thank you for your comment. (1) The SDT believes that it is possible to encounter volts per hertz conditions during normal operation, so this needs to be evaluated. (2) The SDT believes any protection functions that are enabled should be evaluated for proper coordination. (3) The SDT does not prescribe what voltage or frequency to use when evaluating coordination. The entity performing the evaluation can choose the voltage and frequency value to use. (4) The SDT has added a technical reference regarding SSSL equation development to the standard.

7. Do you agree with the data retention language listed in the Compliance section of the draft standard? If not, please comment and provide alternative data retention language.

Summary Consideration: Forty-six stakeholders agreed, 27 stakeholders disagreed, and 18 stakeholders had no opinion.

Three stakeholders were concerned that the TO might be required to retain compliance data for generation equipment that it does not own. The applicability requirements in the draft standard have been clarified.

Eleven stakeholders were concerned that the data retention requirements were unclear, especially as the standard is being phased in. Stakeholders were also concerned that data retention requirements might be excessive. The SDT revised the Measure M1 and the data retention requirements for clarity and to be consistent with the NERC Compliance Process Bulletin #2011-001.

Organization	Yes or No	Question 7 Comment
LG&E and KU Energy		
Northeast Power Coordinating Council	No	The data retention section of the standard is vague with respect to responsibilities of the various parties. It would appear that the data retention responsibility falls to either the Generator Owner or the Transmission Owner with a synchronous condenser on its system. If, however, the Transmission Owner is also required to retain compliance data of generator and transmission system coordination, a substantial amount of time may be required to gather this information as it does not exist today. At the very least, once this standard becomes effective an effort with generators will be needed to assemble the appropriate information demonstrating the proper coordination of transmission system and generator relaying. This could take a considerable amount of time to complete. Responsibility for data retention should be placed on the owner of the equipment.
Response: Thank you for your comment. The equipment owner has responsibility for data retention. If a Transmission Owner owns a synchronous condenser, then the Transmission Owner is only required to retain compliance data for that equipment. The SDT agrees the Application section		

Organization	Yes or No	Question 7 Comment
needed to be clarified, and has modified Section 4.1.2 to state that the standard only applies to Transmission Owners that own synchronous condensers.

9. Do you have any other questions or concerns with the proposed standard that have not been addressed? If yes, please explain in the Comment section.

Summary Consideration: The drafting team received many suggestions for improvements to the standard. Several stakeholders commented on the Applicability section, requesting clarity with regard to Transmission Owners' obligations, threshold equipment nameplate ratings, or capacity factor exemptions. The GVSDT revised the Applicability section to clarify that only Transmission Owners owning synchronous condensers are specified as applicable entities in the standard. The applicability section specifies the same equipment nameplate rating thresholds defined in the Compliance Registry criteria. The standard does not allow other exemptions.

Several stakeholders commented on various aspects of Section G. The GVSDT considered these comments and made minor changes for clarity.

A few stakeholders requested changes to Measure M1 and the Data Retention section to clarify what evidence is necessary during the implementation period and also following changes requiring a coordination review. The GVSDT revised the language to clarify intent and also satisfy the NERC Compliance Guideline #2011-001.

A few stakeholders stated Requirement R1 could be interpreted to require protection settings that operate within the equipment capability. The GVSDT revised the R1 language to clearly state that protection must be set to prevent equipment damage.

A couple of stakeholders indicated the standard lacked clarity on which protective functions must be coordinated with limiters and equipment capability. In response, the GVSDT stated all in-service protective functions that might operate during steady-state system conditions must be evaluated and opted not to revise the standard.

Two stakeholders indicated the standard should require coordination be evaluated with the strongest transmission line out of service. The GVSDT believes doing this would add a great deal of complexity to the process without a corresponding gain in reliability.

Two stakeholders indicated the emphasis on coordination would prevent proper protection of the equipment. The GVSDT disagrees.

Two stakeholders took issue with the terms "in service," and "Point of Interconnection." The GVSDT maintained the term "in-service" (as defined in Footnote 1) in the standard and removed the term "Point of Interconnection" from the standard.

One stakeholder identified inconsistencies between the Title, Purpose, and Requirement R1 language. These inconsistencies were resolved.

One stakeholder identified the discrepancy between the Comment Form and the standard regarding synchronous condenser applicability nameplate rating threshold, and also noted that part of the Effective Date section was missing. In response, the GVSDT provided explanation for the discrepancy identified, and corrected the Effective Date section.

A few individual comments were received requesting the standard be revised to 1) include static var compensators, 2) specify a complete list of elements to be coordinated in R1, 3) change the coordination review time frame following a change in settings or equipment, and 4) add a requirement to activate and set excitation limiters. The GVSDT does not agree the standard would be improved by incorporating these suggestions.

Organization	Yes or No	Question 9 Comment
LG&E and KU Energy		
Northeast Power Coordinating Council	Yes	Related to the "Examples of Coordination", the P-Q diagram, the R-X diagram, and the Inverse Time Diagram are not all interchangeable. For this Standard only the P-Q Diagram can be used for compliance because it provides both under and over excitation capabilities of the machine. This curve is commonly used in industry and is readily understood by Engineers, System Operators and Generator Operators. The R-X Diagram example should be considered optional if impedance relays are used that reach beyond the generator-transformer protection zones. However, the R-X Diagram should not be mandatory. Concerning the Inverse Time Diagram, this example should be deleted since it only provides information on machine overexcitation capabilities and does not address underexcitation settings.
Response: Thank you for your comment. The diagrams in Section G are optional and provided as examples for industry. It is expected more than one diagram would be needed to demonstrate coordination for most units. The GVSDT has revised Section G to clarify this point.		
Imperial Irrigation District (IID)	No	
IRC Standards Review Committee (joint comments)		
Pepco Holdings Inc Affiliates	Yes	Based on the Requirements and Measures identified in the standard it is unclear why the standard was made applicable to Transmission Owners; unless the standard is intended to only

Organization	Yes or No	Question 9 Comment
		apply to Transmission Owners that own synchronous condensers. If that is the case, Section A-4.1.2 should be re-written as follows: "Transmission Owner that owns a synchronous condenser." This qualification is consistent with other PRC standards (PRC-010, PRC-015, PRC-023, etc.) where applicability to a specific sub-set of Transmission Owners is clearly defined.Do the requirements in this new standard overlap or duplicative with PRC-001 R3 and R5?
Response: Thank you for your comment. The SDT agrees proposed language for Section 4.1.2 will improve standard clarity, and has modified the standard accordingly.		
NERC System Protection and Control Subcommittee	Yes	Requirement R1: The standard lacks clarity on which types of protection functions must be coordinated. The standard should specify which types of protection functions must be coordinated if they are present on the generating unit, such as the list in Section G. Additionally, Attachment 2 could be interpreted to require coordination for protection systems that cannot be coordinated (e.g., the generator backup distance and backup overcurrent functions are required to detect faults that may result in an apparent impedance inside the SSSL) or do not require coordination (e.g., the generator out-of-step function will operate only for an unstable power swing and will not operate for stable operation within its operating characteristic). These protection functions should be removed from the figure or clarification should be added that the standard does not require coordination of these protection functions.Requirement R1, part 1.1.2: The word "check" is subject to interpretation and step 1.1.1 in some cases will verify existing settings rather than determine settings. Part 1.1.2 should be revised to address these issues, such as "Demonstrate that the settings used to verify coordination in part 1.1.1 are applied to the in-service equipment."Requirement R1, part 1.2: When the generating unit equipment or settings are modified as part of a planned project the Generator Owner should be required to verify coordination prior to placing the revised equipment or settings in-service.The SSSL derivation should consider the impact of system strength (e.g., strongest transmission line source out-of-service), generation saturation, and AVR status to assure an appropriately conservative limit.Implementing a UEL based on the steady-state stability limit may prevent under-excited operation, which would otherwise be stable and useful in managing system conditions (such as during system restoration activities or in lightly-loaded areas that need to sink reactive power to control voltage or synchronizing a generator to a long line).Where the Generator Owner and Transmission Owner are separate entities, there is difficulty for the Generator Owner to obtain system impedance information and

Organization	Yes or No	Question 9 Comment
		keep it up to date as the transmission system may be re-configured during on-going operations; this information is necessary to represent the SSSL.The foremost reason for protective relaying is to protect power system equipment. There is a concern that the real purpose of relaying may be lost in the overwhelming emphasis of its coordination with controlling equipment throughout the document. The generator protective relays are there to protect the generator and its associated equipment and the standard should acknowledge that this primary objective cannot be violated to obtain the desired coordination.
Response: Thank you for your comment. The SDT believes all in-service protection functions for a generating unit or synchronous condenser should be evaluated for coordination with the limiters, capabilities and protection under steady state conditions at nominal voltage and frequency. **This standard does not require evaluating coordination under transient conditions.** **The SDT believes that all protection functions, including generator backup distance and backup overcurrent, can be coordinated with the limiters and capabilities, as shown on Attachment 2, when considered under steady-state conditions using nominal voltage and frequency.** **The recommendation to demonstrate that the settings used in the coordination evaluation are the same settings applied to the in-service equipment is addressed by Measure M1.** **The SDT agrees that removing lines from service will affect the SSSL characteristic, however this is normally a fairly small change since the equivalent transmission system; impedance is much smaller than the step-up transformer impedance. Proper coordination would allow enough margin between the SSSL with all lines in service and the protection characteristics to allow for minor variations in the SSSL.** **The SDT does not believe a Transmission Owner would refuse to provide a Generator Owner with information requested for a reliability reason.** **The SDT agrees that the primary reason for Protection Systems is to protect power system equipment. The coordination philosophy described is essentially a restatement of that found in Section 3.5 of the NERC Power Plant and Transmission System Protection Coordination document.**		
Midwest Reliability Organization's NERC Standards Review Forum (NSRF)	Yes	Consider adding a note to Attachment 1, which states that the type of D curve should be specified (i.e. based on the data reported per the MOD-010 standard, the data reported per the MOD-025-2 standard, or some other basis).
Response: Thank you for your comment. The SDT does not believe it should prescribe specific evaluation evidence. It is anticipated the equipment owner will utilize information obtained per MOD-010 for the coordination evaluation specified.		
SPP Reliability Standards	Yes	It seems there is room for clean up in the posted standard.

Organization	Yes or No	Question 9 Comment
Development Team		
SERC Planning Standards Subcommittee		
Idaho Power-Power Production	No	
Santee Cooper		
PPL Generation	Yes	PPL Generation suggests the following changes:1. Consider making this standard applicable to generation facilities having a capacity factor for the past three years averaging over 10%. The basis for this request: As presently written this Applicability would require compliance for a small, emergency genset if located in a baseload facility interconnected > 100 kV. 2. In Requirements R.1, R1.1.1, R1.2 and elsewhere where the term "capability" is used, consider using the term "trip limit". As currently written, it appears that Requirement 1.1.1 is semantically misdirected in requiring protectives to be set below equipment capabilities. A capability is what the unit can actually do (ref. MOD-024 and 025). It is not the limit beyond which damage, instability or other problems may occur. A unit with a 875 MVA GSU and 900 MVA generator, for example, may have a real power capability of only 750 MW based on boiler and turbine limitations. It is not possible to have trips set below a unit's capability, unless PRC and MOD apply different meanings for this term, which would not be suitable.Confusion may be caused by generator D-curves also being called “capability curves,” but here also one would not want to require that generator never be operated at the D-curve value.
Response: Thank you for your comment. The Applicability section of this standard correlates with the applicability section of MOD-025-2 because it is anticipated the coordination evaluation performed for PRC-019-1 will be accomplished before the Reactive capability testing required by MOD-025-2. Requirement 1, part 1.1.1, has been revised to address concern with the coordination of protection and capability. D-curves are one way to define equipment capability (and are often called “ Reactive capability curves”).		
Dominion	Yes	1) the phrase “Generating equipment”, in the 3rd bullet of R1, be changed to “Generator” to be consistent with the usage under bullets 1 & 2. 2) The title and purpose of the document do not address synchronous condensers as addressed in Requirement R1; 3) if the standard includes synchronous condensers, why are static VAR compensators not included? The

Organization	Yes or No	Question 9 Comment
		following bullets under R1 are too generic. Should specifically outline required parameters.ï‚•ï€ In-service 1excitation system and voltage regulating system control, limiters and protection functions o In-service generator or synchronous condenser protection system settings o Generating equipment or synchronous condenser capabilities o Steady state stability limit We recommend replacing the bullets with the following: o Generator or syn. Condenser capability curves. o Steady state stability limit. o Loss of field zone 1. o Loss of field zone 2. o Loss of field trip. o Under excitation limiter. o Over excitation limiter. o Power factor line. o Backup over current settings. o Instantaneous field current trip. o Instantaneous field current limit. o Volts per hertz.
Response: Thank you for your comment. (1)The SDT has revised R1 based on your suggestion. (2) The SDT has revised the Title and Purpose based on your suggestion. (3) The SDT has determined that variable static Reactive resources not located at generating Facilities are not within the scope of this standard. As Pepco states in their comment to Question 3: "SVC protective devices are set assuming the full bank is in service. Synchronous machines, however, are a different story entirely. The quantity of Reactive power produced by, or drawn into, the machine is a function of the machine field current. In an under-excited condition, the unit may loose synchronism or trip via loss of field protection, unless the voltage regulator (min. excitation limiter) is properly set and coordinated with the machine's capability and protective devices. Similarly, excessive Var output and/or terminal overvoltage caused by over-excitation of the field can result in equipment damage or unit tripping, unless the voltage regulator is properly set and coordinated with the machine's capability and protective devices." In addition, IESO points out in their response to Question 3: "The SVCs serve quite different purpose and react to system conditions quite differently compared to their generator/synchronous condenser counterparts." (4) The bulleted list in R1 are categories that need to be considered when performing coordination evaluation, and is not intended to be a complete list of specific functions.		
FirstEnergy	Yes	M1 requires that the GO will have evidence that "…voltage regulating system controls and protection functions are coordinated with the generating unit and generating Facility capabilities and protective system settings applied to in-service equipment as specified in Requirement R1, Section 1.1, and one previous dated set of evidence that demonstrates the latest coordination review has been done within the intervals specified in Requirement R1, Section 1.2." For the first verification cycle this would require that units would have to prove compliance as much as 4 years before the standard became enforceable. This is akin to setting up a traffic camera in a 35 mph zone in March, changing the speed limit in that zone to 25 mph in July, and going back and writing tickets for every car that exceeded 25 mph from March through June. This needs to be clarified. Requirement R2 (shown as 1.2 in the standard) should have a violation risk factor of MEDIUM instead of HIGH. Furthermore, it seems that the phrase "within 90 days of making a change to the generating equipment, voltage control limiter settings, or protective function settings that would affect the coordination" is not necessary because a change to equipment

Organization	Yes or No	Question 9 Comment
		setting would already require coordination per Requirement R1. We suggest removing this part of 1.2 (or R2).
Response: Thank you for your comment. The SDT has revised the Measure M1 and the Data Retention sections to address your concerns. Data Retention has been written to be consistent with the NERC Compliance Process Bulletin #2011-001. With respect to your suggestion to remove Requirement 1, part 1.2, the SDT disagrees and believes verification of coordination needs to be performed in a timely manner following a change to equipment or settings.		
SERC Dynamics Review Sub-committee		
NERC Staff	Yes	The standard lacks clarity on which types of protection functions must be coordinated. The standard should specify which types of protection functions must be coordinated if they are present on the generating unit, such as the list in Section G.This should be consistent with protection coordination described in the SPCS Technical Reference “Power Plant and Transmission System Protection Coordination.” Additionally, Attachment 2 could be interpreted to require coordination for protection systems that cannot be coordinated (e.g., the generator backup distance and backup overcurrent functions are required to detect faults that may result in an apparent impedance inside the SSSL) or do not require coordination (e.g., the generator out-of-step function will operate only for an unstable power swing and will not operate for stable operation within its operating characteristic). These protection functions should be removed from the figure or clarification should be added that the standard does not require coordination of these protection functions.Requirement R1, part 1.1.1: The standard emphasizes preventing tripping of generating units and generating facilities due to miscoordination. Another aspect of coordination is to coordinate the protections and controls to coordinate with the equipment capability. Without guidance or direction, the standard could have the unintended consequence of overly conservative settings that limit the ability of the facilities to respond to system disturbances, or inadvertently create a common-mode failure trip point across a generation fleet.Requirement R1, part 1.1.2: The word “check” is subject to interpretation and step 1.1.1 in some cases will verify existing settings rather than determine settings. Part 1.1.2 should be revised to address these issues, such as “Demonstrate that the settings used to verify coordination in part 1.1.1 are applied to the in-service equipment.”Requirement R1, part 1.2: When the generating unit equipment or settings are modified as part of a planned project, the Generator Owner or Transmission Owner should be

Organization	Yes or No	Question 9 Comment
		required to verify coordination PRIOR to placing the revised equipment or settings back in-service. It is important to note that protection setting changes on the transmission system may necessitate generating unit protection setting changes which in turn require a review of coordination with the generating unit or plant voltage regulating controls. While coordination between the transmission system and generating unit protection settings is outside the scope of this standard it is important that this coordination is required by in a reliability standard.The examples emphasize steady-state limits and capability curves without mention of the short-term generating unit capabilities. Proper coordination should also apply to transient response of the generating unit and its associated limiters to meet the reliability objective of this standard. Focusing examples on steady-state coordination may be misleading and result in miscoordination for transient events. Of particular concern is the transient response of exciters in field-forcing during system disturbances; loss of reactive support from generation during such events can be catastrophic and lead to cascading.The foremost reason for protective relaying is to protect power system equipment. There is a concern that the real purpose of relaying may be lost in the overwhelming emphasis of its coordination with controlling equipment throughout the document. The generator protective relays are there to protect the generator and its associated equipment and the standard should acknowledge that this primary objective cannot be violated to obtain the desired coordination.

Response: Thank you for your comment. The SDT believes all in-service protection functions for a generating unit or synchronous condenser should be evaluated for coordination with the limiters, capabilities, and protection under steady-state conditions at nominal voltage and frequency.

This standard does not require evaluating coordination under transient conditions.

The SDT believes that all protection functions, including generator backup distance and backup overcurrent, can be coordinated with the limiters and capabilities, as shown on Attachment 2 ,when considered under steady-state conditions using nominal voltage and frequency.

The recommendation to demonstrate that the settings used in the coordination evaluation are the same settings applied to the in-service equipment is addressed by Measure M1.

With regard to the suggestion to include transient response in the coordination evaluation, the SDT believes the function of the limiters is to prevent operation in regions that would damage the equipment during transient conditions, and that proper coordination of limiters with protection will prevent improper tripping of the equipment.

The SDT agrees that removing lines from service will affect the SSSL characteristic, however this is normally a fairly small change since the equivalent transmission system impedance is much smaller than the step-up transformer impedance. Proper coordination would allow enough margin between the SSSL with all lines in service and the protection characteristics to allow for minor variations in the SSSL.

Organization	Yes or No	Question 9 Comment
The SDT does not believe a Transmission Owner would refuse to provide a Generator Owner with information requested for a reliability reason. **The SDT agrees that the primary reason for Protection Systems is to protect power system equipment. The coordination philosophy described is essentially a restatement of that found in Section 3.5 of the NERC Power Plant and Transmission System Protection Coordination document.**		
Public Service Enterprise Group	Yes	The SDT should review R1. As it reads now, the phrasing of the first paragraph makes it difficult to understand what equipment is included for generator units and what is included for synchronous condensers.
Response: Thank you for your comment. The SDT has revised R1.		
SERC Generation sub-committee		
ACES Power Members	Yes	In part 4.2.3 of the Applicability section, the phrase "regardless of size included in a Transmission Operator's restoration plan" should be struck. It is redundant with definition of Blackstart Resource.
Response: Thank you for your comment. The SDT believes it is necessary to duplicate Registry criteria language in the applicability section to clarify that the standard is applicable to other equipment in addition to synchronous condensers.		
Arizona Public Service Company	Yes	
Westar Energy	No	
Southern Company	Yes	1) The last sentence of Measure M1 is not needed. There is no need to require evidence of the change implemetation, only coordination verification is needed. The requirement for documentation of change identification or implementation is not part of Requirement R1. 2) In several places in the posting documents there is a descrepancy in the size of the synchronous condensor that is in the scope of the standard, some places list the size criteria at 20 MVA, and others state 50MVA. 3) The Implementation plan document effective date is incorrect for the 20% completion step - it states two years rather than the appropriate one year. 4) Section 5.2.5 is missing from effective date in the draft standard.

Organization	Yes or No	Question 9 Comment
Response: Thank you for your comment. (1) The measure supports evidence needed to demonstrate compliance with the 90-day requirement specified in R1.2. Regarding comments (2), (3), (4) Noted, discrepancies have been corrected.		
Tennessee Valley Authority GO	Yes	We recommend that the minimum unit rating to be applicable to this standard should be 75 MVA, and the aggregate plant size to be applicable should be 100 MVA.
Response: Thank you for your comment. The Applicability section of the standard is based on the Registry criteria, and the SDT does not have sufficient technical justification to deviate from this criteria.		
Luminant Power	No	
Lakeland Electric		
Salt River Project	No	
PacifiCorp	No	
South Carolina Electric and Gas	Yes	In regards to Measure 1 it should be clarified that only the latest coordination review will be needed for the first 5 years after the standard is implemented and only after 10 years will the entity be required to show both latest and prior evidence of compliance for 100 % of the applicable units. As stated, it looks like the standard would require the entity to verify the existence of coordination twice on 20% of the applicable units in the first year to show evidence of a latest and prior coordination for those units. If an entity were to be audited 3 years after the effective date of the standard, they would have to show coordination of 60% of the applicable units and should not be required to show a prior documented coordination since a 5 year interval would place the prior coordination possibly before the effective date of the standard. This would also apply in the situation of a newly built applicable unit in which there would be no prior evidence available; only the latest.
Response: Thank you for your comment. The SDT has revised the Measure M1 and the Data Retention sections to address your concerns. Data Retention has been written to be consistent with the NERC Compliance Process Bulletin #2011-001.		
APS		being intentionally left blank (no answer to be provided)

Organization	Yes or No	Question 9 Comment
Associated Electric Cooperative, Inc.	No	
Dynegy Inc.	No	
New York Independent System Operator		
Tri-State Generation and Transmission, In.	No	
Cowlitz County PUD	Yes	Cowlitz understands the difficulty the SDT is under. Although the base line of applicability is in question, this Standard is justifiable and will not present too great a burden to comply with.
Response: Thank you for your comment.		
Xcel Energy	No	
Lakeland Electric		
Exelon	No	
American Wind Energy Association	No	
Tacoma Power		None
Georgia Transmission Corporation		
Austin Energy	No	

Organization	Yes or No	Question 9 Comment
Wisconsin Electric	Yes	1. R1.2 needs to be clarified, and more time allowed. The phrase, "within 90 days following the identification or implementation of systems, equipment, or setting changes..." is vague, and should be replaced with "within 120 days of modifications made to systems, equipment, or setting changes...". The requirement should clarify that the clock starts 120 days after the date that the affected generator returned to service following the modifications. 2. It is not clear how wind generators can be subject to this standard. The information in Section G does not relate to wind machines.
Response: Thank you for your comment. (1) The SDT believes that 90 days is sufficient time to perform a coordination evaluation, and is an appropriate time frame that supports reliability. The SDT believes current language with respect to "starting the clock," is appropriate for covering the possible scenarios. (2) The standard is technology neutral. The information in Section G does not necessarily apply to a particular type of technology. The equipment owner is responsible for providing appropriate compliance evidence.		
Great River Energy		
BC Hydro	Yes	The note in section G may have to be revisited. The main issue is that active excitation limiters can prevent a unit from unneccessary tripping during system transients. The standard should encourage activation and proper setting of avaiable excitation limiters
Response: Thank you for your comment. The SDT believes it is beyond the scope of this standard to recommend additional practices.		
Northeast Utilities	Yes	Related to the "Examples of Coordination", the P-Q diagram, the R-X diagram, and the Inverse Time Diagram are not all interchangeable. For this Standard only the P-Q Diagram can be used for compliance because it provides both under and over excitation capabilities of the machine. This curve is commonly used in industry and is readily understood by Engineers, System Operators and Generator Operators. The R-X Diagram example should be considered optional if impedance relays are used that reach beyond the generator-transformer protection zones. However, the R-X Diagram should not be mandatory. Concerning the Inverse Time Diagram, this example should be deleted since it only provides information on machine overexcitation capabilities and does not address underexcitation settings.
Response: Thank you for your comment. The diagrams in Section G are optional and provided as examples for industry. It is expected more than one diagram would be needed to demonstrate coordination for most units. The GVSDT has revised Section G to clarify this point.		

Organization	Yes or No	Question 9 Comment
Constellation Power Generation	No	
Consolidated Edison Co. of NY, Inc.	Yes	Related to the “Examples of Coordination”, the P-Q diagram, the R-X diagram, and the Inverse Time Diagram are not all interchangeable. For this Standard only the P-Q Diagram can be used for compliance because it provides both under and over excitation capabilities of the machine. This curve is commonly used in industry and is readily understood by Engineers, System Operators and Generator Operators. The R-X Diagram example should be considered optional if impedance relays are used that reach beyond the generator-transformer protection zones. However, the R-X Diagram should not be mandatory. Concerning the Inverse Time Diagram, this example should be deleted since it only provides information on machine overexcitation capabilities and does not address underexcitation settings.
Response: Thank you for your comment. The diagrams in Section G are optional and provided as examples for industry. It is expected more than one diagram would be needed to demonstrate coordination for most units. The GVSDT has revised Section G to clarify this point.		
American Electric Power	Yes	Measure 1 states the need for “one previous dated set of evidence that demonstrates the latest coordination review has been done within the intervals specified in Requirement R1, Section 1.2.”, yet this would not be required by the standard until five years following the initial coordination.
Response: Thank you for your comment. The SDT has revised the Measure M1 and the Data Retention sections to address your concerns. Data Retention has been written to be consistent with the NERC Compliance Process Bulletin #2011-001.		
Ingleside Cogeneration LP	No	
Wisconsin Public Service Corp		
GE Energy		The fourth bullet in Part G “Reference,” paragraph beginning with “Equipment limits,”, page 6: The word “stator” should be removed, in order to make the over voltage protection limits applicable to non-synchronous machines.

Organization	Yes or No	Question 9 Comment
Response: Thank you for your comment. The SDT has revised language accordingly.		
ISO New England		
GenOn Energy	Yes	In some ways, the requirements are too subjective in determining what protection and limiters are subject to coordination. In other ways, the standard provides insufficient or contradictory requirements in defining how coordination is achieved, even for well established protection practices. It is difficult to define all-inclusive coordination principles with so many variables in a simple straightforward standard. As written, the standard is a compliance risk to the applicable entities based upon future arbitrary and subjective interpretation by compliance organizations. Vivid examples are provided in Attachment 1. Loss-of-Excitation Zones 1 & 2 does not “coordinate” with the Steady State Stability Limit. In the diagram of the generator capability curve, SSSL is reached prior to the Loss-of-Excitation protection, contrary to R1.1.1, requiring the protection to operate ahead of the SSSL. Also, Loss-of-Excitation Zones 1 & 2 exceeds the generator capability curve, and does not fulfill R1.1.1 that requires protection to operate before conditions exceed equipment capabilities. Other variables with indirectly relationships are subject to future interpretation. A generator stator may have overvoltage protection set at 118% with a 2 second time delay, allowing it to meet PRC-024-1 ride through capability. Overvoltage protection also has a correlation to field current limiters. To insure and demonstrate absolute “coordination” with a field current limiter under all circumstances, it may be necessary to reduce the field current limit. The move will be counter productive to system performance in most transient conditions, but may be required to insure “coordination.”The SDT should make specific requirements of defined scope rather than broad, subjective, and open-ended requirements, i.e. 1) Volts/Hz limiters shall coordinate with Volts/Hz protection, 2) Under excitation limiters shall coordinate with steady state stability limits and loss-of-field protection, and 3) field current limiters shall coordinate with field current capability. The standard should exclude statements that the protection must operate before conditions exceed equipment capability. It will be difficult to provide definitive evidence of compliance for the use of many protection elements on older equipment with no documentation of equipment capability to withstand conditions such as Volts/Hz. If a generating unit is rated for +/- 5% terminal voltage, how is the generator’s overvoltage withstand capability demonstrated to PRC-024-1 criteria. In a compliance world of absolutes, Generator Owners may not be allowed to use general “rules of thumb” when coordinating protection. In ways that are counterproductive to reliability and equipment protection, Generator Owners could end up removing protection

Organization	Yes or No	Question 9 Comment
		elements when it cannot be demonstrated that it operates before the condition exceeds equipment capabilities.Calculation of the steady state stability limit requires the transmission system Thevenin equivalent impedance. Therefore, it is necessary for the standard to require Transmissions Owners to provide Generator Owners this impedance within 30 days of request. Likewise, the allocated time for Generator Owners to perform coordination studies should increase by 30 days or more to 120 days.In R1.2, a five year coordination study interval is an unnecessarily short duration for generating units without significant changes in the generator protection or an AVR replacement. A company with 150 generating units will average 2.5 coordination studies per month on a non-stop continuous rotation. Ten years is a more appropriate cycle for a coordination study on a unit with no changes. The wording used to trigger an examination should be specific and defined, rather than the ambiguous and nondescript statement of “changes that are expected to affect this coordination.” To meet compliance, it will be necessary to expend needless effort for the possible interpretations of “changes” that otherwise will have little or no impact for the intent or purpose of this standard. Suggest rewording R1.2, “Each Generator Owner or Transmission Owner shall verify the coordination indentified in Requirement R1 at least once every ten years or within 120 calendar days following modifications impacting coordination when the following activities occur: 1) a change in AVR limiters or AVR protection for over-excitation, underexcitation, Volts/Hertz, stator voltage, or field current, or 2) generator protection changes for stator voltage, loss-of-excitation, or Volts/Hertz protection.”For only 30 days of differences (90 to 120), VSLs expand from Lower to Severe. Considering the justifiable allowance for 20% of the fleet to go 5 years without demonstrated coordination, the logic for the acceleration of severity over such a short time duration is not understood.
Response: Thank you for your comment. In response to comments regarding coordination between the loss of field protection and the SSSL in Attachment 1, the loss of field trip curve does coordinate with the SSSL. The Zone 2 and Zone 1 loss of excitation functions are providing backup protection to the primary loss of field trip. With regard to your suggestion of defining specific methods for evaluating coordination, the SDT intends the standard to be technology neutral and cannot define coordination methodologies for all current and future generating technologies. The SDT has revised the wording in R1 to clarify that protection should protect the equipment and may allow capabilities to be exceeded when appropriate. The verification time interval has been set to coordinate with MOD-025-2. Once an initial coordination evaluation has been completed, subsequent verification should not be a hardship. In response to your comment, the SDT has revised language used to trigger an evaluation. The VSL levels are set in accordance with NERC guidelines, and are appropriate for reliability concerns associated with equipment changes.		
Manitoba Hydro	Yes	-The standard should take into account generating units whose capacity is determined based

Organization	Yes or No	Question 9 Comment
		upon the run of the river where it may be difficult to test at design capacity. We suggest that an engineering methodology/calculation be acceptable for these units
Response: Thank you for your comment. The SDT believes the capability of the equipment does not change, even though equipment output may be restricted due to factors, such as run of the river. This standard does not require testing.		
Duke Energy	Yes	1) In several places in the posting documents there is a discrepancy in the size of the synchronous condensor that is in the scope of the standard, some places list the size criteria at 20 MVA, and others state 50MVA. 2) The Implementation plan document effective date is incorrect for the 20% completion step - it states two years rather than the appropriate one year. 3) Section 5.2.5 is missing from effective date in the draft standard. 4) R1.1.1.1 seems to infer that the 40 relays should be set inside the Capability curves and the SSSL. The 40 relay should be set inside the SSSL but may be outside the capability curves as it is intended to prevent a pole slip. AVR protective functions may be set to protect the capability curves.
Response: Thank you for your comment. Regarding comments (1), (2), noted discrepancies have been corrected. (4) The SDT has revised the wording in R1 to clarify that protection should protect the equipment and may allow capabilities to be exceeded when appropriate.		
Lincoln Electric System		
CPS Energy		
Independent Electricity System Operator	Yes	1. The standard introduces a local definition: “in-service”, that is subject to interpretation. Does “in-service” mean:- Installed but may or may not be put to service (e.g. mothballed)?- Installed and can be put to service at any time?- Installed and on-line?Generators/synchronous condensers will have a reliability impact only when they are connected to the grid (put on-line). However, the timing of these facilities to be put on-line is at the discretion of the GOs and perhaps under some conditions specified by other entities such as the TOP or RC. It is thus conceivable that installed facilities can be put on-line at any time. To ensure proper reliability performance, we suggest to change “in-service” to “installed” to make sure the facilities meet the standard requirements if and when they are put on-line. 2. R1.2: The wording: “verify the existence of the coordination” does not drive home the intent of ensuring the settings are coordinated and reviewed once every 5 years or as changes occur. We suggest to change R1.2 to read: “shall review and revise as necessary the coordinated settings identified in

Organization	Yes or No	Question 9 Comment
		Requirement R1 at least once every five years or within....”
Response: Thank you for your comment. Footnote 1 defines “in service” as functions that are installed and activated. Many relays have multiple protection functions that would be “installed,” but not necessarily activated. Installed protection functions that are not active do not need to be evaluated for determining proper coordination. The SDT believes standard language for verifying the existence of coordination is adequate.		
Gainesville Regional Utilities	No	
Ameren	Yes	(1) Standard needs to be more specific and clear on what evidence is need for 1.1.2. (2) Violation Severity Levels seem arbitrary and need to be reviewed, considering the standard is giving four years to be 100% complete. The system is presently operating with few if any miss-coordination on these protection systems. (3) There may be different usage of the term 'point of interconnection" in the industry. We suggest the SDT to consider proposing a formal definition of this term. (4) R1.2 states there must be verification of coordination within 90 calendar days following "...identification or implementation..." of systems or changes. There is typically an enormous difference between the "identification" and the "implementation" of these systems. Would the SDT please clarify what is expected? (5) Sister Unit exemptions should be allowed for plants with multiple identical units that have identical equipment and control systems. (6) This Standard should only apply to generators with a nameplate rating of > 75 MVA and a connection to the interconnected transmission grid > 100 kV. (7) The use of "Stead state stability limit" in bullet #4 in R1 and the use of the phrase "...system steady state operating conditions." in R1.1.1, seem to conflict. Is the term in R1 intended to represent system conditions AFTER an N-1 contingency, or during N-0 conditions?
Response: Thank you for your comment. (1) The measure supports evidence needed to demonstrate compliance (2) The VSL’s are set in accordance with NERC guidelines. (3) The applicability section was revised. The phrase, “point of Interconnection” has been deleted. (4) SDT intent regard “implementation or identification of changes” is to allow the clock to start when the changes that may occur to equipment capabilities is actually identified (recognizing this awareness may not have been immediately apparent). It is expected changes implemented by the equipment owner are “identified” at the time of implementation. (5) Regarding “sister units,” there is minimal burden with verification that the in-service settings are identical (and by extension coordination). (6) The applicability section of the standard is based on the Registry criteria, and the SDT does not have sufficient technical justification to deviate		

Organization	Yes or No	Question 9 Comment
from this criteria. **(7) The standard allows evaluation of N-0 conditions. The equipment owner has discretion to perform evaluation of other conditions.**		
Indeck Energy Services		
Oncor Electric Delivery Company LLC	No	
Indiana Municipal Power Agency	Yes	IMPA does not understand the need to perform the coordination type of study every five years. It should be performed initially and only if something changes that would require a new coordination study. IMPA could see the need to verify the settings on the voltage regulating equipment, etc. just as you would with relay testing but why go through a complete study every 5 years. IMPA recommends performing the coordination study initially as per the timetable listed in the effective dates (section 5) and then again prior to the implementation of systems, equipment, setting changes, etc.IMPA recommends not using the words “verify the existence” in requirement 1.2. This wording is very vague in the sense that it may require just a review of the document to ensure no changes or does it mean that another coordination study needs to be performed. IMPA recommends using the wording “shall review the coordination identified in Requirement R1 at least once every five years or perform the coordination identified in Requirement R1 within 90 calendar days… “ if this is the intent of the SDT.
Response: Thank you for your comment. The intent of the five-year verification interval is to verify that settings have not changed. In addition, changes to the transmission system can affect the SSSL. The SDT believes the words “… verify the existence of coordination…” ensures the settings used to evaluate coordination match the in-service settings.		
Los Angeles Department of Water and Power		LADWP does not have a position on this question at this time.
Chelan County PUD	No	

END OF REPORT

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. SAR posted for comment (April 20–May 21, 2007).
2. Revised SAR and response to comments posted.
3. Revised SAR and response to comments approved by SC (June 14, 2007).
4. SDT appointed on (August 18, 2007).
5. Draft MOD-026-1 was posted for a 45 day comment period from February 17 – April 2, 2009.
6. Draft 2 MOD-026-1 was posted for a 45 day concurrent comment and ballot period from June 15 – August 1, 2011.

Proposed Action Plan and Description of Current Draft:

This is the third draft of the standard and includes Time Horizons, Data Retention, Violation Risk Factors, and Violation Severity Levels. This second posting is for a 30-day comment and successive ballot period.

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Develop responses to comments and develop third version draft standard.	August 2011– February 2012
2. Post response to comments and third version draft revision of standard for 30 day comment and successive ballot period.	February – March 2012
3. Develop responses to successive ballot comments.	April – May 2012
4. Post response to comments.	June 2012
5. Conduct recirculation ballot.	June2012
7. BOT adoption.	July 2012
8. File with regulatory authorities.	September 2012

A. Introduction

1. Title: Verification of Models and Data for Generator Excitation Control System and Plant Volt/Var Control Functions

2. Number: MOD-026-1

3. Purpose: To verify that the generator excitation control system and plant volt/var control[1] function model (including the power system stabilizer model and the impedance compensator model) and the model parameters used in dynamic simulations accurately represent the generator excitation control system and plant volt/var control function behavior when assessing Bulk Electric System (BES) reliability.

4. Applicability:

4.1. Functional Entities:

4.1.1 Generator Owner

4.1.2 Transmission Planner

4.2. Facilities:

For the purpose of this standard, the following Facilities are considered, "applicable units[2]."

Units or plants with an average capacity factor[3] greater than 5 percent over the most recent three calendar years, beginning on January 1 and ending on December 31, that meet the following:

4.2.1 Generating units connected to the Eastern or Quebec Interconnections with the following characteristics:

4.2.1.1 Individual generating unit greater than 100 MVA (gross nameplate rating) directly connected to the bulk power system.

4.2.1.2 For each generating plant / Facility consisting of one or more units that are connected to the bulk power system at a common bus with total generation greater than 100 MVA (gross aggregate rating):

- Each individual generating unit greater than 20 MVA (gross nameplate rating); and

---

[1] Excitation control system and plant volt/var control function:

a. For individual synchronous machines, the generator excitation control system includes the generator, exciter, voltage regulator and power system stabilizer.
b. For an aggregate generating plant, the volt/var control system includes the voltage regulator & reactive power control system controlling and coordinating plant voltage and associated reactive capable resources.

[2] Applicable generating units do not include startup or standby units not normally connected to the grid.

[3] Once a capacity factor exemption is declared by notifying the Transmission Planner, verification is not required for 10 calendar years from the date eligibility occurs. At the end of this 10 calendar year timeframe, the current average 3 year capacity factor (for years 8, 9, and 10) is examined to determine if the capacity factor exemption can be declared for the next 10 calendar year period. If not eligible for the capacity factor exemption, then model verification must be completed within one year of the date the capacity factor exemption expired with the 10 calendar year periodicity requirement reset based on the verification date. For the definition of capacity factor, refer to Appendix F of the GADS Data Reporting Instructions on the NERC website.

- Each generating plant / Facility comprised consisting of individual generating units less than 20 MVA (gross nameplate ratings)

4.2.2 Generating units connected to the Western Interconnection with the following characteristics:

4.2.2.1 Individual generating unit greater than 75 MVA (gross nameplate rating) directly connected to the bulk power system.

4.2.2.2 For each generating plant / Facility consisting of one or more units that are connected to the bulk power system at a common bus with total generation greater than 75 MVA (gross aggregate rating):

- Each individual generating unit greater than 20 MVA (gross nameplate rating); and
- Each generating plant / Facility comprised consisting of individual generating units less than 20 MVA (gross nameplate ratings)

4.2.3 Generating units connected to the ERCOT Interconnection with the following characteristics:

4.2.3.1 Individual generating unit greater than 50 MVA (gross nameplate rating) directly connected to the bulk power system.

4.2.3.2 For each generating plant / Facility consisting of one or more units that are connected to the bulk power system at a common bus with total generation greater than 75 MVA (gross aggregate rating):

- Each individual generating unit greater than 20 MVA (gross nameplate rating); and
- Each generating plant / Facility comprised consisting of individual generating units less than 20 MVA (gross nameplate ratings)

4.2.4 For all Interconnections:

- Any registered technically justified[4] unit requested by the Planning Coordinator.

5. Effective Date:

5.1. In those jurisdictions where regulatory approval is required:

5.1.1 Each responsible entity shall ensure compliance with Requirements R1, and R3 through R6 by the first day of the first calendar quarter, four years following applicable regulatory approval.

[4] Technical justification is achieved by demonstrating that the simulated unit or plant response does not match the measured unit or plant response.

5.1.2 Each Generator Owner shall ensure at least 30 percent of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2 by the first day of the first calendar quarter, four years following applicable regulatory approval.

5.1.3 Each Generator Owner shall ensure at least 50 percent of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2 by the first day of the first calendar quarter, six years following applicable regulatory approval:

5.1.4 Each Generator Owner shall ensure 100 percent of its applicable units are compliant with Requirement R2 by the first day of the first calendar quarter, ten years following applicable regulatory approval:

5.2. In those jurisdictions where no regulatory approval is required:

5.2.1 Each responsible entity shall ensure compliance with Requirements R1, and R3 through R6 by the first day of the first calendar quarter, four years following Board of Trustees adoption.

5.2.2 Each Generator Owner shall ensure at least 30 percent of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2 by the first day of the first calendar quarter, four years following Board of Trustees adoption.

5.2.3 Each Generator Owner shall ensure at least 50 percent of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2 by the first day of the first calendar quarter, six years following Board of Trustees adoption.

5.2.4 Each Generator Owner shall ensure 100 percent of its applicable units are compliant with Requirement R2 by the first day of the first calendar quarter, ten years following Board of Trustees adoption.

B. Requirements

R1. Each Transmission Planner shall provide the following instructions and model data to its requesting Generator Owner within 90 calendar days of receiving a request for those instructions or model data: *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*:

- Instructions on how to obtain the list of excitation control system and plant volt/var control function models acceptable to the Transmission Planner for use in dynamic simulation.
- Instructions on how to obtain the Transmission Planner's software manufacturer's dynamic excitation control system and plant volt/var control function model library block diagrams and/or data sheets.
- Model data for any of the Generator Owner's existing unit or plant specific excitation control system and plant volt/var control function contained in the

Transmission Planner's dynamic database from the current (in-use) models, including generator MVA base.

R2. Each Generator Owner shall provide, for each of its applicable units, a verified generator excitation control system and plant volt/var control function model including documentation and data as specified in Parts 2.1 and 2.2 to its Transmission Planner in accordance with the periodicity specified in MOD-026 Attachment 1, to ensure modeling data is accurate for use in simulation software. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

2.1. Perform verifications using one or more models acceptable to the Transmission Planner that include(s) the following information:

2.1.1. Documentation demonstrating the applicable unit's model response matches the recorded response for a voltage excursion at the applicable unit's point of interconnection from either a staged test or a measured system disturbance.

2.1.2. Manufacturer, model number (if available), and type of excitation control system and plant volt/var control function installed (such as static, AC brushless, DC rotating, volt/var function).

2.1.3. Model structure and data (such as reactance, time constants, saturation factors, rotational inertia, or equivalent data) for the generator (or plant equivalent).

2.1.4. Model structure and data for the excitation control system, for the plant volt/var function, and for the closed loop voltage regulator if the closed loop voltage regulator is installed.

2.1.5. Compensation settings (such as droop, line drop, differential compensation), if used.

2.1.6. Model structure and data for power system stabilizer, if so equipped.

2.2. For plants that are comprised of units that have a gross nameplate rating of less than 20 MVA, each Generator Owner shall perform its verification using plant aggregate model(s) that include the information required by Requirement sub-parts 2.1.1 through 2.1.6

R3. Each Generator Owner shall provide a written response to its Transmission Planner within 90 calendar days of receiving one of the following items. The written response shall contain either the technical basis for maintaining the current model, or the model changes, or a plan to perform model verification[5] (in accordance with Requirement R2) *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*:

- Written notification from its Transmission Planner (in accordance with Requirement R6) that the excitation control system and plant volt/var control function model is not "usable," or

[5] If verification is performed, the 10 year period as outlined in Attachment 1 is reset.

- Written comments from its Transmission Planner identifying technical concerns with the verification documentation related to the excitation control system and plant volt/var control function model, or
- Written comments and supporting evidence from its Transmission Planner indicating that the predicted excitation control system and plant volt/var control function model response did not match the recorded response to a transmission system event.

R4. Each Generator Owner shall provide revised model data or plans to perform model verification[5] (in accordance with Requirement R2) to its Transmission Planner within 180 calendar days of making changes to the excitation control system and plant volt/var control function that alter the equipment response[6] characteristic. *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*

R5. Each Generator Owner shall provide a written response to its Planning Coordinator, within 90 calendar days following receipt of a technically justified request from the Planning Coordinator to perform a model review of any unit/plant not included in the Applicability that includes one of the following *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*:

- Details of plans to verify the model (in accordance with Requirement R2)
- Corrected model data including the source of revised model data such as discovery of manufacturer test values to replace generic model data or updating of data parameters based on a walk down of the equipment.

R6. Each Transmission Planner shall notify the Generator Owner within 90 calendar days of receiving the verified excitation control system and plant volt/var control function model information whether the model is useable (meets the criteria specified in Parts 6.1 through 6.3), or is not useable; and shall include a technical description if the model is not useable. . *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

6.1. The excitation control system and plant volt/var control function model initializes to compute modeling data without error.

6.2. A no-disturbance simulation results in negligible transients.

6.3. For an otherwise stable simulation, a disturbance simulation results in the excitation control and plant volt/var control function model exhibiting positive damping.

C. Measures

---

[6] Exciter, voltage regulator, plant volt/var or power system stabilizer control replacement including software alterations that alter excitation control system equipment response, plant digital control system addition or replacement, plant digital control system software alterations that alter excitation control system equipment response, plant volt/var function equipment addition or replacement (such as static var systems, capacitor banks, individual unit excitation systems, etc), a change in the voltage control mode (such as going from power factor control to automatic voltage control, etc), exciter, voltage regulator, impedance compensator, or power system stabilizer settings change.

M1. Evidence for Requirement R1 must include the transmitted instructions or data and dated evidence of transmission of requested instructions and data, such as dated electronic mail messages, dated postal receipts, dated confirmation of facsimile transmission.

M2. Evidence for Requirement R2 must include, for each of the Generator Owner's applicable Facilities, the verification report showing that the generator excitation control system and plant volt/var control function model was verified and dated evidence of transmission, such as a dated electronic mail messages, dated postal receipts, or dated confirmation of facsimile transmission as specified in Requirement R2.

M3. Evidence for Requirement R3 must include the Generator Owner's dated written response containing the information identified in Requirement R3 and dated evidence of transmittal, such as a dated electronic mail messages, dated postal receipts, or dated confirmation of facsimile transmission.

M4. Evidence for Requirement R4 must include, for each of the Generator Owner's Facilities for which system changes specified in Requirement R4 were made, dated revised model data or dated plans to perform a model verification and dated evidence of transmittal, such as dated electronic mail messages, dated postal receipts, or dated confirmation of facsimile transmittal.

M5. Evidence for Requirement R5 must include, for each request received as specified in Requirement R5, the dated written response provided and dated evidence of transmittal, such as dated electronic mail messages, dated postal receipts, or dated confirmation of facsimile transmittal.

M6. Evidence of Requirement R6 must include, for each model received, the dated response containing the information required in Parts 6.1 through 6.3 and dated evidence of transmittal, such as dated electronic mail messages, dated postal receipts, or dated confirmation of facsimile transmittal.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

Regional Entity

1.2. Data Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Generator Owner and Transmission Planner shall each keep data or evidence to show compliance as identified below unless directed by its Compliance

Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

- The Transmission Planner shall retain the information/data request and provided response evidence of Requirements R1 and R6, Measures M1 and M6 for 3 calendar years from the date the document was provided.
- The Generator Owner shall retain the latest and previous excitation control system and plant volt/var control function model verification evidence of Requirement R2, Measure M2.
- The Generator Owner shall retain the information/data request and provided response evidence of Requirements R3 through R5, and Measures M3 through M5 for 3 calendar years from the date the document was provided.

If a Generator Owner or Transmission Planner is found non-compliant, it shall keep information related to the non-compliance until mitigation is complete or approved or for the time specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes

Compliance Audit

Self-Certification

Spot Checking

Compliance Investigation

Self-Reporting

Complaints

1.4. Additional Compliance Information

None

2. Violation Severity Levels

R #	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The Transmission Planner provided the instructions and data to the Generator Owner more than 90 calendar days but no more than 120 calendar days of receiving a request.	The Transmission Planner provided the instructions and data to the Generator Owner more than 120 calendar days but no more than 150 calendar days of receiving a request.	The Transmission Planner provided the instructions and data to the Generator Owner more than 150 calendar days but no more than 180 calendar days of receiving a request.	The Transmission Planner failed to provide the instructions and data to the Generator Owner within 181 calendar days of receiving a request.
R2	The Generator Owner provided its verified model(s) to its Transmission Planner after the timeframe specified in MOD-026 Attachment 1 but no more than 30 calendar days late; OR The Generator Owner provided the Transmission Planner verified models that omitted one of the six Parts identified in Requirement R2, Subparts 2.1.1 through 2.1.6.	The Generator Owner provided its verified model(s) to its Transmission Planner more than 30 calendar days but no more than 60 calendar days late as specified by the periodicity timeframe in MOD-026 Attachment 1. OR The Generator Owner provided the Transmission Planner verified models that omitted two of the six Parts identified in Requirement R2, Subparts 2.1.1 through 2.1.6.	The Generator Owner provided its verified model(s) to its Transmission Planner more than 60 calendar days but no more than 90 calendar days late as specified by the periodicity timeframe in MOD-026 Attachment 1. OR The Generator Owner provided the Transmission Planner verified models that omitted three of the six Parts identified in Requirement R2, Subparts 2.1.1 through 2.1.6.	The Generator Owner provided its verified generator excitation control system and plant volt/var control function model more than 90 calendar days late or failed to provide the verified model(s) to its Transmission Planner in accordance with the periodicity specified in MOD-026 Attachment 1. OR The Generator Owner failed to use model(s) acceptable to the Transmission Planner as specified in Requirement R2, Subpart 2.1. OR The Generator Owner provided the Transmission Planner verified model(s) that omitted four or more of the six Parts identified in

				Requirement R2, Subparts 2.1.1 through 2.1.6.
R3	The Generator Owner provided a written response more than 90 calendar days but no more than 120 calendar days of receiving written notice. (R3)	The Generator Owner provided a written response more than 120 calendar days but no more than 150 calendar days of receiving written notice. (R3)	The Generator Owner provided a written response more than 150 calendar days but no more than 180 calendar days of receiving written notice. (R3)	The Generator Owner failed to provide a written response within 181 calendar days of receiving written notice (R3). OR The Generator Owner's written response was provided within 181 calendar days of receiving written notice however, the Generator Owner's written response failed to contain either the technical basis for maintaining the current model, or a list of future model changes, or a plan to perform another model verification.
R4	The Generator Owner provided revised model data or plans to perform model verification more than 180 calendar days but no more than 210 calendar days of making changes to the excitation control system and plant volt/var control function that altered the equipment response characteristic. (R4)	The Generator Owner provided revised model data or plans to perform model verification more than 210 calendar days but no more than 240 calendar days of making changes to the excitation control system and plant volt/var control function that altered the equipment response characteristic. (R4)	The Generator Owner provided revised model data or plans to perform model verification more than 240 calendar days but no more than 270 calendar days of making changes to the excitation control system and plant volt/var control function that altered the equipment response characteristic. (R4)	The Generator Owner failed to provide revised model data or failed to provide plans to perform model verification within 271 calendar days of making changes to the excitation control system and plant volt/var control function that altered the equipment response characteristic (R4).
R5	The Generator Owner provided a written response more than 90 calendar days but no more than 120 calendar days to the Planning Coordinator following receipt of a technically justified request to	The Generator Owner provided a written response more than 120 calendar days but no more than 150 calendar days to the Planning Coordinator following receipt of a technically justified request to	The Generator Owner provided a written response more than 150 calendar days but no more than 180 calendar days to the Planning Coordinator following receipt of a technically justified request to	The Generator Owner failed to provide a written response to the Planning Coordinator following receipt of a technically justified request to perform a model review of

	perform a model review of a unit/plant. (R5)	perform a model review of a unit/plant. (R5)	perform a model review of a unit/plant. (R5) OR The Generator Owner provided a written response within 181 calendar days to the Planning Coordinator following receipt of a technically justified request to perform a model review of a unit/plant however the written response failed to include Requirement R5, Subpart 5.2 or Part 5.3.	a unit/plant (R5). OR The Generator Owner provided a written response within 181 calendar days to the Planning Coordinator following receipt of a technically justified request to perform a model review of a unit/plant however the written response failed to include Requirement R5, Subparts 5.2 and 5.3.
R6	The Transmission Planner provided a written response to the Generator Owner indicating whether the model is useable or not useable; including a technical description if the model is not useable, more than 90 calendar days but less than 120 calendar days of receiving verified model information. (R6)	The Transmission Planner provided a written response to the Generator Owner indicating whether the model is useable or not useable; including a technical description if the model is not useable, more than 120 calendar days but less than 150 calendar days of receiving the verified model information. (R6) OR The Transmission Planner provided a written response within 181 calendar days to the Generator Owner however the written response omitted confirmation for one of the specified model criteria listed in Requirement R6, Subparts 6.1 through 6.3.	The Transmission Planner provided a written response to the Generator Owner indicating whether the model is useable or not useable; including a technical description if the model is not useable, more than 150 calendar days but less than 180 calendar days of receiving the verified model information. (R6) OR The Transmission Planner provided a written response within 181 calendar days to the Generator Owner however the written response omitted confirmation for two of the specified model criteria listed in Requirement R6, Subparts 6.1 through 6.3.	The Transmission Planner failed to provide a written response to the Generator Owner within 181 calendar days of receiving the verified model information (R6). OR The Transmission Planner provided a written response within 181 calendar days to the Generator Owner however the written response omitted confirmation for all specified model criteria listed in Requirement R6, Subparts 6.1 through 6.3.

Excitation Control System and Plant Volt/Var Function Model Verification Periodicity

Periodicity Determination Supporting Criteria
Criteria 1: Establishing the Initial Ten Year Unit Verification Period Start Date: **For each applicable unit, set the initial start date for compliance with Requirement R2 to the 30 percent, 50 percent, or 100 percent Standard Implementation Effective Dates established for compliance in accordance with the ten calendar year transition period and in accordance with the following rules:** • **30 percent of the applicable units in the generation fleet unit MVA is compliant within the first 4 years.** • **50 percent of the applicable units in the generation fleet unit MVA is compliant within the first 6 years.** • **100 percent of the applicable units in the generation fleet unit MVA is compliant within the first 10 years.** **Criteria 2: Establishing the Recurring Ten Year Unit Verification Period Start Date:** **The start date is the actual data collection date for the most recently performed applicable unit verification.** **Criteria 3: For the purpose of calculating the initial ten year unit verification period 30 percent, 50 percent, or 100 percent threshold for generation fleet compliance, equivalent unit MVA is included.** **Consideration for Early Compliance** **Existing excitation control system and plant volt/var control function model verification is sufficient for demonstrating compliance for a ten year period from the actual verification date if either of the following applies:** • **The Generator Owner has a verified model that is compliant with the applicable regional policies, guidelines or criteria existing at the time of model verification** • **The Generator Owner has an existing verified model that is compliant with the requirements of this standard.**

Event Triggering Verification	Verification Periodicity	Comments
Establishing the initial verification period (Criteria 1) for an applicable unit (Requirement R2)	Record and collect excitation control system and plant volt/var control response validation data on or before the initial start date per Criteria 1	Transmit the verified model and documentation and data to the Transmission Planner no more than 365 calendar days from the date that the response was recorded. Criteria 3 applies when calculating generation fleet compliance during the 10-year transition period
Subsequent verification for an existing applicable unit (Requirement R2)	Record and collect excitation control system and plant volt/var control function response validation data on or before the ten year anniversary date of the collection of the recorded unit excitation control system and plant volt/var control function response used for the current validation.	Transmit the verified model and documentation and data to the Transmission Planner no more than 365 calendar days from the date that the recorded response was collected.
Initial verification for a new applicable unit or for an existing applicable unit with new excitation control system and plant volt/var control function equipment installed with settings final (Requirement R2)	Record and collect excitation control system and plant volt/var control function response validation data no more than 356 days from the commissioning date	Transmit the verified model and documentation and data to the Transmission Planner no more than 180 calendar days from the date that the recorded response was collected.
Existing applicable unit that is equivalent to another operating unit(s) at the same physical location. AND Each equivalent unit has the same MVA nameplate rating. AND	Verify a different equivalent unit during each ten year verification period. .	Document circumstance with a written statement and include with the verified model and documentation and data provided to the Transmission Provider for the verified equivalent unit.

Event Triggering Verification	Verification Periodicity	Comments
The nameplate rating is ≤ 350 MVA. AND Each equivalent unit has identical applicable components and settings. AND The model for one of these equivalent units has been verified. (Requirement R2)		Criteria 3 applies when calculating generation fleet compliance during the 10-year transition period.
Existing unit was subjected to an activity that resulted in an alteration of the response of the excitation control system and plant volt/var control function model and the altered unit settings are final AND The Generator Owner has submitted a verification plan. (Requirement R4)	Record and collect excitation control system and plant volt/var control response validation data no more than 365 calendar days from the date of the submitted verification plan.	Transmit the verified model and documentation and data to the Transmission Planner no more than 180 calendar days from the date that the recorded response was collected.
The Generator Owner receives written comments including dated electronic or hard copy evidence indicating that the recorded excitation control system and plant volt/var response to a transmission system event did not did not match the predicted excitation control system model response. AND The Generator Owner has submitted a verification plan. (Requirement R3)	Record and collect excitation control system and plant volt/var control response validation data no more than 365 calendar days from the date of the submitted verification plan.	Transmit the verified model and documentation and data to the Transmission Planner no more than 180 calendar days from the date that the recorded response was collected.
The Generator Owner receives written comments detailing technical concerns with the Generator Owner's excitation control system and plant volt/var control function model verification documentation.	Record and collect excitation control system and plant volt/var control response validation data no more than 365 calendar days from the date of the	Transmit the verified model and documentation and data to the Transmission Planner no more than 180 calendar days from the date that

Event Triggering Verification	Verification Periodicity	Comments
AND The Generator Owner has submitted a verification plan (Requirement R3)	submitted verification plan.	the recorded response was collected.
The excitation control system and volt/var control model are identified as unusable by the Transmission Planner. AND The Generator Owner has submitted a verification plan. (Requirement R3)	Record and collect excitation control system and plant volt/var control response validation data no more than 365 calendar days from the date of the submitted verification plan.	Transmit the verified model and documentation and data to the Transmission Planner no more than 180 calendar days from the date that the recorded response was collected.
Planning Coordinator requests a review of the excitation control system and plant volt/var control function model for a unit or plant that is not an applicable unit. AND The Generator Owner has submitted a verification plan. (Requirement R5)	Record and collect excitation control system and plant volt/var control response validation data no more than 365 calendar days from the date of the submitted verification plan.	Transmit the verified model and documentation and data to the Transmission Planner no more than 180 calendar days from the date that the recorded response was collected.
New or existing applicable unit does not include active closed loop function.	Not required until unit has an installed control system	Document circumstance with a written statement Perform verification per the periodicity specified in Row 3 for a “New Generating Unit” (or new equipment) once an active closed loop function is established.

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps ~~-~~Completed:

1. SAR posted for comment (April 20–May 21, 2007).
2. Revised SAR and response to comments posted.
3. Revised SAR and response to comments approved by SC (June 14, 2007).
4. SDT appointed on (August 18, 2007).
5. Draft MOD-026-1 was posted for a 45 day comment period from February 17 – April 2, 2009.
6. Draft 2 MOD-026-1 was posted for a 45 day concurrent comment and ballot period from June 15 – August 1, 2011.

Proposed Action Plan and Description of Current Draft:

This is the ~~first~~third draft of the ~~this~~ standard ~~including~~and includes Time Horizons, Data Retention, Violation Risk Factors, and Violation Severity Levels. This second posting is for a ~~45~~30-day comment and successive ballot period.

Future Development Plan:

Anticipated Actions	Anticipated Date
1. ~~Post first~~Develop responses to comments and develop third version draft ~~revision of~~ standard.	~~April-May~~August 2011– February 2012
2. Post response to comments and third version draft revision of standard for 30 day comment and successive ballot period.	~~July – August 2011~~February – March 2012
3. ~~Post response~~Develop responses to successive ballot comments ~~and request authorization to ballot the revised standard~~.	~~September - October 2011~~April – May 2012
~~4. Conduct initial ballot.~~	~~November 2011~~
~~5~~4. Post response to comments.	~~December 2011~~June 2012
~~6~~5. Conduct recirculation ballot.	~~January 2012~~June2012
7. BOT adoption.	~~February~~July 2012
8. File with regulatory authorities.	~~March~~September 2012

A. Introduction

1. **Title:** Verification of Models and Data for Generator Excitation Control System and Plant Volt/Var Control -Functions

2. **Number:** MOD-026-1

3. **Purpose:** To verify that the generator excitation control system and plant volt/var control[1] [1] function model (including the power system stabilizer model and the impedance compensator model),) and the model parameters used in dynamic simulations accurately represent the generator excitation control ~~systems~~system and plant volt/var control[2] function behavior when assessing Bulk Electric System (BES) reliability.

4. **Applicability:**

   4.1. Functional ~~entities~~Entities:

   4.1.1 Generator Owner

   4.1.2 Transmission Planner

   4.2. Facilities:

   For the purpose of this standard, the following Facilities are considered, "applicable units.~~"~~ [3]."

   Units or plants with an average capacity factor[4] greater than 5~~%~~ percent over the ~~last~~most recent three calendar years, beginning on January 1 and ending on December 31, that meet the following:

   4.2.1 Generating units connected to the Eastern or Quebec Interconnections with the following characteristics:

   ~~•~~**4.2.1.1** ~~Each~~Individual generating unit ~~with a~~ greater than 100 MVA (gross nameplate rating ~~greater than 100 MVA,~~) directly connected

---

[1] Excitation control system and plant volt/var control function:

a. For individual synchronous machines, the generator excitation control system includes the generator, exciter, voltage regulator and power system stabilizer.

b. For an aggregate generating plant, the volt/var control system includes the voltage regulator & reactive power control system controlling and coordinating plant voltage and associated reactive capable resources.

~~[2] Excitation control system or plant volt/var control system:~~

~~a. For individual synchronous machines, the generator excitation control system includes the generator, exciter, voltage regulator and power system stabilizer.~~

~~b. For an aggregate generation plant, the volt/var control system includes the voltage regulator & reactive power control system controlling and coordinating plant voltage and associated reactive capable resources.~~

[3] Applicable generating units do not include startup or standby units not normally connected to the grid.

[4] Once a capacity factor exemption is declared by notifying the Transmission Planner, verification is not required for 10 calendar years from the date eligibility occurs. At the end of this 10 calendar year timeframe, the current average 3 year capacity factor (for years 8, 9, and 10) is examined to determine if the capacity factor exemption can be declared for the next 10 calendar year period. If not eligible for the capacity factor exemption, then model verification must be completed within one year of the date the capacity factor exemption expired with the 10 calendar year periodicity requirement reset based on the verification date. For the definition of capacity factor, refer to Appendix F of the GADS Data Reporting Instructions on the NERC website.

~~at~~to the ~~point of interconnection[5] at greater than or equal to 100 kV~~bulk power system.

- **4.2.1.2** For each generating plant / Facility consisting of one or more units that are connected to the bulk power system at a common bus with ~~a~~ total generation greater than 100 MVA (gross aggregate ~~nameplate~~ rating ~~greater than to 100 MVA, connected at the same point of interconnection at greater than or equal to 100 kV:~~):
  - Each individual generating unit ~~with a~~ greater than 20 MVA (gross nameplate rating ~~greater than 20 MVA;~~); and
  - ~~The remainder of the plant as an aggregate.~~
  - Each generating plant / Facility comprised consisting of individual generating units less than 20 MVA (gross nameplate ratings)

4.2.2 Generating units connected to the Western Interconnection with the following characteristics:

- **4.2.2.1** ~~Each~~Individual generating unit ~~with a~~ greater than 75 MVA (gross nameplate rating ~~greater than 75 MVA,~~) directly connected ~~at~~to the ~~point of interconnection[3] at greater than or equal to 100 kV~~bulk power system.
- **4.2.2.2** For each generating plant / Facility consisting of one or more units that are connected to the bulk power system at a common bus with ~~a~~ total generation greater than 75 MVA (gross aggregate ~~nameplate~~ rating ~~greater than 75 MVA, connected at the same point of interconnection with at greater than or equal to 100 kV:~~):
  - Each individual generating unit ~~with a gross nameplate~~ greater than 20 MVA~~;~~ (gross nameplate rating); and
  - ~~The remainder of the plant as an aggregate.~~
  - Each generating plant / Facility comprised consisting of individual generating units less than 20 MVA (gross nameplate ratings)

4.2.3 Generating units connected to the ERCOT Interconnection with the following characteristics:

- **4.2.3.1** ~~Each~~Individual generating unit ~~with a~~ greater than 50 MVA (gross nameplate rating ~~of greater than 50 MVA,~~) directly connected ~~at~~to the ~~point of interconnection[3] with rating greater than or equal to 100 kV~~bulk power system.
- **4.2.3.2** For each generating plant / Facility consisting of one or more units that are connected to the bulk power system at a common bus with ~~a~~

~~[5] The common transmission bus voltage level at which the generator step-up transformer is connected.~~

total generation greater than 75 MVA (gross aggregate ~~nameplate~~ rating ~~of greater than 75 MVA, connected at the same point of interconnection at greater than or equal to 100 kV:~~):

- Each individual generating unit ~~with a gross nameplate~~ greater than 20 MVA~~;~~ (gross nameplate rating); and
- ~~The remainder of the plant as an aggregate.~~
- Each generating plant / Facility comprised consisting of individual generating units less than 20 MVA (gross nameplate ratings)

4.2.4 For all ~~interconnections:~~Interconnections:

- Any registered technically justified[6] unit requested by the Planning Coordinator.

5. Effective Date:

5.1. In those jurisdictions where regulatory approval is required:

5.1.1 ~~By~~Each responsible entity shall ensure compliance with Requirements R1, and R3 through R6 by the first day of the first calendar quarter, four years following applicable regulatory approval~~:~~.

~~•~~**5.1.2** Each Generator Owner shall ensure at least 30~~%~~ percent of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2 by the first day of the first calendar quarter, four years following applicable regulatory approval.

- ~~•~~ Each ~~responsible entity~~Generator Owner shall ensure ~~compliance~~at least 50 percent of its applicable units per Interconnection on an MVA basis are compliant with ~~Requirements R1, and R3 through R6.~~

~~**5.1.2**~~**5.1.3** ~~By~~Requirement R2 by the first day of the first calendar quarter, six years following applicable regulatory approval:

- ~~•~~ Each Generator Owner shall ensure ~~at least 50%~~100 percent of its applicable units ~~per Interconnection on an MVA basis~~ are compliant with Requirement R2~~.~~

~~**5.1.3**~~**5.1.4** ~~By~~ by the first day of the first calendar quarter, ten years following applicable regulatory approval:

- ~~Each Generator Owner shall ensure 100% of its applicable units are compliant with Requirement R2.~~

5.2. In those jurisdictions where no regulatory approval is required:

[6] ~~A technical~~Technical justification ~~for verifying each of those units or plant(s) that demonstrates through simulation and/or measured response that the unit or plant affects a stability limit, or evidence~~is achieved by demonstrating that the simulated unit or plant response does not match the measured unit or plant response.

5.2.1 ~~By~~Each responsible entity shall ensure compliance with Requirements R1, and R3 through R6 by the first day of the first calendar quarter, four years following Board of Trustees adoption~~:~~.

5.2.2 Each Generator Owner shall ensure at least 30~~%~~ percent of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2 by the first day of the first calendar quarter, four years following Board of Trustees adoption.

- ~~Each responsible entity shall ensure compliance with Requirements R1, and R3 through R6.~~

~~**5.2.2** By the first day of the first calendar quarter, six years following Board of Trustees adoption:~~

5.2.3 Each Generator Owner shall ensure at least 50~~%~~ percent of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2 by the first day of the first calendar quarter, six years following Board of Trustees adoption.

~~**5.2.3** By the first day of the first calendar quarter, ten years following Board of Trustees adoption:~~

5.2.4 Each Generator Owner shall ensure 100~~%~~ percent of its applicable units are compliant with Requirement R2 by the first day of the first calendar quarter, ten years following Board of Trustees adoption.

~~**6. Consideration for Early Compliance**~~

~~**6.1.** Existing excitation control system and plant volt/var control[1] model verification is sufficient for demonstrating compliance for a ten year period from the actual verification date if:~~

- ~~The Generator Owner has a verified model that is compliant with the applicable regional entity policies, guidelines or criteria existing at the time of model verification (provided the model verification addresses the same unit criteria and the same information as required by this standard), or~~
- ~~The Generator Owner has an existing verified model that is compliant with the requirements of this standard.~~

B. Requirements

R1. Each Transmission Planner shall provide the following instructions and model data to its requesting Generator Owner within ~~30~~90 calendar days of receiving ~~the~~a request ~~from its Generator Owner~~ for those instructions ~~and~~or model data: *[Violation Risk Factor: Lower] [Time Horizon: ~~Long-term~~Operations Planning~~]~~]:*

- Instructions on how to obtain the list of ~~acceptable~~ excitation control system and plant volt/var control[1] function ~~model~~models acceptable to the Transmission Planner for use in dynamic simulation.

- Instructions on how to obtain the Transmission Planner's software manufacturer's dynamic excitation control system and plant volt/var control~~[1]~~ function~~ system~~ model library block diagrams and/or data sheets.
- ~~Any~~Model data for any of the Generator Owner's existing unit or plant specific excitation control system and plant volt/var control~~[1]~~~~ model data~~ function contained in the Transmission Planner's dynamic database from the current (in-use) models, including generator MVA base.

R2. Each Generator Owner shall provide, for each of its applicable units, a verified generator excitation control system and plant volt/var control~~[1]~~ function model ~~(for each of its applicable Facilities)~~including documentation and data as specified in Parts 2.1 and 2.2 to its Transmission Planner in accordance with the periodicity specified in MOD-026 Attachment 1, to ensure modeling data is accurate for use in simulation software~~ subject to the following:~~. *[Violation Risk Factor: ~~Lower~~Medium] [Time Horizon: Long-term Planning]*

2.1. ~~Each Generator Owner shall perform its~~Perform verifications ~~with~~using one or more models acceptable to ~~its~~the Transmission Planner that ~~collectively~~ include(s) the following information:

2.1.1. Documentation demonstrating the ~~unit or plant's~~applicable unit's model response matches the recorded response for a voltage excursion at the ~~generator or plant~~applicable unit's point of interconnection from either a staged test or a measured system disturbance.

2.1.2. Manufacturer, model number (if available), and type of excitation control system and plant volt/var control~~[1]~~~~ system~~ function installed (such as static, ~~ac~~AC brushless, ~~dc~~DC rotating, volt/var ~~system~~function).

2.1.3. ~~Generator (or plant equivalent) model~~Model structure and data (such as reactance, time constants, saturation factors, rotational inertia, or equivalent data) for the generator (or plant equivalent).

2.1.4. ~~Excitation~~Model structure and data for the excitation control system~~ and~~, for the plant volt/var ~~system model structure~~function, and ~~data~~ for the closed loop voltage regulator if the closed loop voltage regulator is installed.

2.1.5. Compensation settings (such as droop, line drop, differential compensation), if used.

2.1.6. Model structure and data for power system stabilizer, if so equipped.

2.2. For plants that are comprised of units that have a gross nameplate rating of less than 20 MVA, each Generator Owner shall perform its verification using plant aggregate model(s) that include the information required by Requirement sub-parts 2.1.1 through 2.1.6

R3. Each Generator Owner shall provide a written response ~~that contains~~to its Transmission Planner within 90 calendar days of receiving one of the following items. The written response shall contain either the technical basis for maintaining the current model, ~~a list of future~~or the model changes, or a plan to perform model verification[7] ~~to its Transmission Planner within 90 calendar days of receiving notice of one of the following:~~(in accordance with Requirement R2) *[Violation Risk Factor: Lower] [Time Horizon: ~~Long-term~~Operations Planning~~]~~]:*

- Written notification~~, including a technical description~~ from its Transmission Planner ~~of why~~(in accordance with Requirement R6) that the excitation control system and plant volt/var control~~[1]~~ ~~system~~ function model is not "usable~~" as identified in Requirement R6, Parts 6.1 through 6.3 criteria,~~," or

- Written comments from its Transmission Planner identifying technical concerns with the verification documentation related to the excitation control system and plant volt/var control~~[1]~~ ~~system~~ function model, or

- Written comments and supporting evidence from its Transmission Planner indicating that the predicted excitation control system and plant volt/var control~~[1]~~ function model response did not match the recorded response to a transmission system event.

R4. Each Generator Owner shall provide revised model data or plans to perform model verification[7] (in accordance with Requirement R2) to its Transmission Planner within 180 calendar days of making changes to the excitation control system and plant volt/var control~~[1]~~ ~~system~~ function that alter the equipment response[8] characteristic. *[Violation Risk Factor: Lower] [Time Horizon: ~~Long-term~~Operations Planning]*

R5. Each Generator Owner shall provide a written response to its Planning Coordinator, within 90 calendar days following receipt of a technically justified request from the Planning Coordinator to perform a model review of ~~a~~any unit/plant not included in the Applicability that ~~meets~~includes one of the following~~:~~ *[Violation Risk Factor: Lower] [Time Horizon: ~~Long-term~~Operations Planning~~]~~]:*

~~5.1. Submit within 90 calendar day's receipt~~Details of ~~the technically justified~~[4] ~~request.~~

- ~~Either indicate~~ plans to verify the model ~~or identify~~ (in accordance with Requirement R2)

~~5.2.~~ Corrected model data including the source of revised model data such as~~:~~

- ~~Discovery~~ discovery of manufacturer test values to replace generic model data~~.~~

- ~~Updating~~ or updating of data parameters based on a walk down of the equipment.

---

[7] If verification is performed, the 10 year period as outlined in Attachment 1 is reset.

[8] Exciter, voltage regulator, plant volt/var or power system stabilizer control replacement including software alterations that alter excitation control system equipment response, plant digital control system addition or replacement, plant digital control system software alterations that alter excitation control system equipment response, plant volt/var function equipment addition or replacement (such as static var systems, capacitor banks, individual unit excitation systems, etc), a change in the voltage control mode (such as going from power factor control to automatic voltage control, etc), exciter, voltage regulator, impedance compensator, or power system stabilizer settings change.

~~5.3.~~ ~~Include corrected~~ Each Transmission Planner shall notify the Generator Owner within 90 calendar days of receiving the verified excitation control system and plant volt/var control[1] function model ~~data.~~

R6. ~~Each Transmission Planner shall determine if the verified generator excitation control system and plant volt/control[1] model received~~ information whether the model is useable (meets the criteria ~~identified in Requirement R6~~specified in Parts 6.1 through 6.3 ~~and provide a written response to the Generator Owner indicating whether the model is useable~~), or is not useable; ~~including~~and shall include a technical description if the model is not useable. ~~This written response shall be submitted within 90 calendar days of receiving the excitation control system and plant volt/var control[1] verified model information~~. *[Violation Risk Factor: ~~Lower~~Medium] [Time Horizon: ~~Long-term~~Operations Planning]*

6.1. The excitation control system and plant volt/var control[1] function model ~~can initialize~~initializes to compute modeling data without error.

6.2. A no-disturbance simulation results in negligible transients.

6.3. For an otherwise stable simulation, a disturbance simulation results in the excitation control and plant volt/var control[1] ~~system~~ function model exhibiting positive damping.

C. Measures

M1. ~~Each Transmission Planner shall have evidence to show that it provided~~ Evidence for Requirement R1 must include the transmitted instructions or data and dated evidence of transmission of requested instructions and data ~~(~~, such as dated electronic mail messages ~~or mail~~, dated postal receipts ~~) within 30 calendar days of receiving a request as specified in Requirement R1~~, dated confirmation of facsimile transmission.

~~M2.~~ ~~Each Generator Owner shall have evidence (such as a dated electronic mail messages or mail receipts) including~~Evidence for Requirement R2 must include, for each of the Generator Owner's applicable Facilities, the verification report ~~to show~~showing that ~~it provided~~ the ~~verified~~ generator excitation control system ~~or~~and plant volt/var control[1] function model ~~as specified in Requirement R2.~~

~~M3.~~**M2.** ~~Each Generator Owner shall have~~ was verified and dated evidence ~~to show that it provided a written response (~~of transmission, such as a dated ~~copy of the response, or dated~~ electronic mail messages ~~or mail~~, dated postal receipts ~~) containing identified information and submitted within 90 calendar days~~, or dated confirmation of ~~receiving any written notification~~facsimile transmission as specified in Requirement ~~R3.~~R2.

M3. ~~Each~~ Evidence for Requirement R3 must include the Generator ~~Owner shall have evidence to show that it provided a~~ Owner's dated written response ~~(~~containing the information identified in Requirement R3 and dated evidence of transmittal, such as a dated ~~copy of the request, or dated~~ electronic mail messages ~~or mail~~ , dated postal receipts ~~) submitted within 180 calendar days~~, or dated confirmation of ~~making~~facsimile transmission.

M4. Evidence for Requirement R4 must include, for each of the Generator Owner's Facilities for which system changes specified in Requirement R4 were made, dated revised model data or dated plans to perform a model verification and dated evidence of transmittal, such as dated electronic mail messages, dated postal receipts, or dated confirmation of facsimile transmittal.

M5. ~~Each Generator Owner shall have evidence to show that it provided a written response (~~Evidence for Requirement R5 must include, for each request received as specified in Requirement R5, the dated written response provided and dated evidence of transmittal, such as dated electronic mail messages, dated postal receipts, or dated confirmation of facsimile transmittal.

~~**M5.**~~ Evidence of Requirement R6 must include, for each model received, the dated response containing the information required in Parts 6.1 through 6.3 and dated evidence of transmittal, such as dated electronic mail messages~~ or mail receipts) and submitted within 90 calendar days of receiving the request as specified in Requirement R5.~~

M6. ~~Each Transmission Planner shall have evidence to show that it provided a written response (such as dated electronic mail messages or mail~~, dated postal receipts~~) within 90 calendar days of receiving the model as specified in Requirement R6~~, or dated confirmation of facsimile transmittal.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

Regional Entity

1.2. Data Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Generator Owner and Transmission Planner shall each keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

- The Transmission Planner shall retain the information/data request and provided response evidence of Requirements R1 and R6, Measures M1 and M6 for 3 calendar years from the date the document was provided.
- The Generator Owner shall retain the latest and previous excitation control system and plant volt/var control~~[1] system~~ function model verification evidence of Requirement R2, Measure M2.
- The Generator Owner shall retain the information/data request and provided response evidence of Requirements R3 through R5, and Measures M3 through M5 for 3 calendar years from the date the document was provided.

If a Generator Owner or Transmission Planner is found non-compliant, it shall keep information related to the non-compliance until ~~found compliant~~mitigation is complete or approved or for the time specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes

Compliance ~~Audits~~Audit

Self-~~Certifications~~Certification

Spot Checking

Compliance ~~Violation Investigations~~Investigation

Self-Reporting

Complaints

1.4. Additional Compliance Information

None

2. Violation Severity Levels

R #	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The Transmission Planner provided the instructions and data to the Generator Owner more than 90 calendar days but ~~less~~no more than ~~or equal to~~ 120 calendar days of receiving a request.	The Transmission Planner provided the instructions and data to the Generator Owner more than 120 calendar days but ~~less~~no more than ~~or equal to~~ 150 calendar days of receiving a request.	The Transmission Planner provided the instructions and data to the Generator Owner more than 150 calendar days but ~~less~~no more than ~~or equal to~~ 180 calendar days of receiving a request.	The Transmission Planner failed to provide the instructions and data to the Generator Owner within 181 calendar days of receiving a request.
R2	The Generator Owner provided its verified model(s) to its Transmission Planner after the ~~periodicity~~ timeframe specified in MOD-026 Attachment 1 but ~~less~~no more than ~~or equal to~~ 30 calendar days late; OR The Generator Owner provided the Transmission Planner verified ~~model(s)~~models that omitted one of the six Parts identified in Requirement R2, ~~Parts~~Subparts 2.1.1 through 2.1.6.	The Generator Owner provided its verified model(s) to its Transmission Planner more than 30 calendar days but ~~less~~no more than ~~or equal to~~ 60 calendar days late as specified by the periodicity timeframe in MOD-026 Attachment 1. OR The Generator Owner provided the Transmission Planner verified ~~model(s)~~models that omitted two of the six Parts identified in Requirement R2, ~~Parts~~Subparts 2.1.1 through 2.1.6.	The Generator Owner provided its verified model(s) to its Transmission Planner more than 60 calendar days but ~~less~~no more than ~~or equal to~~ 90 calendar days late as specified by the periodicity timeframe in MOD-026 Attachment 1. OR The Generator Owner provided the Transmission Planner verified ~~model(s)~~models that omitted three of the six Parts identified in Requirement R2, ~~Parts~~Subparts 2.1.1 through 2.1.6.	The Generator Owner ~~failed to provide the~~provided its verified generator excitation control system ~~or~~and plant volt/var control function model~~(s)~~ more than 90 calendar days late or failed to provide the verified model(s) ~~no more than 90 calendar days late~~ to its Transmission Planner in accordance with the periodicity specified in MOD-026 Attachment 1. OR The Generator Owner failed to use model(s) acceptable to the Transmission Planner as specified in Requirement R2, ~~Part~~Subpart 2.1. OR The Generator Owner provided the Transmission Planner verified model(s) that omitted four or more of

				the six Parts identified in Requirement R2, ~~Parts~~Subparts 2.1.1 through 2.1.6.
R3	The Generator Owner provided a written response more than 90 calendar days but ~~less~~no more than ~~or equal to~~ 120 calendar days of receiving written notice. (R3)	The Generator Owner provided a written response more than 120 calendar days but ~~less~~no more than ~~or equal to~~ 150 calendar days of receiving written notice. (R3)	The Generator Owner provided a written response more than 150 calendar days but ~~less~~no more than ~~or equal to~~ 180 calendar days of receiving written notice. (R3)	The Generator Owner failed to provide a written response within 181 calendar days of receiving written notice ~~as specified in Requirement~~ (R3~~.~~). OR The Generator Owner's written response was provided within 181 calendar days of receiving written notice however, the Generator Owner's written response failed to contain either the technical basis for maintaining the current model, or a list of future model changes, or a plan to perform another model verification.
R4	The Generator Owner provided revised model data or plans to perform model verification more than 180 calendar days but ~~less~~no more than ~~or equal to~~ 210 calendar days of making changes to the excitation control system ~~or~~and plant volt/var control[1] ~~system~~ function that altered the equipment response characteristic. (R4)	The Generator Owner provided revised model data or plans to perform model verification more than 210 calendar days but ~~less~~no more than ~~or equal to~~ 240 calendar days of making changes to the excitation control system ~~or~~and plant volt/var control[1] ~~system~~ function that altered the equipment response characteristic. (R4)	The Generator Owner provided revised model data or plans to perform model verification more than 240 calendar days but ~~less~~no more than ~~or equal to~~ 270 calendar days of making changes to the excitation control system ~~or~~and plant volt/var control[1] ~~system~~ function that altered the equipment response characteristic. (R4)	The Generator Owner failed to provide revised model data or failed to provide plans to perform model verification within 271 calendar days of making changes to the excitation control system ~~or~~and plant volt/var control[1] ~~system~~ function that altered the equipment response characteristic ~~as specified in Requirement~~ (R4~~.~~).
R5	The Generator Owner provided a written response more than 90 calendar days but ~~less~~no more than ~~or equal to~~ 120 calendar days to	The Generator Owner provided a written response more than 120 calendar days but ~~less~~no more than ~~or equal to~~ 150 calendar days to the	The Generator Owner provided a written response more than 150 calendar days but ~~less~~no more than ~~or equal to~~ 180 calendar days to the	The Generator Owner failed to provide a written response to the Planning Coordinator following receipt of a technically justified

	the Planning Coordinator following receipt of a technically justified request to perform a model review of a unit/plant. (R5)	Planning Coordinator following receipt of a technically justified request to perform a model review of a unit/plant. (R5)	Planning Coordinator following receipt of a technically justified request to perform a model review of a unit/plant. (R5) OR The Generator Owner provided a written response within 181 calendar days to the Planning Coordinator following receipt of a technically justified request to perform a model review of a unit/plant however the written response failed to include Requirement R5, ~~Part~~Subpart 5.2 or Part 5.3.	request to perform a model review of a unit/plant ~~as specified in Requirement R5.~~(R5). OR The Generator Owner provided a written response within 181 calendar days to the Planning Coordinator following receipt of a technically justified request to perform a model review of a unit/plant however the written response failed to include Requirement R5, ~~Parts~~Subparts 5.2 and 5.3.
R6	The Transmission Planner provided a written response to the Generator Owner indicating whether the model is useable or not useable; including a technical description if the model is not useable, more than 90 calendar days but less than 120 calendar days of receiving verified model information. (R6)	The Transmission Planner provided a written response to the Generator Owner indicating whether the model is useable or not useable; including a technical description if the model is not useable, more than 120 calendar days but less than 150 calendar days of receiving the verified model information. (R6) OR The Transmission Planner provided a written response within 181 calendar days to the Generator Owner however the written response omitted confirmation for one of the specified model criteria listed in Requirement R6, ~~Parts~~Subparts 6.1 through 6.3.	The Transmission Planner provided a written response to the Generator Owner indicating whether the model is useable or not useable; including a technical description if the model is not useable, more than 150 calendar days but less than 180 calendar days of receiving the verified model information. (R6) OR The Transmission Planner provided a written response within 181 calendar days to the Generator Owner however the written response omitted confirmation for two of the specified model criteria listed in Requirement R6, ~~Parts~~Subparts 6.1 through 6.3.	The Transmission Planner failed to provide a written response to the Generator Owner within 181 calendar days of receiving the verified model information ~~as specified in Requirement R6.~~(R6). OR The Transmission Planner provided a written response within 181 calendar days to the Generator Owner however the written response omitted confirmation for all specified model criteria listed in Requirement R6, ~~Parts~~Subparts 6.1 through 6.3.

Applicable Entities

Transmission Planner
Generator Owner

For the purpose of this standard, the following Facilities are considered, "applicable units[1]."

Units or plants with an average capacity factor[2] greater than 5 percent over the last three calendar years, beginning on January 1 and ending on December 31, that meet the following:

Generating units connected to the Eastern or Quebec Interconnections with the following characteristics:

- Individual generating unit greater than 100 MVA (gross nameplate rating) directly connected to the bulk power system.

[1] Applicable generating units do not include startup or standby units not normally connected to the grid.
[2] Once a capacity factor exemption is declared by notifying the Transmission Planner, verification is not required for 10 calendar years from the date eligibility occurs. At the end of this 10 calendar year timeframe, the current average 3 year capacity factor (for years 8, 9, and 10) is examined to determine if the capacity factor exemption can be declared for the next 10 calendar year period. If not eligible for the capacity factor exemption, then model verification must be completed within one year of the date the capacity factor exemption expired with the 10 calendar year periodicity requirement reset based on the verification date. For the definition of capacity factor, refer to Appendix F of the GADS Data Reporting Instructions on the NERC website.

- For each generating plant / Facility consisting of one or more units that are connected to the bulk power system at a common bus with total generation greater than 100 MVA (gross aggregate rating):
  - Each individual generating unit greater than 20 MVA (gross nameplate rating); and
  - Each generating plant / Facility comprised consisting of individual generating units less than 20 MVA (gross nameplate ratings)

Generating units connected to the Western Interconnection with the following characteristics:

- Individual generating unit greater than 75 MVA (gross nameplate rating) directly connected to the bulk power system.
- For each generating plant / Facility consisting of one or more units that are connected to the bulk power system at a common bus with total generation greater than 75 MVA (gross aggregate rating):
  - Each individual generating unit greater than 20 MVA (gross nameplate rating); and
  - Each generating plant / Facility comprised consisting of individual generating units less than 20 MVA (gross nameplate ratings)

Generating units connected to the ERCOT Interconnection with the following characteristics:

- Individual generating unit greater than 50 MVA (gross nameplate rating) directly connected to the bulk power system.
- For each generating plant / Facility consisting of one or more units that are connected to the bulk power system at a common bus with total generation greater than 75 MVA (gross aggregate rating):
  - Each individual generating unit greater than 20 MVA (gross nameplate rating); and
  - Each generating plant / Facility comprised consisting of individual generating units less than 20 MVA (gross nameplate ratings)

For all Interconnections:

- Any registered technically justified[3] unit requested by the Planning Coordinator.

[3] Technical justification is achieved by demonstrating that the simulated unit or plant response does not match the measured unit or plant response.

Conforming Changes to Other Standards

None

Effective Dates

In those jurisdictions where regulatory approval is required:

- Each responsible entity shall ensure compliance with Requirements R1, and R3 through R6 By the first day of the first calendar quarter, four years following applicable regulatory approval.
- Each Generator Owner shall ensure at least 30% of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2 by the first day of the first calendar quarter, four years following applicable regulatory approval.
- Each Generator Owner shall ensure at least 50% of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2 by the first day of the first calendar quarter, six years following applicable regulatory approval.
- Each Generator Owner shall ensure 100% of its applicable units are compliant with Requirement R2 By the first day of the first calendar quarter, ten years following applicable regulatory approval.

In those jurisdictions where no regulatory approval is required:

- Each responsible entity shall ensure compliance with Requirements R1, and R3 through R6 by the first day of the first calendar quarter, four years following Board of Trustees adoption.
- Each Generator Owner shall ensure at least 30% of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2 by the first day of the first calendar quarter, four years following Board of Trustees adoption.
- Each Generator Owner shall ensure at least 50% of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2 By the first day of the first calendar quarter, six years following Board of Trustees adoption.
- Each Generator Owner shall ensure 100% of its applicable units are compliant with Requirement R2 By the first day of the first calendar quarter, ten years following Board of Trustees adoption.

Consideration for Early Compliance

Existing excitation control system and plant volt/var control model verification is sufficient for demonstrating compliance for a ten year period from the actual verification date if either of the following applies:

- The Generator Owner has a verified model that is compliant with the applicable regional entity policies, guidelines or criteria existing at the time of model verification, or
- The Generator Owner has an existing verified model that is compliant with the requirements of this standard.

Justification

This phased implementation supports the ten year cycle for the collection of generator response data necessary for required verifications and typical generating unit outage schedules.

When a Generator Owner has verified its Excitation Control System and Plant Volt/Var Control model(s) in compliance with its regional entity requirements ten years or less prior to the approval date of this Standard, these verifications are deemed sufficient for demonstrating compliance with this Standard for a ten year period from the date of the aforementioned verification.

Compliance with the Standard

The following entities are responsible for being compliant with all requirements of MOD-026-1:

- Transmission Planner
- Generator Owner

- Facilities

  For the purpose of this standard, the following Facilities are considered, "applicable units[1]." Units or plants with an average capacity[2] factor greater than 5% over the last three calendar years, beginning on January 1 and ending on December 31, that meet the following:

[1] Applicable generating units do not include startup or standby units not normally connected to the grid.

[2] Once a capacity factor exemption is declared by notifying the Transmission Planner, verification is not required for 10 calendar years from the date eligibility occurs. At the end of this 10 calendar year timeframe, the current average 3 year capacity factor (for years 8, 9, and 10) is examined to determine if the capacity factor exemption can be declared for the next 10 calendar year period. If not eligible for the capacity factor exemption, then model verification must be completed within one year of the date the capacity factor exemption expired with the 10 calendar year periodicity requirement reset based on the verification date.

Generating units connected to the Eastern or Quebec Interconnections with the following characteristics:

- Individual generating unit greater than 100 MVA (gross nameplate rating) directly connected to the bulk power system.
- For each generating plant / Facility consisting of one or more units that are connected to the bulk power system at a common bus with total generation greater than 100 MVA (gross aggregate rating):
    - Each individual generating unit greater than 20 MVA (gross nameplate rating); and
    - Each generating plant / Facility comprised consisting of individual generating units less than 20 MVA (gross nameplate ratings)

Generating units connected to the Western Interconnection with the following characteristics:

- Individual generating unit greater than 75 MVA (gross nameplate rating) directly connected to the bulk power system.
- For each generating plant / Facility consisting of one or more units that are connected to the bulk power system at a common bus with total generation greater than 75 MVA (gross aggregate rating):
    - Each individual generating unit greater than 20 MVA (gross nameplate rating); and
    - Each generating plant / Facility comprised consisting of individual generating units less than 20 MVA (gross nameplate ratings)

Generating units connected to the ERCOT Interconnection with the following characteristics:

- Individual generating unit greater than 50 MVA (gross nameplate rating) directly connected to the bulk power system.
- For each generating plant / Facility consisting of one or more units that are connected to the bulk power system at a common bus with total generation greater than 75 MVA (gross aggregate rating):
    - Each individual generating unit greater than 20 MVA (gross nameplate rating); and
    - Each generating plant / Facility comprised consisting of individual generating units less than 20 MVA (gross nameplate ratings)

For all Interconnections:

- Any registered technically justified[3] unit requested by the Planning Coordinator.

~~Generating units connected to the Eastern or Quebec Interconnection with the following characteristics:~~

- ~~Each generating unit with a gross nameplate rating greater than or equal to 100 MVA, connected at the point of interconnection[4] with rating greater than or equal to 100 kV.~~
- ~~For each plant with a gross aggregate nameplate rating greater than or equal to 100 MVA, connected at the same point of interconnection with rating greater than or equal to 100 kV:~~
  - ~~Each unit with a gross nameplate rating greater than or equal to 20 MVA; and~~
  - ~~The remainder of the plant as an aggregate.~~

~~Generating units connected to the Western Interconnection with the following characteristics:~~

- ~~Each generating unit with a gross nameplate rating greater than or equal to 75 MVA, connected at the point of interconnection[2] with rating greater than or equal to 100 kV.~~
- ~~For each plant with a gross aggregate nameplate rating greater than or equal to 75 MVA, connected at the same point of interconnection with rating greater than or equal to 100 kV:~~
  - ~~Each unit with a gross nameplate rating greater than or equal to 20 MVA; and~~
  - ~~The remainder of the plant as an aggregate.~~

~~Generating units connected to the ERCOT Interconnection with the following characteristics:~~

- ~~Each generating unit with a gross nameplate rating greater than or equal to 50 MVA, connected at the point of interconnection[2] with rating greater than or equal to 100 kV.~~

Consideration for Early Compliance

Existing excitation control system and plant volt/var control1 model verification is sufficient for demonstrating compliance for a ten year period from the actual verification date if either of the following applies:

- The Generator Owner has a verified model that is compliant with the applicable regional entity policies, guidelines or criteria existing at the time of model verification, or
- The Generator Owner has an existing verified model that is compliant with the requirements of this standard.

Justification

This phased implementation supports the ten year cycle for the collection of generator response data necessary for required verifications and typical generating unit outage schedules.

When a Generator Owner has verified its Excitation Control System and Plant Volt/Var Control model(s) in compliance with its regional entity requirements ten years or less prior to the approval date of this Standard, these verifications are deemed sufficient for demonstrating compliance with this Standard for a ten year period from the date of the aforementioned verification.

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. SAR posted for comment (April 20–May 21, 2007).
2. Revised SAR and response to comments posted.
3. Revised SAR and response to comments approved by SC (June 14, 2007).
4. SDT appointed on (August 18, 2007).
5. Initial draft of PRC-024-1 was posted for a 45 day formal comment period (February 17 – April 2, 2009).
6. Draft 2 PRC-024-1 was posted for a 45 day concurrent comment and ballot period from June 15 – August 1, 2011.

Proposed Action Plan and Description of Current Draft:

This is the third draft of the standard and includes Time Horizons, Data Retention, Violation Risk Factors, and Violation Severity Levels. This second posting is for a 30-day comment and successive ballot period.

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Develop responses to comments and develop third version draft standard.	August 2011 – February 2012
2. Post response to comments and third version draft revision of standard for 30 day comment and successive ballot period.	February – March 2012
3. Develop responses to successive ballot comments.	April – June 2012
4. Post response to comments.	July 2012
5. Conduct recirculation ballot.	July 2012
7. BOT adoption.	August 2012
8. File with regulatory authorities.	October 2012

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

None

A. Introduction

1. **Title:** Generator Performance During Frequency and Voltage Excursions

2. **Number:** **PRC-024-1**

3. **Purpose:** Ensure generating units remain connected during frequency and voltage excursions, and ensure expected generating unit performance during frequency and voltage excursions, is communicated to Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners for accurate system modeling.

4. **Applicability:**

   4.1. Generator Owner

5. **Effective Date:**

   5.1. Each Generator Owner shall verify that at least 33 percent of its applicable units are fully compliant with Requirements R1, R2, R3, R4, and R6 by the first day of the first calendar quarter one year following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter one year following Board of Trustees adoption.

   5.2. Each Generator Owner shall verify that at least 66 percent of its applicable units are fully compliant with Requirements R1, R2, R3, R4, and R6 by the first day of the first calendar quarter two years following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter two years following Board of Trustees adoption.

   5.3. Each Generator Owner shall verify that 100 percent of its applicable units are fully compliant with Requirements R1, R2, R3, R4, and R6 by the first day of the first calendar quarter three years following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter three years following Board of Trustees adoption.

   5.4. Requirement R5 shall be effective on the first day of the first calendar quarter six years following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter six years following Board of Trustees adoption.

B. Requirements

R1. Each Generator Owner that has generator frequency protective relaying[1] activated to trip its new or existing generating unit or generating plant shall set such protective relaying so that it does not trip within the "no trip zone" of PRC-024 Attachment 1, unless the Generator Owner has documented and communicated each equipment limitation in accordance with Requirement R3 for an existing generating unit.[2] *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*

1.1. A generating unit or generating plant is allowed to trip within the "no trip zone" if the frequency rate of change is more than 2.5 Hz/sec.

1.2. A generating unit or generating plant may trip if the protective functions (such as out-of-step or loss-of-field functions) operate due to an impending or actual loss of synchronism or due to instability in power conversion control equipment.

R2. Each Generator Owner that has generator voltage protective relaying[1] activated to trip its new or existing generating unit or generating plant shall set its protective relaying such that it does not trip as a result of a voltage excursion (at the point of interconnection[3]) that remains within the "no trip zone" of PRC-024 Attachment 2 caused by an event on the transmission system external to the generating plant per the following operating conditions and relay settings, unless the Generator Owner has documented and communicated each non-protection system equipment limitation in accordance with Requirement R3 for an existing generating unit or generating plant.: *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*

2.1. When operating within 95 percent to 105 percent of rated generator terminal voltage and during the transmission system operating conditions defined in PRC-024 Attachment 2, with the following clarifications:

2.1.1. If a Transmission Planner's study (based on the location specific voltage recovery characteristics) allows less stringent voltage relay settings than those required to meet PRC-024 Attachment 2, set voltage relays either to

---

[1] Each Generator Owner is not required to have frequency or voltage protective relaying (including but not limited to frequency and voltage protective functions for discrete relays, volts per hertz relays evaluated at nominal frequency, impedance relays, voltage controlled overcurrent relays, multi-function protective devices or protective functions within control systems that directly trip or provide tripping signals to the generator based on frequency or voltage inputs) installed or activated on its unit.

[2] To include generators under construction, generators with an executed interconnection agreement or Power Purchase Agreement by the effective date of this standard, or generators with an executed equipment purchase contract and scheduled delivery of major components within 2 years of the effective date of Requirement R5 of Version 1 of this standard.

[3] For the purposes of this standard, point of interconnection means the transmission (high voltage) side of the generator step-up or collector transformer.

meet the Transmission Planner's voltage recovery characteristics or the characteristics in PRC-024 Attachment 2.

2.1.2. Tripping a generator in accordance with a Special Protection System (SPS) or Remedial Action Scheme (RAS) is acceptable in the "no trip zone" of PRC-024 Attachment 2.

2.1.3. If clearing a system fault necessitates disconnecting a generator, this action is acceptable within the "no trip zone" specified in PRC-024 Attachment 2.

2.1.4. A generating unit or generating plant may trip if the protective functions (such as out-of-step or loss-of-field functions) operate due to an impending or actual loss of synchronism or due to instability in power conversion control equipment.

R3. Each Generator Owner of an existing generating unit or generating plant shall document each equipment limitation (excluding generator frequency and voltage protective relay limitations) that prevents a generating unit or generating plant, from meeting the criteria in Requirements R1 or R2 including study results, experience from an actual event, or manufacturer's advisory *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*.

3.1. The Generator Owner shall communicate the documented limitation, or the removal of a previously documented limitation, to its Reliability Coordinator, Planning Coordinator, Transmission Operator and Transmission Planner within 30 calendar days of identifying the limitation to ensure the accuracy of planning studies and system modeling studies. The existing generating unit or generating plant becomes subject to the full extent of Requirements R1 and R2 coincident with either of the following conditions:

- The equipment causing the limitation is repaired or replaced with equipment that removes the limitation.
- The equipment causing the limitation is modified or upgraded resulting in an increase of generator nameplate capacity rating greater than 10 percent (cumulative from the first effective date of this Standard).

R4. Each Generator Owner of an existing generating unit or generating plant shall provide an estimate of that unit's performance during Frequency/Voltage Excursions to each requesting entity (Reliability Coordinator, Planning Coordinator, Transmission Operator or Transmission Planner that monitors or models the associated generating unit or generating plant) within 60 calendar days of receipt of a written request, to ensure the accuracy of planning studies and system modeling studies. The estimate shall include: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

4.1. An estimate of the time duration the existing generating unit or generating plant will remain connected (considering performance of the auxiliary systems as well as the generator) as a result of a frequency excursion or a voltage excursion defined by the voltage or frequency profile at the point of interconnection described by dynamic simulation provided by the Transmission Planner. If the Generator Owner expects the existing unit, generating plant will remain connected for longer than 10 minutes, the estimate should indicate the existing unit or generating plant is not expected to trip.

4.2. Identification of the bases for the estimates developed for 4.1 which may include, but is not limited to: experience, actual event histories, or sound engineering judgment.

R5. Each Generator Owner shall design, build, and maintain its new [4] unit or new generating plant so that it will not trip due to a frequency excursion or voltage excursion at the point of interconnection, caused by an event on the transmission system external to the generating plant, within the parameters set forth in PRC-024 Attachments 1 and 2 and in accordance with the following conditions and exceptions: *[Violation Risk Factor: High] [Time Horizon: Real-time Operations]*

5.1. (condition) When the generating unit or generating plant is operating at or above the minimum sustainable generation threshold.

5.1.1. For a generating plant consisting of multiple units with total generation greater than 75 MVA (gross aggregate nameplate rating), when the generating plant is producing at least 20 percent of the plant's aggregate nameplate capacity.

5.2. (exception) For a new generating plant consisting of multiple units less than 20 MVA each with total plant generation greater than75 MVA (gross aggregate rating), 10 percent of the individual generating units may disconnect as a result of the frequency or voltage excursion.

5.3. (exception) A generating unit or generating plant may operate to a less stringent voltage ride-through performance criterion than the duration curve identified in PRC-024 Attachment 2 based on the location-specific voltage recovery characteristics if provided by the Transmission Planner as described in Requirement 2, Part 2.1.1.

5.4. (exception) A generating unit or generating plant may trip if this action is designed as part of a Special Protection System (SPS) or Remedial Action Scheme (RAS).

5.5. (exception) A generating unit or generating plant may trip if clearing a system fault necessitates disconnecting the generating unit or generating plant.

[4] Excluding generators in service prior to the effective date of Requirement R5 of Version 1 of this standard and excluding generators referenced in Footnote 2.

5.6. (exception) A generating unit or generating plant may trip if the Generator Owner has a temporary exemption granted by its Reliability Coordinator based on a documented equipment limitation. The Reliability Coordinator may retroactively grant a temporary exemption for an equipment limitation identified following a plant trip caused by a frequency or voltage excursion if the Generator Owner develops and implements an acceptable Mitigation Plan.

5.7. (exception) A generating unit or generating plant may trip if the protective functions (such as out-of-step or loss-of-field functions) operate due to an impending or actual loss of synchronism or due to instability in power conversion control equipment.

R6. Each Generator Owner shall provide its generator protection trip settings to the Reliability Coordinator, Planning Coordinator, Transmission Operator and Transmission Planner (that monitors or models the associated unit), within 30 calendar days of receipt of a written request for the data, and within 30 calendar days of any change to those trip settings, to ensure the accuracy of planning studies and system modeling. *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*

C. Measures

M1. Each Generator Owner shall have evidence such as dated setting sheets, calibration sheets, or other documentation, that generator frequency protective relays have been set in accordance with Requirement R1.

M2. Each Generator Owner shall have evidence such as dated setting sheets, voltage-time curves, calibration sheets, coordination plots or dynamic simulation studies, that generator voltage protective relays have been set in accordance with Requirement R2.

M3. Each Generator Owner shall have evidence that it has documented and communicated any equipment limitations (Protection System excluded) that resulted in an exception to Requirements R1 or R2 in accordance with Requirement R3 such as a dated email or letter that contains such documentation as study results, experience from an actual event, or manufacturer's advisory.

M4. Each Generator Owner shall have evidence such as a copy of the performance report and correspondence, such as dated e-mails, or other documentation that an estimate of the performance of its existing generating unit(s) as a result of a Frequency Excursion or Voltage Excursion has been communicated in accordance with Requirement R4, and copies of any requests it has received for that information.

M5. Each Generator Owner shall have evidence, such as dated unit output records, trip investigation reports or disturbance monitoring records, showing that each unit trip did not result from a Frequency Excursion or Voltage Excursion as specified in Requirement R5, or evidence that a listed exception applied, or provide an attestation that the generating unit or generating plant did not trip.

M6. Each Generator Owner shall have evidence such as dated e-mails, correspondence or other evidence that it communicated generator protective relay settings to a requesting entity within 30 calendar days of a request or change in setting(s) in accordance with Requirement R6 and copies of any requests it has received for that information..

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

Regional Entity

1.2. Data Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Generator Owner shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

- The Generator Owner shall retain the latest evidence of Requirement R1 through R6, Measure M1 through M6; and shall retain prior evidence for 3 calendar years or until the next audit, whichever is longer.

If a Generator Owner is found non-compliant, it shall keep information related to the non-compliance until found compliant or for the time period specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

Voltage Ride-Through Curve Clarifications

Curve Details:

1. The per unit voltage base for these curves is the base voltage specified in the system models used by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission Systems at the point of interconnection to the Bulk Electric System (BES).
2. The curves depicted were derived based on three-phase transmission system zone 1 faults with Normal Clearing not exceeding 9 cycles.
3. The envelope within the curves represents the cumulative voltage duration at the point of interconnection with the BES. For example, if the voltage exceeds 1.15 pu at 0.3 seconds after a fault, does not exceed 1.2 pu voltage, and returns below 1.15 pu at 0.4 seconds, then the cumulative time the voltage is above 1.15 pu voltage is 0.1 seconds and is within the no trip zone of the curve.
4. The curves depicted assume system frequency is 60 Hertz. Adjust the magnitude of the high voltage curve in proportion to deviations of frequency below normal.
5. Voltages in the curve assume minimum fundamental frequency phase-to-ground or phase-to-phase voltage for the low voltage duration curve and maximum crest phase-to-ground or phase-to-phase voltage for the high voltage duration curve.

Evaluating Protective Relay Settings:

6. Use the following assumptions to evaluate voltage protection relay setting calculations on the static case for steady state initial conditions:
    a. All of the units connected to the same transformer are online and operating,
    b. All of the units are at full nameplate real-power output.
    c. Power factor is 0.95 lagging (i.e. supplying reactive power to the system) as measured at the generator terminals).
7. Evaluate voltage protection relay settings assuming that additional installed generating plant reactive support equipment (such as static VAr compensators, synchronous condensers, or capacitors) is available and operating normally.
8. Evaluate voltage protection relay settings accounting for the actual tap settings of transformers between the generator terminals and the point of interconnection.

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. SAR posted for comment (April 20–May 21, 2007).
2. Revised SAR and response to comments posted.
3. Revised SAR and response to comments approved by SC (June 14, 2007).
4. SDT appointed on (August 18, 2007).
5. Initial draft of PRC-024-1 was posted for a 45 day formal comment period (February 17 – April 2, 2009).
6. Draft 2 PRC-024-1 was posted for a 45 day concurrent comment and ballot period from June 15 – August 1, 2011.

Proposed Action Plan and Description of Current Draft:

This is the ~~second~~third draft of the ~~proposed~~ standard ~~including~~and includes Time Horizons, Data Retention, Violation Risk Factors, and Violation Severity Levels. This second posting ~~of the standard~~ is for a 30-day ~~formal~~ comment and successive ballot period.

Future Development Plan:

Anticipated Actions	Anticipated Date
1. ~~Post first~~Develop responses to comments and develop third version draft ~~revision of~~ standard.	~~April-May~~August 2011 – February 2012
2. Post response to comments and third version draft revision of standard for 30 day comment and successive ballot period.	~~July – August 2011~~February – March 2012
3. ~~Post response~~Develop responses to successive ballot comments ~~and request authorization to ballot the revised standard~~.	~~September – October 2011~~April – June 2012
~~4. Conduct initial ballot.~~	~~November 2011~~
~~5~~4. Post response to comments.	~~December 2011~~July 2012

~~6~~5. Conduct recirculation ballot.	~~January~~July 2012
7. BOT adoption.	~~February~~August 2012
8. File with regulatory authorities.	~~March~~October 2012

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

~~**Frequency Excursion** – an exceedance of system frequency beyond a continuous operating band; 60±0.5 Hertz.~~

~~**Voltage Excursion** – an exceedance of system voltage beyond a continuous operating band; ±5% of scheduled voltage.~~

None

A. Introduction

1. **Title:** Generator Performance During Frequency and Voltage Excursions

2. **Number:** **PRC-024-1**

3. **Purpose:** Ensure generating units remain connected during frequency and voltage excursions, and ensure expected generating unit performance during frequency and voltage excursions, is communicated to Reliability Coordinators, Planning Coordinators, Transmission Operators and Transmission Planners for accurate system modeling.

4. **Applicability:**

   ~~**1.1.**~~**4.1.** Generator Owner

5. **Effective Date:**

   ~~**1.2.**~~**5.1.** ~~The~~Each Generator Owner shall verify that at least 33 percent of its applicable units are fully compliant with Requirements R1, R2, R3, R4, and R6 by the first day of the first calendar quarter one year following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter one year following Board of Trustees adoption~~:~~.

      ~~**1.2.1**~~ Each Generator Owner shall verify that at least ~~33%~~66 percent of its applicable units are fully compliant with ~~this standard.~~

   ~~**1.3.**~~**5.2.** ~~The~~Requirements R1, R2, R3, R4, and R6 by the first day of the first calendar quarter two years following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter two years following Board of Trustees adoption~~:~~.

      ~~**1.3.1**~~ Each Generator Owner shall verify that ~~at least 66%~~100 percent of its applicable units are fully compliant with ~~this standard.~~

   ~~**1.4.**~~**5.3.** ~~The~~Requirements R1, R2, R3, R4, and R6 by the first day of the first calendar quarter three years following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter three years following Board of Trustees adoption~~:~~.

      ~~**1.4.1** Each Generator Owner shall verify that 100% of its applicable units are fully compliant with this standard.~~

   5.4. Requirement R5 shall be effective on the first day of the first calendar quarter six years following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter six years following Board of Trustees adoption.

B. Requirements

R1. Each Generator Owner that has generator frequency protective relaying~~ ~~[1] activated to trip its new or existing generating unit or generating plant shall set such protective relaying so that it does not ~~to~~ trip ~~per~~within the ~~following operating conditions and relay settings~~"no trip zone" of PRC-024 Attachment 1, unless the Generator Owner has documented and communicated ~~a non-protection system~~each equipment limitation in accordance with Requirement R3 for an existing generating unit.[2] *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*

~~1.1. When operating~~A generating unit or generating plant is allowed to trip within ~~a frequency range of 59.5 Hz to 60.5 Hz, inclusive.~~

~~1.2. During~~ the ~~off-nominal frequency excursions specified in PRC-024 Attachment 1.~~

~~1.3. By instantaneous under frequency relays set at a frequency higher than 57.8 Hz.~~

~~1.4. By instantaneous over frequency relays set at a frequency lower than 62.2 Hz.~~

~~1.5.~~1.1. ~~When~~"no trip zone" if the ~~transmission system~~ frequency rate of change is ~~less~~more than 2.5 Hz/~~second.~~ sec.

1.2. A generating unit or generating plant may trip if the protective functions (such as out-of-step or loss-of-field functions) operate due to an impending or actual loss of synchronism or due to instability in power conversion control equipment.

R2. Each Generator Owner that has generator voltage protective relaying[1] activated to trip its new or existing generating unit or generating plant ~~or Facility~~ shall set its protective relaying such that it does not ~~to~~ trip as a result of a voltage excursion (at the point of

---

[1] Each Generator Owner is not required to have frequency or voltage protective relaying (~~includes~~including but not limited to frequency and voltage protective functions for discrete relays, volts per hertz relays evaluated at nominal frequency, impedance relays, voltage controlled overcurrent relays, multi-function protective devices or protective functions within ~~excitation controls~~control systems that directly trip or provide tripping signals to the generator based on frequency or voltage inputs) installed or activated on its unit.

[2] To include generators under construction, generators with an executed interconnection agreement or Power Purchase Agreement by the effective date of this standard, or generators with an executed equipment purchase contract and scheduled delivery of major components within 2 years of the effective date of ~~version~~Requirement R5 of Version 1 of this standard.

interconnection~~)~~[3]) that remains within the "no trip zone" of PRC-024 Attachment 2 caused by an event on the transmission system external to the generating plant per the following operating conditions and relay settings, unless the Generator Owner has documented and communicated ~~a~~each non-protection system equipment limitation in accordance with Requirement R3 for an existing generating unit or generating plant ~~or generating Facility:~~.: *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*

2.1. When operating within 95~~%~~ percent to 105~~%~~ percent of rated generator terminal voltage and during the transmission system operating conditions defined in PRC-024 Attachment 2, with the following clarifications:

~~**2.1.1.** For three-phase transmission system zone 1 faults with Normal Clearing, set voltage relays based on actual fault clearing times, not to exceed 9 cycles.~~

~~**2.1.2.**~~**2.1.1.** If a Transmission Planner's study (based on the location specific voltage recovery characteristics) ~~recommends~~allows less stringent voltage relay settings than those ~~in~~required to meet PRC-024 Attachment 2, set voltage relays either to meet the Transmission Planner's ~~settings~~voltage recovery characteristics or the ~~settings~~characteristics in PRC-024 Attachment 2.

~~**2.1.3.**~~**2.1.2.** ~~If~~Tripping a generator in accordance with a Special Protection System (SPS) or Remedial Action Scheme (RAS) ~~includes tripping a generator after fault initiation, then setting the SPS or RAS relays to trip the generator even if~~ is acceptable in the "no trip zone" ~~in~~of PRC-024 Attachment 2 ~~is acceptable~~.

~~**2.1.4.**~~**2.1.3.** If clearing a system fault necessitates disconnecting a generator, ~~then setting relays to trip the generator even if operating~~this action is acceptable within the "no trip zone" specified in PRC-024 Attachment 2 ~~is acceptable~~.

2.1.4. A generating unit or generating plant may trip if the protective functions (such as out-of-step or loss-of-field functions) operate due to an impending or actual loss of synchronism or due to instability in power conversion control equipment.

R3. Each Generator Owner of an existing generating unit or generating plant ~~or Facility~~ shall document each ~~non-protection system~~ equipment limitation (excluding generator frequency and voltage protective relay limitations) that prevents a generating unit~~,~~ or generating plant~~, or Facility~~ from meeting the criteria in ~~Requirement~~Requirements R1 or R2 ~~and~~ including study results, experience from an actual event, or manufacturer's advisory *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*.

[3] For the purposes of this standard, point of interconnection means the transmission (high voltage) side of the generator step-up or collector transformer.

~~R3.~~3.1. The Generator Owner shall communicate the documented limitation, or the removal of a previously documented limitation, to its Reliability Coordinator, Planning Coordinator, Transmission Operator and Transmission Planner within 30 calendar days of identifying the limitation to ensure the accuracy of planning studies and system modeling studies. ~~The equipment limitation expires~~ The existing generating unit or generating plant becomes subject to the full extent of Requirements R1 and R2 coincident with either of the following conditions:

- The equipment causing the limitation is repaired or replaced with equipment that removes the limitation.
- The ~~generating unit continuous~~equipment causing the limitation is modified or upgraded resulting in an increase of generator nameplate capacity rating ~~increases ≥~~greater than 10~~%.~~

~~*[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*~~

~~R4.~~~~•~~ ~~Within 90 calendar days of receipt of a written inquiry~~ percent (cumulative from the ~~Reliability Coordinator, Planning Coordinator, Transmission Operator, or Transmission Planner regarding an equipment limitation identified in accordance with Requirement R3, the Generator Owner shall provide a written response to the entity that submitted the inquiry.~~ first effective date of this Standard).

~~R5.~~**R4.** Each Generator Owner of an existing generating unit or generating plant ~~or generating Facility~~ shall provide an estimate of that unit's performance during Frequency/Voltage Excursions to ~~the~~each requesting entity (Reliability Coordinator, Planning Coordinator, Transmission Operator or Transmission Planner that monitors or models the associated generating unit or generating plant) within ~~30~~60 calendar days of receipt of a written request, to ensure the accuracy of planning studies and system modeling studies. The ~~documentation~~estimate shall include: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

~~5.1.~~ An estimate of the time duration the existing generating unit or generating plant ~~or Facility~~ will remain connected (considering performance of the auxiliary systems as well as the generator) as a result of a ~~Frequency Excursion~~frequency excursion or a voltage excursion defined by the ~~curves in PRC-024 Attachment 1 and a Voltage Excursion defined by the curves in PRC-024 Attachment 2 or the~~ voltage or frequency profile at the ~~Point of Interconnection for the generating unit or generating plant or Facility~~point of ~~the most severe normally-cleared Zone 1 fault~~interconnection described by dynamic simulation provided by the Transmission Planner ~~if this profile is less stringent~~. If the Generator Owner expects the existing unit, generating plant will remain connected for longer than 10 minutes, the ~~curves in Attachment 2.~~

~~5.2.~~4.1. ~~An estimated probability in 25% increments that~~estimate should indicate the existing unit or generating plant ~~or generating Facility will remain connected during a Frequency Excursion defined by the curves in PRC-024 Attachment 1 and a Voltage Excursion defined by the curves in PRC-024 Attachment 2 or the voltage profile at the Point of Interconnection for the generating unit or generating plant or Facility of the most severe normally-cleared Zone 1 fault described by dynamic simulation provided by the Transmission Planner if this profile is less stringent than the curves in Attachment 2.~~ is not expected to trip.

~~5.3.~~4.2. Identification of the ~~basis~~bases for the estimates developed for ~~5~~4.1~~ and 5.2~~ which may include, but is not limited to: experience, actual event histories, or sound engineering judgment.

~~R6.~~R5. Each Generator Owner shall design, build, and maintain its new [4] unit or new generating plant ~~or generating Facility~~ so that it will not trip due to a ~~Frequency Excursion or Voltage Excursion~~frequency excursion or voltage excursion at the ~~Point~~point of ~~Interconnection~~interconnection, caused by an event on the transmission system external to the generating plant, within the parameters set forth in PRC-024 Attachments 1 and 2 and in accordance with the following conditions and exceptions: *[Violation Risk Factor: High] [Time Horizon: Real-time Operations]*

~~6.1.~~5.1. (condition) When the generating unit or generating plant ~~or generating Facility~~ is operating at or above the minimum sustainable generation threshold.

~~6.1.1.~~5.1.1. For a generating plant ~~or generating Facility~~ consisting of multiple units with total generation ~~>~~greater than 75 MVA (gross aggregate nameplate rating), when the ~~Facility~~ generating plant is producing at least 20~~%~~ percent of the ~~Facility's rated~~plant's aggregate nameplate capacity ~~and the voltage support equipment is in service~~.

~~6.2.~~5.2. (~~condition~~exception) For a new generating plant ~~or generating Facility~~ consisting of multiple units less than 20 MVA each with total ~~Facility~~plant generation ~~> 75~~greater than75 MVA (gross aggregate rating), ~~at least 90%~~10 percent of the individual generating units ~~shall remain connected~~may disconnect as a result of the frequency or voltage excursion.

~~6.3.~~5.3. (exception) A generating unit or generating plant ~~or generating Facility~~ may operate to a less stringent voltage ride-through performance criterion than the duration curve identified in PRC-024 Attachment 2 based on the location~~-~~-specific voltage recovery characteristics ~~as specified~~if provided by the Transmission Planner as described in Requirement 2, Part 2.1.1.

[4] Excluding generators in service prior to the effective date of ~~version~~Requirement R5 of Version 1 of this standard and excluding generators referenced in Footnote 2.

~~6.4.~~5.4. (exception) A generating unit or generating plant~~ or generating Facility~~ may trip if this action is designed as part of a Special Protection System (SPS) or Remedial Action Scheme (RAS).

~~6.5.~~5.5. (exception) A generating unit or generating plant ~~or generating Facility~~ may trip if clearing a system fault necessitates disconnecting the generating unit or generating plant~~ or generating Facility~~.

~~6.6.~~5.6. (exception) A generating unit or generating plant~~ or generating Facility~~ may trip if the Generator Owner has a temporary exemption granted by its Reliability Coordinator based on a documented equipment limitation. The Reliability Coordinator may retroactively grant a temporary exemption for an equipment limitation identified following a plant trip caused by a frequency or voltage excursion if the Generator Owner develops and implements an acceptable Mitigation Plan.

~~6.7.~~5.7. (exception) A generating unit or generating plant ~~or generating Facility~~ may trip if the protective functions (such as out-~~-~~of-~~-~~step or loss-~~-~~of-~~-~~field functions) operate due to an impending or actual loss of synchronism or due to instability in power conversion control equipment.

~~R7.~~R6. Each Generator Owner shall provide its generator protection trip settings to the Reliability Coordinator, Planning Coordinator, Transmission Operator and Transmission Planner (that monitors or models the associated unit~~) its generator protection trip settings as specified by Requirements R1 and R2, and documented equipment limitations as specified by Requirement R3~~), within 30 calendar days of receipt of a written request for the data, and within 30 calendar days of any change to those trip settings~~ or limitations and within 30 calendar days of a written request for the data~~, to ensure the accuracy of planning studies and system modeling. *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*

C. Measures

~~R8.~~M1. Each Generator Owner ~~has~~shall have evidence such as dated setting sheets, calibration sheets, or other documentation, that generator frequency protective relays have been set in accordance with Requirement R1.

~~R9.~~M2. Each Generator Owner ~~has~~shall have evidence such as dated setting sheets, voltage-time curves, calibration sheets, coordination plots or dynamic simulation studies, that generator voltage protective relays have been set in accordance with Requirement R2.

~~R10.~~M3. Each Generator Owner ~~has~~shall have evidence that it has documented and communicated any equipment limitations (Protection System excluded) that resulted in an exception to Requirements R1 or R2 in accordance with Requirement R3 such as a dated email or letter that contains such documentation as study results, experience from an actual event, or manufacturer's advisory.

~~M1.~~ Each Generator Owner ~~has evidence such as dated e-mails, mail receipts or other evidence that it provided a written response to an inquiry regarding equipment limitations to a requesting entity within 90 calendar days of a request in accordance with Requirement R4.~~

~~R11.~~**M4.** ~~Each Generator Owner has~~shall have evidence such as a copy of the performance report and correspondence, such as dated e-mails,~~ mail receipts~~ or other documentation that an estimate of the performance of its existing generating unit(s) as a result of a Frequency Excursion or Voltage Excursion has been communicated in accordance with Requirement ~~R5~~R4, and copies of any requests it has received for that information.

~~R12.~~**M5.** Each Generator Owner ~~has~~shall have evidence, such as dated unit output records, trip investigation reports or disturbance monitoring records~~ or a trip report indicating,~~ showing that each unit trip did not result from a Frequency Excursion or Voltage Excursion as specified in Requirement ~~R6~~R5, or evidence that a listed exception applied, or provide an attestation that the generating unit~~,~~ or generating plant~~ or Facility~~ did not trip.

~~R13.~~**M6.** Each Generator Owner ~~has~~shall have evidence such as dated e-mails, ~~mail receipts~~correspondence or other evidence that it communicated generator protective relay settings~~ or equipment limitations~~ to a requesting entity within 30 calendar days of a request or change in setting(s) in accordance with Requirement ~~R7.~~R6 and copies of any requests it has received for that information..

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

Regional Entity

1.2. Data Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Generator Owner shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

- The Generator Owner shall retain the latest evidence of Requirement R1 through ~~R7~~R6, Measure M1 through ~~M7~~M6; and shall retain prior evidence for 3 calendar years or until the next audit, whichever is longer.

If a Generator Owner is found non-compliant, it shall keep information related to the non-compliance until found compliant or for the time period specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

Voltage Ride-Through Curve Clarifications

Curve Details:

1. The per unit voltage base for these curves is the ~~scheduled operating~~base voltage ~~as measured~~specified in the system models used by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission Systems at the point of interconnection to the Bulk Electric System (BES).

2. The curves depicted ~~apply to a~~were derived based on three-phase transmission system zone 1 ~~fault~~faults with Normal Clearing not exceeding 9 cycles.

3. ~~When~~The envelope within the curves represents the cumulative voltage duration at the point of interconnection with the BES~~ is within~~. For example, if the voltage ~~boundaries of these curves, the generator~~exceeds 1.15 pu at 0.3 seconds after a fault, does not exceed 1.2 pu voltage~~ protective relaying will not~~ , and returns below 1.15 pu at 0.4 seconds, then the cumulative time the voltage is above 1.15 pu voltage is 0.1 seconds and is within the no trip zone of the ~~generator.~~curve.

4. The curves depicted assume system frequency is 60 Hertz. Adjust the magnitude of the high voltage curve in proportion to deviations of frequency below normal.

5. Voltages in the curve assume minimum fundamental frequency phase-to-ground or phase-to-phase voltage for the low voltage duration curve and maximum crest phase-to-ground or phase-to-phase voltage for the high voltage duration curve.

Evaluating Protective Relay Settings:

~~5.~~6. Use the following assumptions ~~if basing~~to evaluate voltage protection relay setting calculations on the static case for steady state initial conditions:

   a. All of the units connected to the same transformer are online and operating,

   b. All of the units are at full nameplate real-power output.

   c. Power factor is 0.95 lagging~~.~~ (i.e. supplying reactive power to the system) as measured at the generator terminals).

   ~~d. Scheduled voltage is measured at the point of interconnection.~~

~~6.~~7. ~~Calculate~~Evaluate voltage protection relay settings ~~to comply with these curves~~ assuming that~~ any~~ additional installed generating plant reactive support equipment (such as static VAr compensators, synchronous condensers, or capacitors) is available and operating normally.

~~7.~~8. ~~Calculate~~Evaluate voltage protection relay settings~~ to comply with these curves,~~ accounting for the actual tap settings of transformers between the generator terminals and the point of interconnection.

Implementation Plan

Project 2007-09 Generator Verification

Implementation Plan for PRC-024-1, Generator Performance During Frequency and Voltage Excursions

Approvals Required

PRC-024-1 – Generator Performance During Frequency and Voltage Excursions.

According to its Implementation Plan, PRC-006-1, Requirement R4 (see project 2007-01, Underfrequency Load Shedding) does not become effective until PRC-024 becomes effective. Upon the effective date of PRC-024-1, R4 of PRC-006-1 will also go into effect.

Prerequisite Approvals

None

Revisions to Glossary Terms

None

Applicable Entities

Generator Owner

Conforming Changes to Other Standards

None

Effective Dates

Each Generator Owner shall verify that at least 33 percent of its applicable units are fully compliant with Requirements R1, R2, R3, R4, and R6 by the first day of the first calendar quarter one year following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter one year following Board of Trustees adoption.

Each Generator Owner shall verify that at least 66 percent of its applicable units are fully compliant with Requirements R1, R2, R3, R4, and R6 by the first day of the first calendar quarter two years following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter two years following Board of Trustees adoption.

Each Generator Owner shall verify that 100 percent of its applicable units are fully compliant with Requirements R1, R2, R3, R4, and R6 by the first day of the first calendar quarter three years following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter three years following Board of Trustees adoption. Requirement R5 shall be effective on the first day of the first calendar quarter six years following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter six years following Board of Trustees adoption.

Retirements

None

Justification of Phasing

Requirements R1, R2, R3, R4, and R6 involve evaluation of existing protection system settings and equipment capabilities. Typically, generator protection system setting changes are made during scheduled generator outages. The Implementation Plan allows a three-year window for these changes to be made which corresponds to typical outage cycles. Generating units that have outage cycles that extend longer than three years are not typically base loaded and offer opportunities to effect protection system settings changes during economic shut down periods.

Requirement R5 involves the performance of complete generation facilities (i.e. the prime mover, its fuel supply, and all auxiliary systems). To date, most Generator Owners have not specified this type of performance and the engineering companies designing generating facilities have not designed the facilities to ride through frequency and voltage excursions of the severity specified in PRC-024. In order to allow Generator Owners and architect/engineering companies time to develop new designs to meet R5, the SDT allows six years from regulatory approval for implementation.

Project 2007-09 Generator Verification Implementation Plan

Implementation Plan for PRC-024-1, Generator Performance During Frequency and Voltage Excursions

Approvals Requested:

PRC-024-1 – Generator Performance During Frequency and Voltage Excursions

Definitions:

> ~~**Frequency Excursion** – an exceedance of system frequency beyond a continuous operating band; 60±0.5 Hertz.~~
>
> ~~**Voltage Excursion** – an exceedance of system voltage beyond a continuous operating band; ±5% of scheduled voltage.~~**None**

Revisions to Approved Standards and Definitions

None

Compliance with the Standard

The following entities are responsible for being compliant with all requirements of PRC-024-1:

- Generator Owner

Effective Date

Each Generator Owner shall verify that at least 33 percent of its applicable units are fully compliant with Requirements R1, R2, R3, R4, and R6 by the first day of the first calendar quarter one year following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter one year following Board of Trustees adoption.

Each Generator Owner shall verify that at least 66 percent of its applicable units are fully compliant with Requirements R1, R2, R3, R4, and R6 by the first day of the first calendar quarter two years following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter two years following Board of Trustees adoption.

Each Generator Owner shall verify that 100 percent of its applicable units are fully compliant with Requirements R1, R2, R3, R4, and R6 by the first day of the first calendar quarter three years following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter three years following Board of Trustees adoption.

Requirement R5 shall be effective on the first day of the first calendar quarter six years following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter six years following Board of Trustees adoption.

~~The first day of the first calendar quarter one year following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter one year following Board of Trustees adoption:~~

- ~~Each Generator Owner shall verify at least 33% applicable units fully compliant with this standard.~~

~~The first day of the first calendar quarter two years following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter two years following Board of Trustees adoption:~~

- ~~Each Generator Owner shall verify at least 66% applicable units fully compliant with this standard.~~

~~The first day of the first calendar quarter three years following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter three years following Board of Trustees adoption:~~

- ~~Each Generator Owner shall verify 100% applicable units fully compliant with this standard~~

~~The phasing allows Generator Owners to effect any needed changes to the protective system settings during normally scheduled outages.~~

According to its Implementation Plan, PRC-006-1, Requirement R4 (see project 2007-01, Underfrequency Load Shedding) does not become effective until PRC-024 becomes effective. Upon the effective date of PRC-024-1, R4 of PRC-006-1~~, R4~~ will also go into effect.

Justification of Phasing

Requirements R1, R2, R3, R4, and R6 involve evaluation of existing protection system settings and equipment capabilities. Typically, generator protection system setting changes are made during scheduled generator outages. The Implementation Plan allows a three-year window for these changes to be made which corresponds to typical outage cycles. Generating units that have outage cycles that extend longer than three years are not typically base loaded and offer opportunities to effect protection system settings changes during economic shut down periods.

Requirement R5 involves the performance of complete generation facilities (i.e. the prime mover, its fuel supply, and all auxiliary systems). To date, most Generator Owners have not specified this type of performance and the engineering companies designing generating facilities have not designed the facilities to ride through frequency and voltage excursions of the severity specified in PRC-024. In order to allow Generator Owners and architect/engineering companies time to develop new designs to meet R5, the SDT allows six years from regulatory approval for implementation.

Project 2007-09 Generator Verification

MOD-026-1 and PRC-024-1

Instructions

Please **DO NOT** use this form for commenting. Please use the electronic comment form to submit comments on the proposed revisions to MOD-026-1 and PRC-024-1. Comments must be submitted by **March 29, 2012**. If you have questions please contact Stephen Crutchfield at Stephen.crutchfield@nerc.net or by telephone at 609-651-9455.

Background Information

The Generator Verification Standard Drafting Team posted MOD-026-1, Verification of Models and Data for Generator Excitation Control System and Plant Volt/Var Control Functions, and PRC-024-1, Generator Performance During Frequency and Voltage Excursions, from June 15 through August 1, 2011 for a 45-day concurrent comment/ballot period. Stakeholders were asked to comment on several aspects of the standard.

MOD-026-1

The GVSDT asked stakeholders if they believed any additional generation configurations should be considered for applicability under this standard. None of the comments identified other generation configurations/types that should be covered in the Applicability. Several commenters recommend making the standard applicability match the compliance registry, while other commenters recommend removing the requirement to verify small generator units from the standard applicability. The SDT believes:

- The standard is drafted to provide the proper cost/benefit balance for performing generator verification.

- It is not necessary to have models verified for all units listed in the compliance registry.

- Proposed applicability thresholds will substantially improve the accuracy of the excitation models and associated reliability-based limits determined by dynamic simulation in a cost-effective and time-efficient manner when performing verification.

The SDT recognizes that the excitation system model and modeling data is already captured by the MOD-012 and MOD-013 required processes. This information, with few exceptions, creates a quality dynamics database. Field testing initiated by the Phase III-IV SDT has shown that performing the activities specified in the draft standard will improve the accuracy of the exciter model used in dynamic simulation. Utilizing engineering judgment, based in part on recent experience of entities verifying excitation system models, the SDT is proposing to require verification of excitation systems associated with 80% or greater of the connected MVA in each Interconnection. To accomplish this goal, the SDT has proposed MVA thresholds which correspond to at least 80% of the connected MVA in each

Interconnection. This concept was overwhelmingly supported by industry in response to the previous posting of the standard.

The SDT also proposes requiring verification of an aggregate plant comprised of several smaller sized units because of the increasing impact renewable generation has on the BES. If there is evidence that the model does not match the performance of the equipment, then R3 provides a mechanism for requiring verification. Concern was raised that the language of R5 could require verification of units with ratings less than the thresholds specified in the registry criteria. The SDT asserts that any unit not included in the standard Applicability and deemed to require verification as justified by the Planning Coordinator must, by definition, satisfy the Registry Criteria threshold established. The standard Applicability would have to explicitly identify units with ratings less than the Registry Criteria threshold established in order for the Planning Coordinator to be able to justify verification of the unit. This is not the case.

A few commenters expressed concern that the standard does not require the Generator Owner to notify the Transmission Owner of new equipment and provide the Transmission Planner preliminary models based on OEM design data. The SDT reminds that the scope of the draft standard is model verification, which can occur only after the equipment is installed. The standard does not address development of the original model during the equipment commissioning process.
Also in response to industry comments, the SDT has inserted a footnote in the standard to make clear that standby generator models are not required to be verified.

The GVSDT asked stakeholders if they believed that synchronous condensers should be applicable under MOD-026. The majority of commenters believe that synchronous condensers should not be included in MOD-026. Synchronous condensers are not currently addressed in the NERC Registry Criteria. On an MVA capacity basis, the penetration of synchronous condensers in North America is extremely low, with many units owned by Transmission Owners. As such, the peer review draft requirements would not make sense. The SDT decided that, with the current structure of the Compliance Registry Criteria, if there is a need to develop a reliability standard to model the expected behavior of dynamic voltage devices typically owned by Transmission entities, then a more appropriate strategy is to include synchronous condensers along with other Transmission system dynamic reactive devices (such as SVCs, STATCOMs, etc.) into a separate SAR. The GVSDT will closely monitor BES SDT efforts to define BES and the correlation of BES elements with the ERO Statement of Compliance Registry Criteria, and make appropriate adjustment as necessary to the Applicability of MOD-026-1 regarding the treatment of synchronous condensers.

The GVSDT received many comments concerning various aspects of the standard. As a result of these comments, the SDT has made a number of modifications to the standard including:

1) Correcting several VSL grammatical errors and ensuring consistency between the VSL "increment for tardiness" time period specified and the requirement language.

2) An additional condition was added to Attachment 1 (the Periodicity Table) specifying that validation is not required for an excitation control system or plant volt/var control that does not include an active closed-loop voltage regulation function. This condition exempts wind and solar plants that do not have the capability to regulate plant voltage or respond to grid voltage fluctuations, other than switching capacitor and reactor banks in and out of service.

3) The format and column information of Attachment 1 has been revised for clarity.

4) The typographical errors in R2.1.1 language has been corrected to clearly state expectation that, "The unit or plant's model response matches the recorded response for a voltage excursion at the generator or plant point of Interconnection from either a staged test or a measured system disturbance."

5) The language of R2.1.4 has been revised to align with the style of R2.1.6.

6) Several commenters expressed concern with the new Requirement R5 added to the standard giving the Planning Coordinator authority to require a model review for a unit not specified in the standard Applicability section. The SDT added this language to the draft standard after considering industry comments to the first posting noting that the Applicability section is a subset of the Compliance Registry criteria. Based on the latest round of industry feedback, the SDT now proposes Applicability section language allowing the Planning Coordinator to request additional model information (possibly model verification) only if technical justification demonstrates the simulated unit response does not match the measured unit response. Original technical justification language for units that affect a stability limit has been removed from the standard. To emphasize for understanding, the SDT points out only units that meet or exceed the Registry Criteria unit MVA thresholds (> 20 MVA) are subject to Requirement R5. This observation should allay concern the requirement could be misused inappropriately. In addition, R5 language has been revised for clarity.

7) To clarify concerns regarding calculating unit capacity factor, the SDT has incorporated into the standard the capacity factor calculation specified in Appendix F of the GADS Data Reporting Instructions (which can be obtained from the NERC website).

8) There was some confusion regarding the treatment of small units at plants. The SDT modified the language in the Applicability/Facilities section for clarity and for consistency to the extent possible with the other draft standards in the Generation Verification effort.

As a reminder, the SDT, in its response to industry comments, points out this standard does not address providing notification of equipment changes nor collection of preliminary model data from the equipment manufacturer. The standard addresses verification of models following equipment changes. New equipment models cannot be verified until after the equipment is available.

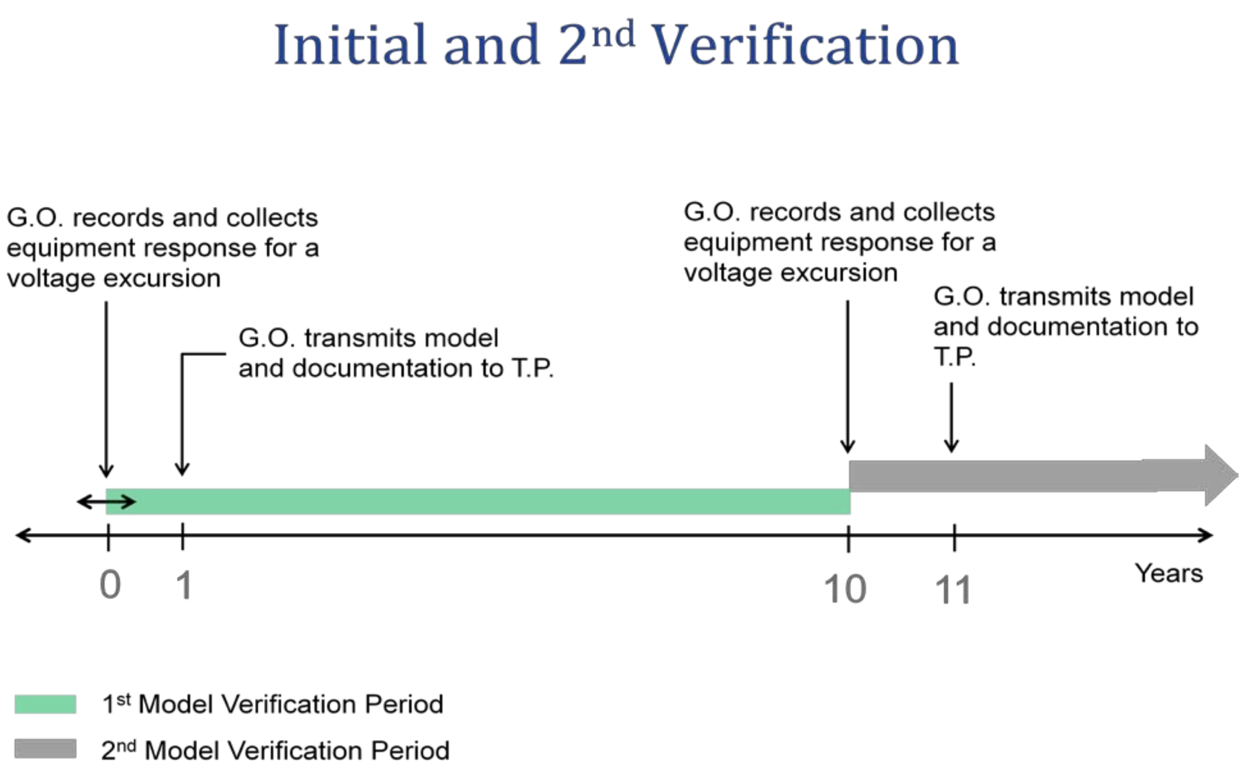
Periodicity Table (Attachment 1) for MOD-026-1:

Based on industry comments from the last posting, the SDT modified the Periodicity Table (Attachment 1) in an effort to convey the required periodicity of model verification in a simple but complete format.

The following examples are offered by the SDT to aid industry in understanding the proposed model verification periodicity:

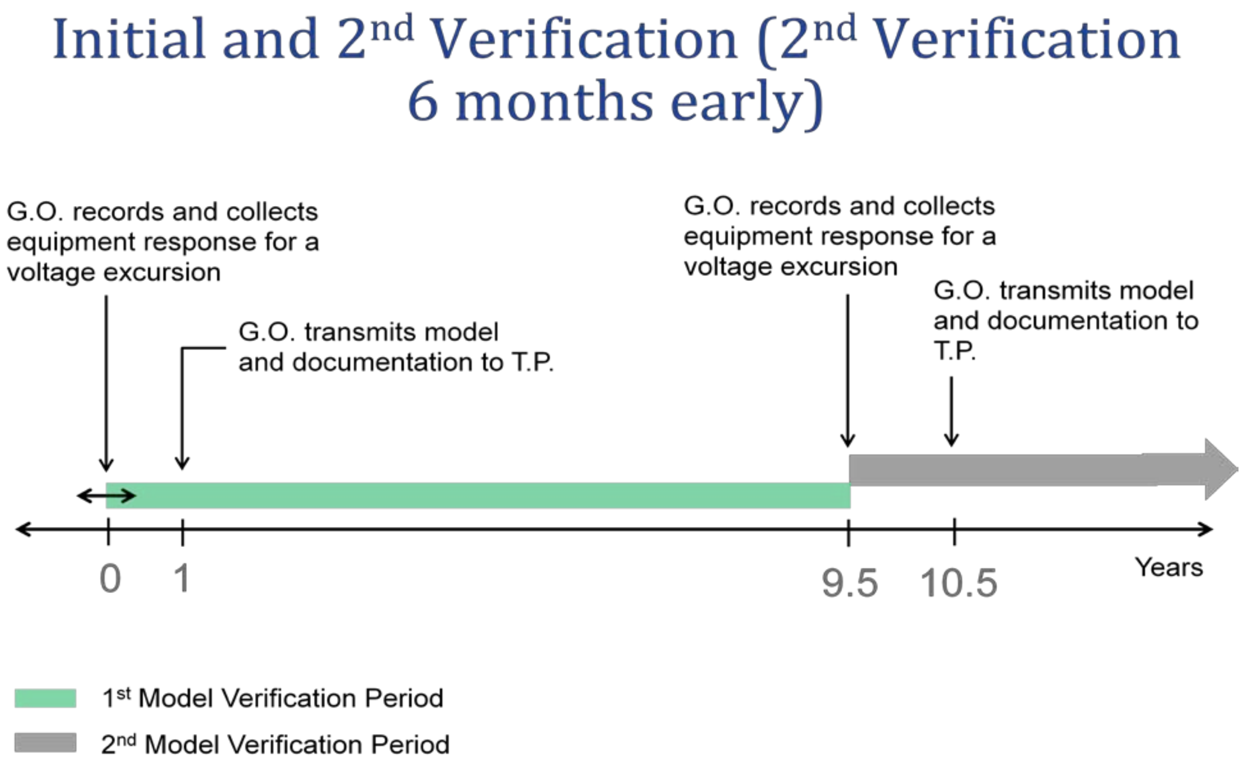
Periodicity Example 1:

The following timeline depicts a model which is initially verified, and then is verified again after a 10-year period. The requirements detailing activities by exception do not occur (R3 – R5) – which is expected to be the situation for the majority of the time. Regarding the third verification (which is not shown on the example below), the GO would need to record and collect equipment response for a voltage excursion on or before the unit's 10-year anniversary date of the collection of the recorded unit excitation control system and plant volt/var control response used for the current validation (i.e., response has to be collected on or before Year 20), and transmit the model and documentation to the Transmission Planner no later than 365 days later (i.e., by Year 21):



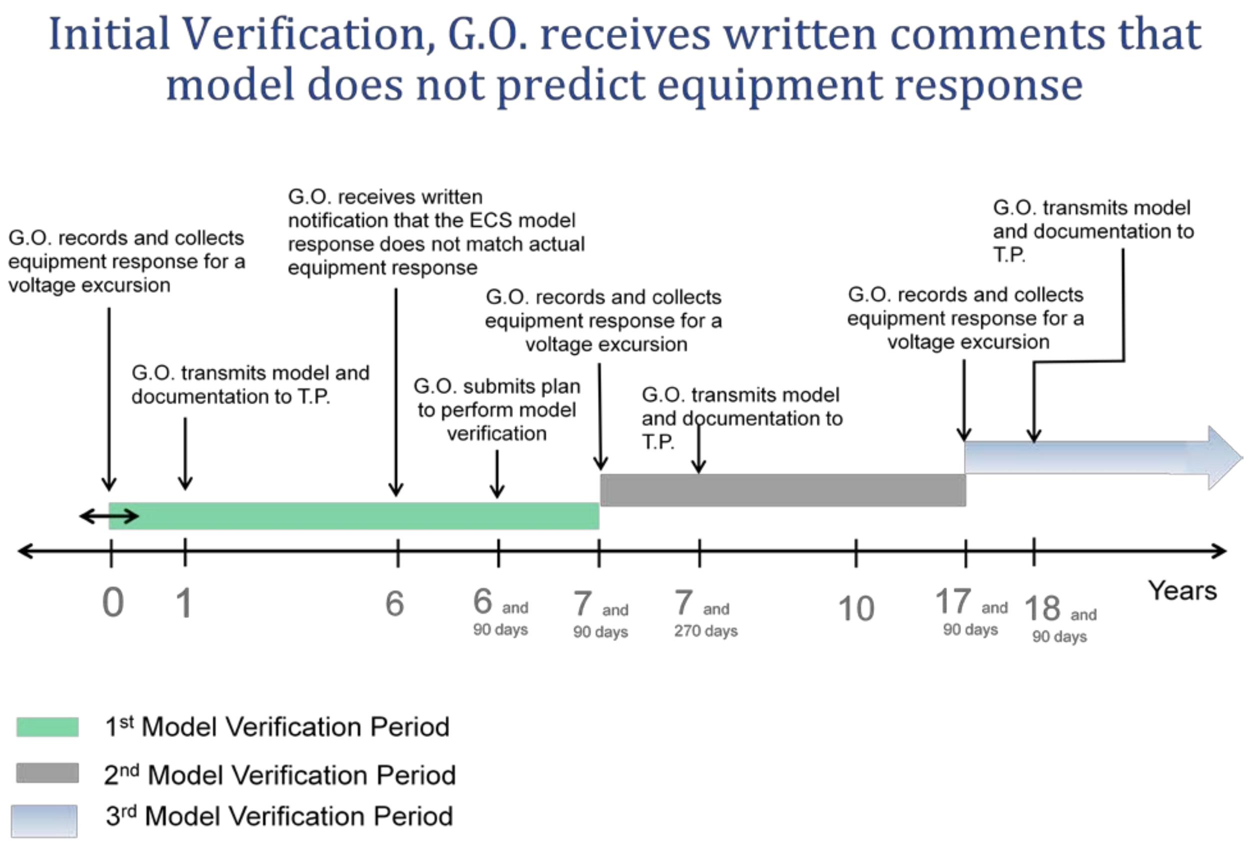
Periodicity Example #2:

The second example is much like Example #1. The only difference is that for the second verification, the equipment response for a voltage excursion was collected on the unit's 9.5 year anniversary date of the collection of the recorded unit excitation control system and plant volt/var control response used for the current validation. Regarding the third verification (which is not shown on the example below), the GO would need to record and collect equipment response for a voltage excursion on or before the unit's 10-year anniversary date of the collection of the recorded unit excitation control system and plant volt/var control response used for the current validation (i.e., response has to be collected on or before Year 19.5), and transmit the model and documentation to the Transmission Planner no later than 365 days later (i.e., by Year 20.5).



Periodicity Example #3:

The third example details a scenario which the SDT anticipates would rarely occur. Specifically, the scenario assumes that at sometime after the initial verification, the Generator Owner receives written notification that there is evidence that the model does not accurately predict the actual response of the equipment. As detailed in Requirement 3, the Generator Owner has 90 days to respond to the notice. The Generator Owner may respond that the model is still appropriate, or submit model changes – or it may submit a plan to re-verify the model. The example below assumes that later – i.e., the Generator Owner submits a plan to re-verify the model on the 90th day. From that point, per the Periodicity Table, the Generator Owner has 365 days to record and collect equipment response for a voltage excursion and then an additional 180 days to transmit the model and documentation to the Transmission Planner. Regarding the third verification, the GO would need to record and collect equipment response for a voltage excursion on or before the unit's 10-year anniversary date of the collection of the recorded unit excitation control system and plant volt/var control response used for the current validation (i.e., response has to be collected on or before Year 17 and 90 days) – and transmit the model and documentation to the Transmission Planner no later than 365 days later (i.e., by Year 18 and 90 days).



PCR-024-1

The GVSDT proposed two new definitions for Voltage Excursion and Frequency Excursion. A slight majority agreed with the proposed definitions. The majority of "No" votes disagreed with the voltage excursion portion of the question, while there was only one vote disagreeing with the frequency excursion portion. After reviewing all comments the SDT made the following changes:

1. The two new terms proposed in the standard were removed. The voltage and frequency excursion values are now located in the requirements where they apply.
2. Attachment 1 (Off Nominal Frequency Capability Curve) was revised to clarify the "no trip" zone.
3. Attachment 2 (Voltage Ride-Through Time Duration Curves) has been clarified. The per-unit-voltage-base for these curves is the base voltage specified in the system models used by the Transmission Planner in the analysis of the reliability of the Interconnected Transmission Systems at

the point of interconnection to the Bulk Electric System (BES). In addition, the definition was modified to include the phrase, "Voltages in the curve assume minimum phase-to-ground or phase-to-phase voltage for the low voltage duration curve and maximum phase-to-ground or phase-to-phase voltage for the high voltage duration curve."

The GVSDT proposed Requirements R1 and R2 to detail the required frequency and voltage protective relaying settings for both new and existing units or generating plant/facilities that opt to activate these relays. Stakeholders were asked if they believed that the draft of these two requirements, including Footnote 1, clarified that a Generator Owner is not required to have protective relaying installed or set for these functions. Stakeholders generally agreed that Footnote 1 does clearly state that a Generator Owner is not required to have protective relaying installed or set for frequency or voltage protection. Many of the stakeholders made additional comments beyond the scope of the question regarding the intention of Requirements R1, R2, and R3 and provided clarifying language examples. In response, the SDT made the following changes:

1. The Requirement Parts were removed from Requirement R1. Part 1.5 is now Part 1.1. The requirement now reads:

"R1. Each Generator Owner that has generator frequency protective relaying1 activated to trip its new or existing generating unit or generating plant shall set such protective relaying so that it does not trip within the "no trip zone" of PRC-024 Attachment 1, unless the Generator Owner has documented and communicated each equipment limitation in accordance with Requirement R3 for an existing generating unit. *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*
1.1. A generating unit or generating plant is allowed to trip within the "no trip zone" if the frequency rate of change is more than 2.5 Hz/sec.
1.2. A generating unit or generating plant may trip if the protective functions (such as out-of-step or loss-of-field functions) operate due to an impending or actual loss of synchronism or due to instability in power conversion control equipment."

2. Requirement Part 2.1.1 was removed from Requirement R2. The body of the requirement and the remaining parts were modified to clarify intent. The requirement now reads:

"R2. Each Generator Owner that has generator voltage protective relaying1 activated to trip its new or existing generating unit or generating plant shall set its protective relaying such that it does not trip

[1] Each Generator Owner is not required to have frequency or voltage protective relaying (including but not limited to frequency and voltage protective functions for discrete relays, volts per hertz relays evaluated at nominal frequency, impedance relays, voltage controlled overcurrent relays, multi-function protective devices or protective functions within control systems that directly trip or provide tripping signals to the generator based on frequency or voltage inputs) installed or activated on its unit.

as a result of a voltage excursion (at the point of Interconnection) that remains within the “no trip zone” of PRC-024 Attachment 2 caused by an event on the transmission system external to the generating plant per the following operating conditions and relay settings, unless the Generator Owner has documented and communicated each non-protection system equipment limitation in accordance with Requirement R3 for an existing generating unit2 or generating plant [Violation Risk Factor: High] [Time Horizon: Long-term Planning].

2.1. When operating within 95 percent to 105 percent of rated generator terminal voltage and during the transmission system operating conditions defined in PRC-024 Attachment 2, with the following clarifications:

2.1.1. If a Transmission Planner’s study (based on the location specific voltage recovery characteristics) allows less stringent voltage relay settings than those required to meet PRC-024 Attachment 2, set voltage relays either to meet the Transmission Planner’s voltage recovery characteristics or the characteristics in PRC-024 Attachment 2.

2.1.2. Tripping a generator in accordance with a Special Protection System (SPS) or Remedial Action Scheme (RAS) is acceptable in the “no trip zone” of PRC-024 Attachment 2.

2.1.3. If clearing a system fault necessitates disconnecting a generator, this action is acceptable within the “no trip zone” specified in PRC-024 Attachment 2.

2.1.4. A generating unit or generating plant may trip if the protective functions (such as out-of-step or loss-of-field functions) operate due to an impending or actual loss of synchronism or due to instability in power conversion control equipment.”

3. Requirement R3 was changed to clarify the intent of non-protection system limitations and when such limitations must be addressed. The requirement now reads:

“R3. Each Generator Owner of an existing generating unit or generating plant shall document each equipment limitation (excluding generator frequency and voltage protective relay limitations) that prevents a generating unit or generating plant, from meeting the criteria in Requirements R1 or R2 including study results, experience from an actual event, or manufacturer’s advisory *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*.

3.1. The Generator Owner shall communicate the documented limitation, or the removal of a previously documented limitation, to its Reliability Coordinator, Planning Coordinator, Transmission Operator, and Transmission Planner within 30 calendar days of identifying the limitation to ensure the accuracy of planning studies and system modeling studies. The existing generating unit or generating plant becomes subject to the full extent of Requirements R1 and R2 coincident with either of the following conditions:

- The equipment causing the limitation is repaired or replaced with equipment that removes the limitation.
- The equipment causing the limitation is modified or upgraded resulting in an increase of generator nameplate capacity rating greater than 10 percent (cumulative from the first effective date of this Standard).”

During the Quality Review process prior to the previous posting, a new Requirement R4 was added based on the comments of the reviewers. This resulted in requirement numbers being incorrect for Questions 3 and 4. The GVSDT will ask these two questions again on the upcoming comment form for the successive ballot. A summary of the comments received is in the following paragraphs.

Relating to question 3 of the previous posting: The GVSDT added Requirement R5 to allow owners of existing units or generating plant/facilities to provide an estimate of the performance of the units during frequency and voltage excursions. This information was intended to provide Transmission Planners with information useful in performing planning studies. In the comment form, the question erroneously asked about R4, rather than R5. A few commenters made comments regarding R4, while the vast majority commented related to R5.

Several commenters felt that there is no additional reliability gain in Requirement R5. Their comments indicated that the information is not useful and that there is little technical value in this information. A few commenters expressed the opinion that it is very difficult, if not impossible, to predict the consistent response of the balance of (a generating) plant to the system excursions shown in Attachment 1 & 2. Further, several commenters expressed the opinion that it is unlikely that any steam plant will survive for the entire “no trip zones” of the attachments. Other less frequent comments included the following:

- R1-R4 adequately fulfill the purpose of the standard.
- Standard requirements should be limited to devices that directly respond to the Generator V and F – write standard to exclude all aux system equipment.
- The TP needs only to know when the protective relaying V-t and F-t will trip the unit so the models can switch the generators off when the simulated V and F levels are reached.
- 30 days is too short for a response.

Based on comments received, the GVSDT revised R5 (which is now R4) to:

“R4. Each Generator Owner of an existing generating unit or generating plant shall provide an estimate of that unit’s performance during Frequency/Voltage Excursions to each requesting entity (Reliability Coordinator, Planning Coordinator, Transmission Operato,r or Transmission Planner that monitors or models the associated generating unit or generating plant) within 60 calendar days of receipt of a written request to ensure the accuracy of planning studies and system modeling studies. The estimate shall include: [Violation Risk Factor: Lower] [Time Horizon: Long-term Planning].
4.1. An estimate of the time duration the existing generating unit or generating plant will remain connected (considering performance of the auxiliary systems as well as the generator) as a result of a frequency excursion or a voltage excursion defined by the voltage or frequency profile at the point of Interconnection described by dynamic simulation provided by the Transmission Planner. If the

Generator Owner expects the existing unit or generating plant will remain connected for longer than 10 minutes, the estimate should indicate the existing unit or generating plant is not expected to trip.
4.2. Identification of the basis for the estimates developed for 4.1 which may include, but is not limited to: experience, actual event histories, or sound engineering judgment."

Relating to Question 4 of the previous posting: The question mistakenly referred to Requirement R5 due to changes to the standard made in response to the Quality Review. This error was observed by the stakeholders and the SDT believes the responses accurately reflect the feelings of industry to the intended question. The slight majority of stakeholders agree with the requirement, while some stakeholders indicated that they do not feel the requirement is technically achievable. Based on the comments received, no major changes were made to Requirement R6 (now R5).

The GVSDT proposed voltage ride-through tables for High Voltage Ride Through (HVRT) and Low Voltage Ride Through (LVRT) time durations in Attachment 2. These tables specify time duration of up to 600 seconds that a unit or a generating plant/facility should ride through a voltage excursion. Stakeholders were asked if they agree with the proposed times in the tables. A majority of stakeholders agreed with the time values. Many of those that responded in the negative to the question indicated that they felt the 600 seconds duration was acceptable but had other concerns with the standard. No substantive suggestions were made for revising R6. As a result, the GVSDT did not make any changes to Attachment 2.

You do not have to answer all questions. Enter All Comments in Simple Text Format.
Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

Questions 1- 5 pertain to MOD-026-1 and Questions 6-8 pertain to PRC-024-1.

Questions

1. The GVSDT has added an additional condition to Attachment 1 (the Periodicity Table) specifying that validation is not required for an excitation control system or plant volt/var control that does not include an active closed-loop voltage regulation function. This condition exempts wind and solar plants that do not have the capability to regulate plant voltage or respond to grid voltage fluctuations other than switching capacitor and reactor banks in and out of service. Do you agree with this concept? If not, please explain in the comment area below.

☐ Yes

☐ No

Comments:

2. The GVSDT has provided guidance on the periodicity aspects of Attachment 1 (see above). Do you agree? If not, please explain in the comment area below.

☐ Yes

☐ No

Comments:

3. Based on the latest round of industry feedback, the GVSDT now proposes Applicability Section language allowing the Planning Coordinator to request additional model information (possibly leading to model verification) only if technical justification demonstrates the simulated unit response does not match the measured unit response. Original technical justification language for units that affect a stability limit has been removed from the standard. Though not a change from the previous posting, the SDT emphasizes for clarity that only units that meet or exceed the Registry Criteria unit MVA thresholds (> 20 MVA) or units that are already registered (for reasons such as being required to by their RRO) are subject to Requirement R5. Do you agree with the revisions to applicability and to Requirement R5? If not, please explain in the comment area below.

☐ Yes

☐ No

Comments:

4. To clarify concerns regarding calculating unit capacity factor, the SDT has incorporated into the standard the capacity factor calculation specified in Appendix F of the GADS Data Reporting Instructions. Do you agree with this revisions? If not, please explain in the comment area below.

☐ Yes

☐ No

Comments:

5. Do you have any other comment, not expressed in questions above, for the GVSDT regarding MOD-026-1?

Comments:

6. Requirement R4 has been added for owners of existing units or generating plant/facilities to provide an estimate of the performance of the units during frequency and voltage excursions. This information is intended to provide Transmission Planners with information useful in performing planning studies. Do you agree with this approach? If not please explain and provide alternative language.

☐ Yes

☐ No

Comments:

7. Requirement R5 requires a Generator Owner's new unit or generating plant/facility to be able to stay on line when exposed to point-of-interconnection frequency or voltage excursions depicted in the curves of Attachment 1 and Attachment 2. Do you believe this requirement is technically achievable for new units or generating plant/facilities? Please provide comments supporting your answer. Please provide along with your comment, what you believe the timeframe is needed to implement this requirement.

☐ Yes

☐ No

Comments:

8. Do you have any other comment, not expressed in questions above, for the GVSDT regarding PRC-024-1?

Comments:

RELIABILITY CORPORATION

Violation Risk Factor and Violation Severity Level Assignments

Project 2007-09 Generator Verification

This document provides the drafting team's justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in MOD-026-1 — Verification of Models and Data for Generator Excitation Control System and Plant Volt/Var Control Functions.

Each primary requirement is assigned a VRF and a set of one or more VSLs. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the ERO Sanction Guidelines.

Justification for Assignment of Violation Risk Factors

The Generator Verification Standard Drafting Team applied the following NERC criteria when proposing VRFs for the requirements under this project:

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

The SDT also considered consistency with the FERC Violation Risk Factor Guidelines for setting VRFs:[1]

Guideline (1) — Consistency with the Conclusions of the Final Blackout Report

The Commission seeks to ensure that Violation Risk Factors assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System.

In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:[2]

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief

Guideline (2) — Consistency within a Reliability Standard

The Commission expects a rational connection between the sub-Requirement Violation Risk Factor assignments and the main Requirement Violation Risk Factor assignment.

Guideline (3) — Consistency among Reliability Standards

---

[1] North American Electric Reliability Corp., 119 FERC ¶ 61,145, order on reh'g and compliance filing, 120 FERC ¶ 61,145 (2007) ("VRF Rehearing Order").

[2] Id. at footnote 15.

The Commission expects the assignment of Violation Risk Factors corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) — Consistency with NERC's Definition of the Violation Risk Factor Level

Guideline (4) was developed to evaluate whether the assignment of a particular Violation Risk Factor level conforms to NERC's definition of that risk level.

Guideline (5) — Treatment of Requirements that Co-mingle More Than One Obligation

Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

The following discussion addresses how the SDT considered FERC's VRF Guidelines 2 through 5. The team did not address Guideline 1 directly because of an apparent conflict between Guidelines 1 and 4. Whereas Guideline 1 identifies a list of topics that encompass nearly all topics within NERC's Reliability Standards and implies that these requirements should be assigned a "High" VRF, Guideline 4 directs assignment of VRFs based on the impact of a specific requirement to the reliability of the system. The SDT believes that Guideline 4 is reflective of the intent of VRFs in the first instance and therefore concentrated its approach on the reliability impact of the requirements.

VRF for MOD-026-1:

There are six requirements in MOD-026-1. Four requirements were assigned a "Lower" VRF while the remaining two were assigned a "Medium" VRF.

VRF for MOD-026-1, Requirement R1:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R1 does not contain Parts. Requirement obligations include actions similar in scope to actions specified in Requirement R6; and all standard requirements specify a Long-term Planning Time Horizon.
- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar to MOD-004-1, Requirement R9 that has an approved Lower VRF. This requirement is also similar to draft standard MOD-027-1 Requirement R1 which also specifies a Lower VRF.
- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to provide requested information is a requirement that is administrative in nature for the planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. Therefore the assigned "Lower" VRF is appropriate.

- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R1 high risk objective is to provide requested information. This requirement is administrative in nature for providing instructions and data used for performing model verification. The “Lower” VRF assigned is based on the high risk objective specified.

VRF for MOD-026-1, Requirement R2:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R2 contains Parts specifying supporting obligations for satisfying the main requirement. The VRFs are only applied at the Requirement level and each Requirement Part is treated equally. Requirement obligations include actions similar in scope to actions specified in Requirement R1 and R6; and all standard requirements specify a Long-term Planning Time Horizon.
- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar with MOD-010-0 and MOD-012-0 Requirements R1 and R2 that have approved VRFs of Medium. This requirement is also similar to draft standard MOD-027-1 Requirement R2 which also specifies a Medium VRF.
- FERC Guideline 4 — Consistency with NERC’s Definition of the VRF Level selected exists. Failure to verify models in the Long-term Planning Time Horizon is a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. Therefore the assigned “Medium” VRF is appropriate.
- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R2 high risk objective is to verify models per specified periodicity. Requirement Parts and obligations are lower risk elements that ensure main requirement completeness which are administrative in nature consisting of documentation, information revision obligation and submission requirements. The “Medium” VRF assigned is based on the high risk objective specified.

VRF for MOD-026-1, Requirement R3:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R3 does not contain Parts. Requirement obligations include actions similar in scope to actions specified in Requirement R1 and R6; and all standard requirements specify a Long-term Planning Time Horizon.
- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar to MOD-004-1, Requirement R7 and R8 that has an approved Lower VRF. This requirement is also similar to draft standard MOD-027-1 Requirement R3 which also specifies a Lower VRF.

- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to verify models in the Long-term Planning Time Horizon is a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. Therefore the assigned "Lower" VRF is appropriate.
- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R3 high risk objective is to provide a written response after receiving notice. The Requirement is administrative in nature consisting of documentation, information revision obligation and submission requirements. The "Lower" VRF assigned is based on the high risk objective specified.

VRF for MOD-026-1, Requirement R4:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R4 does not contain Parts. Requirement obligations include actions similar in scope to actions specified in Requirement R1 and R6; and all standard requirements specify a Long-term Planning Time Horizon.
- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar to MOD-004-1, Requirement R1 and R2 that has an approved Lower VRF. This requirement is also similar to draft standard MOD-027-1 Requirement R4 which also specifies a Lower VRF.
- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to verify models in the Long-term Planning Time Horizon is a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. Therefore the assigned "Lower" VRF is appropriate.
- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R4 high risk objective is to provide revised data after making changes to equipment. The Requirement is administrative in nature consisting of documentation, information revision obligation and submission requirements. The "Lower" VRF assigned is based on the high risk objective specified.

VRF for MOD-026-1, Requirement R5:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R5 contains Parts specifying supporting obligations for satisfying the main requirement. The VRFs are only applied at the Requirement level and each Requirement Part is treated equally. Requirement obligations include actions similar in scope to actions specified in Requirement R1 and R6; and all standard requirements specify a Long-term Planning Time Horizon.

- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar to MOD-004-1, Requirement R7 and R8 that has an approved Lower VRF. This requirement is also similar to draft standard MOD-027-1 Requirement R3 which also specifies a Lower VRF.
- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to verify models in the Long-term Planning Time Horizon is a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. Therefore the assigned "Lower" VRF is appropriate.
- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R5 high risk objective is to provide a written response after receiving a request. Requirement Parts and obligations are lower risk elements that ensure main requirement completeness which are administrative in nature consisting of documentation, information revision obligation and submission requirements. The "Lower" VRF assigned is based on the high risk objective specified.

VRF for MOD-026-1, Requirement R6:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R6 contains Parts specifying supporting obligations for satisfying the main requirement. The VRFs are only applied at the Requirement level and each Requirement Part represents an obligation for ensuring main requirement completeness. Requirement obligations include actions similar in scope to actions specified in Requirement R1; and all standard requirements specify a Long-term Planning Time Horizon.
- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar with MOD-010-0 and MOD-012-0 Requirements R1 and R2 that have approved VRFs of Medium. This requirement is also similar to draft standard MOD-027-1 Requirement R5 which also specifies a Medium VRF.
- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to identify if a model is useable or not is a requirement that is administrative in nature for the planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. Therefore the assigned "Medium" VRF is appropriate.
- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R6 high risk objective is to verify if the model is useable or not.

Requirement Parts and obligations are lower risk elements that ensure main requirement completeness which are administrative in nature consisting of documentation and submission requirements. The “Medium” VRF assigned is based on the high risk objective specified.

Justification for Assignment of Violation Severity Levels:

In developing the VSLs for the standards under this project, the SDT anticipated the evidence that would be reviewed during an audit, and developed its VSLs based on the noncompliance an auditor may find during a typical audit. The SDT based its assignment of VSLs on the following NERC criteria:

Lower	Moderate	High	Severe
Missing a minor element (or a small percentage) of the required performance The performance or product measured has significant value as it almost meets the full intent of the requirement.	Missing at least one significant element (or a moderate percentage) of the required performance. The performance or product measured still has significant value in meeting the intent of the requirement.	Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital component. The performance or product has limited value in meeting the intent of the requirement.	Missing most or all of the significant elements (or a significant percentage) of the required performance. The performance measured does not meet the intent of the requirement or the product delivered cannot be used in meeting the intent of the requirement.

FERC's VSL guidelines are presented below, followed by an analysis of whether the VSLs proposed for each requirement in MOD-026-1 meet the FERC Guidelines for assessing VSLs:

Guideline 1: Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

Compare the VSLs to any prior levels of non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when levels of non-compliance were used.

Guideline 2: Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

A violation of a "binary" type requirement must be a "Severe" VSL.

Do not use ambiguous terms such as "minor" and "significant" to describe noncompliant performance.

Guideline 3: Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

VSLs should not expand on what is required in the requirement.

Guideline 4: Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations

. . . unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the “default” for penalty calculations.

VSLs for MOD-026-1 Requirement R1:

R#	Compliance with NERC VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R1.	The NERC VSL guidelines are satisfied by incorporating increments for tardiness VSL elements. The SDT has determined a 30 day “Increments for Tardiness” period is appropriate for standard VSLs proposed.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL’s incorporate the increments for tardiness methodology. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on timeliness of the action specified.	Proposed VSL’s do not expand on what is required in the requirement. The VSL’s assigned only consider performing required action and if information submission is timely. Proposed VSL’s are consistent with the requirement.	Proposed VSL’s are based on a single violation and not a cumulative violation methodology.

VSLs for MOD-026-1 Requirement R2:

R#	Compliance with NERC Revised VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R2.	The NERC VSL guidelines are satisfied by incorporating increments for tardiness with completeness of information required for the main Requirement action. The SDT has determined a 30 day "Increments for Tardiness" period is appropriate for standard VSLs proposed.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL's consider completeness of listed parts deemed to possess equal reliability weight and also increments for tardiness. Binary requirements are categorized as severe. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on binary performance, and both completeness and timeliness of the actions and obligations specified.	Proposed VSL's do not expand on what is required in the requirement. The VSL's assigned only consider performing required action and if information submission is complete. Proposed VSL's are consistent with the requirement.	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

VSLs for MOD-026-1 Requirement R3:

R#	Compliance with NERC Revised VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R3.	The NERC VSL guidelines are satisfied by incorporating increments for tardiness VSL elements for the main Requirement action. Actions and obligations specified in the Requirement Parts incorporate a binary element, consideration for omitting required information. The SDT has determined a 30 day “Increments for Tardiness” period is appropriate for standard VSLs proposed.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL’s are a combination of a binary element and increments for tardiness. Binary requirements are categorized as severe. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on binary performance, and both completeness and timeliness of the actions and obligations specified.	Proposed VSL’s do not expand on what is required in the requirement. The VSL’s assigned only consider performing required action and if information submission is both complete and provided in a timely manner. Proposed VSL’s are consistent with the requirement.	Proposed VSL’s are based on a single violation and not a cumulative violation methodology.

VSLs for MOD-026-1 Requirement R4:

R#	Compliance with NERC Revised VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R4.	The NERC VSL guidelines are satisfied by incorporating increments for tardiness VSL elements for the main Requirement action. The SDT has determined a 30 day "Increments for Tardiness" period is appropriate for standard VSLs proposed.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL's utilize increments for tardiness rationale. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on timeliness of the actions and obligations specified.	Proposed VSL's do not expand on what is required in the requirement. The VSL's assigned only consider performing required action and if information submission is complete and provided in a timely manner. Proposed VSL's are consistent with the requirement.	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

VSLs for MOD-026-1 Requirement R5:

R#	Compliance with NERC Revised VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R5.	The NERC VSL guidelines are satisfied by incorporating equal multiple parts criteria VSL elements for the main Requirement action. Actions and obligations specified in the Requirement Parts also incorporate increments for tardiness consideration. The SDT has determined a 30 day “Increments for Tardiness” period is appropriate for standard VSLs proposed.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL’s are a combination of completeness of listed parts deemed to possess equal reliability weight and also increments for tardiness. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on both completeness and timeliness of the actions and obligations specified.	Proposed VSL’s do not expand on what is required in the requirement. The VSL’s assigned only consider performing required action and if information submission is both complete and provided in a timely manner. Proposed VSL’s are consistent with the requirement.	Proposed VSL’s are based on a single violation and not a cumulative violation methodology.

VSLs for MOD-026-1 Requirement R6:

R#	Compliance with NERC VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R6.	The NERC VSL guidelines are satisfied by incorporating increments for tardiness VSL elements for the Main Requirement action. Actions specified in the Requirement Parts incorporate completeness of the actions and obligations specified. The SDT has determined a 30 day “Increments for Tardiness” period is appropriate for standard VSLs proposed.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL’s are a combination of completeness of listed parts and also increments for tardiness. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on both completeness and timeliness of the actions and obligations specified.	Proposed VSL’s do not expand on what is required in the requirement. The VSL’s assigned only consider performing required action and if information submission is both complete provided in a timely manner. Proposed VSL’s are consistent with the requirement.	Proposed VSL’s are based on a single violation and not a cumulative violation methodology.

Project 2007-09 Generator Verification Consideration of Issues and Directives

Project 2007-09 Generator Verification — PRC-024		
Issue or Directive	**Source**	**Consideration of Issue or Directive**
Paragraph 1787 states "… the Commission directs the ERO to modify the Reliability Standard to explicitly require either that all generators are capable of riding through the same set of Category B and C contingencies, as required by wind generators in Order No. 661, or that those generators that cannot ride through be simulated as tripping. "	FERC Order 693	The GVSDT believes that Requirement R2 and the voltage ride through curves in PRC-024 Attachment 2 accomplish this. While the curves were developed based on three phase normally cleared faults located at a generating plant substation (the most severe condition for generating equipment), the curves cover voltages depressed as low as 0.65 per unit for two seconds, which the GVSDT feels will cover the Category B and C events of concern to the Commission. Requirement R5 directs all new generating facilities following approval of this standard to be designed, built and maintained so that they are able to ride through the excursions defined in the standard. For existing units, Requirement R3 allows an exemption from portions of the ride through curves in PRC-024 Attachments 1 and 2 for documented technical reasons, but directs those generators to communicate that limitation to the RC, PC, TOP and TP so its performance can be modeled correctly. In addition, Requirement R4 allows the RC, PC, TOP, or TP to request an estimate of performance (ride through duration) from the GO for a defined excursion. The estimate would cover process upsets to the generating equipment that might result in a delayed trip, even if the

Project 2007-09 Generator Verification — PRC-024		
Issue or Directive	**Source**	**Consideration of Issue or Directive**
		generator protection itself did not cause a trip.
Paragraph 1787 also states "… the Commission agrees that NRC requirements should be used when implementing the Reliability Standards."	FERC Order 693	The GVSDT believes that Requirement R3 allows NRC requirements to supersede portions of the voltage and frequency ride through criteria in PRC-024-1. This Requirement allows generators an exemption from portions of the ride through curves for documented technical limitations. The GVSDT believes that NRC requirements qualify as technical limitations for the purposes of this standard.

Violation Risk Factor and Violation Severity Level Assignments

Project 2007-09 Generator Verification

This document provides the drafting team's justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in PRC-024-1 — Generator Performance During Frequency and Voltage Excursions.

Each primary requirement is assigned a VRF and a set of one or more VSLs. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the ERO Sanction Guidelines.

Justification for Assignment of Violation Risk Factors

The Generator Verification Standard Drafting Team applied the following NERC criteria when proposing VRFs for the requirements under this project:

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement
A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

The SDT also considered consistency with the FERC Violation Risk Factor Guidelines for setting VRFs:[1]

Guideline (1) — Consistency with the Conclusions of the Final Blackout Report
The Commission seeks to ensure that Violation Risk Factors assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System.

In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:[2]

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief

Guideline (2) — Consistency within a Reliability Standard
The Commission expects a rational connection between the sub-Requirement Violation Risk Factor assignments and the main Requirement Violation Risk Factor assignment.

Guideline (3) — Consistency among Reliability Standards

[1] North American Electric Reliability Corp., 119 FERC ¶ 61,145, order on reh'g and compliance filing, 120 FERC ¶ 61,145 (2007) ("VRF Rehearing Order").
[2] Id. at footnote 15.

The Commission expects the assignment of Violation Risk Factors corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) — Consistency with NERC's Definition of the Violation Risk Factor Level
Guideline (4) was developed to evaluate whether the assignment of a particular Violation Risk Factor level conforms to NERC's definition of that risk level.

Guideline (5) — Treatment of Requirements that Co-mingle More Than One Obligation
Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

The following discussion addresses how the SDT considered FERC's VRF Guidelines 2 through 5. The team did not address Guideline 1 directly because of an apparent conflict between Guidelines 1 and 4. Whereas Guideline 1 identifies a list of topics that encompass nearly all topics within NERC's Reliability Standards and implies that these requirements should be assigned a "High" VRF, Guideline 4 directs assignment of VRFs based on the impact of a specific requirement to the reliability of the system. The SDT believes that Guideline 4 is reflective of the intent of VRFs in the first instance and therefore concentrated its approach on the reliability impact of the requirements.

VRF for PRC-024-1:
There are six requirements in PRC-024-1. Three of the Requirements (R1, R2, and R5) were assigned a "High" VRF and the remaining three requirements were assigned a "Lower" VRF.

VRF for PRC-024-1, Requirement R1:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R1 contains Parts specifying conditions for satisfying the main requirement. The VRFs are only applied at the Requirement level and each Requirement Part is treated equally. Requirement obligations include actions similar in scope to actions specified in Requirement R2; which remaining standard requirements rationally relate by defining documentation, estimation, expectations during external events, and response expectations.
- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar in concept with both PRC-012-0 Requirement R1 and PRC-023-1 Requirement R1, both of which require protection coordination or settings. In addition, and as is generally the case with PRC standard VRF definitions, this requirement is assigned a "High" VRF.
- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to ensure a proper frequency "no-trip" operating window is a requirement in the planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated

by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition. Therefore the assigned "High" VRF is appropriate.

- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R1 high risk objective is to ensure a proper frequency "no-trip" operating window. Requirement Parts are lower risk condition elements that establish main requirement criteria for completeness. The "High" VRF assigned is based on the high risk objective specified.

VRF for PRC-024-1, Requirement R2:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R2 contains Parts specifying conditions for satisfying the main requirement. The VRFs are only applied at the Requirement level and each Requirement Part is treated equally. Requirement obligations include actions similar in scope to actions specified in Requirement R1; which remaining standard requirements rationally relate by defining documentation, estimation, expectations during external events, and response expectations.
- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar in concept with both PRC-012-0 Requirement R1 and PRC-023-1 Requirement R1, both of which require protection coordination or settings. In addition, and as is generally the case with PRC standard VRF definitions, this requirement is assigned a "High" VRF.
- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to ensure proper voltage "no-trip" criteria is a requirement in the planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition. Therefore the assigned "High" VRF is appropriate.
- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R2 high risk objective is to ensure proper voltage "no-trip" criteria. Requirement Parts are lower risk condition elements that establish main requirement criteria for completeness. The "High" VRF assigned is based on the high risk objective specified.

VRF for PRC-024-1, Requirements R3:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R3 contains Parts specifying response expectation and limitation reset conditions for satisfying the main requirement. The VRFs are only applied at the Requirement level and each Requirement Part is treated equally.
- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar in concept with PRC-006-0 Requirement R1 which specifies documentation requirements. In addition, as is generally the case with reliability standard VRF definitions for documentation and administrative requirements, this requirement is assigned a "Lower" VRF.
- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to document limitations preventing compliance is a requirement that is administrative in nature for the planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. Therefore the assigned "Lower" VRF is appropriate.
- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R3 high risk objective is to document limitations preventing compliance. Requirement Parts and obligations are lower risk elements that ensure main requirement completeness which are administrative in nature consisting of response submission and limitation reset condition requirements. The "Lower" VRF assigned is based on the high risk objective specified.

VRF for PRC-024-1, Requirement R4:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R4 contains Parts that are procedural in nature defining criteria associated with the main requirement. The VRFs are only applied at the Requirement level and each Requirement Part is treated equally.
- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement requires an estimate of performance and is somewhat similar in concept with both PRC-009-0 Requirement R1 and PRC-014-0 Requirement R2, both of which reference protection analysis or assessment for determining adequacy. In addition, as is generally the case with reliability standard VRF definitions for analysis & assessment planning type requirements, this requirement is assigned a "Lower" VRF.
- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to estimate performance during a frequency or voltage excursion is a requirement that is administrative in nature for the planning time frame that, if violated, would not, under the

emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. Therefore the assigned "Lower" VRF is appropriate.

- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R4 high risk objective is to estimate performance during a frequency or voltage excursion. Requirement Parts and obligations are lower risk procedure based criteria for the main requirement. The "Lower" VRF assigned is based on the high risk objective specified.

VRF for PRC-024-1, Requirements R5:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R5 contains Parts specifying conditions and exceptions for satisfying the main requirement during external events. The VRFs are only applied at the Requirement level and each Requirement Part is treated equally.
- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement requires generation to remain connected during external events and as such does not have strong correlation to similar reliability goals listed in different reliability standards. A good approximation in regards to maintaining stable and continuous power operations can be found in standards BAL-002-0 and EOP-008-0; both of which possess a High VRF. Therefore this requirement is assigned a "High" VRF.
- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to remain connected during an external event is a requirement during real-time operation that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures Therefore the assigned "High" VRF is appropriate.
- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R5 high risk objective is to remain connected during an external event. Requirement Parts specify conditions and exceptions elements that establish main requirement criteria for completeness. The "High" VRF assigned is based on the high risk objective specified.

VRF for PRC-024-1, Requirement R6:

- FERC Guideline 2 — Consistency within a Reliability Standard exists. Requirement R6 does not contain Parts. Requirement obligations specify the type of response and response time frame to be observed.
- FERC Guideline 3 — Consistency among Reliability Standards exists. This requirement is similar in concept with both PRC-007-0 Requirement R3 and PRC-010-0 Requirement R2, both of which require providing information within a specified time frame on request. In addition, as is generally the case with reliability standard VRF definitions for documentation and administrative requirements, this requirement is assigned a "Lower" VRF.
- FERC Guideline 4 — Consistency with NERC's Definition of the VRF Level selected exists. Failure to provide setting and limitation information as requested is a requirement that is administrative in nature for the planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. Therefore the assigned "Lower" VRF is appropriate.
- FERC Guideline 5 — Treatment of Requirements that Co-mingle More Than One Obligation is satisfactory. The Requirement R6 high risk objective is to provide setting and limitation information as requested. Requirement obligations are lower risk condition elements administrative in nature for ensuring the main requirement is satisfied in a timely manner. The "Lower" VRF assigned is based on the high risk objective specified.

Justification for Assignment of Violation Severity Levels:
In developing the VSLs for the standards under this project, the SDT anticipated the evidence that would be reviewed during an audit, and developed its VSLs based on the noncompliance an auditor may find during a typical audit. The SDT based its assignment of VSLs on the following NERC criteria:

Lower	Moderate	High	Severe
Missing a minor element (or a small percentage) of the required performance The performance or product measured has significant value as it almost meets the full intent of the requirement.	Missing at least one significant element (or a moderate percentage) of the required performance. The performance or product measured still has significant value in meeting the intent of the requirement.	Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital component. The performance or product has limited value in meeting the intent of the requirement.	Missing most or all of the significant elements (or a significant percentage) of the required performance. The performance measured does not meet the intent of the requirement or the product delivered cannot be used in meeting the intent of the requirement.

FERC's VSL guidelines are presented below, followed by an analysis of whether the VSLs proposed for each requirement in PRC-024-1 meet the FERC Guidelines for assessing VSLs:

Guideline 1: Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

Compare the VSLs to any prior levels of non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when levels of non-compliance were used.

Guideline 2: Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

A violation of a "binary" type requirement must be a "Severe" VSL.

Do not use ambiguous terms such as "minor" and "significant" to describe noncompliant performance.

Guideline 3: Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

VSLs should not expand on what is required in the requirement.

Guideline 4: Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations

. . . unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the "default" for penalty calculations.

VSLs for PRC-024-1 Requirement R1:

R#	Compliance with NERC VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R1.	The NERC VSL guidelines are satisfied by incorporating binary VSL elements.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL's are a combination of binary elements and are categorized as severe. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on binary performance, and timeliness of the actions and obligations	Proposed VSL's do not expand on what is required in the requirement. The VSL's assigned only consider performing required action per the conditions specified by listed parts. Proposed VSL's are consistent with the requirement.	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

VSLs for PRC-024-1 Requirement R2:

R#	Compliance with NERC VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R2.	The NERC VSL guidelines are satisfied by incorporating binary VSL elements.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL's are a combination of binary elements and are categorized as severe. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on binary performance, and timeliness of the actions and obligations specified.	Proposed VSL's do not expand on what is required in the requirement. The VSL's assigned only consider performing required action per the conditions specified by listed parts. Proposed VSL's are consistent with the requirement.	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

VSLs for PRC-024-1 Requirement R3:

R#	Compliance with NERC VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R3.	The NERC VSL guidelines are satisfied by incorporating increments for tardiness elements.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL's incorporate the increments for tardiness methodology. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on timeliness of the action specified.	Proposed VSL's do not expand on what is required in the requirement. The VSL's assigned only consider performing required action in a timely manner including response obligation and reset conditions specified by listed parts. Proposed VSL's are consistent with the requirement.	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

VSLs for PRC-024-1 Requirement R4:

R#	Compliance with NERC VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R4.	The NERC VSL guidelines are satisfied by incorporating increments for tardiness. The Requirement Parts incorporate procedure based criteria elements incorporated as equal multiple parts rationale for completeness of the main Requirement. Requirement Parts are conditions that, if not performed, represent noncompliance of increasing severity based on the number of conditions not observed.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL's are a combination of binary elements with additional consideration for completeness of listed parts and also increments for tardiness. Binary requirements are categorized as severe. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on binary performance, and both completeness and timeliness of the actions and obligations specified.	Proposed VSL's do not expand on what is required in the requirement. The VSL's assigned only consider performing required action in a timely manner per the procedure criteria specified by listed parts. Proposed VSL's are consistent with the requirement.	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

VSLs for PRC-024-1 Requirement R5:

R#	Compliance with NERC VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R5.	The NERC VSL guidelines are satisfied by incorporating binary VSL elements. Requirement Parts merely identify conditions and exceptions for determining binary VSL status.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL's incorporate binary methodology. Binary requirements are categorized as severe. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on binary performance of the actions and obligations specified.	Proposed VSL's do not expand on what is required in the requirement. The VSL's assigned only consider performing required action per the conditions and exceptions specified by listed parts. Proposed VSL's are consistent with the requirement.	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

VSLs for PRC-024-1 Requirement R6:

R#	Compliance with NERC VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R6.	The NERC VSL guidelines are satisfied by incorporating increments for tardiness elements.	This is a new Requirement and does not have a prior level of compliance.	Proposed VSL's incorporate the increments for tardiness methodology. Proposed VSL language does not include ambiguous terms and ensure uniformity and consistency in the determination of penalties based on timeliness of the action specified.	Proposed VSL's do not expand on what is required in the requirement. The VSL's assigned only consider performing required action in a timely manner. Proposed VSL's are consistent with the requirement.	Proposed VSL's are based on a single violation and not a cumulative violation methodology.

Standards Announcement

Project 2007-09 Generator Verification

Ballot Pool Windows Open – Three Ballots and Three Non-binding Polls: Feb. 29 – Mar. 29, 2012

Two Formal Comment Periods Open:

MOD-026-1 & PRC-024-1 Feb. 29 – Mar. 29, 2012

PRC-019-1, MOD-025-2, & MOD-027-1 – Feb. 29 – Apr. 16, 2012

Ballot Windows Open – Two Ballots and Two Non-binding Polls:

(MOD-026-1 & PRC-024-1) March 19 – March 29, 2012

Ballot Windows Open – Three Ballots and Three Non-binding Polls:

PRC-019-1, MOD-025-2, & MOD-027-1) April 6 – April 16, 2012

Now available

The Generator Verification standard drafting team has posted five standards and their associated implementation plans for a formal comment period. Please read the following announcement carefully because, although the five standards are being posted together, they are at different stages in the standards process. In order to facilitate moving forward those standards that reach consensus, the standards are being balloted independently.

MOD-026-1 and PRC-024-1 Formal 30-day Comment Period, Successive Ballot and Non-binding Poll

Two standards, MOD-026-1 – Verification of Models and Data for Generator Excitation Control System Functions , and PRC-024-1– Generator Performance During Frequency and Voltage Excursions, are posted for a 30-day formal comment period through March 29, 2012. A successive ballot and non-binding poll of the associated VRFs and VSLs will be conducted for MOD-026-1 and PRC-024-1 from March 19 through March 29, 2012. Please note that **separate ballot pools were formed for each standard and non-binding poll**.

Instructions for Commenting

Please use this electronic form to submit comments on MOD-026-1 and PRC-024-1. If you experience any difficulties in using the electronic form, please contact Monica Benson at monica.benson@nerc.net. An off-line, unofficial copy of the comment form is posted on the project page.

Please note that comments submitted with ballots will use the same form, and it is NOT necessary for ballot pool members to submit multiple separate sets of comments (one during the comment period and one with each ballot). Comments submitted with ballots are extremely valuable to help the drafting team revise its work. However, in an effort to reduce the burden on stakeholders providing comments, the drafting team requests that all comments (both those submitted with a ballot and those submitted by stakeholders not balloting) be submitted through the electronic form. This will ensure that stakeholders provide a single set of comments. Further instructions will be provided in the announcement that the ballot window is open.

MOD-025-2, MOD-027-1, and PRC-019-1 Formal 45-day Comment Period and Ballot Pool Formation

Three additional standards have been posted for a 45-day formal comment period:

- MOD-025-2 – Verification and Data Reporting of Generator Real and Reactive Power Capability
- MOD-027-1 – Verification of Models and Data for Turbine/Governor and Load Control or Active Power/Frequency Control Functions
- PRC-019-1 – Coordination of Generating Unit or Plant Voltage Regulating Controls with Generating Unit or Plant Capabilities and Protection

An initial ballot and non-binding poll of the associated VRFs and VSLs will be conducted for MOD-025-1, MOD-027-1 and PRC-019-1 from April 6 through April 16, 2012. Please note that **separate ballot pools are being formed for each standard and non-binding poll**.

Ballot Pools Open through 8 a.m. EST on March 29, 2012 for MOD-025-2, MOD-027-1, and PRC-019-1 Ballots and Non-binding Polls

The Standards Committee has authorized posting these standards and their associated implementation plans for a 45-day formal comment period, with an initial ballot and concurrent non-binding poll conducted during the last 10 days of that comment period. A separate ballot pool is being formed for each standard and for each non-binding poll in order to allow NERC Registered Ballot Body members to selectively join those ballot pools in which they have an interest. To submit an opinion in a non-binding poll for any standard, you must join the ballot poll for that non-binding poll. Each of the six ballot pools will be open through 8 a.m. EST on March 29, 2012.

Instructions for Joining Ballot Pools for MOD-025-2, MOD-027-1, and PRC-019-1 Ballots and Non-binding Polls

NERC Registered Ballot Body members must join each of the ballot pools to be eligible to vote in the upcoming ballots and non-binding polls. Join

During the pre-ballot window, members of the ballot pool may communicate with one another by using their “ballot pool list server.” (Once the balloting begins, ballot pool members are prohibited from using the ballot pool list servers.) The list servers for this project are:

MOD-025-2 ballot	bp-2007-09_MOD-025-2_in@nerc.com
MOD-027-1 ballot	bp-2007-09_MOD-027-1_in@nerc.com
PRC-019-1 ballot	bp-2007-09_PRC-019-1_in@nerc.com

Instructions for Commenting

Please use this electronic form to submit comments on MOD-025-2, MOD-027-1, and PRC-019-1. If you experience any difficulties in using the electronic form, please contact Monica Benson at monica.benson@nerc.net. An off-line, unofficial copy of the comment form is posted on the project page.

Please note that comments submitted with ballots will use the same form, and it is NOT necessary for ballot pool members to submit multiple separate sets of comments (one during the comment period and one with each ballot). Comments submitted with ballots are extremely valuable to help the drafting team revise its work. However, in an effort to reduce the burden on stakeholders providing comments, the drafting team requests that all comments (both those submitted with a ballot and those submitted by stakeholders not balloting) be submitted through the electronic form. This will ensure that stakeholders provide a single set of comments. Further instructions will be provided in the announcement that the ballot window is open.

Next Steps

Successive ballots of MOD-026-1 and PRC-024-1and concurrent non-binding polls of the associated VRFs and VSLs will begin on March 19, 2012 and end at 8 p.m. Eastern on March 29, 2012. Initial ballots of MOD-025-2, MOD-027-1 and PRC-019-1 and concurrent non-binding polls of the associated VRFs and VSLs will begin on Friday, April 6, 2012 and end at 8 p.m. Eastern on Monday, April 16, 2012. Following the formal comments periods for MOD-026-1, PRC-024-1, MOD-025-2, MOD-027-1, and PRC-019-1, the drafting team will consider all comments and determine whether to make changes to the standards, implementation plans, or associated VRFs and VSLs.

Background

The purpose of Project 2007-09 - Generator Verification - is to ensure that: 1) generators will not trip off-line during specified voltage and frequency excursions or as a result of improper coordination between generator-protective relays and generator voltage regulator controls and limit functions (such coordination will include the generating unit's capabilities); and 2) that generator models accurately reflect the generator's capabilities and operating characteristics.

The standard drafting team (SDT) for Project 2007-09 - Generator Verification - based its work on two existing NERC Board-approved standards, MOD-024-1 — Verification of Generator Gross and Net Real Power Capability and MOD-025-1 — Verification of Generator Gross and Net Reactive Power Capability. The drafting team has recently moved the Requirements of MOD-024-1 into MOD-025-2, and recommends retiring MOD-024-1.

The drafting team has also based its work on four draft standards developed by the Phase III & IV SDT that were field tested by four Regions from mid 2006 through mid 2007:

- PRC-019-1 — Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection
- PRC-024-1 — Generator Performance During Frequency and Voltage Excursions
  MOD-026-1 —Verification of Models and Data for Generator Excitation Control System Functions and Plant Volt/Var Control Functions
- MOD-027-1 — Verification of Models and Data for Turbine/Governor and Load Control or Active Power/Frequency Control Functions

Additional details are available on the project web page.

Standards Process

The Standard Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

For more information or assistance, please contact Monica Benson,
Standards Process Administrator, at monica.benson@nerc.net or at 404-446-2560.

Standards Announcement

Project 2007-09 – Generator Verification

Successive Ballot Results – Updated 4/1/2012

Now Available

Ballots of two Generator Verification standards concluded Thursday, March 29, 2012:

- MOD-026-1 – Verification of Models and Data for Generator Excitation System Functions and Plant Volt/Var Control Functions

- PRC-024-1 – Generator Performance During Frequency and Voltage Excursions

Voting statistics for each ballot are listed below, and the Ballots Results page provides a link to the detailed results.

Standard	Quorum	Approval
MOD-026-1 – Verification of Models and Data for Generator Excitation System Functions and Plant Volt/Var Control Functions	Quorum: 81.45%	Approval: 61.21%
PRC-024-1 – Generator Performance During Frequency and Voltage Excursions	Quorum: 80.38%	Approval: 41.09%

Next Steps

The drafting team will consider all comments submitted and make revisions to the standards and other documents to respond to the comments. If the drafting team makes substantive revisions, the drafting team will submit the revised standards along with its consideration of comments received for a quality review prior to posting for a parallel formal 30-day comment period and successive ballot.

Background

The purpose of Project 2007-09 - Generator Verification - is to ensure that: 1) generators will not trip off-line during specified voltage and frequency excursions or as a result of improper coordination between generator-protective relays and generator voltage regulator controls and limit functions (such coordination will include the generating unit's capabilities); and 2) that generator models accurately reflect the generator's capabilities and operating characteristics.

The standard drafting team (SDT) for Project 2007-09 - Generator Verification - based its work on two existing NERC Board-approved standards, MOD-024-1 — Verification of Generator Gross and Net Real Power Capability and MOD-025-1 — Verification of Generator Gross and Net Reactive Power Capability. The drafting team has recently moved the Requirements of MOD-024-1 into MOD-025-2, and recommends retiring MOD-024-1.

The drafting team has also based its work on four draft standards developed by the Phase III & IV SDT that were field tested by four Regions from mid-2006 through mid-2007:

- PRC-019-1 — Coordination of Generating Unit or Plant Capabilities , Voltage Regulating Controls, and Protection
- PRC-024-1 — Generator Performance During Frequency and Voltage Excursions
- MOD-026-1 —Verification of Models and Data for Generator Excitation Control System Functions and Plant Volt/Var Control Functions
- MOD-027-1 — Verification of Models and Data for Turbine/Governor and Load Control or Active Power/Frequency Control Functions

Additional details are available on the project web page at: http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html.

Individual
Frederick R Plett
Massachusetts Attorney General
No
a particular unit may not pose much problem to a system but an aggregation may. One would think that over a threshold # of MW that active close loop regulation functions should be present.
Yes
No
I am concerned about units that may be individually less than 20 MVA but collectively could eb much larger - wind farms.
Yes
Yes
Group
Northeast Power Coordinating Council
Guy Zito
No
While some plants may not have excitation systems, they can have complex reactive coordination controllers whose settings and functions should be tested and verified.
Yes
No
Footnote 4 in the Applicability Section implies comparing simulated unit or plant responses to dynamic system events. Verifying the model only after an event as is called for in footnote 4 is completely counter to increasing system reliability. Analyzing an event and determining that a particular generating unit model is inaccurate will prove difficult in practice. The Applicability Section needs

further revision because by requiring only generators above 100 MVA with unit capacity factors above 5 % to test excludes an unacceptably large amount of installed generation. For example, about 30% of the installed generation in New England would not therefore, require model validation. This is an excessively large portion of the generation that is being exempted. Additionally, the low capacity factor units will likely be running during the periods when the system is being most stressed and reliable operation is being most challenged. If the objective of the Standard is to develop the right models for dynamic suimualtions, models must include high and low capacity factor units, transient and long term models, etc. for all network conditions. A model for the generators and associated equipment is supplied in accordance with MOD-012. The accuracy of such models may be limited and a higher percentage of generator validation is required. Footnote 4 should be changed to allow verification of generator models not required under the Applicability Section to be at the discretion of the Transmission Planner. In some areas of the system, generator models have a considerable impact on dynamic performance and model accuracy is critical. Requirement R5 authorizes the PC to apply MOD-026 to any generator not included in the Applicability section of MOD-026. This would authorize the PC to apply the standard to non-BES generation, which is not appropriate. What is meant by a “technically justified request” from the PC? R5 refers to the Planning coordinator, yet the Planning Coordinator is not listed in the Applicability Section of MOD-026. MOD-026 deviates from the NERC Functional Model Version 5 in that MOD-026 R5 has the Generator Owner communicating with the Planning Coordinator. The NERC Functional Model stipulates that the Transmission Planner communicates with the GO/GOP. The PC then collects the data from the TPs in its area, and from adjacent PCs. The Standard should be consistent with the NERC Functional Model.
Yes
While supporting the clarification of capacity factor concerns, there is concern with the exclusion for units with less than a five percent capacity factor. See comments provided to Question 3. Average Capacity Factor should be defined.
Use of the terms Bulk Electric System (BES) in the Purpose and bulk power system in the Facilities Section should be reconciled. NERC is standardizing on the term Bulk Electric System (BES). In the Applicability Section under the Introduction, the bullets under 4.2.1.2 are unnecessary. The wording of 4.2.1.2 already covers what the bullets detail. Regarding Requirement 2: • R2.1.1: requires that model results must “match” results from field testing. This language implies that there is zero tolerance which is unreasonable. There should be a stipulated allowable tolerance band. Suggest that a tolerance be a specific value based on per unit. For example, the model and actual response shall match within a tolerance of .02 per unit of the bus voltage being controlled. • R2.1.1: A unit’s “point of interconnection” is open to interpretation and could create compliance uncertainty. Almost all generator excitation systems control the generator terminal voltage (low side of the GSU) while the term “point of interconnection” may be interpreted as on the substation bus (high side of the GSU). A suggestion is use the following: at the bus controlled by the generator excitation system. Tables following Attachment 1: the purpose of these tables is not clear, they are not referenced in the Requirements. Why are the References listed in Section G included? They are described as being “beyond the scope of this Standard”. The language for R4 should be reworded as follows: “R4. Each Generator Owner shall provide revised model data or plans to perform model verification7 (in accordance with Requirement R2) to its Transmission Planner within 180 calendar days of prior to making changes to the excitation control system and plant volt/var control function that alter the equipment response8 characteristic.” The way the language is currently written, the generator has to provide its revised model data or plans to perform model verification within 180 days of making the change. For up to 180 days after a change has been made the correct data still may not have been made available to the Transmission Planner. This could have a significant impact on reliability. The suggested rewording addresses this possibility. The suggested language would be in line with FERC approved language that is currently part of ISO Tariffs. What is the definition of Gross Nameplate Rating as used in the Standard?
Yes
No
The exception in 5.2 should not be allowed. Each generating unit that is registered based on the NERC Registry Criteria as a single unit, or as part of a generating facility, should comply with PRC-024 without exception. Simultaneous loss of 10 percent of the generators at a number of installations could introduce severe reliability concerns. This standard allows loopholes which undermine reliability.

Suggest revising Requirement 5.6 from “may retroactively grant a temporary exemption” to “may grant a retroactive temporary exemption”. The magnitude of voltage excursions at the point of interconnection may be different from the generator terminals where generator relays receive their voltage inputs.
The definitions of the terms Frequency Excursion and Voltage Excursion were deleted. All references to these terms should be lower case. Measures M4 and M5 continue to carry the prior wording and need to be revised to use the lower case terms. Regarding requirement R2, the time duration is acceptable. However, the band is shown as 0.95 per unit to 1.05 per unit at the point of interconnection, and there are areas of the power system that have not been designed to maintain steady state operation within this band. The band needs to be expanded to 0.90 per unit to 1.05 per unit. Failure to make this change means that it would be acceptable for generators to trip during steady state operation of the system on “low” voltage. Unanticipated and unncecessary tripping of generators under steady state conditions could lead to significant reliability concerns on the system. The PTs connected to the high voltage terminals of the GSU may not be used as a source for generator protective relaying. Generator protective relays may be connected to the generator output terminals for their source of potential. The wording of R2 should incorporate generator terminals in addition to point of interconnection. Regarding R3, in the event that a generator has a piece of equipment which prevents it from meeting the requirements of R1 and R2, such as a motor contactor which drops out on voltages in the “No Trip Zone”, there is no requirement to correct the issue. The generator must only document the limitation. This completely undermines the intent of this standard. It is counterproductive to set undervoltage relays to meet the curve if other equipment is still going to trip the plant for those same conditions. This standard appears to simply document system concerns rather than identify and correct them. Under Requirement R5, 5.5 (exception) is unnecessary. It does not have to be stated that a generating unit or generating plant may trip if clearing a system fault necessitates disconnecting the generating unit or generating plant.

Appendix F of the GADS Data reporting has two Capacity Factor calculations (Gross and Net). The standard should specify Net Capacity Factor.
No
An estimate of the time that a unit would remain on-line during or following a voltage or frequency event described by a Transmission Planner would be difficult if not impossible considering the complexity of the auxiliary system and would result in little value to the Transmission Planner. There is no known methodology to provide a consistent estimation or calculation of the value. Luminant recommends that the requirement be removed from the standard.
No
Although this requirement may be achieveable, it is highly probably that as the unit ages, components will begin deteriate such that they will not be able to ride through severe voltage or frequency excursions. For example, Luminant has done testing of 480v contactors that when purchased new exhibit a drop out voltage level but over time, the drop out level will deteriate to a level. Since there is no method for determining when to replace equipment susceptible to voltage ride through criteria, this requirement is not auditable for the maintain requirement. The “maintain” requirement should be removed. The cost of meeting this requirement could potentially discourage new generation. Overall, requirement R5 provides little benefit to the reliability of the BES, and Luminant recommends that this requirement be removed.

1. Requirement R1 and R2 discuss generator frequency and voltage relaying to be set such that they do not trip within the “no trip zone” of Attachement 1 and 2 respectively. Luminant believes that these requirements should only apply to relays that use frequency or voltage sensing only. Impedance, and voltage controlled over-current relays should not be included since they are part of the Generator Loadability and AVR Control standards. Relays using both voltage and frequency should not be part of the standard. Alternately, if volts per hertz relays are included, Luminant recommends that an additional requirement R2.2 be added to take in consideration volts per hertz relays. R2.2 would become “Generator volts per hertz relaying shall not cause a unit trip for conditions that are less than 116% of generator rated design voltage and frequency and last for less than 1.5 seconds.” For footnote 1, individual curves would have to be listed for each protective relay function, as the Attachement 1 curve is for voltage relays only. 2. R3 is an administrative requirement that provides little or no benefit to the BES. Luminant recommends that the requirement be removed, and Requirements R1 and R2 should be modified to delete the reference to R3 as follows; “ … unless the generator owner has identified an equipment limitation …” 3. R6 should be at a minimum of 90 days due to some entities have a large number of generating units. 4. Overall, this standard should address voltage and frequency relay settings only.

Our AFFIRMATIVE vote is conditional upon the "Clean" version being voted on. There are major differences between the Red-line and clean version in Section 5 "Effective Date". The Clean version 5.1.3 requires 50 % where as Red-line version has 100 %
No
Progress Energy has a concern associated with the voltage ride through curve referenced in R5 (Attachment 2). The concern is not about setting the relay protection to ride through this transient or the generators capability of riding through such a transient but of the physical capability associated with the large pumps and motors in the auxiliary equipment that would be subjected to this transient. A lot has to do with the size of the motors at the 4160 or 6900 volt level and the control relays at the 480 volt level. After 9 cycles at zero voltage the phase of the motor decay voltage and the incoming line voltage of the large motors may have shifted significantly causing large currents to be drawn when the voltage is restored to the motor. This could cause significant cyclical torques on motor shafts that can damage the shaft over time. Also the control contactors for most 480 volt control circuits do not hold in for less than 60 -70 % voltage. The capability of UPS systems are not sufficient to power the large motors being discussed and it may not be feasible to UPS all the plant 480 volt control circuitry. (We wouldn’t be concerned with 480 if we thought we would lose higher voltage equip…) To implement this requirement as presently worded appears to be impractical and could prevent building of any new generating facilities at reasonable cost. There needs to be some ability to deviate for the specific requirements of the voltage curve in Attachment 2 if it can be show that the fault clearing time for the bulk electric system that the unit is connected to is different than the specific voltage requirements of Attachment 2 or there needs to be some more specific wording excluding the auxiliary equipment from the requirements of this voltage curve.

The division of responsibility (between GO and TP) in the task of ‘verifying’ the model should be revisited. Some GOs have neither the modeling expertise nor the software for this task. TPs typically have more experience running these types of models. We believe a more appropriate division of responsibility is to have the GO supply the field data from the response test and let the TP run and ‘verify’ the models. This would also eliminate the question of what constitutes a ‘verified’ model, i.e., how good is good enough.

(a) R5 should be limited to generating units and plants that meet the Registry Criteria. For clarity, we suggest rewording R5 with “…perform a model review of any generation unit or plant meeting the Registry Criteria, but not included as an applicable unit in Section 4.2, that includes one of the following…”. (b) Does similar language (i.e. section 4.2.4) need to be added to MOD-027-1?
No
We disagree with using a capacity factor to determine which units need to comply with this Standard. The requirements should apply to all generating units meeting the MVA thresholds, regardless of capacity factor. If the SDT decides to use the capacity factor, then the applicable facility definition needs to clearly state whether it is using the gross or net capacity per the GADS definition. The SDT also needs to define how new generation units will be captured under this Standard. In our opinion, it is unacceptable to wait three years to determine if a new generation unit meets the capacity factor limit before it is determined to be an “applicable unit”.
1) Applicability: The applicable Facility requirements should be the same for every Standard in this Project! 2) Section 4.2 should reference the Bulk Electric System definition for generation facilities or Transmission Planner requirements whichever is more inclusive. At a minimum, the BES definition should be used without differences for each interconnection. 3) Effective Dates: Ten years is too long of an implementation period and should be shortened. The reliability implications of not validating responses within the models are significant. More emphasis (a shorter time frame) should be given to correcting model errors that may lead to (or have led to) improper planning of the system based on the current model results. 4) The SDT should consider moving the “Consideration for Early Compliance” criteria from Attachment 1 into the Effective Dates section. 5) Regarding Requirements R3 and R4: The inclusion of “or a plan” extends the timeframe associated with getting good modeling data to the TP. What does the Transmission Planner do in the interim? Who is responsible for the use of the unusable or invalid data? Does the unusable or invalid data get used at all (do the plants need to disconnect until “usable” data is provided)? 6) Regarding VSLs for R1, R3, R4, R5 and R6: The numbers of days stated in the Severe VSLs need to be reconsidered. For example, in the Severe VSL for R1, no VSL applies if the performance occurs on day 181. 7) Regarding VSL R5: There is reference to Subpart(s) 5.2 and 5.3 in the High and Severe VSL text, but there are no corresponding subparts in the Standard. 8) Regarding Attachment 1: The allowed time to provide usable verified models is far too long. For example, as written there could be a gap of almost two years between the time a TP learns that a model is “unusable” and the time the GO has to provide a verified model. 9) In

Attachment 1, change “356 days” to “365 calendar days” in the third line of the table for consistency.
No
Most existing facilities are likely not designed to a frequency or voltage ride-through standard, and a useful estimate may be very difficult for owners to provide. Generator Operators may be able to document “known” equipment limitations. There are probably many examples of unknown equipment limitations, simply because a plant may not have experienced a fault condition that could expose the limitation.
No
While it is technically feasible to set generator protective relays to meet the intent of this Standard, there are technical limitations that may prevent manufacturers from achieving it, especially if the term “generating plant” includes auxiliary equipment within the plant that is required for the generator to continue to operate. The standard needs to clarify if and how the limitations of auxiliary equipment are to be addressed in connection with applicable generating facilities.
1) Purpose Statement: If we correctly understand the intent, the second comma should be removed. 2) Does the SDT want to consider any specific requirements regarding generators that are connected as synchronous condensers, and is it the intent of the standard to cover this operating mode? 3) All requirements: Need to clarify the phrase “generating unit or generating plant”. Does the “generating plant” phrase imply that the frequency and voltage setting criteria also applies to plant auxiliary equipment (referenced in R4)? In ERCOT, we have seen multiple instances where close-in faults have created low voltage conditions which caused auxiliary equipment to trip (boiler feed pumps, baghouse fans, etc.) which in turn caused a unit runback and trip. If the intent of this standard is to also cover plant auxiliary equipment, then this needs to be very clearly stated in the Applicability section and/or in the Requirements. 4) R1 and R2: The SDT may want to consider adding Volts per Hertz criteria. For example: ERCOT region criteria currently states a generator must remain connected if Volts/Hertz is less than 105% of generator design voltage and frequency, and also if Volts/Hertz is less than 116% of generator design voltage and frequency for less than 1.5 seconds. 5) R1: Need to add “or generating plant” to end of R1. 6) R2: Need to specify that the undervoltage “no trip zone” applies to both single-phase and three-phase voltage excursions. 7) R2.1.2 and 2.1.3 need to include the phrase “generating unit or generating plant” versus “generator” to be inclusive of a plant site and provide consistency throughout Standard. 8) R1 and R2 Exclusions: The SDT may want to consider these additional exclusions: a. A generating unit may trip by frequency or voltage protection while a unit is being brought on or off-line, if the trip does not result in the loss of generation to the system. b. A generation unit may trip by frequency or voltage protection if the unit is being operated below its Low Sustained Limit (LSL), where LSL is defined as the limit established by the Generator Operator that describes the minimum sustained energy production capability of the generator. c. A generator unit may trip by frequency or voltage protection if the unit is being operated in a “Test” status and is not under AGC control. 9) R3: Generator Operators should be required to document “known” equipment limitations. There are probably many examples of unknown equipment limitations, simply because a plant may not have experienced a fault condition that could expose the limitation. Also need to clearly state if this requirement (i.e. due to the phrase “generating plant”) also applies to plant auxiliary equipment, which would require the GO to provide extensive review and documentation on all of their plant auxiliary systems as well. 10) R5: Need to clearly state if this requirement applies to plant auxiliary equipment. 11) In 5.2, insert “nameplate” after “aggregate” to be consistent with R5.1.1. 12) R5 Exceptions: The SDT may want to consider these additional exceptions: (a) A generating unit may trip by frequency or voltage protection while a unit is being brought on or off-line, if the trip does not result in the loss of generation to the system. (b) A generator unit may trip by frequency or voltage protection if the unit is being operated in a “Test” status and is not under AGC control. 13) In Measures M1 and M2: See comment 3 above regarding the use of the phrase “generating plant”. Is it the intent of these measures to also cover frequency and voltage setting sheets for plant auxiliary equipment protection systems? 14) In Requirement R4, Measures M4 and M5, and some VSLs: Remove capitalization of “Frequency/Voltage Excursions” and similar terms (e.g. Frequency Excursion), which are not formally defined in this standard nor in the NERC glossary. 15) VSLs for R1, R2, and R3: What is the SDT’s intent regarding a GO that has set its relays per R1 and R2, and has no documented equipment limitations per R3, but still experiences a unit trip within the one of the “no trip” zones in Attachment 1? Is that intended to be a violation of this standard? There is not a VSL for this situation. The VSL for R5 contemplates a violation for tripping in the no-trip zone, but it only covers “new” generation units, and there is not a similar VSL

for existing units. 16) VSL for R1 and R2: The term “technical” should be replaced with “equipment” to be consistent with the Requirements. Need to replace “generator” with “generating unit or generating plant” to be consistent with the Requirements. 17) VSL for R2: Language should be similar to VSL for R1 with respect to “activated to trip” phrase and to be consistent with the Requirement itself. Suggest replacing “conditions” with “criteria” to be consistent with VSL for R1. 18) VSL for R3 and R4: What VSL applies if the communication occurs on day 61? It looks like the answer is “none.” 19) VSL for R3: See comment 9 regarding requirement R3 above. The requirement and VSL should only apply to “known” equipment limitations. 20) VSL for R4: Consider changing “unit’s performance” to “unit’s or plant’s performance.” 21) VSL for R6: Remove the phrase “or limitations,” because R3 discusses limitations and the reporting thereof and it is out of place here. 22) Attachment 1- Change “Texas Interconnection” to “ERCOT Interconnection”. 23) Regarding the Voltage Ride-Through Curve Clarifications: The reference to a generation facility’s “point of interconnection to the Bulk Electric System” is incorrect, because the generation facility is itself part of the BES. We assume this is intended to refer to the point of interconnection between the generation facility and the transmission facility, and the text should be modified accordingly.

I believe that the threshold of 20 MVA is too low. I would recommend a threshold of a (> 75 MVA)
Yes
No
My concern with this requirement is that if a GO provides an estimate of how long they believe that the unit can ride out the event, then what will happen if they do not make this target? Will the GO be held responsible for not making this time? Due to this concern how accurate are these times that are provided by the GO going to be and how much will be a built in cushion?
No
In my opinion, there needs to a definition of what is considered to be a new plant. Many plants are being built that were actually plants and projects that started 10 years ago. I do not believe that those plants should be included.

The examples in the unofficial comment form should be incorporated into an attachment to the standard for ease of reference.
Yes
Yes
We have these additional comments: a. The exclusion of synchronous condensers (and other reactive devices) in MOD-026-1 per the rationale provided in the Background (with which we agree) states “Synchronous condensers are not currently addressed in the NERC Registry Criteria” However,

companion standards under Project 2007-09 (MOD-025-2 and PRC-019-1) are applicable to synchronous condensers. The GVSDT should address this inconsistency. b. The entire section 4.2 has language that includes “directly connected to the bulk power system.” The BES is a subset of the BPS (per Order 743), and the GVSDT should consult with the SDT for Project 2010-17 – Definition of BES – to develop alternate language that instead refers to the BES.
Yes
We do not know whether new units installed 6+ years out can meet the requirements. We suggest that the team should reach out to OEMs for their input.
We have these additional comments: a. In Part 4.1 of R4, the first sentence has this proposed change, indicated by capilatization: “An estimate of the time duration the existing generating unit or generating plant will remain connected (considering performance of the auxiliary systems as well as the generator) as a result of a frequency excursion or a voltage excursion defined by the voltage or frequency profile at the point of interconnection [deleted “described by”] THAT WAS DEVELOPED FROM A dynamic simulation provided by the Transmission Planner. b. M5 is confusing. M5 states “Each Generator Owner shall have evidence, such as dated unit output records, trip investigation reports or disturbance monitoring records, showing that each unit trip did not result from a Frequency Excursion or Voltage Excursion as specified in Requirement R5, or evidence that a listed exception applied, or provide an attestation that the generating unit or generating plant did not trip.” i. Frequency Excursion and Voltage Excursion are capitalized terms – the previous version’s defined terms were supposed to be removed. ii. While is appears that an “attestation that the generating unit or generating plant did not trip” is only required for a unit or plant that remained on line during a frequency or voltage excursion, the language should be made clearer. iii. We suggest that the GVSDT consider rewording M5 to clearly state what trips should be reported, whether non-trips that occur during frequency and voltage excursions are to be reported, and what supporting evidence (or attestations) is required for each reported item. A table may be the best way to display this. Finally, M5 should be developed to produce the VSL metric for R5. c. The previously defined terms “Frequency Excursion” and “Voltage Excursion” were to be removed from this draft; however they are used in R4 and in the VSL table. The GVSDT should search the standard for all such usage and correct it.

We would suggest revision of M5 to read. Also since the two terms Frequency Excursion and Voltage Excursion are no longer to be defined by this project we would ask that you use the lower case for these terms in the standard. M5. Each Generator Owner shall have evidence, such as dated unit output records, trip investigation reports or disturbance monitoring records, showing that each unit trip did not result from a frequency excursion or voltage excursion as specified in Requirement R5, or evidence that a listed exception applied.

Consolidated Edison Co. of NY, Inc.
No
Requirement 5: • R5 authorizes the PC to apply MOD-026 to any generator not included in the Applicability section of MOD-026. This would authorize the PC to apply the standard to non-BES generation, which is not appropriate. • It is not clear what constitutes a “technically justified request” from the PC. • Refers to Planning Coordinator, but PC is not listed in Applicability section of MOD-026. • Further, under NERC Functional Model Version 5 the Transmission Planner communicates with the GO/GOP. The PC collects data from the TP’s in its area and from adjacent PC’s. See NERC Functional Model Version 5. The standards should conform to the NERC Functional Model.
Use of terms Bulk Electric System (BES) in the purpose and bulk power system in the Applicability section should be reconciled. NERC is standardizing on the term Bulk Electric System (BES). Requirement 2: • R2.1.1: requires that model results must “match” results from field testing. This language implies that there is zero tolerance which is unreasonable. There should be some stipulated allowed tolerance band. We suggest that a tolerance is a specific value based on per unit. For example, the model and actual response shall match within a tolerance of .02 per unit of the buss voltage being controlled. • The units “point of interconnection” is open to interpretation and could create compliance uncertainty. Almost all generator excitation systems control the generator terminal voltage (low side of the GSU) while the term “point of interconnection” may be interpreted as on the substation bus (high side of the GSU). A suggestion is use the following: at the buss controlled by the generator excitation system. The Applicability Section of the Standard, Section 4.2 permits exclusion of generators with a low capacity factor (< 5%). Why should the Standard allow an exemption for low capacity factor units? The objective of the Standard is to develop good excitation models for dynamics simulations, which are often conducted under high load conditions. At higher loads, these lower capacity factor units are frequently needed and operating. Therefore the Standard should apply to even lower capacity factor units. Tables following Attachment 1: the purpose of these tables is not clear, they are not referenced in the Requirements. Note, there is an entire page of technical references included in the Standard (section G). It is not clear why this is necessary, as the references are described as “beyond the scope of this Standard”.
Requirement 5.6 suggested wording revieion: Replace “may retroactively grant a temporary exemption” with “may grant a reactoactive temporary exemption”
The definition of the terms Frequency Excursion and Voltage Excursion were deleted. All references to these terms should now be lower case. Measures M4 and M5 continue to carry the prior wording and need to be revised to use lower case terms.

The examples included in the Unofficial Comment Form are helpful in understanding the periodicity requirements associated with verifying the excitatation and volt/VAr control systems model and should be moved into an attachment in the standard. The standard is not as clear as the examples and the periodicities could be misinterpreted in the future without examples.
No
We appreciate the drafting team explaining their intent that only those units that meet the Compliance Registry Criteria are included. However, the language in the standard does not communicate this and the Statement of Compliance Registry Criteria has some ambiguous criteria that makes it unclear if a generator is applicable which is further discussed below. First, applicability section 4.2.4 of the standard discusses “any registered technically justified unit”. Units are not registered. Entities (i.e. companies) are registered. A Generation Owner certainly becomes registered

by the application of the Compliance Registry Criteria to its generating fleet but there is no publicly available list to which the applicable entities can refer to identify if a generating unit met the Compliance Registry Criteria. Thus, how would a Planning Coordinator know they could make a request? Second, the Compliance Registry Criteria includes units smaller than the 20 MVA unit threshold and 75 MVA plant threshold referenced by the drafting team. Blackstart Resources are included in the Compliance Registery Criteria and there is a statement that any generator that is material to the reliability of the Bulk Power System can be included. Blackstart Resources are usually very small and most likely do not meet the 5% capacity factor requirement established in other areas of the applicability section. We are guessing the drafting team did not intend to include these Blackstart units or any others units that don't meet the 20 MVA unit threshold and 75 MVA plant threshold established in Criteria III(c).1 and III(c).2 with the Appendix 5B – Statement of Compliance Registry Criteria. For clarity, the drafting team should modify applicability section 4.2.4 accordingly to eliminate units that are not intended to be included. Third, we disagree with the statement in the Background Information section of the comment form that the applicability section would have to explicitly identify units below the Compliance Registry Criteria. Because the standards applicability is not specifically limited to the Bulk Electric System, the statement in Requirement R5 that "any/plant not included in the Applicability" means that any unit that is considered part of the Bulk Power System could be requested by the Planning Coordinator. NERC enforces standards to the Bulk Power System which could include units below the Compliance Registry Criteria. They have made this clear in response to comments on CAN-0016 that the standards are enforced to the Bulk Power System. They stated clearly "According to Section 39 of the Energy Policy Act of 2005, NERC defines the Interconnected Power Grid as the Bulk Power System. Unless otherwise restricted by a standard, it is applicable to the BPS." While the Bulk Power System has never been clearly defined, we know that it is broader than the Bulk Electric System and could certainly include units below the Compliance Registry Criteria. One solution to more fully implement the expressed intent of the drafting team would be to limit the applicability section to the Bulk Electric System. Another would be to modify "any unit/plant not included in the Applicability" in Requirement R5 to "any unit/plant on the Bulk Electric System and not included in the Applicability". While the question posed by the drafting team here indicates that their intent was for the Planning Coordinator's technical justification to indicate that the actual unit response does not match the simulated response, there is nothing in the standard or requirement that indicates this intent. In fact, it only states the request from the Planning Coordinator must be technically justified. We suggest the drafting team modify Requirement R5 to make it clearer the actual system response does not match simulated response.
Yes
We continue to believe that this standard is overly administrative by memorializing the interactions between the Generator Owner, Transmission Planner and Planning Coordinator that occur to model the generator's excitation system. Most of the requirements are purely administrative and present compliance risk to the registered owners without commensurate reliability benefit. Addition of administrative requirements acts contrary to the recent efforts of FERC and NERC to eliminate compliance backlogs created by violations of requirements that present no reliability risk or benefits. This is the purpose of the FFT process that NERC initiated and FERC recently approved. Interestingly, within the approval order, FERC even suggested that these types of requirements need to be eliminated. Only two requirements are really needed to accomplish the purpose of this standard. They are: one requirement for the Generator Owner to perform the test and one for the Transmission Planner to verify the model is accurate. Requirement R3 highlights the overly administrative nature of the standard and the problem with attempting to memorialize the cooperation that must occur between the Generator Owner and Transmission Planner to model the generator's excitation and volt/VAr control functions accurately. Requirement R3 allows a Generator Owner to simply respond with a technical basis for leaving its model intact which does not solve the Transmission Planner's model issue. Thus, this requirement does nothing for reliability because modeling problems can not be left unsolved. It should be struck. We are not convinced Requirement R4 is needed. The situation of providing model updates when changes are made to the covered control systems is already covered in Attachment 1. Since Attachment 1 is referenced in Requirement R2, why is this additional Requirement R4 needed? If Requirement R4 is needed, we are assuming the drafting team did not think this situation was covered in Requirement R2. If this is the case, at the very least, Requirement R4 should reference Attachment 1. Otherwise, Attachment 1 would not ever apply to the situation of

applicable control system changes. For Requirement R5, there is no clarity for how soon the Generator Owner has to address the model concerns communicated by the Planning Coordinator. If the Generator Owner has the unit in its 10 year plan to test their generation fleet's control systems, they could simply communicate that plan which might be much longer than the Planning Coordinator intended. The drafting team needs to provide more guidance on whether the Generation Owner is expected to accelerate their plans for the unit in question by the Planning Coordinator and by how much. For Requirement R5, who decides if the request is technically justified? Could the Generator Owner simply choose not to respond because they do not believe the request is technically justified? In the Background Information section of the comments, the drafting team indicated that the "standard is drafted to provide the proper cost/benefit balance for performing generator verification". Since the summaries of field test results posted with the second draft of the SAR indicate the costs of these tests could range from $5,000 to $50,000 for a single unit and that does not even include opportunity costs from lost energy sales should the test cause the unit to trip, we believe it would be helpful for the drafting team to provide information on the cost/benefit that was discussed in the Background Information section of the comment form in the next posting. The response to our comments regarding consideration for early compliance from the last posting was not satisfactory. In our comments we stated that we appreciated the drafting team's consideration to allow for early compliance based on past tests. However, we stated concerns regarding how to demonstrate this compliance because a registered entity was not required to retain documentation and may not be able to prove they completed a test. The drafting team responded that demonstration of compliance was beyond the scope of the drafting team. While we agree demonstration of compliance for specific companies and situations are likely beyond the scope, demonstration of compliance in general is never beyond the scope. Drafting teams must write standard requirements with which can be complied. Given that the issue of evidence retention from before the effective date of the standard was one of the key subjects in the High-level review conducted by NERC for CAN-0008 recently at the request of the Trade Associations, we suggest the drafting team should consult the appropriate NERC subject matter experts to determine how to avoid these similar issues with this draft standard. Sections 4.2.1.2, 4.2.2.2, and 4.2.3.2 are confusing and potentially contradictory. First, these sections state that they apply to each generating plant/Facility greater than 100, 75 and 50 MVA respectively. Then, the second bullet under each of these sections applies to generating plant/Facility. How can there be a plant within a plant? With the first bullet, it appears the intent is to include generating units 20 MVA and greater within generating plants meeting the 100, 75, or 50 MVA thresholds, respectively. However, the second bullet really confuses us because it appears to bring in everything below 20 MVA which is not covered in the first bullet. These sections are further confused by the fact that they potentially apply a different threshold for individual generating units than section 4.2.1.1, 4.2.2.1, and 4.2.3.1 which apply to individual generating units. For example, 4.2.2.1 applies a 75 MVA threshold to an individual generating unit and then the first bullet of section 4.2.2.2 applies a 20 MVA unit threshold because it defines a generating plant/Facility as including one or more units. Using plant/Facility confuses the matter further. The NERC Glossary of Terms uses a generator as an example of a Facility. In the second bullet under each segment, it appears the discussion is totally focused on a plant but despite the use of the singular Facility. The VRFs simply do not meet the NERC definitions for anything greater than Lower. Requirements R2 and R6 are written with Medium VRFs. All other requirements have Lower VRFs. Neither Requirement R2 nor R6 could be construed as affecting the electrical state or capability of the Bulk Electric System or the ability to monitor, control or restore it. Per NERC definition of Medium VRF, these are prerequisites for meeting a Medium VRF. For Requirement R1, the VRF justification for FERC Guideline 5 refers to the requirement having a high risk objective. This is not consistent with a Lower VRF. We agree with the Lower VRF and recommend removing the "high risk objective" language. All of the measurements use language that sounds like it is creating a new a requirement and is not consistent with language used in any other NERC standard. They all use "must include". It is more typical to use "shall demonstrate", "shall make available", etc. These measurements should be made consistent with other NERC standards. All evidence requirements for proof of transmission should be dropped as they go above and beyond basic evidence requirements. Some examples of the proof include dated postal receipts, dated confirmation of facsimile, etc. When is a dated and signed letter not sufficient proof? Must it also be sent by registered mail? Furthermore, any of the proofs of transmission do not prove anything other than something was transmitted. They do not prove the evidence was transmitted. For example, a confirmation report will not prove anything other than some fax was sent. Even dated and time stamped email proves only that the email was sent. It does not prove it was received. The

Compliance Enforcement Authority section is not the latest approved language being used by NERC. In the data retention section, there is no length of time given for how long a Generation Owner must retain information for Requirement R2 and its associated measurement. The High and Severe VSLs for Requirement R5 need to be updated. They still refer to Subparts 5.2 and 5.3. The Subparts have been changed to a bulleted list which means they are options. Thus, missing one and meeting the other is full compliance and not partial compliance as the VSLs suggest. We suggest the drafting team write a brief paragraph at the beginning of the Reference section to explain the inclusion of the References. Currently, it states that those references contain technical information that is out of scope of the standard. If so, what is the purpose of including them? We are not against including them but just believe a short explanation for their inclusion is necessary. The verification periodicity for row 3 in Attachment 1 needs to be updated from 356 days to 365 days. Furthermore, the drafting team should consider using a year to account for leap years. Otherwise, every four years we are shifting the compliance date up by one calendar day.
No
This requirement will essentially be redundant with standards MOD-026 and MOD-027. MOD-026 already requires the Generator Owner to verify its excitation and volt/VAr control systems. MOD-027 already requires the Generator Owner to verify its frequency response and its turbine/governor, load control and active power/frequency control models.
No
It is not clear to us why this requirement is needed given the many tariffs that already exist to govern interconnection requests. These tariffs already have well established facility connection requirements. If the requirement persists, we believe it actually belongs in the FAC-001 standard which establishes facility connection requirements for new facilities including generators. While we believe that this requirement is probably technically achievable in most cases, there should be exceptions available. It looks like Part 5.3 will allow the Transmission Planner to offer these exceptions. However, this does not consider that the Transmission Planner in many cases (especially organized markets) is not the entity evaluating interconnection requests. Thus, the Planning Coordinator should be allowed to grant exceptions in those situations as well. The need to supply the bases for the estimate in Part 4.2 is not clear, offers no reliability benefit and is administrative in nature. Of the three bases listed, (experience, actual event histories, or sound engineering judgment) what will the RC, PC, TOP, or TP do with the bases? Will they decide the bases are invalid and substitute their own judgment? If so, what is the purpose of getting an estimate from the Generation Owner anyway? It appears to be a documentation requirement that offers no reliability benefit or even information for which the recipient of the information could take action.
Because NERC has made clear that standards are enforced against the BPS and not the BES, the applicability section should be modified to state clearly that it applies to Facilities that are part of the BES. Otherwise small generators that do not affect reliability could be impacted by these standards. NERC enforcement has made this clear in response to comments on CAN-0016 that the CIP-001 standard applied only to the BES. They stated clearly: “According to Section 39 of the Energy Policy Act of 2005, NERC defines the Interconnected Power Grid as the Bulk Power System. Unless otherwise restricted by a standard, it is applicable to the BPS.” Use of “new or existing” as a description for the generators in Requirements R1, R2 and R5 is confusing. What exactly constitutes new and why is it relevant? The requirements are performance requirements that apply to in-service generators so how does new help explain this further? The footnote in Requirement R5 only further confuses the situation since it is not included in Requirements R1 and R2. Part of the confusion likely centers around Requirement R5 applying to maintaining new generators frequency and voltage excursion performance as well as designing and building it. If “maintain” was removed from Requirement R5, we believe “new” could be removed from Requirement R1 and R2 and they essentially become the maintenance requirements. Furthermore, “new and existing” is not used consistently within other requirements such as Requirement R4. It is not obvious why it would not apply to Requirement R4 it if applies to Requirements R1 and R2. Neither Requirement R1 nor R2 state within the main body of the requirement that the Parts are intended to be exceptions to the requirement. For clarity, there should be a statement (i.e. except when the Parts 1.1 and 1.2 are met) within the requirement that makes this clear. For Requirements R1 and R2, it is not clear if the sub-parts are the only reasons that allow for exceptions if other equipment limitations exceptions are allowed. Other equipment limitations should be allowed, and these requirements should be clarified to allow them. As written, Requirement R5 appears to be assumed to apply to a new generator in perpetuity. We draw this

conclusion from the inclusion of "maintain" in the requirement. We think it makes more sense to have this requirement apply only to designing and building a new unit and then have the requirements that apply to existing units apply to the maintenance of the new units once they are established. The standard does not appear to allow "new" generating units to have frequency and voltage excursion performance limited by equipment. It should allow "new" equipment as it experiences normal wear and tear as well as damage for any other reasons to document its equipment limited frequency and voltage performance and communicate it similar to Requirements R1 through R3. Otherwise, a Geneator Operator with a "new" generator that has damaged equipment will be forced between operating the unit in a limited manner providing reliability support to the BES and possibly in violation of this standard or taking a forced outage to avoid violating the standard and experiencing escalated penalties for knowingly violating the standard. We do not believe that Reliability Coordinator is the proper entity to grant a temporary exemption in Part 5.6. Rather, it is the Planning Coordinator that should grant the exemption. Furthermore, this is not consistent with other requirements such as Parts 2.1 and 2.1.1 that specify the Transmission Planner grant the exemption. Of course, Part 5.6 would not be necessary if Requirement R5 did not deal with maintaining the unit and allowed the other requirements that apply to existing units to address maintenance. We do not believe the VRFs for Requirements R1, R2 and R5 warrant High VRFs. The BES is already operated within each BA and TOP for the loss of a single unit. Tripping of a generator due to a frequency or voltage excursion is an uncommon event that is already planned for. It is highly unlikely that tripping of such a generator or even several generators will lead to instability, system separation or cascading which is required for the VRF to be High. Furthermore, by setting the VRF to High, this increases the potential that every single unit outage could become subject to a Compliance Violation Investigation which is simply not necessary.

We Energies
Yes
add more explicit detail to the Table to indicate that the exemption may apply to some wind farms, solar resources, etc.
No
We strongly oppose this Requirement as unnecessary to the reliability of the BES. Requirement R5 should be removed from the draft Standard. Either the standard is applicable to a generating unit, or it is not. A generating unit that is not covered in the Applicability section should be exempt from the requirements of this standard unless the standard is revised under the approved standards development process. The SDT's assurances to the contrary are not sufficient. This requirement will allow the possibility of sweeping more generators into the requirements than is necessary.
a. In Section A3. reference is made to Bulk Electric System (BES) reliability. Then, in Section A4, there are repeated references to the "bulk power system" (BPS). Please clarify the distinction, and why the standard needs to refer to both the BES and the BPS. We believe all references should be to the BES. The use of "bulk power system" could possibly lead to the inclusion of generating units in the Applicability which are not connected to the BES, and should not be subject to this standard. b. In Requirement R1, instead of the TP providing "instructions", the standard should require the TP to simply "provide" the model data and the list of acceptable models, block diagrams, etc, to the GO upon request. The TP already has the expertise with these models and the dynamics software applications, and has easy access to the necessary information. Since the Generator Owners in most cases will not have access to the dynamics software and associated libraries, it would be more efficient to have the Transmission Planner provide the information (list of acceptable models, block diagrams/data, and existing in-use model data) instead of instructing the Generator Owner how to obtain it. c. In Requirement R2.2, the GO is responsible to provide a verified aggregate model for multiple generating units rated less than 20 MVA. This will be an unreasonable burden on the GO, which typically does not have the modeling experience or the need to develop these equivalent models. The requirement should be more flexible to allow the GO the option to provide the same unit-specific data that is required for units rated 20 MVA or higher, or else to make the requirement applicable to both the GO and TP to allow them to work together to develop a suitable aggregate

model. d. In R2.1.1, the GO is required to provide documentation that the generator model response matches the recorded response for a voltage excursion. Since the GO often does not have the capability to run dynamic studies, how will it obtain the “model response” for comparing to the recorded response? We suggest that this requirement be modified to require that the GO “provide the recorded response for a voltage excursion”. As presently written, R2.1.1. can only be required of the TP. Further thought and guidance needs to be given to this matter, as well as the availability and type of recording equipment needed to capture the voltage data as required in R2.1.1. There needs to be a recognition that the Transmission Planner and Generator Owner will need to work cooperatively on this. The goal is good, but this standard is not nearly developed enough to be a useful standard.
No
It is very difficult to estimate generator performance during frequency or voltage excursions, especially frequency, and the best efforts to provide an estimate may not provide a meaningful result. It is proposed that the TO or TP could achieve the objective better by tracking transmission system voltage/frequency events that could have resulted in abnormal voltages at generating stations, and work cooperatively with the GO informally to determine the generator performance.
a. Most generator voltage relaying is supplied from generator voltage transformers on the low-voltage side of the generator step-up transformer (GSU). It is necessary to provide the information needed for the Generator Owner to relate relay settings on the low-side of the GSU to the No Trip characteristic in Attachment 2, which is based on voltages on the GSU high-side. b. In Attachment 2, please clarify whether the No Trip zone includes the lines, similar to what was done in Attachment 1.

Manitoba Hydro
No
Manitoba Hydro agrees with the concept for manually switched capacitor banks but disagrees for automatic capacitor banks. A model should be required for automatic capacitor banks.
Yes
The implementation plans/effective dates for the standards MOD-025, MOD-026, MOD-027, and PRC-019 in Project 2007-09 should be the same to reduce unnecessary outages and to maximize the productivity of site visits. Manitoba Hydro suggests that the implementation plan for MOD-026 be applied to MOD-025, MOD-027 and PRC-019.
Yes
Yes
Manitoba Hydro is voting negative for the following reasons: 1 - Implementation time frames - the implementation plans/effective dates for the standards MOD-025, MOD-026, MOD-027, and PRC-019 in Project 2007-09 should be the same to reduce unnecessary outages and to maximize the productivity of site visits. Manitoba Hydro suggests that the implementation plan for MOD-026 be applied to MOD-025, MOD-027 and PRC-019. 2 - R5 ‘walk down’ - the requirement of a ‘walk down’ of equipment in R5 is unclear. Manitoba Hydro suggests that the wording be revised to ‘based on an onsite review of the equipment.’ 3 - Data Retention - The data retention requirements are too uncertain for two reasons. First, the requirement to “provide other evidence” if the evidence retention period specified is shorter than the time since the last audit introduces uncertainty because a responsible entity has no means of knowing if or when an audit may occur of the relevant standard. Secondly, it is unclear what ‘other evidence’, besides the specified evidence in the Measures, an entity may be asked to provide to demonstrate it was compliant for the full time period since their last audit. Manitoba Hydro also suggests that synchronous condensers be included in MOD-026.
No
More detail is required in R4 to ensure that the Transmission Planner can model behavior before and after the disturbance. Information should be provided on how long the unit should take to ramp back to full power following a voltage or frequency excursion that doesn’t cause the unit to trip.
Yes

Manitoba Hydro is voting negative for the following reasons: 1 - R1 - the facility interconnection document required through FAC-001 should supersede Attachment 1 in order to best address local area issues. R1 should be revised to specify this. 2 - NERC IVGTF Task Force Document - the SDT should consider the recommendations from the NERC IVGTF Task Force 1.3 document. Specifically, the recommendations regarding clarifying the potential coordination issues between TPL-001 and PRC-024, clearly defining performance requirements for unbalanced and balanced faults, and defining the performance required during and after disturbances and making clear and unambiguous statements as to what remaining “connected” entails (i.e. how much real power is expected to be delivered post disturbance and how long until the normal pre-disturbance power can delivered) should be considered. 3 - Low Voltage Ride Through clarification - more information is required on the low voltage ride through curve. The GO should be required to provide unit outputs and ramp rates for the different voltage transitions and levels on the ride-through curve. 4 - Data Retention - The data retention requirements are too uncertain for two reasons. First, the requirement to “provide other evidence” if the evidence retention period specified is shorter than the time since the last audit introduces uncertainty because a responsible entity has no means of knowing if or when an audit may occur of the relevant standard. Secondly, it is unclear what ‘other evidence’, besides the specified evidence in the Measures, an entity may be asked to provide to demonstrate it was compliant for the full time period since their last audit.

Attachment 1 is confusing, in 2 aspects: a. Attachment 1 starts off with a heading and a blue-shaded page in which the verification periodicity requirements are clearly stated. It is not clear whether or not the 3 by 12 table that follows is a part of Attachment 1 and whose content is part of the periodicity requirements that must be complied with. b. This question (Q2) suggests that guidance is provided on the periodicity aspects of Attachment 1. Is the content in the 3x12 table meant to be guidance? If so, it should be clearly stated so that it does not need to be complied with. If not, where and what is the guidance that the SDT refers to?
Yes
Yes
a. Requirement R2.1: We continue to disagree with the phrase “models acceptable to the Transmission Planners” as it is a potential source of dispute between the TP and the GO. Requirement R1 already asks the TP to provide instructions and model data to its requesting GO but makes no reference to “acceptability”. To avoid potential disputes, we suggest that R2.1 be reworded to: R2.1. Perform verifications using one or more models provided by the Transmission Planner in R1, that include(s) the following information: ….. b. We continue to disagree with Parts R6.1 to R6.3 which set the criteria for usable model. The stipulated criteria may not be accomplished even if the GO provides an accurate excitation control system and plant volt/var control function model, especially if such devices are new for which there are no previous simulations to benchmark with. A computer model may fail to initialize due to reasons other than inaccuracy in the submitted excitation control system and plant volt/var control function model itself, and a no-disturbance simulation may not result in the excitation control system and plant volt/var control system model exhibiting positive damping due to other system parameters. System damping is affected by many other dynamic performance contributors such as other generators, system topology, power flow levels, voltage levels, excitation system and power system stabilizer settings, etc. In short, having an accurate excitation control system and plant volt/var control function model does not necessary guarantee or equate to meeting the conditions stipulated in the three parts. We suggest this requirement be removed.
No
As indicated in our previous comment, we do not support having a requirement to obtain such an

estimate. First of all, the requirement does not distinguish whether it applies to units that are equipped with frequency/voltage protective relays or otherwise. Secondly, the intent of providing the suggested estimate is to allow Transmission Planners to apply valid or supported assumptions in their planning studies. Given the requirements in Attachments 1 and 2 and Requirement R3 and the information already received, a TP can apply the following relevant assumptions to its planning studies: i. For units that are equipped with frequency/voltage protective relays, the GO's submitted relay settings will determine when the units will trip; ii. For units that are NOT equipped with frequency/voltage protective relays, the units are conservatively assumed to trip when the simulated frequency/voltage goes outside the bounds of Attachments 1 and 2. We do not see what other estimates that can be more relevant and valid than the above. We see that there may be some value in providing these estimates but only in the case of generators not equipped with frequency/voltage protective relays where tripping takes place beyond the no-trip zones of Attachments 1 and 2. For this information to be useful however, the generator's behavior must be predictable. While it may facilitate some "what-if" analysis, it is not clear that using this information would be more valid than applying the conservative assumption "b" above. We cannot envisage a Transmission Planner to use this additional information if this information cannot be ascertained to be more valid. In short, we do not believe provision of this estimate will provide any more valid assessment of a generator's expected performance than a TP's conservative assumptions drawn from available information already provided by the GO and Attachments 1 and 2. The estimate does not provide any reliability benefit at all. We suggest the SDT remove this requirement altogether.
We believe this requirement is achievable for most cases. However, provision should be given to the Generator Owners which for specific technical reasons are unable to design a generating unit to comply with the requirements. As worded, R5 does not contain this provision. We therefore suggest that R5 be appended with ", or provide the technical reasons why this is not achieveable" after "the following conditions and exceptions".
a. Requirement R1: We believe the words "or generating plant" are missing at the end of R1 since the requirement addresses frequency protection relay settings for new or existing generating unit and generating plant. b. Requirement 4: In the last posting, we commented that: "We do not support the requirement to provide an estimate of the performance of the units during frequency and voltage excursions. First of all, the requirement does not distinguish whether it applies to units that are equipped with frequency/voltage protective relays or otherwise. Secondly, the intent of providing the suggested estimate is to allow Transmission Planners to apply valid or supported assumptions in their planning studies. Given the requirements in Attachments 1 and 2, and Requirement R3, the TPs can apply the following relevant assumptions: (i) For units that are equipped with frequency/voltage protective relays, the GO's submitted relay settings will determine when the units will trip; (ii) For units that are NOT equipped with frequency/voltage protective relays, the units are conservatively assumed to trip when the simulated frequency/voltage goes outside the bounds of Attachments 1 and 2. We do not see what other estimates that can be more relevant and valid than the above. We see that there may be some value in providing these estimates but only in the case of generators not equipped with frequency/voltage protective relays where tripping takes place beyond the no-trip zones of Attachments 1 and 2. For this information to be useful however, the generator's behavior must be predictable. While it may facilitate some "what-if" analysis, it is not clear that using this information would be better than the conservative assumption "b" above. How does the SDT envisage that the Transmission Planner will use this additional information if it cannot be relied upon? The SDT responded that "The "estimate of performance in 25% increments" portion of the requirement has been removed. The SDT agrees that it would not improve reliability." We do not agree that removing the 20% increment part goes far enough to achieve a good quality standard. In our view, based in argument put forth in our previous comments, the whole requirement does not add any value to reliability. We again suggest the SDT to remove this requirement altogether." c. Requirement R4.1, last sentence "If the Generator Owner expects the existing unit, generating plant will remain connected…..". We believe the "," before "generating plant" should read "or". d. The proposed implementation plan for both standards conflicts with Ontario regulatory practice respecting the effective date of implementing approved standards. It is suggested that this conflict be removed by appending to each of the sentences in Section A5, after "following applicable regulatory approval", of the two standards to the following effect: ", or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities."

Agree with the generating unit nameplate thresholds as defined in this standard, but do not agree with eliminating the 100kV interconnection criteria from section 4.2 of this standard and replacing it with the undefined term “bulk power system.” This subtle difference greatly expands the applicable scope of the standard from the previous draft version and would now include units that are not defined as being a part of the BES. The term “bulk power system” (BPS) is not defined within this standard, nor is it found in the NERC glossary of terms. Section 215 of the FPA defines the term “Bulk Power System” as follows: (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof) and (B) electric energy from generating facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy. In effect, the statutory term “Bulk Power System” defines the jurisdiction of FERC. On November 18, 2010 FERC issued Order 743 (amended by Order 743A) and directed NERC to revise their definition of “Bulk Electric System” (ref. Project 2010-17) so that the definition encompasses all Elements and Facilities necessary for the reliable operation and planning of the interconnected bulk power system. As such, the applicability of this Reliability Standard should be limited to those generation facilities included in the BES definition, and not those subject to the broader BPS definition. The latest NERC BES definition includes generation resources consistent with the capacity thresholds in the Compliance Registry; however, the 100kV interconnection voltage clause in the BES definition limits the scope to those units necessary for the reliable operation of the interconnected bulk power system. In conclusion, Section 4.2 should be modified to remove the undefined term “bulk power system” and either re-instate the 100kV interconnection constraint, or reference those generation facilities as defined in the NERC BES definition.
Yes
Agree in principle with attempting to quantify the ability of the unit (including affect on plant auxiliary systems) to remain connected during voltage and frequency excursions. However, the present wording of this requirement may not result in sufficient information to fully model the performance of the unit in dynamic studies. It may be more constructive to request a modified set of voltage and frequency ride through curves (similar to Attachments 1 & 2) that represent the Generator Owner’s best estimate of a no trip zone for each unit, taking into account the performance of plant auxiliary systems, as well as any other protection / control setting, or operational limitation, that would prevent the unit from remaining on line within the no-trip zone as defined in Attachments 1 & 2. This would provide the Transmission Planner with sufficient information to fully model the anticipated performance of the unit in their dynamic studies.
Yes
Yes, it is possible to design a new facility to operate within the requirements identified in this standard. However, it may require specification of equipment with higher than normal overvoltage capabilities. Also, significant analyses would have to be conducted on the behavior of plant control systems (exciter controls, boiler controls, etc.), as well as equipment connected to auxiliary busses (including low voltage motor contactors) to ensure that all systems are designed with appropriate ride-through capabilities.
1) If it is critical to the reliability of the BES to not have generators trip off line for voltage excursions associated with close in three phase faults, then it is equally as important to have them remain on-line for single line to ground faults, which are much more common. During a phase to ground fault at the point of interconnection the faulted phase voltage collapses to zero but the unfaulted RMS phase to ground voltages could rise as high as 80% of the RMS line to line voltage for an effectively grounded system (with a coefficient of grounding = 80%). This is well in excess of the 1.2 p.u. overvoltage requirement presently shown in Attachment 2. As such, for the unit to ride through phase to ground faults at the point of interconnection then the short time 1.2 p.u. overvoltage threshold at the point of interconnection needs to be raised above 0.8 x 1.73 = 1.38 p.u.. In summary, the overvoltage portion of the curve in Attachment 2 should be modified to require the unit to stay

connected with a 138% phase to ground overvoltage appearing at the point of interconnection for up to the expected clearing time of a Zone 1 phase to ground fault. 2) The standard should make clear whether the no-trip zone shown in Attachments 1 and 2 includes the boundary curves themselves. 3) To add clarity and avoid confusion, the ordinate of the graph in Attachment 2 should be labeled Per-unit RMS Voltage Measured at the Point of Interconnection. 4) The current language in Item #1 of the "Voltage Ride-Through Curve Clarifications," which appears on the last page of the standard, may cause problems for generator interconnections on the 500kV system. Most transmission Planners use "nominal" transmission system voltage levels as the "base voltage" in their system models. These are the same "nominal" system voltages specified in ANSI C84.1. In most cases, C84.1 shows the maximum allowable system voltage as 105% of nominal, with the exception of 500kV. For 500kV systems the maximum system voltage is 550kV, and it is routine to operate the transmission system above 525kV (105% of nominal). If the "base voltage" at the point of interconnection used in planning studies is 500kV but the system is normally operated above 105%, then the generation protective systems must be capable of maintaining operation with the continuous voltage at the point of interconnection above 105% of "nominal" (at least for 500kV systems). This being the case the voltage base in Attachment 2 for 500kV systems will by necessity have to be something other the "nominal base voltage" used by the Transmission Planner in their system models. Perhaps this could be addressed by re-wording Item #1 to read "1. The per unit voltage base for these curves is to be specified by the Transmission Planner at the point of interconnection to the Bulk Electric System (BES)." By removing the reference to "the base voltage used in the system models by the Transmission Planner" it eliminates the conflict mentioned above. On the other hand it now requires the Transmission Planner to provide this "other than nominal base voltage for 500kV systems" to the Generator Owners. 5) The word "crest" should be removed from Item #5 of the "Voltage Ride-Through Curve Clarifications," which appears on the last page of the standard . The voltages referred to in this standard are all per-unit "RMS" voltages, not "peak" or "crest" voltages. 6) Typically unit connected generator protection packages, which include frequency and voltage protective elements, are supplied by voltage transformers connected on the terminals of the generator rather than on the high side of the generator step-up (GSU) transformer. For frequency elements, the frequency at the terminals of the generator is the same as on the high side of the GSU transformer. So comparison of frequency protective element set points can be made directly with Attachment 1. However, this is not true for voltage. The generator terminal voltage could be higher, or lower, than the system voltage on the high side of the GSU transformer depending on the voltage drop across the transformer, which varies depending on the generator real power output and whether the generator is supplying or absorbing reactive power. Since this standard requires the generation to remain connected for specific voltage criteria as measured at the point of interconnection, but the voltage sensing protection is connected to the generator terminals, some technical guidance (with specific examples) must be provided to allow the Generator Owner to properly translate these voltage criteria to the voltages seen by the protective relays on the terminals of the generator. Otherwise an incorrect evaluation may result. It is recommended that a Technical Reference Document similar to the "Power Plant and Transmission System Protection Coordination" document developed by the NERC System Protection and Control Subcommittee be produced, or the above mentioned document revised, to provide illustrative examples of how to apply the Attachment 2 POI voltage criteria to voltage sensing protective elements connected to the terminals of the generator.

ISO New England Inc
No
While some plants may not have excitation systems, per se, they can have complex reactive coordination controllers, whose settings and functions should be tested and verified.
Yes
No
No, Footnote 4 in the Applicability Section implies comparing simulated unit or plant response to a dynamic system event. This is not acceptable, verifying the model only after an event as called for is completely counter to increasing system reliability. In addition, analyzing an event and determining that a particular generating unit model is inaccurate will prove difficult in practice. We feel the

applicability section needs further revision, by requiring only generators above 100 MVA with unit capacity factors above 5 % to test, about 30% of the installed generation in New England does not require model validation. We believe this is a large portion of the generation that is being exempted. Additionally, the low capacity factor units will likely be running during the periods when the system is being stressed the most and reliable operation is being most challenged. We realize that a model for the generators and associated equipment is supplied in accordance with MOD-012 but we feel the accuracy of such models may be limited and a higher percentage of generator validation is required. Footnote 4 should be changed to allow verification of generator models not required under the applicability to be at the discretion of the Transmission Planner. In some areas of the system, generator models have a considerable impact on dynamic performance and model accuracy is critical.
Yes
While we support the clarifcation of capacity factor, please note our concerns with an exclusion for units with less than a five percent capacity factor that are included with question 3.
We suggest that the language for R4 be made more clear and state as follows. “R4. Each Generator Owner shall provide revised model data or plans to perform model verification5 (in accordance with Requirement R2) to its Transmission Planner 180 calendar days prior to making changes to the excitation control system and plant volt/var control function that alter the equipment response6characteristic. The way the language is currently written, the generator merely has to provide its plans for model verification. This means that 6 months after a change has been made, the correct data still may not have been made available to the Transmission Planning. This could have a significant impact on reliability. The suggested language would be in line with FERC approved language that is currently part of ISO Tariffs.
Yes
Yes
The exception in 5.2 should not be allowed. Each generating unit that is registered based on the NERC Registry Criteria as a single unit, or as part of a generating facility, should comply with PRC-024 without exception. Simultaneous loss of 10 percent of the generators at a number of installations could introduce severe reliability concerns. This standard appears to allow loopholes which undermine reliability.
ISO New England has comments on Requirement R2 and R3: R2 Although the time duration is acceptable ISO-NE does not agree with the band shown. The band is shown as 0.95 p.u to 1.05 p.u at the point of interconnection. Parts of the New England system have not been designed to maintain steady state operation within this band. The band needs to be expanded to 0.90 pu to 1.05 pu. We also believe there are a number of other parts of the system outside of New England which would have similar concerns. Failure to make this change means that it is acceptable for generators to trip during steady state operation of the system on “low” voltage. Unanticipated tripping of generators under steady state conditions could lead to significant reliability concerns on the system. R3 The ISO would like to reiterate its previous comment that R3 is a significant concern. In the event that a generator has a piece of equipment which prevents it from meeting the requirements of R1 and R2, such as a motor contactor which drops out on voltages in the “No Trip Zone”, there is no requirement to correct the issue. Instead, the generator must only document the limitation. This completely undermines the intent of this standard. There is no point to setting undervoltage relays to meet the curve if other equipment is still going to trip the plant. This standard appears to simply documenting system concerns rather than identifying and correcting them.

Yes
Yes
We agree that the current wording (which removes the requirement to provide a probability of ride through) is an adequate means of achieving the reliability goal.
Yes
We believe the requirement is technically achievable, but question whether the additional cost to design and build plants to meet this goal is the most effective way to spend money to increase grid reliability.

ATC recommends that the SDT give consideration to the following: 1. In Requirements, R1, bullet 2 – change the wording to be more similar to bullet 1, "obtain model library block diagrams and/or data sheets that are acceptable to the Transmission Planner for use in dynamic simulations". Software manaufacturer model library block diagrams and data sheets are usually proprietary and most Generator Owners do not own the license to receive them. As in the more general wording bullet 1, requiring instructions to simply obtain acceptable diagrams and data sheets, allows the Transmission Planner to provide instructions for obtaining either public (IEEE standard) or proprietary diagrams and data sheets depending on the Generator Owner licenses or lack of licenses. 2. In Event Triggering Verification Table, Item 6, Cell 1 – fix typographical error of ". . . system event did not "did not" match . . ."
Yes
Yes
ATC recommends the SDT give consideration to the following: 1. In Requirements R2 – the text refers to "non-protection system equipment" but this terminology is not defined. ATC recommends that the SDT provide some definition/description and perhaps a list of this type of equipment in a footnote to improve clarity. 2. In Requirements, R3 – ATC recommends that the SDT add the requirement that the GO provides the expected duration of the limitation, if it is known.

Florida Municipal Power Agency
Frank Gaffney
The applicability refers to the "bulk power system", e.g., "4.2.1.1 Individual generating unit greater than 100 MVA (gross nameplate rating) directly connected to the bulk power system". The term "bulk-power system" should not be used in the standards as it is ambiguous and should be replaced

with “Bulk Electric System” We do not understand how the Applicability of 4.2.1.2 means. We suggest making the language clearer. R2.1.1 should only apply if a system disturbance actually happens and should not require a staged test. A staged test could threaten the reliability of the BES more than inaccuracy of an excitation system model. R4 should specifically exclude temporary changes, e.g., generator AVR settings are often changed when the unit is started or shut-down, if the AVR is planned out of service, etc., we believe the intent of the standard is only to communicate more permanent changes and not temporary changes. R5 is ambiguous. What is technically justified? Who gets to decide what is technically qualfied?
R3.1, the second bullet, should be clarified to explain that the equipment replaced is plural, meaning all equipment causing a limitation would need to be replaced, e.g., if one piece of equipment was replaced, but another stil causes a limitation, the “grandfathering” of existing equipment lmimtations should still be in place. R1 and R2 are inconsistent with R5, bullet 5.2. R1 and R2 provide no exceptions for a new plant/wind farm/solar farm, R5 bullet 5.2 does. R6 is ambiguous as to whether or not any time any protection settings are changed, whether or not they violate the curves, the entity has to notify and provide the settings. It should be limited to only generators that violate the curves. Or is it that all trip settings of all generators are intended to be modeled? We would think that we do not need to model the generator trip settings for those that meet the curves because the UFLS program is supposed to prevent us from reaching those curves. Hence, we should only need to model the trip settings of those generators that do not meet the curves.

ReliabilityFirst
ReliabilityFirst abstains on the MOD-026-1 ballot and offers the following comments for consideration: 1. Facilities a. What is the rationale/justification for the size qualification for applicable units (i.e. greater than 100 MVA)? ReliabilityFirst believes all generating units connected to the BES and referenced in the NERC Statement of Compliance Registry Criteria should be included within this standard. 2. Requirement R1 a. For the purposes of NERC standards, “bullets points” are to be considered “OR” statement. ReliabilityFirst believes all the “bullets points” in R1 are required and should renumbered into sub-parts (i.e. 1.1, 1.2, 1.3) 3. Requirement R5 a. ReliabilityFirst is unclear on the meaning of the term “walk down of the equipment” in the second bullet? ReliabilityFirst request further clarification of the term “walk down of the equipment?” 4. Requirement R6 a. ReliabilityFirst requests further clarification on the term “initializes” as referenced in Subpart 6.1. Is this in the context of excitation control system and plant volt/var control function model initialization within a PSSE application? 5. Section G. References a. ReliabilityFirst recommends removing the references in Reference Section G and place it into a reference type document. Even though this good information, it is not needed in a Reliability Standard. 6. VSL Requirement R2 a. Requirement R2 contains a sub-part 2.2 which is not mentioned in the corresponding Violation Severity Level (VSL). ReliabilityFirst recommends including a VSL covering Subpart 2.2. Here is an example of a “lower” VSL: “For plants that are comprised of units that have a gross nameplate rating of less than 20 MVA in Requirement R2, Subpart 2.2, the Generator provided the Transmission Planner verified models, using plant aggregate model(s), that omitted one of the six Parts identified in Requirement R2, Subparts 2.1.1 through 2.1.6.” 7. VSL Requirement R5 a. The VSL for “High” and “Severe” mention Subparts 5.2 and 5.3 though there are no associated subparts referenced in Requirement R5 (there are only 2 bullet points). ReliabilityFirst recommends removing the references to Subparts 5.2 and 5.3. 8. VSL Requirement R6 a. R6 requires the Transmission Planners to “…notify the Generator Owner within 90 calendar days… “, while the corresponding VSL states “The Transmission Planner provided a written response to the Generator Owner indicating…” Based on the FERC Guideline #3 "Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement," ReliabilityFirst recommends the following as an example of the “Lower” VSL: “The Transmission Planner notified the Generator Owner indicating whether the model is useable or not useable;

including a technical description if the model is not useable, more than 90 calendar days but less than 120 calendar days of receiving verified model information. (R6)”
ReliabilityFirst votes in the affirmative for the the PRC-024-1 standard because the standard further enhances reliability by ensuring that generating units remain connected during frequency excursions. Even though ReliabilityFirst votes in the affirmative, we offer the following comments for consideration: 1. Requirement R5 and associated Subpart 5.1 a. ReliabilityFirst believes there is a potential conflict and seeks clarification on the choice of words between Requirement R5 and associated Subparts 5.1 and 5.1.1. Requirement R5 begins by stating “Each Generator Owner shall design, build, and maintain its new unit or new generating plant…” which lends itself more to the “planning” type stages while Subpart 5.1 states “When the generating unit or generating plant is operating at or above the minimum sustainable generation threshold” which lends itself to actual “operation” of the unit. ReliabilityFirst questions how the conditions in Subpart 5.1 and 5.1.1 can be utilized if the actual “operation” of the unit has yet to be observed since Requirement R5 is dealing with the design stages of a new unit? 2. Requirement R6 a. ReliabilityFirst request further clarity regarding whether the parenthetical, “(that monitors or models the associated unit),” is associated with all the requesting entities listed in Requirement R6 (RC, PC, TOP, and TP) or just the TP. 3. VSL Requirement R5 a. Requirement R5 states “Each Generator Owner shall design, build, and maintain its new unit or new generating plant so that it will not trip due to a frequency excursion or voltage excursion.” The VSL states “The Generator Owner’s generator tripped due to a Frequency Excursion within the no-trip parameters set forth in attachment 1”. Based on the FERC Guideline #3 "Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement," the language in the requirement is not consistent with the associated VSL. It is not a violation of Requirement R5 if the generator tripped offline within the no-trip parameters, rather it is a violation if the GO failed to design, build, and maintain its new unit or new generating plant so that it will not trip due to a frequency excursion or voltage excursion. ReliabilityFirst recommends the following language for the “High” VSL, “The Generator Owner failed to design, build, and maintain its new unit or new generating plant so that it will not trip during a frequency excursion within the no-trip parameters set forth in Attachment 1. OR The Generator Owner failed to design, build, and maintain its new unit or new generating plant so that it will not trip during a voltage excursion within the no-trip parameters set forth in Attachment 1. b. ReliabilityFirst also noted there is no mention of the Subparts 1.1 through 1.7 in the VSL (ReliabilityFirst understands that these are “Conditions and Exceptions” but they should somehow be incorporated into the VSLs.

Yes
No
The tiered approach of MOD-026 Attachment 1 are both unorganized and more complex than necessary, and is confusing as a result. The same approach could be communicated in a more succinct format. In addition, there is content within the attachment that is not mentioned anywhere else in the standard, such as the initial verification of new units and dealing with equivalent units at the same physical location.
Yes
The team might wish to consider if the Transmission Planner should also be included in the applicable facilities 4.2.4 and 5. Point of clarification: one does not “register” units, rather entities are registered for NERC functions.
For section 4.2 we suggest the term “bulk power system” be replaced with “Bulk Electric System”. BES is currently being defined, while bulk power system currently does not have a definition and thus is ambiguous. In the second bullet of 4.2.1.2, one of the words “comprised” or “consisting” needs to be removed as they are redundant. Also, we are confused by the bullets in 4.2.1.2 which should be re-worded to clarify the intent. For example, would diesel generators at a larger facility be in scope of

this requirement? Furthermore, the qualifier between the two bullets should be “or” rather than “and”. For the effective date, we recommend not mixing years and quarters. Instead, we recommend that the total number of quarters be used, otherwise it is unclear if the effective date is the quarter following the year or the quarter at the end of that year. Throughout the standard, “generator excitation control system and plant volt/var control function model” should have an “or” rather than an “and”. The second footnote in requirement 4 could be interpreted to be all-inclusive. Please check the numbering of all footnotes and the pages that those footnotes reference. References should only be made to footnotes on the same page as the referring number.
Yes
AEP agrees with this approach for Attachment 1 only. We also have the following comments about the reference to Attachment 2 in R4. The reliability advantage to be gained from the inclusion of Attachment 2 is unclear, unprecedented and potentially costly. With respect to Attachment 1, any information that a GO can provide about a potential for their unit to trip within the no-trip zone of Attachment 1 will assist the Planning Coordinator in devising a UFLS program for their area, which they are obligated to do under PRC-006-1. A successfully designed UFLS program depends on knowing whether or not generation would trip prior to operation of all stages of UFLS. If it is known that a generator could trip prior to all stages of UFLS, apart from protection settings that would be reported to them under R1 of this standard, the PC ought to know that. Of course, we understand that a GO would not be held accountable under R4 for unknown factors that may result in tripping of their unit within the no-trip zone of Attachment 1. Attachment 1 should be referenced because it would be difficult for the TP to come up with simulation results that would adequately convey in a comprehensive fashion the coordination that should take place between UFLS and generation tripping apart from Attachment 1. We also believe reference to Attachment 1 is necessary for consistency in the application of R4 throughout an interconnection. We therefore conclude that it is desirable for overall reliability purposes to reference Attachment 1 in R4. We also point out that curves of the nature of those in Attachment 1 have long existed as guidelines for generation performance during frequency excursions in each of the reliability regions. GOs are familiar with these types of curves, and generating units have been designed with these guidelines in mind. With respect to Attachment 2 being referenced in R4, the reliability advantage is not as clear, but we ask the SDT to consider again that it may be difficult for the TP to come up with simulation results that would adequately convey in a comprehensive fashion the possible voltage excursion events that a generating unit may be subject to, and for which it may be desirable to know whether or not a given generating unit would be able to ride through that disturbance. Reference to Attachment 2 may be desirable for, again, consistency in the application of R4 throughout an interconnection. However, in contrast to frequency, voltage is a local quantity and so it is not as critical to system reliability that GOs report voltage excursion trips within the no-trip zone of Attachment 2. The translation of the no-trip zone of Attachment 2 to internal generating plant voltages that would need to be determined is not straightforward, though that translation would need to be made by a GO regardless of whether they would receive point-of-interconnection voltage simulations from a TP or be directed to Attachment 2. We conclude that reference to Attachment 2 in R4 may have reliability benefits that the SDT may want to consider, but we do not believe reference to Attachment 2 is as essential as reference to Attachment 1. If the SDT did not include reference to Attachment 2, that should not have a bearing on the reference to Attachment 1. We assert that, because of the different characteristics of frequency and voltage, it would not be inconsistent to reference Attachment 1 but not Attachment 2.
No
AEP believes that the requirement for new units and plants to not trip within the no-trip zone of Attachment 1 is reasonable, and has precedence in existing reliability region guidelines. To not trip within the no-trip zone of the Attachment 2 is another matter. AEP believes Attachment 2 is inappropriate as a requirement on conventional generation for the following reasons: (1) It has not been found necessary to impose such a requirement as Attachment 2 on conventional generation in the past and we question why this should be proposed now. The appearance of such graphs seems to have been in response to the performance of wind farms that tripped off-line by protective relays when minor fault disturbances occurred on the transmission system. Attachment 2 may thus be an appropriate requirement for wind turbine generators and other non-conventional generation. We ask the SDT why such a requirement now needs to be imposed on conventional generation. If this is being done solely for the standard to appear technology neutral, it does not remove the fact that a new, unnecessary, and possibly onerous requirement is being imposed. (2) Application of Attachment 2 to

conventional generation is not straightforward because of the need to translate point-of-interconnection voltage to plant or unit internal voltage, particularly in the time period following fault removal (.15 seconds). Conventional synchronous generators have a substantial capability to control the voltage they are subjected to during a system disturbance (unlike most wind farms) and whose critical auxiliary systems are usually (and should be) served from the generator bus (low side of GSU) and are thus shielded to some degree by the GSU impedance from voltage excursions on the transmission system. (3) Back in 2005, FERC Order 661-A contained a requirement for wind farms to ride through point-of-interconnection faults up to 9 cycles as determined by the actual fault clearing time at the interconnection station. The final order was thought to be sufficient to ensure wind farm fault ride-through by intervening parties including NERC and AWEA without the need for a graph along the lines of Attachment 2. Justification for the content of the final order was that all generation would be treated equitably. Why does the SDT now think it necessary to impose Attachment 2 on new generation? It would seem that deference to TPL standards for the types of transmission system disturbances where stability should be maintained should continue to be an acceptable ride-through criterion for all types of generation. Reference to Attachment 2 in R5 should thus be replaced by a requirement for all generation to ride through normally cleared 3-phase or unbalanced faults at the POI not to exceed 9 cycles. (4) We do not know the incremental cost to comply with Attachment 2 under R5; however, we believe that it could be very costly to design and build synchronous generating units that would, with a high degree of confidence, remain on-line for any and all disturbances whose POI voltage falls within the no-trip zone. Attachment 2 would also be a new requirement without historical precedent and the SDT has not stated how reliability would be improved. With uncertain reliability benefits and uncertain and potentially high incremental costs to comply, we do not think the SDT is in a position to impose this requirement. For these reasons, we believe that reference to Attachment 2 in R5 should be removed.
R2 is very “wordy”, essentially a single run-on sentence which references yet additional material in its two footnotes, making it difficult to follow. This could be made more clear with the usage of bulleted items. R2.1.1 through R2.1.4 could be and perhaps should be R2.2 through R2.5. R3: We recommend adding “known” to R3 such as “…shall document each known equipment limitation…” to make clear that a GO is not responsible for a cause they are not aware of. R3: The second point under R3 causes the limitation to expire with rating increases. Is a 10 percent or more rating increase a realistic scenario and common enough to justify attention? 10 percent seems arbitrary and this provision could pose a hindrance to rating increases that may supply other reliability benefits. It may be advisable to remove this point. R4.1 should include the Planning Coordinator in addition to the TP because the PC is responsible for UFLS coordination and assessment in PRC-006-1. R5.2 should be removed because of its obvious partiality toward wind farms. R5.6 needs to include coordination with the Planning Coordinator because of the PC’s responsibilities with respect to automatic UFLS. This should also perhaps include coordination with the Transmission Planner for exceptions on voltage excursion ride-through.
Individual
Michelle R D'Antuono
Ingleside Cogeneration LP
Yes
We agree that there is no useful purpose served by requiring a GO to validate voltage performance on those generators where an active voltage regulator is not used. The modeling of passive capacitor and reactor banks has been established for many years and does not likely need any improvement.
Yes
We support the efforts by all project teams to clearly define the implementation and subsequent periodic evaluation time frames – as well as those that may result from changes in the facility or models. Unfortunately, any assumptions or gaps in the timelines will force NERC’s Compliance team to address them through a CAN, which do not allow for sufficient vetting by the industry. In the case of MOD-026-1, we believe that the proposed intervals are sufficient to perform the voltage performance model validations; however they are initiated.
No
Ingleside Cogeneration believes that Item 4.2.4 under the “Applicability” section was intended to capture the concept that a Planning Coordinator’s request for additional information is limited to NERC-registered units. However, the language of requirement R5 will predominate, and it reads as

follows: “R5. Each Generator Owner shall provide a written response to its Planning Coordinator,within 90 calendar days following receipt of a technically justified request from the Planning Coordinator to perform a model review of any unit/plant NOT INCLUDED IN THE APPLICABILITY (our emphasis) that includes one of the following” This provides clear instruction that the entire Applicability section may be ignored – even Item 4.2.4. We suggest the following language instead: “R5. Each Generator Owner shall provide a written response to its Planning Coordinator,within 90 calendar days following receipt of a technically justified1 request from the Planning Coordinator to perform a model review of any NERC-REGISTERED unit/plant not included in the Appliability that includes one of the following” 1 Technical justification is achieved by demonstrating that the simulated unit or plant response does not match the measured unit or plant response Please notice that we also added the footnote under Item 4.2.4 to R5. Although this update is essentially a duplicate, it leaves no doubt to the limits of an exceptional model validation request by the Planning Coordinator. Secondly, MOD-026-1 already takes Ingleside Cogeneration LP out of its comfort zone by requiring the ownership and validation of interconnected system performance simulations. This is normally a Transmission Planner or Transmission Operator function, not a Generator Owner. We believe that the Planning Coordinator must first engage these entities before issuing such a request to the GO.
Yes
Ingleside Cogeneration strongly agrees with the SDT’s use of the capacity factor calculation used in the GADS system. It is always important to establish links to time-tested parameters – and eliminating any possibility that some other calculation is used.
1. Ingleside Cogeneration LP cannot agree with the change in the applicability section of MOD-026-1, which references generation connected to the “bulk power system” rather than the NERC-defined term “Bulk Electric System”. This bypasses the express intent of the NERC Glossary to carefully describe concepts which otherwise can be unevenly applied at the disrection of Regional audit teams. In fact, this action ignores the work output of Project 2010-17 “Definition of the Bulk Electric System” which was carefully crafted by the entire industry in response to FERC Docket RR09-6-000 – which was issued to eliminate exactly these kinds of ambiguities. 2. What could possibly be a technical justicfication for including generators below that included in the Applicability Section. Without this in the Standard, it leaves it open to whatever the PC is inlinded to do. If you have a “catch all” requirement, you need to have a specific set of technical requirements to limit the PC’s descretiion. 3. Registered Entities below the individual unit thresholds of 100MVA, 75MVA, and 50MVA do not need to be modeled unless there is technical justification. This is a significant burden on small generators. Small generators should only be required to provide model verfication where the PC can show justification through a set of criteria.
No
Ingleside Cogeneration believes that this is an open-ended requirement that allows multiple planning and operations entities – not just Transmission Planners – to require complex assessments completely at their discretion. There is no allowance for the availability of GO resources nor any need for the requestor to provide a reliability justification. Furthermore, we would like to point out that the modeling validation requirements of MOD-027-1 (frequency) and MOD-026-1 (voltage) must, by definition, include the impact of protective relay settings. This means that a need for an estimate of performance is not necessary as real performance data will always be available. In addition, these Standards already allow recourse for a re-validation if Transmission Planners cannot reconcile their models with actual generator performance.
Yes
In our view, the time frame allotted to accommodate PRC-024-1’s frequency and voltage ride-through specifications for new generating facilities is reasonable.
Ingleside Cogeneration LP fully supports the goal to standardize voltage and frequency ride-through settings. In addition, we recognize the benefit to provide accurate generator modeling information and perform regular performance validations to system planners. However, such activities come at a price and compete for the same resources needed to support BES reliability in other ways. Furthermore, there is a cost to develop new PRC-024-1 compliant generation technologies – or to harden existing ones. This may improve reliability over the longer term, but could delay or even rule out the deployment of promising capabilities early on. These are all considerations that we know that the project team is aware of, but we will continue to point out the hidden costs of compliance

wherever we believe that a justification of its advantages is not immediately obvious.

Appendix F of the GADS Data reporting has two Capacity Factor calculations (Gross and Net). The standard should specify Net Capacity Factor.
No
An estimate of the time that a unit would remain on-line during or following a voltage or frequency event described by a Transmission Planner would be difficult if not impossible considering the complexity of the auxiliary system and would result in little value to the Transmission Planner. There is no known methodology to provide a consistent estimation or calculation of the value. Luminant recommends that the requirement be removed from the standard.
No
Although this requirement may be achieveable, it is highly probably that as the unit ages, components will begin deteriate such that they will not be able to ride through severe voltage or frequency excursions. For example, Luminant has done testing of 480v contactors that when purchased new exhibit a drop out voltage level but over time, the drop out level will deteriate to a level. Since there is no method for determining when to replace equipment susceptible to voltage ride through criteria, this requirement is not auditable for the maintain requirement. The “maintain” requirement should be removed. The cost of meeting this requirement could potentially discourage new generation. Overall, requirement R5 provides little benefit to the reliability of the BES, and Luminant recommends that this requirement be removed.
1. Requirement R1 and R2 discuss generator frequency and voltage relaying to be set such that they do not trip within the “no trip zone” of Attachement 1 and 2 respectively. Luminant believes that these requirements should only apply to relays that use frequency or voltage sensing only. Impedance, and voltage controlled over-current relays should not be included since they are part of the Generator Loadability and AVR Control standards. Relays using both voltage and frequency should not be part of the standard. Alternately, if volts per hertz relays are included, Luminant recommends that an additional requirement R2.2 be added to take in consideration volts per hertz relays. R2.2 would become “Generator volts per hertz relaying shall not cause a unit trip for conditions that are less than 116% of generator rated design voltage and frequency and last for less than 1.5 seconds.” For footnote 1, individual curves would have to be listed for each protective relay function, as the Attachement 1 curve is for voltage relays only. 2. R3 is an administrative requirement that provides little or no benefit to the BES. Luminant recommends that the requirement be removed, and Requirements R1 and R2 should be modified to delete the reference to R3 as follows; “ … unless the generator owner has identified an equipment limitation …” 3. R6 should be at a minimum of 90 days due to some entities have a large number of generating units. 4. Overall, this standard should address voltage and frequency relay settings only.

Footnote 4 – strike the phrase “or plant” in both places, since this only applies to a unit. Also add the phrase “and by demonstrating a reliability need” to the end of Footenote 4. Otherwise, this standard could be made applicable to a small unit that has no impact on reliability.
No
Need to specify “net” or “gross” capacity factor for the calculation.
• R2, 2.1.3 – Please revise to specify total inertia. Total unit inertia should be given to include all coupled rotating elements. The way this is currently worded, it could lead generators to only provide the generator H values. • R2, 2.2 – Insert the phrase “or individual unit” after the word “aggregate”. • Page 15, Equivalent applicable unit - Identically designed generation units are identical in control response, independent of site location. New techniques for validation eliminate the impact of the grid on the validation efforts. Thus, credit for sister unit validations should be available independent of the location of a unit or connected voltage.
No
Generator Owners don’t currently have the capability to provide this information, and will need time to obtain the capability and perform the studies. Requirement R4 should be removed from Effective Date sections 5.1, 5.2 and 5.3 because one, two or three years is insufficient time. R4 should have its own effective date section specifying an effective date of the first day of the first calendar quarter five years following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter five years following Board of Trustees adoption. Requirement R4 should also be revised to allow the Generator Owner 180 days (instead of 60 days) to respond to a request and provide an estimate of a unit’s performance during frequency/voltage excursions.
No
The proposed bands should be considered by new plant designers and incorporated into their design basis if feasible. Specific criteria have not been provided in new plant design guidance provided by EPRI Utility Requirements Document (URD) nor in other industry standards used by new plant designers. The frequency band was considered for some new plant design basis and no concerns were identified. It's not clear if all or even most of the designers for other nuclear/fossil designs have considered this. The proposed voltage band has caused many concerns and probably is not achievable for existing or new steam plants because electrically powered equipment (motors, MCC components, contactors, etc.) has been and is normally designed for proper operation as follows: The normal voltage boundaries have been specified to be for the steady-state operating conditions based on the ANSI C84.1-2006 “American National Standard for Electric Power Systems and Equipment – Voltage Ratings (60Hz)”as follows: a. Normal Conditions: ±5% Continuous Duration b. Emergency Conditions: ±10% not specified Duration These Criteria are currently widely used in practice and can be complied with by all types of new generating plants designed with an in-plant voltage regulation capability. In connection with these criteria, all new equipment, both on the transmission system and in new generation plants must be chosen in order to be able to operate and withstand these voltage excursions. For transients, the above should be applied for conditions lasting more than one second. Transient conditions lasting more than one second, can be more severe and the equipment can still ride through it. A design solution to address severely degraded voltage lasting more than one second is to utilize expensive voltage regulation devices, normally not utilized at power generation plants. This standard shouldn’t dictate a solution to the situation where a generator goes offline due to low voltage on the transmission system, because in many cases the generator going offline may not be a problem for the overall transmission system. In situations where it is a problem, a collaborative effort between the Transmission Planner and the Generator Owner would be the best approach (see AREVA white paper that has been provided to the SDT). An R&D effort should be considered to investigate steam plant ride through capabilities if a criteria is needed.
The frequency and voltage ride-through curves are at the point of interconnection. Conditions inside a generating plant will depend upon how the generator responds to the transient. Models will have to be

built and validated against plant-specific auxiliary equipment performance expectations.

MRO NSRF
WILL SMITH
Yes
Yes
No
It is suggested the following modification to R5 will more clearly mirror the SDT intent as depicted in the question: "…any unit/plant meeting the Registry Criteria not included in the Applicability that includes one of the following…"
Yes
Please give consideration to the following suggestions from the MRO NSRF: 1. In Requirements, R1, bullet 2 – change the wording to be more similar to bullet 1, "obtain model library block diagrams and/or data sheets that are acceptable to the Transmission Planner for use in dynamic simulations". Software manaufacturer model library block diagrams and data sheets are usually proprietary and most Generator Owners do not own the license to receive them. As in the more general wording bullet 1, requiring instructions to simply obtain acceptable diagrams and data sheets allows the Transmission Planner to provide instructions for obtaining either public (IEEE standard) or proprietary diagrams and data sheets depending on the Generator Owner licenses or lack of licenses. 2. In Event Triggering Verification Table, Item 6, Cell 1 – fix typographical error of ". . . system event did not did not match . . ." 3. Please restructure requirements and evidence to allow for posted instructions and model data to meet compliance for appropriate requirements such as R1,R2, etc… 4. In the second bullet item under Applicability Section 4.2.1.2, recommend the drafting team remove the word "consisting" and add the word "solely" to avoid confusion. Section 4.2.1.2 would instead read "Each generating plant / Facility comprised consisting solely of …". 5. Recommend the capacity factor test in Applicability Section 4.2 be revised to state: "Applicable units or plants with an average capacity factor greater than 5 percent …" As currently drafted, it is unclear as to whether all units, applicable or not, are included in the calculation of the Capacity Factor (CF). In cases where an entity has a plant with one 60 MVA unit and three 15 MVA units, the units less than 20 MVA would not be applicable per the criteria in MOD-026-1. However, would all units still be factored into the CF calculation? 6. Requirement R6.3 specifies "a disturbance simulation results in …. exhibiting positive damping". Guidance is needed as to what is considered acceptable positive damping. 7. R6 has two periods at the end of the paragraph just before [Violation Risk Factor …] 8. In the applicability section 4.2, the undefined term bulk power system is used. To avoid confusion regarding the applicability, it is recommended the defined term Bulk Electric System be used.
No
Since most existing facilities are likely not designed to a frequency or voltage ride-through standard, the estimate may be very difficult for owners to provide. Staged testing would not be practical for making this determination and engineering analysis may not have the accuracy to make it useful for use by Transmission Planners.
No
A Standard cannot tell us what or how a generator needs to be built. Section 215 of the Federal Powers Act "(i) Savings Provisions, (2) This section does not authorize the ERO or the Commission to order the construction of additional generation or transmission capacity or to set and enforce compliance with standards for adequacy or safety of electric facilities or services". We believe that R5 is directing "GO's to design, build and maintain new unit…" and is in violation to the Federal Power Act as stated above. As R5 is written, if an entity builds a new unit and it trips for a voltage or excursion event within the parameters of Attachment 1 and 2, the entity is non compliant. This Requirement seems to be based on future technology that does not exist today. The SDT should state that the parameters of Attachment 1 and 2 "should" prevent a unit from tripping. R5 is written as an absolute and may reduce a new unit from being built. With the risk of non compliance being $1 million per day, it is easier and less risky not to even build a new unit.

The MRO NSRF believes that an entity having to attest to the fact that a generating unit or plant did not trip offers no foreseeable benefit to reliability. As currently stated, Measure M5 could be interpreted to mean that an entity would need to provide a letter of attestation each day or month a generating unit or plant were to function as intended. The MRO NSRF recommends the drafting team either remove this statement or else rephrase the Measure to avoid the expectation that entities verify normal operation. Additionally, as frequency excursion and voltage excursion are not NERC-defined terms nor terms to be defined as part of this project, recommend the terms be placed in lowercase letters to maintain consistency with the Requirement. M5. Each Generator Owner shall have evidence, such as dated unit output records, trip investigation reports or disturbance monitoring records, showing that each unit trip did not result from a FfrequencyEexcursion or VvoltageEexcursion as specified in Requirement R5, or evidence that a listed exception applied, or provide an attestation that the generating unit or generating plant did not trip. Please give consideration to the following suggestions: 1. In Requirements R2 – the text refers to “non-protection system equipment” but this terminology is not defined. Provide some definition/description and perhaps a list of this type of equipment in a footnote to improve clarity. 2. In Requirements, R3 – add the requirement that the GO provides the expected duration of the limitation, if it is known. 3. Request MOD-026 and MOD-027 be verified for redundancy with PRC-024. In the applicability section the only reference is to Generator Owner. It is recommended the applicability section include a statement that the affected units are only those that are a part of the Bulk Electric System.

Richard Vine
California Independent System Operator
The California Independent System Operator Corporation has adopted tariff requirements for generator frequency and voltage ride through capabilities that apply to synchronous generators as well as requirements for generator frequency and voltage ride through capabilities that apply to asynchronous generators. As written, the requirements of draft PRC-024-1 apply to both synchronous and asynchronous generators. The ISO requests that the Generator Verification Standard Drafting Team confirm this reading of draft PRC-024-1, and suggests making this clarification in PRC-024-1 as well.

Yes
The SDT has done a great job. The requirement is simple, clearer and supports reliability.
Yes
No
This type of data is not going to result into any more accurate simulation than the existing methodology which does not include this data. There are many other inaccuracies involved in modeling and scenario planning for islanding studies. It is a misconception that just by having more complex modeling will improve accuracy and thus reliability.

No
Yes, the requirement is technically achievable. However there is a problem with measure and how compliance may enforce it. Generating units trip for many other reasons other than frequency and voltage excursions. The meaure, as written, will require a GO to prove that the unit(s) did not trip due to frequency or voltage excursion which may be impossible to prove. Even if it finds other reasons, it may be hard to prove that frequency and voltage excursion did not contribute to that other reason. Thus, a GO may be non-compliant unless for each unit trip it can clearly prove that the frequency and voltage excursion did not contribute to trip, which may be impossible to prove.

Yes
Yes
Conditionally yes; unconditionally no. It is achievable for any plant with a modern AVR and unit connected auxiliaries. Problems arises for unique circumstances that may require auxiliaries that are not unit connected (directly connected to transmission systems). Existing plants orginally designed with unit connected auxiliaries have been forced to extend auxilary power feeds directly from transmission level voltages. It is believed that transmission system performance better than Attachment 2 is available at the majority of locations, and therefore, it is not necessarily appropriate to make this the design criteria for every future generating station.
Thank you to the SDT for you efforts to produce a quality standards. R3 should be worded in a similar manner to R4. “The Generator Owner shall document the estimated equipment limitations…” The problem with a requirement like R3, is that documenting “each” equipment limitation on older

facilities will contain uncertainties and unknowns. The implementation schedule for the requirements will be more efficient if the schedule is aligned with the PRC-019 schedule rather than having the two similar efforts on different tracks.

If the GVSDT intends to incorporate definitions or calculations from Appendix F of the GADS Data Reporting Instructions, the relevant information needs to be expressly incorporated, perhaps in an additional attachment to the standard. Requirements that refer to outside materials are not helpful and should be avoided (notwithstanding the desire to avoid a future need to modify the standard to the extent that Appendix F is amended from time to time in the future).
Yes. See below: 1. PacifiCorp does not support the addition of the term "bulk power system" to Section 4.2.2.1 of the "Applicability" section. The term is ambiguous and, in this context, fails to provide the clarity afforded by either the previous language ("at greater than or equal to 100 kV") or the defined term of "Bulk Electric System." PacifiCorp suggests maintaining the existing applicability language, including the "directly connected" qualifier so that the sentence reads as follows: "Individual generating unit greater than 75 MVA (gross nameplate rating) directly connected to the point of interconnection at greater than or equal to 100 kV." 2. PacifiCorp believes that the second bullet under Section 4.2.2.2 of the "Applicability" section introduces confusion for registered entities. If we correctly understand the intent of the GVSDT, then please consider the following language to replace the two existing bullets: • "Each individual generating unit greater than 20 MVA (gross nameplate rating), plus an aggregate model for the other generating units of less than 20 MVA at the plant/Facility; and • Where there are no individual generating units greater than 20 MVA in a plant/Facility with total generation greater than 75 MVA (gross aggregate rating), an aggregate model for the generating units of less than 20 MVA." 3. PacifiCorp agrees that the addition of sub-Requirement 2.2 is a good clarification, but believe that the language could be further clarified to remove unnecessary confusion by amending the sub-Requirement as follows: "For generating plants/Facilities with total generation greater than the thresholds established in the Applicability

section of this standard that are comprised of units that have gross nameplate rating of less than 20 MVA, each Generator Owner shall perform its verification using plant aggregate model(s) that include the information required by Requirement sub-parts 2.1.1 through 2.1.6."
Yes
No
While PacifiCorp has no concerns with this Requirement R5 as applied to new units or generating plant/facilities meeting the point of interconnection frequency excursion performance depicted in Attachment 1 (for the corrected WECC curve), PacifiCorp believes that new units or generating plant/facilities should meet the voltage excursions performance depicted in Attachment 2; however, ultimately it will be up to generator manufacturers to implement necessary facility changes to withstand the voltage excursions.

The comments and guidance of the GVSDT are greatly appreciated. However, we have a concern/question, how would the periodic verification/testing requirements for MOD-026 would align with other such requirements in place for MOD-024, MOD-025 and with reporting requirements of MOD-012 and MOD-013? We would like the GVSDT to consider a well-coordinated periodic verification and reporting needs for all such requirements to provide the GO flexibility to schedule their tasks to meet these requirements without undue burden to take facility out of service at different times.
No
We believe and recommend that this should be the responsibility of the Transmission Planner rather than the Planning Coordinator. At a minimum the language should state “Planning Coordinator and Transmission Planner”.

Yes
(1) The requirements 4.2.1.1 and 4.2.1.2 refer to bulk power system (BPS). We suggest that GVSDT includes definition of BPS in the standard. (2) We suggest that GVSDT clearly specify that "point of interconnection" referred to in R2.1.1 to be the same as defined in PRC-024-1. (3) In Attachment 1, Row 4 it seems to imply to us that some use of "Sister Units" is allowed to meet the requirement. . We suggest that the GVSDT clarify and include this option in the body of the Standard (preferably) or in Attachment 1 as an option? (4) Requirement R2.2 states that an Applicable plant with gross nameplate ratings of the units < 20 MVA should use a plant aggregate model. Can the GVSDT clarify the type of model and provide example for each? (5) There are 17 technical papers referenced in Section G of the Standard. Would the GVSDT make them available on the NERC website? (6) For Requirement R3, we did not find anything in the standard that specifies how closely a model response must match the tested response of a generator. We believe that unless this is clearly specified, it could lead to disagreements between the Generator Owner and Transmission Planner over what constitutes a verified model.
No
At the end of R4.2, we suggest to add “the Transmission Planner’s voltage recovery characteristic from R2 part 2.1.1” since that may well have bearing on the estimate. We understand the reasons for such studies, but we ask the GVSDT to consider the fact that more than 60 days may be needed to estimate generating unit performance especially the first time it is done for each unit. As long as this applies only to generator frequency and voltage protective relaying (and not to station auxiliaries) developing these estimates in the time frame mentioned earlier is achievable.
No
(1) We understand this to include generating plant auxiliary load based on the GVSDT reply to our draft 2 comments. If still is the case, please clarify and explicitly insert “including its auxiliary systems” after generating plant so that all GO understand it. (2) Many 480V class contactors drop out in the 70% to 80% voltage range, so we doubt they’ll ride through the 2 to 3 second portion of the voltage excursion. The middle portion of your voltage excursion curve is more stringent than the CBEMA and SEMI curves, both of which recover to 80% in 0.5 sec. Transmission system protection in our system will clear faults faster than the proposed voltage excursion curve, thus in effect yielding a voltage recovery curve with shorter durations for the voltages specified. We would ask the GVSDT to consider what we feel is a more realistic approach of designing a new generating facility to the Transmission Planner’s voltage recovery characteristic allowed for in R2 part 2.1.1 is achievable now. What was the basis on which the proposed voltage excursion curve developed?
(1)Under Applicability it should state that ‘all existing generators meeting registry criteria’ and also ‘new generating units that will meet the registry criteria.’(2)Please modify the Effective Date and Implementation Plan to provide a five year phase-in to match that of the companion PRC-019-1. Generator voltage protective relaying must be reviewed in both these standards, and we believe that doing so on the same schedule will yield a better coordinated result and less confusion. Each of these standards will consume valuable resource time and the efficiency of reviewing each generator concurrently will improve BES reliability. (3)Please add ‘R1, 1.3 If clearing a system fault necessitates disconnecting a generator, then this action is acceptable within the “no trip zone”.’ This affords the same practical reality recognized for voltage excursions.(4)Please be clearer regarding the Voltage Ride-Through curve. Attachment 2 Voltage Ride-Through Curve Clarification #2 could be interpreted to imply that the curve is based on three phase faults. But the inclusion of #5 states that phase-to-ground or phase-to-phase voltages (minimum or maximum as appropriate) are assumed. Of course, for a three phase fault the each phase’s voltage is equal. So we interpret #5 to mean that the actual fault type to be simulated should match the Transmission Planning criteria, which for example may be double or single line to ground faults with delayed clearing. We recommend to the GVSDT to align this with the TPL standards, which use three phase fault or single line to ground fault with Normal Clearing, but only single line to ground fault with Delayed Clearing. We would appreciate an example or in depth explanation to tie these together. Please annotate Attachment 2 with references to R2 and clarifications on page 18. (5)Delete ‘or generating plant’ from R1, R2, and R3 to be clear that the generating plant auxiliary loads are not subject to these requirements. Alternatively, restate R3 as “…that prevents a generator frequency or voltage protective relay generating unit or generating plant, from meeting the criteria in Requirements R1 or R2 including study results, experience from an actual event, or manufacturer’s advisory” to be consistent with R1 and R2. (6)At the end of Requirement

R4.2, please add “the Transmission Planner’s voltage recovery characteristic from R2 part 2.1.1” since that may well have bearing on the estimate. (7)From our perspective, Requirement R5 doesn’t make sense for a newly designed generator. We would suggest the GVSDT to realign M5 to be prospective and to require the GO to provide design basis evidence appropriate for the stage of design of new generators. In early conception stages, the GO would request the Transmission Planner’s frequency and voltage excursions. Then the GO would design the generator train and auxiliary system to ride through, and if infeasible, request technical exceptions. Late in the design process the generator frequency and voltage protective trip settings would be determined; it would be appropriate at that time to provide them R6 requests for future system studies. (8)For Requirement R6 we oppose providing this specific information to all these functional entities, given that they are getting the R4 estimate of performance during such excursions. (9)If R6 is retained, please make the following changes: (a) We strongly prefer a reporting of exceptions to the standards frequency and voltage excursion ride-through curves rather than reporting all these relay settings. Use PRC-006-1 Attachment 1 page 28 of that standard for frequency reporting. Develop a similar envelope for voltage reporting. If a Transmission Planner’s voltage recovery characteristic allowed for in R2 part 2.1.1 differs that should be provided for the generators in their area. Generator Owners would then report exceptions. (b)Insert “frequency and voltage” between generator and protection in the first line.(c)Delete “and within 30 calendar days of any change to those trip settings,” because this creates an open ended obligation on the GO. (10)We would suggest the GVSDT to not capitalize frequency and voltage excursions as they are no longer defined terms. (11)We suggest the GVSDT to replace the time-based or binary VSL for R1, R2, R3, R4 and R6 with a VSL in terms of the GO % of MWh produced for the time period of violation. This better characterizes the risk to BES reliability. We propose <5% for Lower, 5 to 10% for Moderate, 10 to 15% for High, and >15% for Severe. As presently proposed a generator with no operating hours could cause a GO to incur a Severe violation though it posed no risk to the BES. (12)From our perspective, the VSL for R5 doesn’t make sense for a newly designed generator. We suggest, a time-based VSL with x days late in providing R4 or R6 type information. . In this regard, we propose to the GVSDT 30 days late for Lower, 31 to 60 days late for Moderate, 61 to 90 days late for High, and >90 days for Severe. (13)PRC-024-1, R2.1 states that generator terminal voltage refers to Attachment 2. However, in R2 itself, footnote 3 states that voltage excursion applies to point of interconnection, meaning the GSU high-side. We suggest the SDT resolve this discrepancy. (14)Attachment 2 should include footnote similar to footnote 3 provided for R2.

FirstEnergy would like to make the following comments on this standard: 1)Under the Applicability section 4.2.1.2, the use if the term "common bus" should be clarified as either the low-side or high-side of the GSU. 2)Footnote 1a on Page 2, says that “... the generator excitation control system includes the generator, exciter, voltage regulator and power system stabilizer.” While we understand that the excitation system supplies the generator field, there is a separate Model for the Generator (typically GENROU). We suggest omitting the word generator from the footnote to avoid confusion. 3)Suggest rewording 2.1 to begin with, “Provide models acceptable to the Transmission Planner, including verified parameters ...”, rather than “Perform verifications ...”. The GO provides information on applicable models as well as the parameters. The TP actually runs the models to determine system impact. 4)Requirement 2.1.1 requires “Documentation demonstrating the applicable unit’s model response matches the recorded response for a voltage excursion at the applicable unit’s point of interconnections from either a staged test or a measured system disturbance. •Please define or qualify the term “matches”. This is a subjective term, subject to interpretation of results; i.e., what %

error is considered “matching”. •Refers to recorded response “… at the applicable unit’s point of interconnection …”. This should be reworded to “at generator terminals”. An excitation system controls to the generator terminals since this is where Voltage and Current inputs to the AVR originate. Further, this is where measurements are taken during dynamic testing. •"a measured system disturbance” is not practical for a GO, and should be eliminated. DME is owned by the TO, and do not have access to results of disturbances.

Mark B Thompson
Alberta Electric System Operator
The AESO does not support the changes made to the Curve Details, in the Voltage Ride-Through Curve Clarifications section of the standard, in particular the use of the term “base voltage” . In many parts of the Alberta transmission system the maximum normal operating voltages are significantly higher than 1.05pu of than the “base voltage” used in studies. The system has been studied, planned and designed around these higher voltages. For example; in a study the base (nominal) voltage is chosen to be one per unit (1.0 pu) equals 240 kV but in the study area typical operating voltages are 256 kV (1.07 pu) and can be as high as 1.10 pu.

The term “standby” in footnote 2 on p.2 bears definition. Is 5% capacity factor the criterion to be used in establishing standby status? If so, it would be best to make this standard entirely unit-based, eliminating all references to plants.
Yes
a. Independent generators provide model data to the TP/TOP and TO, who then run their models, but we do not ourselves have means of running dynamic models or representing within the model the system we connect-to. R2.1 1 should require the TP, not GOs, to run models and develop the referenced documentation (or, if the result is not suitable, open a dialogue per R3). The same comment applies for R2.2. b. There is presently no definition of the voltage excursion magnitude and intensity or the recording instrumentation sampling rate required for a valid verification event, nor are there any specifics regarding how closely the model must match the recorded response. The references in MOD-026 provide guidance but not necessarily NERC pass/fail criteria, especially since Transmission Planners may differ in their preferences. Perceived shortcomings in these respects would presumably trigger the Transmission Planner expression of concern described in R3, but it would be better to establish the rules up-front rather than addressing the matter only after a GO has attempted

to comply with MOD-026. It was stated in the 7/29/11 webinar that a signal-to-noise ratio of at least 5:1 is needed for a meaningful validation, but this criterion is not included in the draft standard. c. We suggest replacing “rotational inertia” in R2.1.3 with “inertia constant (H),” the rotational inertia divided by MVA rating, since this is the parameter of interest for stability studies. d. The 4/6/10-year periods specified in paras. 5.1.1-5.1.4 and 5.2.1-5.2.4 on pp. 3-4 of MOD-026-1 should provide for existing plants enough time to catch a disturbance of sufficient magnitude for verification purposes; but the one-year allowance in row 3 on p.15 for plants that are new or have replaced controls equipment may prove inadequate, especially since (per comment 5b above) we don’t currently know what sort of transient is needed. At least a four-year window should be granted for the initial verification. It is also unclear how one decides up-front the applicability of this standard to a new facility. The past-years test of para. 4.2 cannot be used; and a unit anticipated to have less than a 5% capacity factor may prove otherwise depending on market conditions or other factors. In any event the one-year verification limit for new and modified units is inadequate if it takes longer than this amount of time just to determine whether or not MOD-026-1 is applicable. e. The use of the undefined term “technically justified request” in R5 is unclear. Does this term apply only if a model fails to meet the requirements of R6.1-R6.3, or can there be other reasons? Further, the 90 day time period should not begin until both parties fully understand the “technically justified request.” f. The means by which a walk-down would lead to identification of model parameters in the second bull-dot of R.5.2 is not understood.
No
Independent generators provide model data to the TP/TOP and TO, who then run their models, but we do not ourselves have means of predicting responses to voltage and frequency excursions. This is especially the case when one must, per R4.1, engage in the phenomenal complexity of calculating the transient performance of auxiliary buses and identifying the short-term drop-out thresholds of the multitudinous pieces of equipment they power. The references in R4.1 and 4.2 to experience, actual event histories or sound engineering judgment as alternatives to a computer model are not helpful, because meaningful assessments can be made only if one has relevant data (i.e. high-speed records of past disturbances, at HV, MV and LV voltage levels) and issue a PV. Further on the subject of complexity, there are a variety of aux bus configurations possible for our multiple-unit plants, any one of which could be deemed normal depending on circumstances. Having to check every aux bus configuration for every units-running combination would be unduly burdensome, even if it were possible. The fact that R4 cites “Frequency/Voltage Excursions” (apparently meaning simultaneous deviations of these parameters), while R5 is careful to refer to “frequency excursion or voltage excursion,” adds confusion. Another concern is that the boundary conditions for the above-described analysis are presently undefined, with the standard invoking instead a “dynamic simulation provided by the Transmission Planner.” For the reasons stated above, the proposed requirement R.4 should be eliminated.
No
It is possible for new facilities to buy steam turbines that permit operation in accordance with Att.1. We cannot confirm that it is possible to do so for all fossil unit sizes or generation unit types, however, and recommend that question 7 above be put to OEMs. This is particularly the case for gas turbine engines, for which the limiting factor may be surge avoidance rather than resonance margins. Note also that such units may auto-unload at abnormal frequencies. This action may not provide the grid ride-out capability wanted, despite satisfying R5’s no-trip requirement. The general acceptability stated above for steam turbines bears clarification, however, because OEM guidelines for off-frequency operation typically have a lifetime basis. That is, each transient results in cumulative fatigue damage. The frequency curves of PRC-024-1 are consequently not acceptable for an unstable grid that often swings to the max-specified deviations, and a statement should be added to this standard to the effect that the no-trip zones of Att. 1 apply for frequency excursions to the extremes no more frequently than once per decade. Att. 2 presents a problem in that the deviation location is specified to be the point of interconnection, but GOs are being asked to confirm that all MV and LV devices required to maintain the unit on-line will not drop-out. An excursion to -10% voltage on the 230 kV span would correspond to -10% on the LV and MV systems only for theoretically ideal transformers, and the actual transient at critical loads may be greater. It would not be possible in any event to get OEMs to guarantee that the auxiliary equipment they supply will not drop-out for the Att. 2 excursions of 10 minutes at -10% voltage, 2 sec at -35% or 0.2 sec at -55%. The industry standard on this subject is ANSI C84.1, which stipulates voltage boundaries of +/- 5% for continuous operation

and +/- 10% for emergency operation of no specified duration. If NERC feels that the criteria of Att. 2 are important for BES reliability they should start by asking the appropriate ANSI and IEEE committees to revise their standards accordingly. We cannot support PRC-024-1 until its criteria become the nationally-accepted norm, because we otherwise would be making a commitment that it is impossible to fulfill.
a. A standard-specific definition of the word “plant” is needed, restricting applicability to NERC-registered generators. A plant consisting of two 750 MW fossil units and a standby 10 MW diesel generator, for example, should not have to model the diesel unit’s behavior. b. Clarity is needed for the expression, “it does not trip,” in R1 and R2. Does this mean that the protective relaying does not trip, or that the unit does not trip? In the latter case do the requirements pertain only to interlocks, or do they also cover disturbances that may result in a trip? Such differentiations were clearly spelled-out in the PRC-005-2 draft currently out for voting, and they are needed here also. What seems at first to be relay-setting requirements may in fact also incorporate aux equipment drop-out, invoking for existing equipment the concerns stated above in response to question 7 (with regard to designing a standard based on a technology for which vendors may not guaranty performance).

No
Per R1. the TP should provide periodicity.
Yes
The standard is not applicable to the Planning Coordinator. Does the SDT mean TP?
No
The NERC Glossary is the correct reference for definitions used in the Standards. Referencing GADS is not appropriate.
The standard drafting team may consider adding the sentences in footnotes 2 & 3 directly to section 4.2 Facilities to avoid potentially unecessary complexity. Also in section 4.2 Facilities, the term bulk power system (BPS), not BES is used. Would use of BES instead of BPS remove the need for footnote 2 without changing the overall intent of the SDT?
Yes
Individual
Randall McCamish
City of Vero Beach
The applicability refers to the “bulk power system”, e.g., “4.2.1.1 Individual generating unit greater than 100 MVA (gross nameplate rating) directly connected to the bulk power system”. The term “bulk-power system” should not be used in the standards as it is ambiguous and should be replaced with “Bulk Electric System” We do not understand how the Applicability of 4.2.1.2 means. We suggest making the language clearer. R2.1.1 should only apply if a system disturbance actually happens and should not require a staged test. A staged test could threaten the reliability of the BES more than inaccuracy of an excitation system model. R4 should specifically exclude temporary changes, e.g., generator AVR settings are often changed when the unit is started or shut-down, if the AVR is planned out of service, etc., we believe the intent of the standard is only to communicate more permanent changes and not temporary changes. R5 is ambiguous. What is technically justified? Who gets to decide what is technically qualfied?

R3.1, the second bullet, should be clarified to explain that the equipment replaced is plural, meaning all equipment causing a limitation would need to be replaced, e.g., if one piece of equipment was replaced, but another stil causes a limitation, the “grandfathering” of existing equipment lmimtations should still be in place. R1 and R2 are inconsistent with R5, bullet 5.2. R1 and R2 provide no exceptions for a new plant/wind farm/solar farm, R5 bullet 5.2 does. R6 is ambiguous as to whether or not any time any protection settings are changed, whether or not they violate the curves, the entity has to notify and provide the settings. It should be limited to only generators that violate the curves. Or is it that all trip settings of all generators are intended to be modeled? We would think that we do not need to model the generator trip settings for those that meet the curves because the UFLS program is supposed to prevent us from reaching those curves. Hence, we should only need to model the trip settings of those generators that do not meet the curves.
Individual
Christine Hasha
ERCOT
Comment 1: Requirement R2 and voltage ride through curve in the PRC-024 Attachment 2 are applicable to the voltage at point of interconnection to the Bulk Electric System (BES). However, in requirement R2.1 “When operating within 95 percent to 105 percent of rated generator terminal voltage and during the transmission system operating conditions defined in PRC-024 Attachment 2, with the following clarifications:” The clarification is needed for R2.1 that describes how the generator terminal voltage will affect the applicability to this requirement. Comment 2: In the attachment 1 and attachment 2, it is not clear if a unit can be allowed to trip instantaneously under extreme high voltage or high/low frequency occurred during and post disturbance period. For example, the physical limitation requires a wind farm to trip the turbine instantaneously when voltage is above 1.25 pu. If there is a short duration of overvoltage, 1.3pu for 0.15 second, during and post disturbance period that cause the wind farm trip the turbines, does this wind farm violate the requirement as stated in attachment 2 that requires the wind farm to remain in service for 0.2 second when voltage is above 1.2 pu?
Comment 1: In the Applicability section, it is not clear in 4.2.3.2 which units/plants are required to meet this standard. For example, a generating plant that is greater than 75 MVA and consisted of 75 1MW generating units, is this generating plant required to meet MOD-026-1? Another example, a generating plant that is greater than 75 MVA and consisted of one 45MVA generating unit and two 15MVA generating unit, is only the 45MVA generating unit required to meet MOD-026-1?
Individual
Ed Davis
Entergy Services
MOD-026-1 R2.1.1 is: 2.1.1. Documentation demonstrating the applicable unit’s model response matches the recorded response for a voltage excursion at the applicable unit’s POINT OF INTERCONNECTION from either a staged test or a measured system disturbance. We recommend the POINT OF INTERCONNECTION be changed to GENERATOR TERMINALS.

Yes
While an active closed-loop voltage regulation function is useful in distinguishing transient voltage and frequency responses within mere cycles or seconds of perturbations, a similar requirement should be added to MOD-026-1 to require variable generators who were exempted from the standard by the condition added to Attachment 1 to provide similar plant voltage/var control, design, and test data to the Transmission Planner. The automatic switching of capacitor banks and reactor banks can play a role in maintaining the voltage stability of the system.
Yes
No
The language in the requirement is acceptable, but the frequency curve identified for generators is too restrictive for hydro facilities, which are often dispatched to provide VAR and voltage support. SCE's hydro generation plants operate at very low RPM, which provides them with the ability to operate safely above (60-78 Hz) and below (<58 Hz) the frequency curves in Attachment 1 and Attachment 2, respectively. As a transmission operator, SCE applies this flexibility in its hydro generation plants to compensate for system instabilities resulting from VAR and voltage excursions. In addition, SCE's employs its hydro plants to support system restoration.
The standard should allow for wider regional variances - for example, WECC allows lower frequency and voltage excursions.

Yes
The introduction to this comment form indicates that "The typographical errors in R2.1.1 language has been corrected to clearly state expectation that, “The unit or plant’s model response matches the recorded response for a voltage excursion at the generator or plant point of Interconnection..." However, the versions posted for review (clean and redline) do not indicate that the "unit or plan's model..." They say the "applicable unit's model response matches..." There is no reference to plants in part 2.1.1
I am unsure of the intent of the phrase "estimate of the performance of the units during frequency and voltage excursions." Is this intended to mean that the owners should estimate whether or not the unit will stay connected, or provide some estimate of the unit's dynamic performance and response to an event? I also don't understand the purpose of this requirement. If models already exist and are available to the Transmission Planners, then the owners should be validating the model. As part of the validatio process the owners should be able to tell the Transmission Planner what the performance will be. Is this for units for which models have not been validated?

The Attachment depicting the No Trip Zone for frequency excursions for the WECC Interconnection is incorrect. It is missing one of the steps from the materials provided to the drafting team in July. The table is also missing a step. This must be corrected. In my opinion, the table identifying the High and Low Frequency Duration information is hard to interpret. As depicted, the table appears to be giving a range of time that a generator must stay interconnected at a specific frequency. I am not familiar with the requirements in other regions, but in WECC, we have specified a specific time that a generator must stay interconnected for a frequency range. In looking at the WECC table included int he draft standard I would not be able to discern how long a generator had to stay interconnected if the frequency were at 59.0 Hz. Similarly, I have the same problem with the information in the tables for the other interconnections. After discussions with drafting team representatives, an suggested revision for the format of the tables has been proveded to the drafting team for consideration. Even with the inclusion of the (not including the lines) statement on the No Trip Zone plot, it is still difficult to determine minute specifications from the plot. Depending on the quality of the diagram and the thickness of the line, there will still be the potential for debate. I believe a solution is to indicate the plot is for illusrative purposes only, and the specifics are provided in the tables. With the suggested format changes provided to the drafting team, there should be no room for speculation. Whether the Off-Nominal Frequency Capability Curve is used for illustrative purposes as suggested above, or for specifying details, it is difficult to view as presented. One option would be to provide three individual plots, one for each interconnection, and include them all as Attachment 2. This way you could still refer to Attachment A in Requirement R2, and perhaps add language such as "appropriate plot in Attachment 2" to the requirement.

Yes
Yes
Yes
Requirement 5 seems to imply that GO’s must provide a written response regarding units below the Registry Criteria unit MVA thresholds (< 20MVA) if a Planning Coordinator provides a technically justified request to perform a model review. Can the SDT confirm this intent? Additionally, there could be some confusion with the language as written to imply the PC’s “technical justification” includes the bulleted items of R5. GTC is assuming the SDT’s intent is for the “GO’s written response” to include the bulleted items and therefore requests additional clarity. GTC recommends the following: Each Generator Owner shall provide a written response to its Planning Coordinator, within 90 calendar days following receipt of a technically justified request from the Planning Coordinator to perform a model review of any unit/plant not included in the Applicability. The written response shall include one of the following [Violation Risk Factor: Lower] [Time Horizon: Operations Planning]: • Details of plans to verify/correct the model documentation and data as needed (in accordance with Requirement R2) • Corrected model documentation and data including the source of revised model data.
No
We ought to be able to verify FIDVR mitigating machines below 5% capacity factor.
Yes
Don't know
Comment on R6, Severe VSL. Time limit is within 60 calendar days, however the time limit for R3, R4 and R5 state 61 calendar days. Wording for Severe VSL for R3, R4, R5 and R6 should have the same time limitations of either “...within 61 calendar days” or revised so that the documentation was “communicated greater than 60 calendar days....”.

Southern Company
Antonio Grayson

Yes
Yes we agree with this concept. It is not practical, and there is no benefit to reliability, to require validation for units which do not include an active closed-loop voltage regulator function.
Yes
A periodicity of ten years between model verifications when there are no special circumstances is appropriate. What is the basis for a ten year re-verification for units where no changes to the excitation system have occurred? A ten year verification basis for an non-modified digital excitation system does not seem to be justified.
Yes
Allowing a Planning Coordinator to request additional model information only if technical justification demonstrates a mis-match between the measured unit response and the model's predictied response is appropriate. Even if the unit was a contributor to a stability limit, additional model information is really only needed if the model did not sufficiently emulate actual equipment response.
Yes
We agree that the collection of preliminary excitation control system model data from the equipment manufacturer is outside the scope of this standard. Also, any pre-COD staged testing to collect equipment responses to be used to verify the model can be required via Interconnection Agreements. It is understood that any equipment responses collected through pre-COD staged testing with final equipment settings in place that is subsequently used for model verification per the Requirements in the standard would result in fulfilling the requirements for model verficiation for the next 10 years per the Periodicity Table or until a special circumstance occurs leading to an earlier model re-verification as detailed in Requirements R3, R4, R5, or R5. The limitation to allow sisterhood for only those units at the same physical location should be extended to all identical units for the same GO/GOP - a sister is a sister is a sister. The GO should be allowed to take credit if he can show that the physical location is not a factor in the comparison. In section 4.2.1.1, and other places, we don't understand the use of "bulk power system" –shouldn't this be "Bulk Electric System". In 4.2.1.2, second bullet, eliminate the word "comprised" as it is redundant with "consisting". The same redundant use of "comprised" is insection 4.2.2.2 and 4.2.3.2, second bullet. In R2.1.4, the intended information is not clear – the closed loop voltage regulator part is not needed – it is part of the previous wording. In R2.2, replace "For plants" with "For applicable plants". Please add "where applicable" each time the "plant volt/var control" is used. Due to R5, the Planning Coordinator should be listed in the 4.1 Functional Entitles. R5 is confusing – the bullet items list what the GO response should include, but the sentence is written such that the list is what the model review must include. In R2.1.1, please insert "or voltage at the generator terminal" to "at unit's point of interconnection".
No
We cannot agree with the approach of Requirement R4 due to the uncertainty about how to estimate the performance of "each" plant system, sub-system, or component that could cause the unit to trip for the voltage excursion profile of Attachment 2. For most units, this estimate may vary from a few cycles (examples: dropout of low voltage motor contactors or an auxiliary control relay) to up to 1-2 seconds (examples: tripping of boiler controls or medium voltage motors). Determination of a more accurate time estimate would require detailed dynamic analysis, which would entail significant engineering study and involve assumptions and judgment based on experience. Data from actual event histories, if available, would likely not match all points of the Attachment 2 time-voltage profile. The voltage excursion profile needed for an evaluation would be the voltages present on the generator bus and plant distribution system auxiliary buses rather than at the point of interconnect. Without detailed analysis, only a rough estimate could be made which would probably be of limited value for transmission system analyses. A conservative approach would be the "go/no-go" approach and identify those units that are likely to trip for a specified voltage excursion. For the current requirements stated in R4, the 60 day time requirement would be a significant challenge for a GO to meet for a single unit. For GOs who have a large number of units and limited engineering resources, the 3-year phase-in period will be impractical to establish on many units the estimated performance of "each" plant system, sub-system, and component that could trip. Bottom line is, the concept may seem simple enough in principle, but these requirements cannot be practically met. We believe the scope of the standard should be limited to identification of the protection function trips per R1, R2, R3, and R6 only.

No
We recommend R5 be eliminated. New plants should be subjected to the same requirements as existing plants. The design of plant systems, sub-systems, and components are based on industry technical standards (ANSI, IEEE, ASME, etc.). Establishment of new NERC plant performance requirements must be coordinated with the industry through those standard processes. We believe significant R&D will be required to achieve significant new plant design requirements that can be used to revise the industry technical standards and that plant, system, and equipment designers and builders can meet. The scope of systems and components that must be addressed includes, but is not limited to, turbine generators, transformers, feed pump systems/controls, boiler control systems, reactor protection systems, emergency diesel generators, AC motors, pumps, fans, AC motor contactors, auxiliary relays, etc. In addition, significant costs will be incurred by the industry that we believe demand further justification.
Yes: 1) We respectfully disagree with the SDT's response to our prior comment related to maintaining the safety of the reactor core at nuclear plants for voltage or frequency transients. The intent of our comments is to ensure that application of this standard to nuclear units is coordinated per the requirements of NUC-001. Employing any changes to the grid frequency and voltage ride-through requirements may impact the licensing and design basis of nuclear facilities. NUC-001-1 requires coordination between Nuclear Plant Generator Operators and Transmission Entities for the purpose of ensuring nuclear plant safe operation and shutdown. This is achieved through development of Nuclear Plant Interface Requirements (NPIRs) for each nuclear unit that are based on plant-specific Nuclear Plant Licensing Requirements (NPLRs) and Bulk Electric System requirements that have been mutually agreed to by the Nuclear Plant Generator Operator and the applicable Transmission Entities. The NPLRs are requirements included in the design basis of the nuclear plant and statutorily mandated for the operation of the plant, including nuclear power plant licensing requirements for 1) Off-site power supply to enable safe shutdown of the plant during an electric system or plant event; and 2) Avoiding preventable challenges to nuclear safety as a result of an electric system disturbance or transient condition is important. It is essential that this process be followed closely in attempting to apply any new grid frequency and voltage requirements that are more extreme than those currently addressed in each plant’s licensing and design basis. The safety of nuclear power plants is of paramount importance. 2) R1, R2, and R3 state “each” non-protection system equipment limitation. This should be clarified to state "each non-protection system equipment limitation associated with the applicable protection function." 3) Event monitoring equipment required by M5 will be a significant burden on GOs to only prove a negative. We believe M5 should be removed from the standard, because the benefits gained do not justify the costs.

Yes
LADWP agrees with this concept since no feedback signal is available (in an open loop control) to regulate against for Setpoint (Reference) control.
Yes
LADWP agrees with the guidance.
LADWP recommends that “technical justification” is defined and/or replaced with more specific language, i.e.: “Based on the latest round of industry feedback, the GVSDT now proposes Applicability Section language allowing the Planning Coordinator to request additional model information (possibly leading to model verification) only if documentation such as model structure and data values for the excitation control system demonstrates the ....”
Yes
LADWP agrees with this revision.
LADWP supports the language under Attachment 1, “Consideration for Early Compliance”.
LADWP does not have comments on this question at this time.
LADWP does not have comments on this question at this time.
LADWP supports the following comment below: “The curve depicting the “no trip zone” for WECC in Attachment A is not consistent with the overfrequency and underfrequency requirements of the WECC Coordinated Off-Nominal Frequency Load Shedding Plan (Plan). A step is missing in the curve for the

underfrequency requirements. The table representing the points on the “no trip zone” curve for WECC is also missing the same step as the plot. Additionally the presentation of the information in the table is confusing. As presented, the table specifies a time range of staying connected for selected specific frequencies. The table should specify a specific time for staying connected for frequency ranges. For example, as currently depicted in the table, a generator would need to stay connected up to 0.75 seconds (or between 0 and 0.75 seconds) at 57.0 Hz. The WECC Plan allows for instantaneous trips at 57.0 Hz. Further, the WECC Plan requires the generator to stay connected for 45 cycles (0.75 seconds) for frequencies greater than 57.0 Hz. but less than or equal to 57.3 Hz. This is not accurately reflected in the Table. The plot in Attachment A and the associated tables must be corrected to accurately reflect the requirements of the WECC Coordinated Off-Nominal Frequency Load Shedding Plan.”

Cowltiz PUD
Yes
Yes
No
Technical justification should also include reasonable demonstration that the improved model will improve the Reliability of the Bulk Electric System.
Yes
Cowlitz PUD respectfully disagrees with the use of the statutory term bulk[-]power system in the applicability section of any reliability standard. This term is not adequately defined to be used anywhere excepting arguments as to whether a proposed standard falls within the jurisdiction of the Federal Power Act of 2005. Use of the statutory term will hamper any future efforts to revise the Statement of Compliance Registry Criteria. The Bulk Electric System is a subset of the bulk-power system. If the intent of the SDT is to include any generation of stated MVA name plate capacity connected to a “transmission system” operated at an undefined voltage, the result will be to defeat

work being done to technically justify exclusion of certain bulk-power system facilities which have no substantial impact on Reliability. If however, the intent of the SDT is to follow the Statement of Compliance Registry Criteria and imply that the “BPS” is equal to the BES, it is preferable to specify generation connection voltage than use BPS. Cowlitz agrees that non-BES generation may need to be included in this standard’s applicability section (as users of the BES), however specific generation that a particular GO may own which by itself would not have required registration of the entity should not be inadvertently included in the applicability of this standard.
No
Cowlitz is only concerned with the 60-day response time. The responding entity should be given some leeway to negotiate a delivery time if the 60-day response is not feasible. Otherwise, substandard estimates will be provided to avoid violation of the standard.
No
Cowlitz supports Clark County PUD's position. Please verify the following: The problem is that PRC-024 skips a frequency step in the low frequency operating area. The generator frequency ride through of Attachment 1 is inconsistent with the current WECC Off Nominal Frequency plan and the frequency ride through in the proposed WECC-0065 regional criteria. The PRC-024 ride through could cause a combustion turbine to operate at 58 Hz for a duration that would cause damage to the turbine blades. The current WECC ONF ride through avoids this.

Yes
IMPA believes that the reference of “bulk power system” should be replaced with Bulk Electric System throughout the standard. Bulk power system is used in the Compliance Registery, but it is not a NERC defined term. FERC even agrees that bulk power system goes beyond the Bulk Electric System (FERC Order 693). IMPA is troubled by the requirement in R2.1.1 that requires a voltage excursion from a staged test or a measured system disturbance. Are there an ample supply of contractors or consultants that can perform such a test? What is the risk to a unit to perform the staged test?

No
IMPA does not agree that there would be any gain in reliability by requiring Generator Owners to give an estimate on the performance of a unit or the overall plant during a frequency or voltage excursion. Will such a request include specific parameters that would be expected on the system to narrow down this imposition of an estimate upon the Generator Owner? Will Generator Owners be capable of providing an estimate that may be required under this item? In addition, the Transmission Planner is to provide the dynamic simulation of the voltage and frequency profile at the point of interconnection. There is no guidance in the Standard as to how often or what means will be used to submit the (new) profile(s) to the GO – will it be annually, seasonally or?? IMPA also has concerns with attempting to accurately predict the ride-thru capabilities of a generating unit/plant on a consistent basis. As an example, if the unit/plant was operating during an extreme and prolonged period of heat and humidity it's characteristics and ability to ride thru a frequency and/or voltage event will be different than if running during the opposite – extreme cold and wind. Many of the unit/plant auxiliary systems may be located in areas that are not climate controlled and it would be extremely difficult to consistently predicte how they will react during temperature extremes.
No
Is the technology to meet this requirement even currently available to a newly built generating facility? To force such a requirement on newly built generating facilities at this time, one is speculating that the technology will be available. Can we risk reliability of the gird on such speculation (Generator Owners not building generating facilities because they cannot meet this requirement)? What if the technology is not available? IMPA believes that this standard will be reviewed by NERC in five years or sooner and at the time the SDT can revisit this possible requirement to see if the technology to keep a generating facility on line during a voltage or frequency excursion has been proven. Or a condition could be added that says new units shall be designed and built with the frequency and voltage excursion equipment if it is the industry standard, readily and commercially available and comes at competitive market prices.
This standard should concentrate on being a relay standard because it is not practical to include equipment limitations (excluding generator frequency and voltage protective relay equipment) that might trip the generating unit or generating plant offline. Just to figure out what the equipment limitations are at a generating plant an entity would have to perform a complete analysis and stability study on the generating plant including all auxiliary systems. If an entity cannot do this within it's organization, it will have to hire a contractor and/or outside consultant to inventory, test, and model the unit/plant. This type of analysis will be expensive and will come without any guarantees from the contractor that all the equipment limitations have been noted or discovered. In addition to the initial testing that a unit/plant will require to meet this standard, an entity will have to perform some type of routine testing and maintenance program in this area to ensure equipment characteristics have not changed enough to become a plant limitation (heat and age changes equipment characteristics). Based on this standard, entities will have to have equipment tested and built to certain specifications that will allow it to ride through a voltage and/or frequency excursion which will increase equipment and maintenance costs and could potentially limit equipment suppliers. One has to wonder if all of this cost will guarantee an increase in BES reliability that makes it worth paying for the work and equipment that will be needed for compliance (with the chance that the plant will still trip offline). In how many past instances has what this standard is trying to protect against been a proven issue? There term "power conversion control equipmen"t is not defined and will allow entities to apply this term to different equipment which may or may not be correct. The SDT should take the time to define it now and not allow a CAN to define it. Measure five (M5) is currently written so that it appears that an entity will have to purchase a Digital Fault Recorder(s) for the unit/plant in order to produce the evidence needed to show a unit tripped offline (i.e. frequency rate of change greater than 2.5 Hz/sec) outside of the "no trip" zone. IMPA does not agree with this philosophy since the cost to purchase and install DFR's can be costly, especially to smaller entities. Why is 5.2 allowed for new units but not existing units? In 5.6, what makes the Mitigation Plan acceptable? Who needs to approve or make the Mitigation Plan acceptable. Where is the Mitigation Plan defined? IMPA believes the word "acceptable" should be removed.
Individual
John
John Bee

Yes
No
The SDT needs to clarify and state that generating units will be able to use testing and verification data developed prior to the standard being approved and going into effect. Please consider adding text specifically stating this to the Standard itself similar to MOD-026 Attachment 1 that provides a “Consideration for Early Compliance” provision. Refer to MOD-026-1 draft revision 2 Section 6, “Consideration for Early Compliance.”
Draft MOD-026-1 R.2.1 requires that the Generator Owner perform verifications subject to include certain information as specified in sub requirements 2.1.1 through 2.1.6. R 2.1.1 requires that the unit model response is matched to the recorded response for a voltage excursion at the “point of interconnection”. For certain generating units the “point of interconnection” is on the high voltage side of the main power transformer (i.e., the switchyard disconnect switch). Because of this, the model would have to consider the impact of the main power transformer, auxiliary transformer, and auxiliary transformer loads all of which are not part of the generator/excitation system model. The Standard should be revised to state the response of interest is at the generator terminals and not at the “point of interconnection.” Typically individual synchronous machines have generator excitation control systems and do not have volt/var control systems. The text “and / or” or “as applicable” should be added to all references to “volt/var model” in the Standard and the associated attachments. With respect to the SDTs response to Exelon’s comment regarding the lack of acceptance criteria (refer to MOD-026-1 Consideration of Comments dated 2-23-12 pp 89-90), the following statements by the SDT need to be more clearly articulated within the body of the Standard. “It should be noted that the standard is written so that the Generator Owner “owns’ the model, and as such, even with the peer review process described, the Generator Owner has final say on the voltage excursion used, including sampling rate, for model verification as well as determining if the equipment recorded response satisfactorily matches the model’s predicted response.” The current draft (draft 3) of MOD-026-1 R.3 requires that a Generator Owner provide a written response to its Transmission Planner if the Transmission Planner deems the functional model is not “usable”, if there are technical concerns with the verification documentation, or if the model response did not match an actual event. This written response is to contain either plans for performing model verification, model changes or a technical basis for maintaining the current model. It appears from the comments of the SDT (see question 3 above) that the Generator Owner has final say on the model; however, if the opinion of the Transmission Planner differs from that of the Generator Owner there is the potential for a disagreement between the two entities. Given the potential for a dispute to occur and the lack of an “acceptance criteria” the SDT should consider adding in a provision for dispute resolution between the parties or clearly delineate that the GO has the final say.
No
The Frequency/Voltage Excursions should be limited to those listed in the standard, this should be explicitly stated in the requirement. 60 calendar days is an unreasonable amount of time to perform a study of this magnitude, suggest increasing the amount of time perform this study.
No
: It should be noted that even if a relay is not set to operate according to the curves in the attachments, a minute deviation will exist in the operation of the relay, and as such, a protection system may operate in what the SDT has deemed the “no trip zone.” If a relay operates in that zone, then an entity will technically be out of compliance with this standard even though it set its protection system correctly as per the standard. An allowable tolerance needs to be included in the requirements in order to capture real world conditions.
The Off Normal Frequency Capability Curve should consist of separate tables for each Interconnect to make it easier to read. Exelon still feels that Footnote 1 belongs in the Applicability section of the standard. Suggest that the Applicability section be revised to state “GO shall set applicable protective relaying so as not to impact R1.1, R1.2, R1.3, R1.5 unless exempted by non-protection system equipment limitations per the exclusion criteria. It should be noted that even if a relay is not set to operate according to the curves in the attachments, a minute deviation will exist in the operation of the relay, and as such, a protection system may operate in what the SDT has deemed the “no trip

zone." If a relay operates in that zone, then an entity will technically be out of compliance with this standard even though it set its protection system correctly as per the standard. An allowable tolerance needs to be included in the requirements in order to capture real world conditions.

Project 2007-09 Generator Verification

MOD-026-1 and PRC-024-1

The Generator Verification Drafting Team thanks all commenters who submitted comments on the proposed revisions to MOD-026-1 and PRC-024-1. These standards were posted for a 30-day public comment period from February 29, 2012 through March 29, 2012. Stakeholders were asked to provide feedback on the standards and associated documents through a special electronic comment form. There were 53 sets of comments, including comments from approximately 127 different people from approximately 88 companies representing 9 of the 10 Industry Segments as shown in the table on the following pages.

All comments submitted may be reviewed in their original format on the standard's project page:

http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Mark Lauby, at 404-446-2560 or at Mark.lauby@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

Index to Questions, Comments, and Responses

1. The GVSDT has added an additional condition to Attachment 1 (the Periodicity Table) specifying that validation is not required for an excitation control system or plant volt/var control that does not include an active closed loop voltage regulation function. This condition exempts wind and solar plants that do not have the capability to regulate plant voltage or respond to grid voltage fluctuations other than switching capacitor and reactor banks in and out of service. Do you agree with this concept? If not, please explain in the comment area below. 13
2. The GVSDT has provided guidance on the periodicity aspects of Attachment 1 (see above). Do you agree? If not, please explain in the comment area below. 20
3. Based on the latest round of industry feedback, the GVSDT now proposes Applicability Section language allowing the Planning Coordinator to request additional model information (possibly leading to model verification) only if technical justification demonstrates the simulated unit response does not match the measured unit response. Original technical justification language for units that affect a stability limit has been removed from the standard. Though not a change from the previous posting, the SDT emphasizes for clarity that only units that meet or exceed the Registry Criteria unit MVA thresholds (> 20 MVA) or units that are already registered (for reasons such as being required to by their RRO) are subject to Requirement R5. Do you agree with the revisions to applicability and to Requirement R5? If not, please explain in the comment area below. 29
4 To clarify concerns regarding calculating unit capacity factor, the SDT has incorporated into the standard the capacity factor calculation specified in Appendix F of the GADS Data Reporting Instructions. Do you agree with this revisions? If not, please explain in the comment area below.51
5. Do you have any other comment, not expressed in questions above, for the GVSDT regarding MOD-026-1? 58
6. Requirement R4 has been added for owners of existing units or generating plant/facilities to provide an estimate of the performance of the units during frequency and voltage excursions. This information is intended to provide Transmission Planners with information useful in performing planning studies. Do you agree with this approach? If not please explain and provide alternative language. 129
7. Requirement R5 requires a Generator Owner’s new unit or generating plant/facility to be able to stay on line when exposed to point-of-interconnection frequency or voltage excursions depicted in the curves of Attachment 1 and Attachment 2. Do you believe this requirement is technically achievable for new units or generating plant/facilities? Please provide comments supporting your answer. Please provide along with your comment, what you believe the timeframe is needed to implement this requirement. 148

8. Do you have any other comment, not expressed in questions above, for the GVSDT regarding PRC-024-1? 178

MOD-026 Overall Summary Consideration: The GVSDT received valuable feedback from stakeholders regarding improvements to the standard. Many of the suggested edits were incorporated into the revised standard.

The vast majority of the industry commenters agreed with the concept of specifying that validation is not required for an excitation control system or plant volt/var control that does not include an active closed loop voltage regulation function. The GVSDT received comments regarding other aspects of the standard. Several Industry commenters indicated that it was not clear if the table was associated with Attachment 1 or not. In response, the SDT has re-formatted Attachment 1 to make it clear that the table is a part of Attachment 1. Also, some commenters were concerned that Table 1 inferred that plants with complex reactive coordination controllers may be unduly exempted from being applicable. The SDT clarified that for plants that include devices that provide dynamic voltage regulation (such as a STATCOM, DVAR or SVC, commonly found in Renewable Plants) these devices should be included in the model and should be validated. The intent of this language was to exempt only those units or plants that do not contain any closed loop voltage regulation function. The SDT added some clarifying verbiage to row 6 Table 1 that ultimately references Footnote 1 in the standard.

Most of industry commented that they agreed with the guidance provided by the SDT on the periodicity aspects of Attachment 1. Unfortunately, many commenters did not correlate the guidance on the periodicity aspects of Attachment 1 to the examples "above" in the Background section of the Comment Form. Please see the Summary Consideration section for Question 5 as there were several comments regarding the periodicity examples.

The majority of the industry commenters agreed with specifying the capacity factor calculation in Appendix F of the GADS Data Reporting Instructions. Also, many of the commenters pointed out that neither the net or gross calculation was specified in the standard and suggested the SDT use the "net" calculation. As such, the SDT has revised the draft standard to reference the net capacity factor calculation in Appendix F of the GADS Data Reporting Instructions. Finally, the SDT moved the details of the capacity factor exemption concept form a footnote in the Applicability section to a row (Row 7) in the Periodicity Table. The team thought that would be appropriate as the Periodicity Table already included the "equivalent" unit concept (Row 4)

The following modifications to the draft standard were incorporated as a result of industry comments:

1. **A significant number of industry commenters opposed the use of the term "bulk power system" in the Applicability section. The SDT did not mean to convey a modification in the breadth of units which would be covered by the standard as "bulk power system" is a term used in the Compliance Registry. But based on the concerns expressed by industry, the SDT has replaced the term "bulk power system" with the NERC defined term "Bulk Electric System".**

2. The SDT has refined verbiage and the format in the standard applicability and Requirement R2, Part 2.1 to clarify the use of individual and aggregate models for plants.
3. The SDT removed the footnote regarding standby units as industry comments suggested that it did not provide additional clarity to the Applicability.
4. The SDT replaced "Planning Coordinator" with "Transmission Planner" in the standard. The Functional Model for the Transmission Planner is more in line with the task described in the standard. This revision was made in Section 4.2.4 under Applicability, in Requirement R5, and in Attachment 1.
5. The SDT revised the Applicability section 4.2.4 to make it clear that it applied to technically justified units that meet the NERC Registry criteria. It is emphasized that "technical justification" is defined by demonstrating that the simulated unit or plant response does not match the measured unit or plant response.
6. Requirement R2, Part 2.2 has been re-worded and merged into Part 2.1. The new verbiage makes it clear that the entity performing the model verification has flexibility regarding if the model should be represented by individual unit or plant aggregate models or any combination therein as dictated by the specific situation. This merger also results in appropriate mapping to the VSLs.
7. The SDT has refined section 4.2.1, 4.2.2, and 4.2.3 of the Facilities section under Applicability.
8. The SDT has re-formatted the Periodicity Table (Attachment 1) to make it clearer that the table is included.
9. Revised the Periodicity Table (Attachment 1) extensively for clarity, including removing specificity regarding when the voltage excursion used for model verification had to be captured. This resulted in a modification of the required times for re-verifying the model for exception (Requirements R3 and R4) type activities.
10. The SDT made corrections to VSL verbiage (less than or equal to with respect to days late) and replaced Planning Coordinator with Transmission Planner.
11. In Requirement R5, in describing checking the actual equipment to determine if updated model data could be obtained, the expression "walk down" was replaced by "on-site review" of the equipment
12. The term "inertia" in sub part 2.1.3. was modified to "total rotational inertia" as some industry commenters expressed concern that reference to "inertia" only would lead to submittal of an inertia constant reflective only of the generator, as opposed to all of the mass attached to the shaft.
13. In Requirement R2, Part2.1.1, the specific reference to point of interconnection has been removed. The location where the unit's response is measured is left to the model verification entity.

14. **The second bullet in Requirement R1 has been modified to be the same style and sentence structure used in the first bullet of R1.**
15. **The SDT has removed the term “generating plant / Facility” and replaced it with “individual generating plant consisting of multiple generation units that are directly connected at a common BES bus” at the top level of the Facilities section (A4.2).**
16. **The SDT modified the phrase "generator excitation control system and plant volt/var control functions” to “generator excitation control system or plant volt/var control functions” to recognize that the use of the phrase “or” is technically correct the vast majority of the time.**

1. **The GVSDT has added an additional condition to Attachment 1 (the Periodicity Table) specifying that validation is not required for an excitation control system or plant volt/var control that does not include an active closed loop voltage regulation function. This condition exempts wind and solar plants that do not have the capability to regulate plant voltage or respond to grid voltage fluctuations other than switching capacitor and reactor banks in and out of service. Do you agree with this concept? If not, please explain in the comment area below.**

Summary Consideration: The vast majority of the industry commenters agreed with the concept of specifying that validation is not required for an excitation control system or plant volt/var control that does not include an active closed loop voltage regulation function.

Several Industry commenters indicated that it was not clear if the table was associated with Attachment 1 or not. In response, the SDT has re-formatted Attachment 1 to make it clear that the table is a part of Attachment 1.

Also, some commenters were concerned that Table 1 inferred that plants with complex reactive coordination controllers may be unduly exempted from being applicable. The SDT clarified that for plants that include devices that provide dynamic voltage regulation (such as a STATCOM, DVAR or SVC, commonly found in Renewable Plants), these devices should be included in the model and should be validated. The intent of this language was to exempt only those units or plants that did not contain any closed loop voltage regulation function. The SDT added some clarifying verbiage to the appropriate row in Table 1 (referencing back to Footnote 1).

Organization	Yes or No	Question 1 Comment
Independent Electricity System Operator	Negative	Requirement R6: The criteria for deeming the model data provided by the GO acceptable may not be achievable. The difficulty to meet this requirement may not be due to inaccuracy or errors in the verification process, but simply due to the poor design of the devices to be verified. The requirement can deem a GO non-compliant despite its goodwill and effort to provide the most accurate verification data. **Requirement R6 represents established industry practice for assuring model usability. The Transmission Planner is required to notify the**

Organization	Yes or No	Question 1 Comment
		Generator Owner within 90 calendar days of receiving the verified model so that the Generator Owner knows if the model is useable or not. However, if the Generator Owner is notified that a model is not useable, per Requirement 3, the GO is only responsible for providing a written response. Thus, if the Generator Owner responds with a written response as detailed in Requirement R3, the GO will be in compliance. The revised Attachment 1 is confusing, in 2 aspects: a. It is not clear whether or not the 3 by 12 table part is part of Attachment 1 and whose content is part of the periodicity requirements that must be complied with. **The table is included in Attachment 1. The format has been modified to emphasize that the table is included in Attachment 1.** b. Question 2 in the Comment Form suggests that guidance is provided on the periodicity aspects of Attachment 1. It is not clear whether the content in the 3x12 table is meant to be guidance. If so, it needs to be clearly stated so that it does not need to be complied with. If the content is not guidance, then it is not clear where and what is the guidance that the SDT is referring to. **The "guidance" that was referred in question 2 of the Comment Form was referencing the graphical examples in the MOD-026 Background Information portion of the Comment Form (specifically reference Periodicity Example 1, Periodicity Example 2, and Periodicity Example 3).**
Response: Thank you for your comment. Please see responses above.		
Northeast Power Coordinating Council	No	While some plants may not have excitation systems, they can have complex reactive coordination controllers whose settings and functions should be tested and verified.

Organization	Yes or No	Question 1 Comment
Response: Thank you for your comment. The intent was not to give an exemption to any unit or plant that has a closed loop voltage regulation function. If a plant has a device that provides dynamic voltage regulation (such as a STATCOM, DVAR or SVC, commonly found in Renewable Plants), these devices should be included in the model and should be validated. The intent of this language was to exempt only those units or plants that did not contain any closed loop voltage regulation function (and therefore nothing to model or validate in the scope of this standard). **To clarify this point, a reference to Footnote 1 in Row 6 of the Periodicity Table has been made for clarification of what constitutes a closed loop function.**		
Massachusetts Attorney General	No	a particular unit may not pose much problem to a system but an aggregation may. One would think that over a threshold # of MW that active close loop regulation functions should be present.
Response: Thank you for your comment. The scope of the draft standard is to ensure that excitation control system and plant volt/var control function models and the model parameters used in dynamic simulations accurately represent the generator excitation control system and plant volt/var control function behavior when assessing Bulk Electric System (BES) reliability. Requirements specifying thresholds requiring active closed loop regulation functions are outside the scope of the standard as stated in the SAR.		
Manitoba Hydro	No	Manitoba Hydro agrees with the concept for manually switched capacitor banks but disagrees for automatic capacitor banks. A model should be required for automatic capacitor banks.
Response: Thank you for your comment. The intent was not to give an exemption to any unit or plant that has a closed loop voltage regulation function. If a plant has a device that provides dynamic voltage regulation (such as a STATCOM, DVAR or SVC, and perhaps automatically controlled capacitors commonly found in Renewable Plants), these devices should be included in the model and should be validated. If the automatically controlled (mechanically switched) capacitor bank is in whole or a part of		

Organization	Yes or No	Question 1 Comment
the primary dynamic volt/var response of the plant, it should be modeled and validated. Both PSS/e and PSLF have standard library models to represent automatically switched capacitor banks (SWSHNT in PSS/e and MSC1 in PSLF). Ultimately, the local interconnection requirements should be used to determine if the automatically controlled capacitor banks are a primary means for dynamic volt/var regulation within any particular application. Based on review of a plant's application requirements, the testing /validation entity should determine if the automatic capacitor bank should be validated.		
ISO New England Inc	No	While some plants may not have excitation systems, per se, they can have complex reactive coordination controllers, whose settings and functions should be tested and verified.
Response: Thank you for your comment. The intent was not to give an exemption to any unit or plant that has a closed loop voltage regulation function. If a plant has a device that provides dynamic voltage regulation (such as a STATCOM, DVAR or SVC, commonly found in Renewable Plants), these devices should be included in the model and should be validated. The intent of this language was to exempt only those units or plants that do not contain any closed loop voltage regulation function (and therefore nothing to model or validate in the scope of this standard). **To clarify this point, a reference to Footnote 1 in Row 6 of the Periodicity Table has been made for clarification of what constitutes a closed loop function.**		
Southern Company	Yes	Yes we agree with this concept. It is not practical, and there is no benefit to reliability, to require validation for units which do not include an active closed-loop voltage regulator function.
Response: The SDT thanks you for your comment.		
We Energies	Yes	Add more explicit detail to the Table to indicate that the exemption may apply to some wind farms, solar resources, etc.

Organization	Yes or No	Question 1 Comment
Response: Thank you for your comment. To clarify this point, a reference to footnote 1 in Row 6 of the Periodicity Table has been made for clarification of what constitutes a closed loop function to determine if, in part, an exemption is allowable for a particular plant.		
Ingleside Cogeneration LP	Yes	We agree that there is no useful purpose served by requiring a GO to validate voltage performance on those generators where an active voltage regulator is not used. The modeling of passive capacitor and reactor banks has been established for many years and does not likely need any improvement.
Response: The SDT thanks you for your comment.		
Los Angeles Department of Water and Power	Yes	LADWP agrees with this concept since no feedback signal is available (in an open loop control) to regulate against for Setpoint (Reference) control.
Response: The SDT thanks you for your comment.

2. **The GVSDT has provided guidance on the periodicity aspects of Attachment 1 (see above). Do you agree? If not, please explain in the comment area below.**

Summary Consideration: Most of industry commented that they agreed with the guidance provided by the SDT on the periodicity aspects of Attachment 1.

Several Industry commenters indicated that it was not clear if the table was associated with Attachment 1 or not. In response, the SDT has re-formatted Attachment 1 to make it clear that the table is a part of Attachment 1. Unfortunately, many commenters did not correlate the guidance on the periodicity aspects of Attachment 1 to the examples "above" in the Background section of the Comment Form. Please see the Summary Consideration section for Question 5 as there were several comments regarding the periodicity examples.

Organization	Yes or No	Question 2 Comment
Independent Electricity System Operator	Negative	Requirement R6: The criteria for deeming the model data provided by the GO acceptable may not be achievable. The difficulty to meet this requirement may not be due to inaccuracy or errors in the verification process, but simply due to the poor design of the devices to be verified. The requirement can deem a GO non-compliant despite its goodwill and effort to provide the most accurate verification data. The revised Attachment 1 is confusing, in 2 aspects: **Requirement R6 is intended for the Transmission Planner. If the Transmission Planner deems that the model is not useable, then the Generator Owner has to reply to the Transmission Planner's written comments. The Generator Owner's obligation is to respond to the Transmission Planners written comments, therefore, the only way the Generator Owner could be found non-compliant is if he did not respond at all.** a. It is not clear whether or not the 3 by 12 table part is part of Attachment 1 and whose content is part of the periodicity requirements that must be complied with.

Organization	Yes or No	Question 2 Comment
		b. Question 2 in the Comment Form suggests that guidance is provided on the periodicity aspects of Attachment 1. It is not clear whether the content in the 3x12 table is meant to be guidance. If so, it needs to be clearly stated so that it does not need to be complied with. If the content is not guidance, then it is not clear where and what is the guidance that the SDT is referring to. **The intent is that Attachment 1 includes the table. Based on your comment, Attachment 1 has been re-formatted in such a way that it is clear that the table is included in Attachment 1. The "guidance" that was referred in question 2 of the Comment Form was referencing the graphical examples in the MOD-026 Background Information portion of the Comment Form (specifically reference Periodicity Example 1, Periodicity Example 2, and Periodicity Example 3). Given that Requirement R2 requires model verification per the periodicity specified in Attachment 1, and Attachment 1 contains the table, then the table does dictate required model verification periodicity.**
Response: Thank you for your comment. Please see responses above.		
Independent Electricity System Operator	No	Attachment 1 is confusing, in 2 aspects: a. Attachment 1 starts off with a heading and a blue-shaded page in which the verification periodicity requirements are clearly stated. It is not clear whether or not the 3 by 12 table that follows is a part of Attachment 1 and whose content is part of the periodicity requirements that must be complied with. b. This question (Q2) suggests that guidance is provided on the periodicity aspects of Attachment 1. Is the content in the 3x12 table meant to be guidance? If so, it should be clearly stated so that it does not need to be complied with. If not, where and what is the guidance that the SDT refers to?

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 2 Comment</th></tr>
<tr><td colspan="3">Response: Thank you for your comment. The intent is that Attachment 1 includes the table. Based on your comment, Attachment 1 has been re-formatted in such a way that it is clear that the table is included in Attachment 1. The “guidance” that was referred in question 2 of the Comment Form was referencing the graphical examples in the MOD-026 Background Information portion of the Comment Form (specifically reference Periodicity Example 1, Periodicity Example 2, and Periodicity Example 3). Given that Requirement R2 requires model verification per the periodicity specified in Attachment 1, and Attachment 1 contains the table, then the table does dictate required model verification periodicity.</td></tr>
<tr><td>American Electric Power</td><td>No</td><td>The tiered approach of MOD-026 Attachment 1 are both unorganized and more complex than necessary, and is confusing as a result. The same approach could be communicated in a more succinct format. In addition, there is content within the attachment that is not mentioned anywhere else in the standard, such as the initial verification of new units and dealing with equivalent units at the same physical location.</td></tr>
<tr><td colspan="3">Response: Thank you for your comment. The intent of the Periodicity Table is to specify periodicity details which would not be considered reliability related requirements. However, the SDT is always open to specific suggestions regarding the formatting of the standard and supporting attachments.</td></tr>
<tr><td>Ameren</td><td>No</td><td>The comments and guidance of the GVSDT are greatly appreciated. However, we have a concern/question, how would the periodic verification/testing requirements for MOD-026 would align with other such requirements in place for MOD-024, MOD-025 and with reporting requirements of MOD-012 and MOD-013?

We would like the GVSDT to consider a well-coordinated periodic verification and reporting needs for all such requirements to provide the GO flexibility to schedule their tasks to meet these requirements without undue burden to take facility out of service at different times.</td></tr>
<tr><td colspan="3">Response: Thank you for your comment. MOD-024 and MOD-025 have now been combined. The verification of steady state MW and MVAR capabilities would be accomplished by test which is distinctly different than the activities required for verification of excitation control systems. Also, the verification of steady state MW and MVAR capabilities would be accomplished without</td></tr>
</table>

Organization	Yes or No	Question 2 Comment
taking the unit out of service. Personnel involved in steady state MW and MVAR capabilities will almost certainly be different than personnel involved in the verification of excitation control systems. Also, the verification of excitation control systems per the current draft of MOD-026 will almost always be ten years, whereas the periodicity of steady state MW and MVAR capabilities per the current draft of MOD-025 is only five years. MOD-012 and MOD-013 are simply data submittal standards as opposed to data verification standards.		
Austin Energy	No	Per R1. the TP should provide periodicity.
Response: Thank you for your comment. The SDT believes that a national standard for dynamic model verification has to include periodicity to ensure that excitation control system models used in studies to set BES limits are of sufficient accuracy.		
Exelon Corp.	No	The SDT needs to clarify and state that generating units will be able to use testing and verification data developed prior to the standard being approved and going into effect. Please consider adding text specifically stating this to the Standard itself similar to MOD-026 Attachment 1 that provides a “Consideration for Early Compliance” provision. Refer to MOD-026-1 draft revision 2 Section 6, “Consideration for Early Compliance.
Response: Thank you for your comment. The SDT re-formatted Attachment 1 in part to emphasize activities that would result in an entity being able to take credit for model verification prior to the effective data, as long as that activity either met the requirements of the standard or was performed compliant with the applicable regional policies, guidelines or criteria existing at the time of model verification (reference Note 2 at the end of the table).		
ACES Power Marketing Standards Collaborators	Yes	The examples included in the Unofficial Comment Form are helpful in understanding the periodicity requirements associated with verifying the excitatation and volt/VAr control systems model and should be moved into an attachment in the standard. The standard is not as clear as the examples and the periodicities could be misinterpreted in the future without examples.
Response: Thank you for your comment. The examples provided were for clarification, and the SDT does not believe that all		

Organization	Yes or No	Question 2 Comment
possible scenarios are considered. The SDT does not believe the examples are appropriate for inclusion in the standard itself.		
Southern Company	Yes	A periodicity of ten years between model verifications when there are no special circumstances is appropriate. What is the basis for a ten year re-verification for units where no changes to the excitation system have occurred? A ten year verification basis for an non-modified digital excitation system does not seem to be justified.
Response: Thank you for your comment. The SDT believes that the 10 year periodicity is appropriate and has received industry support for this concept, specifically as a result of the first posting. Digital excitation systems settings can be modified, and there are other components in the closed loop system that can degrade with heat and stress over time (SCRs, any discrete electronic component, etc).		
PSEG	Yes	The examples in the unofficial comment form should be incorporated into an attachment to the standard for ease of reference.
Response: Thank you for your comment. The examples provided were for clarification, and the SDT does not believe that all possible scenarios are considered. The SDT does not believe the examples are appropriate for inclusion in the standard itself.		
Manitoba Hydro	Yes	The implementation plans/effective dates for the standards MOD-025 , MOD-026, MOD-027, and PRC-019 in Project 2007-09 should be the same to reduce unnecessary outages and to maximize the productivity of site visits. Manitoba Hydro suggests that the implementation plan for MOD-026 be applied to MOD-025, MOD-027 and PRC-019.
Response: Thank you for your comment. MOD-024 and MOD-025 have now been combined. The verification of steady state MW and MVAR capabilities would be accomplished by test which is distinctly different than the activities required for verification of excitation control systems. Also, the verification of steady state MW and MVAR capabilities would be accomplished without taking the unit out of service. Personnel involved in steady state MW and MVAR capabilities will almost certainly be different than personnel involved in the verification of excitation control systems. Also, the verification of excitation control systems per the current draft of MOD-026 will almost always be ten years, whereas the periodicity of steady state MW and MVAR capabilities		

Organization	Yes or No	Question 2 Comment
per the current draft of MOD-025 is only five years. Also, the effective and implementation dates for the current drafts of MOD-026 and MOD-027 (dynamic model verification standards) are effectively the same.		
Ingleside Cogeneration LP	Yes	We support the effort by all project teams to clearly define the implementation and subsequent periodic evaluation time frames - as well as those that may result from changes in the facility or models. Unfortunately, any assumptions or gaps in the timelines will force NERC's Compliance team to address them through a CAN, which do not allow for sufficient vetting by the industry. In the case of MOD-026-1, we believe that the proposed intervals are sufficient to perform the voltage performance model validations; however they are initiated.
Response: The SDT thanks you for your comment.		
GenOn Energy	Yes	In Attachment 1, the title "Consideration for Early Compliance" should be changed to "Compliance for Prior Verification"
Response: Thank you for your comment. The SDT re-formatted Attachment 1 in part to emphasize activities that would result in an entity being able to take credit for model verification prior to the effective data, as long as that activity either met the requirements of the standard or was performed compliant with the applicable regional policies, guidelines or criteria existing at the time of model verification.

3. **Based on the latest round of industry feedback, the GVSDT now proposes Applicability Section language allowing the Planning Coordinator to request additional model information (possibly leading to model verification) only if technical justification demonstrates the simulated unit response does not match the measured unit response. Original technical justification language for units that affect a stability limit has been removed from the standard. Though not a change from the previous posting, the SDT emphasizes for clarity that only units that meet or exceed the Registry Criteria unit MVA thresholds (> 20 MVA) or units that are already registered (for reasons such as being required to by their RRO) are subject to Requirement R5. Do you agree with the revisions to applicability and to Requirement R5? If not, please explain in the comment area below.**

Summary Consideration:

1) **The SDT has refined section 4.2.4 of the Facilities section under Applicability to clarify that any technically justified unit that meet NERC registry criteria is potentially in the scope of the standard**

   Additionally, though not specifically related to the SDT's question, the following modifications were made to the standard based on industry responses in this question:

2) **A significant number of industry commenters opposed the use of the term "bulk power system" in the Applicability section. The SDT did not mean to convey a modification in the breadth of units which would be covered by the standard as "bulk power system" is a term used in the Compliance Registry. But based on the concerns expressed by industry, the SDT has replaced the term "bulk power system" with the NERC defined term "Bulk Electric System".**
3) **The SDT has refined verbiage and the format in the standard applicability and Requirement R2, Part 2.1 to clarify the use of individual and aggregate models for plants.**
4) **The SDT removed the footnote regarding standby units as industry comments suggested that it did not provide additional clarity to the Applicability.**
5) **The SDT replaced "Planning Coordinator" with "Transmission Planner" in the standard. The Functional Model for the Transmission Planner is more in line with the task described in the standard.**

Organization	Yes or No	Question 3 Comment
Beaches Energy Services, City	Negative	The applicability refers to the "bulk power system", e.g., "4.2.1.1 Individual generating unit greater than 100 MVA (gross nameplate rating) directly connected to

Organization	Yes or No	Question 3 Comment
of Green Cove Springs		the bulk power system". The term "bulk-power system" should not be used in the standards as it is ambiguous and should be replaced with "Bulk Electric System" We do not understand how the Applicability of 4.2.1.2 means. We suggest making the language clearer. **We appreciate your thoughtful comments. Based upon your comments and others, the SDT replaced references to the BPS with references to the BES which is the NERC defined term.** R2.1.1 should only apply if a system disturbance actually happens and should not require a staged test. A staged test could threaten the reliability of the BES more than inaccuracy of an excitation system model. **A staged test to obtain data to verify excitation control system models does not involve an actual BES voltage excursion. A staged test typically involves injecting a step change signal into the unit's voltage regulator – which makes the voltage regulator "think" that a voltage excursion has occurred. Usually a laptop PC can be used to record the resulting staged testing data. There has been ample experience in industry with safely and effectively using a staged test.** R4 should specifically exclude temporary changes, e.g., generator AVR settings are often changed when the unit is started or shut-down, if the AVR is planned out of service, etc., we believe the intent of the standard is only to communicate more permanent changes and not temporary changes. **Changes in operating mode (auto/manual, PSS on/off, etc.) do not trigger the need to provide a revised model or re-verification as described in Requirement R4. The following sentence has been added to Footnote 5 to clarify the intent: "Changes in settings that occur due to changes in operating mode do not apply to Requirement R4".** R5 is ambiguous. What is technically justified? Who gets to decide what is technically qualified? **"Technical justification" is defined by the TP as demonstrating that the simulated**

Organization	Yes or No	Question 3 Comment
		unit or plant response does not match the measured unit or plant response.
Response: The GVSDT thanks you for your comment. Please see responses above.		
PacifiCorp	Negative	1. PacifiCorp does not support the addition of the term "bulk power system" to Section 4.2.2.1 of the "Applicability" section. The term is ambiguous and, in this context, fails to provide the clarity afforded by either the previous language ("at greater than or equal to 100 kV") or the defined term of "Bulk Electric System." PacifiCorp suggests maintaining the existing applicability language, including the "directly connected" qualifier so that the sentence reads as follows: "Individual generating unit greater than 75 MVA (gross nameplate rating) directly connected to the point of interconnection at greater than or equal to 100 kV." **We appreciate your thoughtful comments. Based upon your comments and others, the SDT replaced references to the BPS with references to the BES which is the NERC defined term.** 2. PacifiCorp believes that the second bullet under Section 4.2.2.2 of the "Applicability" section introduces confusion for registered entities. If we correctly understand the intent of the GVSDT, then please consider the following language to replace the two existing bullets: o "Each individual generating unit greater than 20 MVA (gross nameplate rating), plus an aggregate model for the other generating units of less than 20 MVA at the plant/Facility; and o Where there are no individual generating units greater than 20 MVA in a plant/Facility with total generation greater than 75 MVA (gross aggregate rating), an aggregate model for the generating units of less than 20 MVA." **The SDT has refined section 4.2.2 of the Facilities section under Applicability and Part 2.1 to clarify the use of individual and aggregate models for plants.** 3. PacifiCorp agrees that the addition of sub-Requirement 2.2 is a good clarification, but believe that the language could be further clarified to remove unnecessary confusion by amending the sub-Requirement as follows: "For generating

Organization	Yes or No	Question 3 Comment
		plants/Facilities with total generation greater than the thresholds established in the Applicability section of this standard that are comprised of units that have gross nameplate rating of less than 20 MVA, each Generator Owner shall perform its verification using plant aggregate model(s) that include the information required by Requirement sub-parts 2.1.1 through 2.1.6." **The SDT moved the language that was in Part 2.2 to Part 2.1, and modified the language to make it clear that the use of individual or aggregate models for units less than 20 MVA (gross nameplate capability) is left to the discretion of the entity performing the model verification.**
Response: The GVSDT thanks you for your comment. Please see responses above.		
Public Utility District No. 1 of Lewis County	Negative	As a generator owner of a small plant we do not have the experience or expertise in modeling therefore all model and explanation of model would come from a testing and consultant firm. There is a high cost for a small plant to obtain this test data. Standard should only apply to 100MVA generators as in the Eastern and Quebec interchange. **The individual unit and aggregate plant ratings used in the applicability section were carefully derived for each Interconnection to capture validation of approximately 80% of the total installed base in that region. The selection of these applicability requirements intend to strike the most reasonable balance between managing the costs to perform tests and validation vs. ultimately assuring that the reliability of the Bulk System is not compromised due to poor models.** If we run the model testing and the Transmission Planner does not like the modeling, then we have to run the model testing again? More cost and no benefit to us or the system. **There is no requirement or measurement in the standard where the planning authority accepts or denies quality of the match between the model and field tests. The SDT strongly believes that the judgment of an “adequate model” is best**

Organization	Yes or No	Question 3 Comment
		left to the Generator Owner and their testing and validation entity. In the SDT's experience, the adequacy of the validated models is not questioned by planning authorities. However, per Requirement R6, questions regarding the usability of these models (i.e. initialization, numerical stability, etc) may exist and would need to be addressed. The Transmission Planner should select plant and units that are critical to system operation, not one size fits all as stated in the standard. **The SDT was unable to identify a methodology that is consistently applicable to all regions and interconnections regarding "critical system components". Therefore, MVA thresholds are the only common means to be used as a proxy for defining "critical system components".**
Response: The GVSDT thanks you for your comment. Please see responses above.		
Northeast Power Coordinating Council	No	Footnote 4 in the Applicability Section implies comparing simulated unit or plant responses to dynamic system events. Verifying the model only after an event as is called for in footnote 4 is completely counter to increasing system reliability. Analyzing an event and determining that a particular generating unit model is inaccurate will prove difficult in practice. The Applicability Section needs further revision because by requiring only generators above 100 MVA with unit capacity factors above 5 % to test excludes an unacceptably large amount of installed generation. For example, about 30% of the installed generation in New England would not therefore, require model validation. This is an excessively large portion of the generation that is being exempted. Additionally, the low capacity factor units will likely be running during the periods when the system is being most stressed and reliable operation is being most challenged. If the objective of the Standard is to develop the right models for dynamic simulations, models must include high and low capacity factor units, transient and

Organization	Yes or No	Question 3 Comment
		long term models, etc. for all network conditions. A model for the generators and associated equipment is supplied in accordance with MOD-012. The accuracy of such models may be limited and a higher percentage of generator validation is required. **As discussed in the Comment Form with the first posting of the draft MOD-026 standard, the SDT considered the extent of the facilities to be verified and how to reflect this in the "applicability" of this proposed standard. As a basis, the SDT recognized that the excitation system models and model data are already collected through the processes identified in MOD-012 and MOD-013. These models and data should, with few exceptions, already result in a quality dynamics database. However, as confirmed through the Field Test, performing the activities specified in the draft standard is expected to result in an improvement of the accuracy of the exciter models used in dynamic simulations. Utilizing engineering judgment, based in part on recent entity experiences in verifying excitation system models, the SDT is proposing to require verification of excitation systems associated with 80% or greater of the connected MVA per Interconnection. Therefore, specific MVA thresholds corresponding to 80% of connected MVA or greater for each Interconnection are proposed. It is recognized that certain boundaries within an interconnection, such as BA boundaries, may have more or less than 80% of the connected MVA.** **The SDT further believes that a minimum unit interconnection of >100 kV, consistent with the Compliance Registry Guidelines, is appropriate. Finally, the SDT believes that the standard should apply to units with a capacity factor such that they are on-line 400 hours or greater a year. The SDT believes that these three applicability thresholds will result in substantial accuracy improvement to the excitation models and associated Reliability based limits determined by dynamic simulations, while not unduly mandating costly and time consuming verification efforts. Footnote 4 (footnote 2 in the current draft) is intended to allow the Transmission Planner to request model information, possibly leading to model verification, for units which fall within the NERC Compliance Registry but are not of the base Applicability of this**

Organization	Yes or No	Question 3 Comment
		proposed standard. **Also, the SDT does recognize that Regional variances can be considered if a Region desires to include additional unit MVA in this standard.** Footnote 4 should be changed to allow verification of generator models not required under the Applicability Section to be at the discretion of the Transmission Planner. In some areas of the system, generator models have a considerable impact on dynamic performance and model accuracy is critical. Requirement R5 authorizes the PC to apply MOD-026 to any generator not included in the Applicability section of MOD-026. This would authorize the PC to apply the standard to non-BES generation, which is not appropriate. What is meant by a “technically justified request” from the PC? R5 refers to the Planning coordinator, yet the Planning Coordinator is not listed in the Applicability Section of MOD-026. MOD-026 deviates from the NERC Functional Model Version 5 in that MOD-026 R5 has the Generator Owner communicating with the Planning Coordinator. T The NERC Functional Model stipulates that the Transmission Planner communicates with the GO/GOP. The PC then collects the data from the TPs in its area, and from adjacent PCs. The Standard should be consistent with the NERC Functional Model. **Thank you for your comment. The SDT has refined section 4.2.4 of the Facilities section under Applicability to clarify that any technically justified unit that meets NERC registry criteria is potentially in the scope of the standard – notably excluding units and plants that do not meet the thresholds of the registry criteria. The SDT also has replaced references to the Planning Coordinator with the Transmission Planner, in large part due to the reasons you have stated.** **Also, the SDT does recognize that Regional variances can be considered if a Region desires to include units based on other criteria to this standard.**

Organization	Yes or No	Question 3 Comment
Response: The GVSDT thanks you for your comment. Please see responses above.		
ACES Power Marketing Standards Collaborators	No	We appreciate the drafting team explaining their intent that only those units that meet the Compliance Registry Criteria are included. However, the language in the standard does not communicate this and the Statement of Compliance Registry Criteria has some ambiguous criteria that makes it unclear if a generator is applicable which is further discussed below. First, applicability section 4.2.4 of the standard discusses "any registered technically justified unit". Units are not registered. Entities (i.e. companies) are registered. A Generation Owner certainly becomes registered by the application of the Compliance Registry Criteria to its generating fleet but there is no publicly available list to which the applicable entities can refer to identify if a generating unit met the Compliance Registry Criteria. Thus, how would a Planning Coordinator know they could make a request? **The SDT has refined section 4.2.4 of the standard applicability to clarify that any technically justified unit that meets NERC registry criteria is potentially in the scope of the standard.** Second, the Compliance Registry Criteria includes units smaller than the 20 MVA unit threshold and 75 MVA plant threshold referenced by the drafting team. Blackstart Resources are included in the Compliance Registry Criteria and there is a statement that any generator that is material to the reliability of the Bulk Power System can be included. Blackstart Resources are usually very small and most likely do not meet the 5% capacity factor requirement established in other areas of the applicability section. **The SDT did not intend to treat black start units differently from any other units.** We are guessing the drafting team did not intend to include these Blackstart units or any others units that don't meet the 20 MVA unit threshold and 75 MVA plant threshold established in Criteria III(c).1 and III(c).2 with the Appendix 5B - Statement of Compliance Registry Criteria.

Organization	Yes or No	Question 3 Comment
		For clarity, the drafting team should modify applicability section 4.2.4 accordingly to eliminate units that are not intended to be included. Third, we disagree with the statement in the Background Information section of the comment form that the applicability section would have to explicitly identify units below the Compliance Registry Criteria. **The SDT has refined section 4.2.4 of the standard applicability to clarify that any technically justified unit that meets NERC registry criteria is potentially in the scope of the standard.** Because the standards applicability is not specifically limited to the Bulk Electric System, the statement in Requirement R5 that "any/plant not included in the Applicability" means that any unit that is considered part of the Bulk Power System could be requested by the Planning Coordinator. NERC enforces standards to the Bulk Power System which could include units below the Compliance Registry Criteria. They have made this clear in response to comments on CAN-0016 that the standards are enforced to the Bulk Power System. **The SDT has refined section 4.2.4 of the Facilities section under Applicability to clarify that any technically justified unit that meet NERC registry criteria is potentially in the scope of the standard. Also the SDT has replaced the term "BPS" with the defined term "BES".** They stated clearly "According to Section 39 of the Energy Policy Act of 2005, NERC defines the Interconnected Power Grid as the Bulk Power System. Unless otherwise restricted by a standard, it is applicable to the BPS." While the Bulk Power System has never been clearly defined, we know that it is broader than the Bulk Electric System and could certainly include units below the Compliance Registry Criteria. One solution to more fully implement the expressed intent of the drafting team would be to limit the applicability section to the Bulk Electric System. **Based upon your comments and others, the SDT replaced references to the BPS with references to the BES which is the NERC defined term.**

Organization	Yes or No	Question 3 Comment
		Another would be to modify “any unit/plant not included in the Applicability” in Requirement R5 to “any unit/plant on the Bulk Electric System and not included in the Applicability”. While the question posed by the drafting team here indicates that their intent was for the Planning Coordinator’s technical justification to indicate that the actual unit response does not match the simulated response, there is nothing in the standard or requirement that indicates this intent. In fact, it only states the request from the Planning Coordinator must be technically justified. **The SDT has refined section 4.2.4 of the Facilities section under Applicability to clarify that any technically justified unit that meets NERC registry criteria is potentially in the scope of the standard.** We suggest the drafting team modify Requirement R5 to make it clearer the actual system response does not match simulated response. **The clarification for technical justification from Transmission Planner that actual unit response does not match simulated response is included in the referenced Footnote 2.**
Response: The GVSDT thanks you for your comment. Please see responses above.		
MRO NSRF	No	It is suggested the following modification to R5 will more clearly mirror the SDT intent as depicted in the question: “...any unit/plant meeting the Registry Criteria not included in the Applicability that includes one of the following...”
Response: Thanks you for your comment. The SDT has refined section 4.2.4 of the Facilities section under Applicability to clarify that any technically justified unit that meets NERC registry criteria is potentially in the scope of the standard.		

Organization	Yes or No	Question 3 Comment
PPL Electric Utilities and PPL Supply NERC Registered Organizations	No	The term “standby” in footnote 2 on p.2 bears definition. Is 5% capacity factor the criterion to be used in establishing standby status? If so, it would be best to make this standard entirely unit-based, eliminating all references to plants.
Response: Thank you for your comment. The SDT decided to remove Footnote 2 as the term did not provide clarity to industry as was hoped.		
Massachusetts Attorney General	No	I am concerned about units that may be individually less than 20 MVA but collectively could be much larger - wind farms.
Response: Thank you for your comment. The applicability and Part 2.1 was refined to clarify the use of individual and aggregate models for plants. With this change in the applicability, the SDT believes that this has been addressed, since the objective has always been to validate models for units or plants larger than a certain threshold (different for each interconnection).		
AECI	No	I believe that the threshold of 20 MVA is too low. I would recommend a threshold of a (> 75 MVA)
Response: Thank you for your comment. The applicability was refined to clarify the use of individual and aggregate models for plants. With this change in the applicability, the SDT believes that this has been addressed, since the objective has always been to validate models for units or plants larger than a certain threshold. In other words, validation for small units are only required when these units are part of a plant with total output above the threshold for the given interconnection (75 MVA for ERCOT and WECC and 100 MVA for the Eastern Interconnection).		
Consolidated Edison Co. of NY, Inc.	No	Requirement 5: o R5 authorizes the PC to apply MOD-026 to any generator not included in the Applicability section of MOD-026. This would authorize the PC to apply the standard to non-BES generation, which is not appropriate.

Organization	Yes or No	Question 3 Comment
		The SDT has refined section 4.2.4 of the Facilities section under Applicability to clarify that any technically justified unit that meet NERC registry criteria is potentially in the scope of the standard. o It is not clear what constitutes a “technically justified request” from the PC. **The technical justification for a request is described in footnote 2 of the current draft of the standard.** o Refers to Planning Coordinator, but PC is not listed in Applicability section of MOD-026. **The reference to Planning Coordinator has been changed to Transmission Planner to be consistent with the Applicability section of the standard and to conform to NERC functional model.** o Further, under NERC Functional Model Version 5 the Transmission Planner communicates with the GO/GOP. The PC collects data from the TP’s in its area and from adjacent PC’s. See NERC Functional Model Version 5. The standards should conform to the NERC Functional Model. **The reference to Planning Coordinator has been changed to Transmission Planner to be consistent with the Applicability section of the standard and to conform to NERC functional model.**
Response: The GVSDT thanks you for your comment. Please see responses above.		
We Energies	No	We strongly oppose this Requirement as unnecessary to the reliability of the BES. Requirement R5 should be removed from the draft Standard. Either the standard is applicable to a generating unit, or it is not. A generating unit that is not covered in the Applicability section should be exempt from the requirements of this standard unless the standard is revised under the approved

Organization	Yes or No	Question 3 Comment
		standards development process. The SDT's assurances to the contrary are not sufficient. This requirement will allow the possibility of sweeping more generators into the requirements than is necessary.
Response: Thanks you for your comment. The SDT has refined section 4.2.4 of the Facilities section under Applicability to clarify that any technically justified unit that meet NERC registry criteria is potentially in the scope of the standard. Also the SDT has replaced the term "BPS" with the defined term "BES".		
ISO New England Inc	No	No, Footnote 4 in the Applicability Section implies comparing simulated unit or plant response to a dynamic system event. This is not acceptable, verifying the model only after an event as called for is completely counter to increasing system reliability. In addition, analyzing an event and determining that a particular generating unit model is inaccurate will prove difficult in practice. **The majority of industry supports an applicability which results in the required verification of 80% of the Interconnected MVA. The associated Requirement R5 does allow the TP a means to pursue additional model information if the model's predicted response does not match the actual equipment response. The SDT believes this is a reasonable way to allow the TP to pursue model information in the rare instances where there is an issue with a model that is not part of the base applicability.** We feel the applicability section needs further revision, by requiring only generators above 100 MVA with unit capacity factors above 5 % to test, about 30% of the installed generation in New England does not require model validation. We believe this is a large portion of the generation that is being exempted. Additionally, the low capacity factor units will likely be running during the periods when the system is being stressed the most and reliable operation is being most challenged. We realize that a model for the generators and associated equipment is

Organization	Yes or No	Question 3 Comment
		supplied in accordance with MOD-012 but we feel the accuracy of such models may be limited and a higher percentage of generator validation is required. **As discussed in the Comment Form with the first posting of the draft MOD-026 standard, the SDT considered the extent of the facilities to be verified and how to reflect this in the "applicability" of this proposed standard. As a basis, the SDT recognized that the excitation system models and model data are already collected through the processes identified in MOD-012 and MOD-013. These models and data should, with few exceptions, already result in a quality dynamics database. However, as confirmed through the Field Test, performing the activities specified in the draft standard is expected to result in an improvement of the accuracy of the exciter models used in dynamic simulations. Utilizing engineering judgment, based in part on recent entity experiences in verifying excitation system models, the SDT is proposing to require verification of excitation systems associated with 80% or greater of the connected MVA per Interconnection. Therefore, specific MVA thresholds corresponding to 80% of connected MVA or greater for each Interconnection are proposed. It is recognized that certain boundaries within an interconnection, such as BA boundaries, may have more or less than 80% of the connected MVA.** **The SDT further believes that a minimum unit interconnection of >100 kV, consistent with the Compliance Registry Guidelines, is appropriate. Finally, the SDT believes that the standard should apply to units with a capacity factor such that they are on-line 400 hours or greater a year. The SDT believes that these three applicability thresholds will result in substantial accuracy improvement to the excitation models and associated Reliability based limits determined by dynamic simulations, while not unduly mandating costly and time consuming verification efforts. Footnote 4 is intended to allow the Transmission Planner to request model information, possibly leading to model verification, for units which fall within the NERC Compliance Registry but are not of the base Applicability of this proposed standard.**

Organization	Yes or No	Question 3 Comment
		Also, the SDT does recognize that regional variances can be considered if a Region desires to include additional unit MVA in this standard. Footnote 4 should be changed to allow verification of generator models not required under the applicability to be at the discretion of the Transmission Planner. In some areas of the system, generator models have a considerable impact on dynamic performance and model accuracy is critical. **Footnote 2 (in the current draft of the standard) is intended to allow the Transmission Planner to request model information, possibly leading to model verification, for "technically justified" units which fall within the NERC Compliance Registry but are not of the base Applicability of this proposed standard. Per Footnote 2, a "technically justified" unit is one whose model response does not match the actual equipment response. Industry disagreed with a GV SDT proposal to expand the concept of "technical justification" to include units that were identified through a study to contribute to a stability limit.**
Response: The GVSDT thanks you for your comment. Please see responses above.		
Ingleside Cogeneration LP	No	Ingleside Cogeneration believes that Item 4.2.4 under the "Applicability" section was intended to capture the concept that a Planning Coordinator's request for additional information is limited to NERC-registered units. **Your interpretation is correct** However, the language of requirement R5 will predominate, and it reads as follows:"R5. Each Generator Owner shall provide a written response to its Planning Coordinator, within 90 calendar days following receipt of a technically justified request from the Planning Coordinator to perform a model review of any unit/plant NOT INCLUDED IN THE APPLICABILITY (our emphasis) that includes one of the following" This provides clear instruction that the entire Applicability section may be

Organization	Yes or No	Question 3 Comment
		ignored - even Item 4.2.4. **Item 4.2.4 has been clarified that only units included in the thresholds listed in the NERC registry criteria would be applicable. The GV SDT feels that this covers the concern of Requirement R5 being misinterpreted** We suggest the following language instead:"R5. Each Generator Owner shall provide a written response to its Planning Coordinator, within 90 calendar days following receipt of a technically justified1 request from the Planning Coordinator to perform a model review of any NERC-REGISTERED unit/plant not included in the Applicability that includes one of the following"1 Technical justification is achieved by demonstrating that the simulated unit or plant response does not match the measured unit or plant response Please notice that we also added the footnote under Item 4.2.4 to R5. Although this update is essentially a duplicate, it leaves no doubt to the limits of an exceptional model validation request by the Planning Coordinator. Secondly, MOD-026-1 already takes Ingleside Cogeneration LP out of its comfort zone by requiring the ownership and validation of interconnected system performance simulations. This is normally a Transmission Planner or Transmission Operator function, not a Generator Owner. We believe that the Planning Coordinator must first engage these entities before issuing such a request to the GO. **It is expected that the vast majority of the time, the Transmission Planner will work with the Generator Operator to resolve model issues for units that are not in the base applicability. The requirement does provide structure to such collaboration to ensure that it can be made to occur in case one of the parties is otherwise unwilling, and to ensure that the required process is bounded with reasonableness.**
Response: The GVSDT thanks you for your comment. Please see responses above.		
Duke Energy	No	Footnote 4 - strike the phrase "or plant" in both places, since this only applies to a unit. Also add the phrase "and by demonstrating a reliability need" to the end of

Organization	Yes or No	Question 3 Comment
		Footnote 4. Otherwise, this standard could be made applicable to a small unit that has no impact on reliability.
Response: Thank you for your comment. Though it would admittedly be a rare occurrence, the use of the technical justification concept per Footnote 2 in the current draft of the standard could also apply to a plant. The language in 4.2.4 has been modified to make it clear that only units that meet the NERC Registry Criteria thresholds will be considered.		
Ameren	No	We believe and recommend that this should be the responsibility of the Transmission Planner rather than the Planning Coordinator. At a minimum the language should state "Planning Coordinator and Transmission Planner".
Response: Thank you for your comment. Based on your and other comments, the SDT decided to replace "Planning Coordinator" with "Transmission Planner" in the standard. The Functional Model for the Transmission Planner is more in line with the task described in the standard.		
Cowltiz PUD	No	Technical justification should also include reasonable demonstration that the improved model will improve the Reliability of the Bulk Electric System.
Response: Thank you for your comment. The SDT believes that any correction of any excitation control system model of a unit that is beyond the MVA thresholds set by the Registry Criteria results in more accurate dynamic simulation assessments which does reasonably improve the reliability of the Bulk Electric System.		
Los Angeles Department of Water and Power		LADWP recommends that "technical justification" is defined and/or replaced with more specific language, i.e.:"Based on the latest round of industry feedback, the GVSDT now proposes Applicability Section language allowing the Planning Coordinator to request additional model information (possibly leading to model verification) only if documentation such as model structure and data values for the

Organization	Yes or No	Question 3 Comment
		excitation control system demonstrates the ....”
Response: Thank you for your comment. The SDT believes that the term “technical justification” is adequately defined per the footnote.		
Texas Reliability Entity	Yes	(a) R5 should be limited to generating units and plants that meet the Registry Criteria. For clarity, we suggest rewording R5 with “...perform a model review of any generation unit or plant meeting the Registry Criteria, but not included as an applicable unit in Section 4.2, that includes one of the following...”. **The SDT agrees that more clarity could be achieved and thus, in response to yours and other comments, revised the verbiage to include the phrase “…that meets NERC registry criteria….”.** (b) Does similar language (i.e. section 4.2.4) need to be added to MOD-027-1? **The GVSDT did not propose a requirement in MOD-027-1 where the Planning Coordinator can request a review of a turbine/governor and Load control and active power/frequency control system model for a unit not specified in the standard Applicability section. The GVSDT does not believe that it is likely that the turbine/governor and Load control and active power/frequency control system will contribute to a stability limit because governor response is not consistent from one frequency excursion event to the next. Please refer back to the GVSDT responses to comments for MOD-027 for additional information.**
Response: The GVSDT thanks you for your comment. Please see responses above.		
Arizona Public Service Company	Yes	The SDT has done a great job. The requirement is simple, clearer and supports reliability.

Organization	Yes or No	Question 3 Comment
Response: The SDT thanks you for your comment.		
Southern Company	Yes	Allowing a Planning Coordinator to request additional model information only if technical justification demonstrates a mismatch between the measured unit response and the model's predicted response is appropriate. Even if the unit was a contributor to a stability limit, additional model information is really only needed if the model did not sufficiently emulate actual equipment response.
Response: The SDT thanks you for your comment.		
American Electric Power	Yes	The team might wish to consider if the Transmission Planner should also be included in the applicable facilities 4.2.4 and 5.Point of clarification: one does not "register" units, rather entities are registered for NERC functions.
Response: Thank you for your comment. Based on your and other comments, the SDT decided to replace "Planning Coordinator" with "Transmission Planner" in the standard. The Functional Model for the Transmission Planner is more in line with the task described in the standard.		
Austin Energy	Yes	The standard is not applicable to the Planning Coordinator. Does the SDT mean TP?
Response: Thank you for your comment. Based on your and other comments, the SDT decided to replace "Planning Coordinator" with "Transmission Planner" in the standard. Thank you for your comment. The Functional Model for the Transmission Planner is more in line with the task described in the standard.		
Georgia Transmission Corporation	Yes	Requirement 5 seems to imply that GO's must provide a written response regarding units below the Registry Criteria unit MVA thresholds (< 20MVA) if a Planning Coordinator provides a technically justified request to perform a model review. Can

Organization	Yes or No	Question 3 Comment
		the SDT confirm this intent? **No - units that could apply to Requirement 5 are units which are below those which would be included per the standard's Applicability section but above units which are included in the NERC Registry Criteria. Also, the SDT decided to replace "Planning Coordinator" with "Transmission Planner" in the standard. The Functional Model for the Transmission Planner is more in line with the task described in the standard.** Additionally, there could be some confusion with the language as written to imply the PC's "technical justification" includes the bulleted items of R5. **The term "technically justified unit" is defined in the footnote associated with the first occurrence of the term in Section 4.2.4.** GTC is assuming the SDT's intent is for the "GO's written response" to include the bulleted items and therefore requests additional clarity. GTC recommends the following: Each Generator Owner shall provide a written response to its Planning Coordinator, within 90 calendar days following receipt of a technically justified request from the Planning Coordinator to perform a model review of any unit/plant not included in the Applicability. The written response shall include one of the following [Violation Risk Factor: Lower] [Time Horizon: Operations Planning]: o Details of plans to verify/correct the model documentation and data as needed (in accordance with Requirement R2) o Corrected model documentation and data including the source of revised model data. **The bulleted items in Requirement R3 define the types of written responses that, if received from their Transmission Planner, the Generator Owner would have to respond to per the parameters detailed in the main body of the requirement.**

4) To clarify concerns regarding calculating unit capacity factor, the SDT has incorporated into the standard the capacity factor calculation specified in Appendix F of the GADS Data Reporting Instructions. Do you agree with this revisions? If not, please explain in the comment area below.

Summary Consideration: The majority of the industry commenters agreed with specifying the capacity factor calculation in Appendix F of the GADS Data Reporting Instructions. Also, many of the commenters pointed out that neither the net or gross calculation was specified in the standard and suggested the SDT use the "net" calculation. As such, the SDT has revised the draft standard to reference the net capacity factor calculation in Appendix F of the GADS Data Reporting Instructions. This revision was made in Section 4.2 Facilities and in Footnote 4 (now Footnote 2). Finally, the SDT moved the details of the capacity factor exemption concept form a footnote in the Applicability section to a row (Row 7) in the Periodicity Table. The team thought that would be appropriate as the Periodicity Table already included the "equivalent" unit concept (Row 4)

Organization	Yes or No	Question 4 Comment
Texas Reliability Entity	No	We disagree with using a capacity factor to determine which units need to comply with this Standard. The requirements should apply to all generating units meeting the MVA thresholds, regardless of capacity factor. If the SDT decides to use the capacity factor, then the applicable facility definition needs to clearly state whether it is using the gross or net capacity per the GADS definition. The SDT also needs to define how new generation units will be captured under this Standard. In our opinion, it is unacceptable to wait three years to determine if a new generation unit meets the capacity factor limit before it is determined to be an "applicable unit".
Response: Thank you for your comment. The SDT believes that capacity factor is the best available tool for use to determine a threshold for applicability. Capacity factor has been defined and is already being used in GADS reporting. This standard has been revised to specify the "net capacity factor" is to be used. Units with less than 5% capacity factor are not likely to be on-line during a system event, and also are difficult to test because they are operated so rarely. New units are required to be verified within one year (refer to the table in Attachment 1).		
Luminant Power	No	Appendix F of the GADS Data reporting has two Capacity Factor calculations (Gross

Organization	Yes or No	Question 4 Comment
		and Net). The standard should specify Net Capacity Factor.
ank you for your comment. The standard has been revised to specify the "net capacity factor" is to be used. The SDT moved the capacity factor exemption concept form a footnote in the Applicability section to a row (Row 7) in the Periodicity Table. The team would be appropriate as the Periodicity Table already included the "equivalent" unit concept (Row 4)		
PacifiCorp	No	If the GVSDT intends to incorporate definitions or calculations from Appendix F of the GADS Data Reporting Instructions, the relevant information needs to be expressly incorporated, perhaps in an additional attachment to the standard. Requirements that refer to outside materials are not helpful and should be avoided (notwithstanding the desire to avoid a future need to modify the standard to the extent that Appendix F is amended from time to time in the future).
Response: Thank you for your comment. The SDT believes the reference to the GADS reporting document is appropriate because it is well established and is now a NERC requirement. Including the capacity factor definition into this standard would create the additional problem of having to revise this procedure if the GADS reporting document is revised.		
Luminant Energy	No	Appendix F of the GADS Data reporting has two Capacity Factor calculations (Gross and Net). The standard should specify Net Capacity Factor.
Response: Thank you for your comment. The standard has been revised to specify the "net capacity factor" is to be used.		
Duke Energy	No	Need to specify "net" or "gross" capacity factor for the calculation.
Response: Thank you for your comment. The standard has been revised to specify the "net capacity factor" is to be used.		
Austin Energy	No	The NERC Glossary is the correct reference for definitions used in the Standards. Referencing GADS is not appropriate.
Response: Thank you for your comment. The SDT believes the reference to the GADS reporting document is appropriate because it is well established and is now a NERC requirement. The SDT believes that the reference to the GADS reporting document is		

Organization	Yes or No	Question 4 Comment
appropriate, and as such, since it is well established, there is no need to make it a defined term in the NERC Glossary.		
Georgia Transmission Corporation	No	We ought to be able to verify FIDVR mitigating machines below 5% capacity factor.
Response: Thank you for your comment. Units that are below the 5% capacity factor but are equal to or greater than the MVA thresholds in the Registry Criteria could be subjected to the terms in Requirement R5 if there is evidence that the equipment's actual response does not match the model's predicted response.		
Northeast Power Coordinating Council	Yes	While supporting the clarification of capacity factor concerns, there is concern with the exclusion for units with less than a five percent capacity factor. See comments provided to Question 3. Average Capacity Factor should be defined.
Response: Thank you for your comment. The SDT believes that capacity factor is the best available tool for use to determine a threshold for applicability. Capacity factor has been defined and is already being used in GADS reporting. Units with less than 5% capacity factor are not likely to be on-line during a system event, and also are difficult to test because they are operated so rarely.		
ISO New England Inc	Yes	While we support the clarification of capacity factor, please note our concerns with an exclusion for units with less than a five percent capacity factor that are included with question 3.
Response: Thank you for your comment. The SDT believes that capacity factor is the best available tool for use to determine a threshold for applicability. Capacity factor has been defined and is already being used in GADS reporting. Units with less than 5% capacity factor are not likely to be on-line during a system event, and also are difficult to test because they are operated so rarely.		
Ingleside Cogeneration LP	Yes	Ingleside Cogeneration strongly agrees with the SDT's use of the capacity factor calculation used in the GADS system. It is always important to establish links to time-tested parameters - and eliminating any possibility that some other calculation is used.

5. Do you have any other comment, not expressed in questions above, for the GVSDT regarding MOD-026-1?

Summary Consideration:

The following modifications to the draft standard were incorporated as a result of industry responses to this question:

1) The SDT replaced "Planning Coordinator" with "Transmission Planner" in the standard. The Functional Model for the Transmission Planner is more in line with the task described in the standard.
2) Requirement R2 Part 2.2 has been re-worded and merged into Part 2.1. The new verbiage makes it clear that the entity performing the model verification has flexibility regarding if the model should be represented by individual unit or plant aggregate models or any combination therein as dictated by the specific situation. This merger also results in appropriate mapping to the VSLs.
3) A significant number of industry commenters opposed the use of the term "bulk power system" in the Applicability section. The SDT did not mean to convey a modification in the breadth of units which would be covered by the standard as "bulk power system" is a term used in the Compliance Registry. But based on the concerns expressed by industry, the SDT has replaced the term "bulk power system" with the NERC defined term "Bulk Electric System".
4) The SDT has refined section 4.2.1, 4.2.2, and 4.2.3 of the Facilities section under Applicability.
5) The SDT refined Part 2.1 to clarify the use of individual and aggregate models for plants.
6) The SDT has re-formatted the Periodicity Table (Attachment 1) to make it clearer that the table is included.
7) Revised the Periodicity Table (Attachment 1) extensively for clarity, including removing specificity regarding when the voltage excursion used for model verification had to be captured. This resulted in a modification of the required times for re-verifying the model for exception (R3 and R4) type activities.
8) The SDT made corrections to VSL verbiage.
9) The SDT made corrections to a reference in Attachment 1 to 356 days (changed to 365 days).
10) In Requirement R5, in describing checking the actual equipment to determine if updated model data could be obtained, the expression "walk down" was replaced by "on-site review" of the equipment.
11) The term "inertia" was modified to "total inertia" in sub part 2.1.3 as some industry commenters expressed concern that reference to "inertia" only would lead to submittal of an inertia constant reflective only of the generator, as opposed to all of the mass attached to the shaft.
12) In Requirement R2, Part 2.1.1, the specific reference to point of interconnection has been removed. The location where the unit's response is measured is left to the model verification entity.
13) The second bullet in Requirement R1 has been modified to be the same style and sentence structure used in the first bullet of R1.

14) The SDT has removed the term "generating plant / Facility" and replaced it with "individual generating plant consisting of multiple generation units that are directly connected at a common BES bus" at the top level of the Facilities section (A4.2).

15) The SDT modified the phrase "generator excitation control system and plant volt/var control functions" to "generator excitation control system or plant volt/var control functions" to recognize that the use of the phrase "or" is technically correct the vast majority of the time.

Organization	Yes or No	Question 5 Comment
Lower Colorado River Authority	Negative	1. Requirement R1- Transmission Planner should be replaced with (Planning Authority, Reliability Coordinator, or Resource Planner) and a requirement placed on the (Planning Authority, Reliability Coordinator, or Resource Planner) to provide data to the Transmission Planner should be added. In ERCOT, the (Planning Authority, Reliability Coordinator, or Resource Planner) and Transmission Planner are separate entities and the (Planning Authority, Reliability Coordinator, or Resource Planner) maintains this information on the ERCOT website, is the first point of contact for new generator interconnection requests, and is the recipient of generation data that is revised after generator compliance testing. The following shows how LCRA TSC's suggested change should be applied to the first paragraph of R1. Transmission Planner should be replaced with (Planning Authority, Reliability Coordinator, or Resource Planner) in the remaining elements of R1. "Each Transmission Planner (Planning Authority, Reliability Coordinator, or Resource Planner) shall provide the following instructions and model data to its requesting Generator Owner or Transmission Planner within 90 calendar days of receiving a request for those instructions or model data:" 2. Requirement R2 - Transmission Planner should be replaced with (Planning Authority, Reliability Coordinator, or Resource Planner) and Transmission Planner. 3. Requirement R3 - Transmission Planner should be replaced with Planning Authority, Reliability Coordinator, or Resource Planner and Transmission Planner in the first paragraph. Transmission Planner should be replaced with (Planning Authority, Reliability Coordinator, or Resource Planner) or Transmission Planner in

Organization	Yes or No	Question 5 Comment
		the sub parts of R3. 4. Requirement R4 - Transmission Planner should be replaces with (Planning Authority, Reliability Coordinator, or Resource Planner) and Transmission Planner. In addition, the requirement to provide the data within 180 days seems excessively permissive since this is after a change has been implemented on the system. LCRA TSC recommends 30 days. The second bullet in Section 4.2.3.2 is confusing. o Each generating plant / Facility comprised consisting of individual generating units less than 20 MVA (gross nameplate ratings). 5. Requirement R5 - Allowing generators up to 10 years from the date of regulatory approval to become compliant as stated in Section 5 seems excessively long. In addition, the effective date described in Section 5 appears to be applicable to new generation and modifications to existing generating units, meaning a new or newly modified generating facility would have up to ten years to provide the data. LCRA TSC believes that MOD 26 should be effective immediately to new or newly modified generators who interconnect after the standard is adopted. 6. Requirement R6 - In R6.3, the concern should be when an excitation system and/or volt/var control does not contribute to a well-damped generator response following a fault. LCRA TSC recommends the following changes. " For an otherwise stable simulation, a disturbance simulation results in the excitation control and plant volt/var control function model does not contribute to a well-damped generator response."
Response: Thank you for your comment. Regarding the responsibilities that would be assigned to the Transmission Planner in the draft standard, the SDT believes that this arrangement lines up with the vast majority of North American utilities current business practices regarding interactions between generation and transmission entities for collaboration of generator dynamic models. Given that ERCOT is the exception, a regional variance could be considered. Alternatively, the Transmission Planner could		

Organization	Yes or No	Question 5 Comment
delegate the responsibility to others, include their Planning Authority. The transmission planner must maintain a model of their system to meet the TPL standards, but they need input from other embedded entities for generation and other equipment models. For the purposes of the standard, there must be a clear assignment of responsibilities and using “or” in the assignment leaves ambiguity. The SDT has removed the term “generating plant / Facility” and replaced it with “individual generating plant consisting of multiple generation units that are directly connected at a common BES bus” at the top level of the Facilities section (A4.2). As a result of comments received from the prior posting, the standard drafting team extended the time to 180 days to allow more time to work through the technical challenges relating to these models. In order to meet the requirements of the standard, the generator owner needs to have time to schedule someone to test the units, and there needs to be flexibility to allow for units that are not always running, and for such units, often when they are running there are “no touch” rules in place. The 180 days is to provide for enough flexibility to balance the data need with required expenses (especially those associated with running some units) associated with meeting these requirements. New units are required to be verified within one year (refer to the table in Attachment 1). With regard to Requirement R6.3 the SDT believes the language as presently drafted already addresses the commenters stated concerns.		
BC Hydro and Power Authority	Negative	BC Hydro is voting Negative as the motivation and purpose for the 10 year recurring validation period is not clearly defined. BC Hydro recommends supplying better supporting justification, or consideration should be given to modify this criteria, ie remove the blanket 10 year requirement. In place of the blanket interval, alternative criteria recommended are a) for machines equipped with digital excitation and governor control, no recurring testing required because there is nothing that can change (software doesn’t drift), b) for machines with either or both non-digital exciter and governor control, recurring testing should be required every X years (analog control is more susceptible to setting drift and other issues) BC Hydro supports the remaining reasons for requiring validation.

Organization	Yes or No	Question 5 Comment
Response: Thank you for your comment. The SDT believes that the ten year periodicity is appropriate and has received industry support for this concept, specifically as a result of the first posting. Digital excitation systems settings can be modified, and there are other components in the closed loop system that can degrade with heat and stress over time (SCRs, discrete electronic components, etc).		
Southwest Transmission Cooperative, Inc.	Negative	Because NERC has made clear that standards are enforced against the BPS and not the BES, the applicability section should be modified to state clearly that it applies to Facilities that are part of the BES. Otherwise small generators that do not affect reliability could be impacted by these standards. NERC enforcement has made this clear in response to comments on CAN-0016 that the CIP-001 standard applied only to the BES. They stated clearly: "According to Section 39 of the Energy Policy Act of 2005, NERC defines the Interconnected Power Grid as the Bulk Power System. Unless otherwise restricted by a standard, it is applicable to the BPS." **Based upon your comments and others, the SDT replaced references to the BPS with references to the BES which is the NERC defined term.** The following comments pertain to PRC-024: Use of "new or existing" as a description for the generators in Requirements R1, R2 and R5 is confusing. **This phrase has been removed from Requirements R1 and R2 in PRC-024.** What exactly constitutes new and why is it relevant? The requirements are performance requirements that apply to in-service generators so how does new help explain this further. The footnote in Requirement R5 only further confuses the situation since it is not included in Requirements R1 and R2. Part of the confusion likely centers around Requirement R5 applying to maintaining new generators frequency and voltage excursion performance as well as designing and building it. If "maintain" was removed from Requirement R5, we believe "new" could be removed from Requirement R1 and R2 and they essentially become the maintenance

Organization	Yes or No	Question 5 Comment
		requirements. Furthermore, “new and existing” is not used consistently within other requirements such as Requirement R4. It is not obvious why it would not apply to Requirement R4 it if applies to Requirements R1 and R2. **A new unit is one that is not addressed in Footnote 2 which are units “generating units previously commissioned, or generating units under construction, or generating units with an executed interconnection agreement or power purchase agreement by the effective date of PRC-024-1 Requirement R5.” Requirement R5 applies to future units which must be built to meet the performance requirements of PRC-024. There is no allowance for exceptions or exemptions from any requirement in PRC-024 except as stated in Parts 5.1 – 5.6. Requirement R5 requires the design, construction and maintenance of any future unit once PRC-024 becomes enforceable.** Neither Requirement R1 nor R2 state within the main body of the requirement that the Parts are intended to be exceptions to the requirement. For clarity, there should be a statement (i.e. except when the Parts 1.1 and 1.2 are met) within the requirement the makes this clear. **Requirement R1 now reads, in part, “…with the following exceptions:”Requirement R2 was revised to make the requirement clearer.** For Requirements R1 and R2, it is not clear if the sub-parts are the only reasons that allow for exceptions if other equipment limitations exceptions are allowed. Other equipment limitations should be allowed, and these requirements should be clarified to allow them. **Exceptions for other equipment limitations are addressed under Requirement R3.** As written, Requirement R5 appears to be assumed to apply to a new generator in perpetuity. We draw this conclusion from the inclusion of “maintain” in the requirement. We think it makes more sense to have this requirement apply only to designing and building a new unit and then have the requirements that apply to existing units apply to the maintenance of the new units once they are established.

Organization	Yes or No	Question 5 Comment
		You assumption is correct. That is the intent of Requirement R5. The standard does not appear to allow "new" generating units to have frequency and voltage excursion performance limited by equipment. It should allow "new" equipment as it experiences normal wear and tear as well as damage for any other reasons to document its equipment limited frequency and voltage performance and communicate it similar to Requirements R1 through R3. **Requirement R5 is written with an implementation plan of six years after approval before it is enforceable. This is to allow sufficient time for manufacturers to design and build generation facilities that can meet the performance requirements. Manufacturers have representation on the GVSDT and are aware of this.** Otherwise, a Generator Operator with a "new" generator that has damaged equipment will be forced between operating the unit in a limited manner providing reliability support to the BES and possibly in violation of this standard or taking a forced outage to avoid violating the standard and experiencing escalated penalties for knowingly violating the standard. **Requirement R5, Part 5.5 (was Part 5.6) allows for temporary exemptions to be granted by the Reliability Coordinator in such instances.** We do not believe that Reliability Coordinator is the proper entity to grant a temporary exemption in Part 5.6. Rather, it is the Planning Coordinator that should grant the exemption. Furthermore, this is not consistent with other requirements such as Parts 2.1 and 2.1.1 that specify the Transmission Planner grant the exemption. Of course, Part 5.6 would not be necessary if Requirement R5 did not deal with maintaining the unit and allowed the other requirements that apply to existing units to address maintenance. **Requirement R5 is a performance requirement and is more appropriately addressed in a real-time environment. The GVSDT believes that the Reliability Coordinator is the appropriate entity.** We do not believe the VRFs for Requirements R1, R2 and R5 warrant High VRFs. The

Organization	Yes or No	Question 5 Comment
		BES is already operated within each BA and TOP for the loss of a single unit. Tripping of a generator due to a frequency or voltage excursion is an uncommon event that is already planned for. It is highly unlikely that tripping of such a generator or even several generators will lead to instability, system separation or cascading which is required for the VRF to be High. Furthermore, by setting the VRF to High, this increases the potential that every single unit outage could become subject to a Compliance Violation Investigation which is simply not necessary. **The VRF for Requirements R1, R2 and R5 have been revised to "Medium".**
Response: The GVSDT thanks you for your comments. Please see responses above.		
Ohio Edison Company	Negative	FE appreciates the hard work of the drafting team but has some concerns that we ask be addressed so that we can support the standard on the next ballot. Please see our comments and suggestions submitted through the formal comment period.
Response: The SDT thanks you for your comments and has strived to properly consider and respond to all comments and suggestions. Please refer to our responses to your comments.		
Oncor Electric Delivery	Negative	In a deregulated market, the Balancing Authority (BA) and Planning Authority (PA) are in the best position to provide a more strategic look at gathering this type of information and ensuring the necessary broad distribution. As a result, the receiving and requesting of modeling data from a Generator Owner (GO) should be the responsibility of the PA or the BA and not the Transmission Planner. This approach provides a single clearinghouse for generator data, ensuring accuracy and consistency, to and from the GO which then can accessed by any impacted Registered Entities.
Response: Thank you for your comment. After much consideration, and a review of the functional model, the SDT realized that the TP is the appropriate entity to receive the modeling data. In instances where the BA or PA aggregates the model data, the TP		

Organization	Yes or No	Question 5 Comment
is delegating their responsibility under the functional model to other entities.		
Lakeland Electric	Negative	LAK is a member of FMPA, please refer to their comments.
Wisconsin Energy Corp.	Negative	MOD-026-1: Requirement R2.1.1 requires modification to properly include the Transmission Planner in the effort to compare the model response to the recorded response. **The SDT has drafted the standard such that the Generator Owner is the "owner of the model". The vast majority of industry supports this concept, as demonstrated in response to a specific question on the Applicability posed in a prior posting. Peer review type requirements (for example, Requirement R3) have been drafted that can result in the inclusion of the Transmission Planner in a process to review models which result in issues requiring collaboration.** Requirement R2.2 also needs more flexibility for the Generator Owner to provide individual model information in place of an aggregate model for multiple small units. **Requirement R2 Part 2.2 has been re-worded and merged into Part 2.1. The new verbiage makes it clear that the entity performing the model verification has flexibility regarding if the model should be represented by individual unit or plant aggregate models or any combination therein as dictated by the specific situation.** Also, we oppose the addition of Requirement R5 as unnecessary to the reliability of the BES. This Requirement should be removed from the draft Standard. **The SDT believes that Requirement R5 is necessary to the reliability of the BES. This requirement was added by the SDT in response to industry asking if a transmission entity should be allowed to identify additional units beyond those identified in the base Applicability. The base applicability, contains unit and plant MVA thresholds which include a subset of those units which are identified in the NERC Compliance Registry. The ability of the Transmission Planner to request model information is well bounded and defined to ensure that the Generator**

Wisconsin Electric Power Co., Wisconsin Electric Power Marketing	Negative	Requirement R2.1.1 requires modification to properly include the Transmission Planner in the effort to compare the model response to the recorded response. **The SDT has drafted the standard such that the Generator Owner is the "owner of the model". The vast majority of industry supports this concept, as demonstrated in response to a specific question on the Applicability posed in a prior posting. Peer review type requirements (for example, Requirement R3) have been drafted that can result in the inclusion of the Transmission Planner in a process to review models which result in issues requiring collaboration.** Requirement R2.2 also needs more flexibility for the Generator Owner to provide individual model information in place of an aggregate model for multiple small units. **Requirement R2 Part 2.2 has been re-worded and merged into Part 2.1. The new verbiage makes it clear that the entity performing the model verification has flexibility regarding if the model should be represented by individual unit or plant aggregate models or any combination therein as dictated by the specific situation.** Also, we oppose the addition of Requirement R5 as unnecessary to the reliability of the BES. This Requirement should be removed from the draft Standard. **The SDT believes that Requirement R5 is necessary to the reliability of the BES. This requirement was added by the SDT in response to industry asking if a transmission entity should be allowed to identify additional units beyond those identified in the base applicability. The base applicability contains unit and plant**

Organization	Yes or No	Question 5 Comment
		MVA thresholds which include a subset of those units which are identified in the NERC Compliance Registry. The ability of the Transmission Planner to request model information is well bounded and defined to ensure that the Generator Owner is not unduly burdened with frivolous requests for model information.

Response: Thank you for your comment. The SDT has reviewed and simplified Attachment 1 and believe that it is consistent with the draft standard.		
Old Dominion Electric Coop.	Negative	This standard needs a QR as they are many inconsistencies in the language used, I only pointed out a few major errors: R2: You say PC, should be PC or PC must be included in the Applicability Section. **The SDT could not find use of term PC in Requirement R2.** R2: Replace 'Part's with 'Requirements' R2.1: requires GO to comply with a specified TP model, this may not be economic or even feasible to do so. **Regarding ‘Parts’ vs. ‘Requirements’, NERC specifically changed this language to**

Organization	Yes or No	Question 5 Comment
		'Parts' based on the official definition of this term. **Regarding Requirement R2, Part 2.1, the TP models (which are typically standard library models in the PSS/e and PSLF simulation programs) are widely available and representative of excitation systems and volt/var control on all types of generation technologies. While there is no requirement for quality of match between test and simulation, there is a need to assure the TP can use the submitted model in their bulk system analysis (also expanded by language in R6). This is the reason for the language around models acceptable to the TP.** **If your question is related to performance, there is no performance requirement in this standard and therefore there is no need to alter equipment hardware or settings based on these TP models.** R2.2: Parts and Requirements R3: This conflicts with R2 on how the GO must present the data to the TP... **These requirements intend to address separate activities. Requirement R2 is intended to define what is required in the verification. Requirement R3 requires the GO to respond to a TP inquiry.** R5: GO should be allowed to challenge thier units being included by the TP as technically justified! Market issues in RTOs and ISOs. **The intent of Requirement R5 is for TPs to use technical justification for validating models that meet NERC reliability criteria but did not meet applicability criteria. The GO has 90 days to respond. If the GO decides to verify the model, they have a year to do so. The SDT believes that since technical justification requires demonstration the model does not match actual equipment response, this requirement is reasonable.** R6: Perts and Requirements again. Some of my comments are minor, some are deal breakers (R3 and R5). **Regarding 'Parts' vs. 'Requirements', NERC specifically changed this language to**

Organization	Yes or No	Question 5 Comment
		'Parts' based on the official definition of this term.

Pepco Holdings Inc. & Affiliates		Agree with the generating unit nameplate thresholds as defined in this standard, but do not agree with eliminating the 100kV interconnection criteria from section 4.2 of this standard and replacing it with the undefined term "bulk power system." This subtle difference greatly expands the applicable scope of the standard from the previous draft version and would now include units that are not defined as being a part of the BES. The term "bulk power system" (BPS) is not defined within this standard, nor is it found in the NERC glossary of terms. Section 215 of the FPA defines the term "Bulk Power System" as follows: (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof) and (B) electric energy from generating facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy. In effect, the statutory term "Bulk Power System" defines the jurisdiction of FERC. On November 18, 2010 FERC issued Order 743 (amended by Order 743A) and directed NERC to revise their definition of "Bulk Electric System" (ref. Project 2010-17) so that the definition encompasses all Elements and Facilities necessary for the reliable operation and planning of the interconnected bulk power system. As such, the applicability of this Reliability Standard should be limited to those generation facilities included in the BES definition, and not those subject to the broader BPS definition. The latest NERC BES definition includes generation resources consistent with the capacity thresholds in the Compliance Registry; however, the 100kV interconnection voltage clause in the

Organization	Yes or No	Question 5 Comment
		BES definition limits the scope to those units necessary for the reliable operation of the interconnected bulk power system. In conclusion, Section 4.2 should be modified to remove the undefined term "bulk power system" and either re-instate the 100kV interconnection constraint, or reference those generation facilities as defined in the NERC BES definition.
Response: We appreciate your thoughtful comments. Based upon your comments and others, the SDT replaced references to the BPS with references to the BES which is the NERC defined term.		
PacifiCorp	Yes.	See below: 1. PacifiCorp does not support the addition of the term "bulk power system" to Section 4.2.2.1 of the "Applicability" section. The term is ambiguous and, in this context, fails to provide the clarity afforded by either the previous language ("at greater than or equal to 100 kV") or the defined term of "Bulk Electric System." PacifiCorp suggests maintaining the existing applicability language, including the "directly connected" qualifier so that the sentence reads as follows: "Individual generating unit greater than 75 MVA (gross nameplate rating) directly connected to the point of interconnection at greater than or equal to 100 kV." **Based upon your comments and others, the SDT replaced references to the BPS with references to the BES which is the NERC defined term.** 2. PacifiCorp believes that the second bullet under Section 4.2.2.2 of the "Applicability" section introduces confusion for registered entities. If we correctly understand the intent of the GVSDT, then please consider the following language to replace the two existing bullets: o "Each individual generating unit greater than 20 MVA (gross nameplate rating), plus an aggregate model for the other generating units of less than 20 MVA at the plant/Facility; and

Organization	Yes or No	Question 5 Comment
		o Where there are no individual generating units greater than 20 MVA in a plant/Facility with total generation greater than 75 MVA (gross aggregate rating), an aggregate model for the generating units of less than 20 MVA." **The SDT has refined section 4.2.2 of the Facilities section under Applicability and Part 2.1 to clarify the use of individual and aggregate models for plants.** 3. PacifiCorp agrees that the addition of sub-Requirement 2.2 is a good clarification, but believe that the language could be further clarified to remove unnecessary confusion by amending the sub-Requirement as follows:"For generating plants/Facilities with total generation greater than the thresholds established in the Applicability section of this standard that are comprised of units that have gross nameplate rating of less than 20 MVA, each Generator Owner shall perform its verification using plant aggregate model(s) that include the information required by Requirement sub-parts 2.1.1 through 2.1.6." **Requirement R2 Part 2.2 has been re-worded and merged into Part 2.1. The new verbiage makes it clear that the entity performing the model verification has flexibility regarding if the model should be represented by individual unit or plant aggregate models or any combination therein as dictated by the specific situation.**
Response: Thank you for your comment. Please see responses above.		
Ameren		(1) The requirements 4.2.1.1 and 4.2.1.2 refer to bulk power system (BPS). We suggest that GVSDT includes definition of BPS in the standard. **Based upon your comments and others, the SDT replaced references to the BPS with references to the BES which is the NERC defined term.** (2) We suggest that GVSDT clearly specify that "point of interconnection" referred to in R2.1.1 to be the same as defined in PRC-024-1.

Organization	Yes or No	Question 5 Comment
		Specific reference to point of connection is removed from R2.1.1. Language has been modified to: "Documentation demonstrating the applicable unit's model response matches the recorded response for a voltage excursion from either a staged test or a measured system disturbance." (3) In Attachment 1, Row 4 it seems to imply to us that some use of "Sister Units" is allowed to meet the requirement. . We suggest that the GVSDT clarify and include this option in the body of the Standard (preferably) or in Attachment 1 as an option? **The proxy or sister unit concept is intended to be a part of Attachment 1. The SDT has re-formatted the Periodicity Table (Attachment 1) to make it clearer that the table is included.** (4) Requirement R2.2 states that an Applicable plant with gross nameplate ratings of the units < 20 MVA should use a plant aggregate model. Can the GVSDT clarify the type of model and provide example for each? **The SDT wants to avoid including specific examples in the standard at risk of creating bias or confusion to its captive audience. That said, a primary reason for this language is to capture variable energy resources (wind and large solar plants) that are widely modeled using an aggregated equivalent generator rather than separately modeling each machine. One example would be using the WECC generic wind models (which are aggregate models) to represent wind plants. Also, Part 2.1 contains refined verbiage makes it clear that the entity performing the model verification has flexibility regarding if the model should be represented by individual unit or plant aggregate models or any combination therein as dictated by the specific situation.** (5) There are 17 technical papers referenced in Section G of the Standard. Would the GVSDT make them available on the NERC website? **Information necessary to obtain copies of these papers is listed in each of the**

Organization	Yes or No	Question 5 Comment
		paper references. (6) For Requirement R3, we did not find anything in the standard that specifies how closely a model response must match the tested response of a generator. We believe that unless this is clearly specified, it could lead to disagreements between the Generator Owner and Transmission Planner over what constitutes a verified model. **The SDT has drafted the standard such that the Generator Owner is the "owner of the model". The vast majority of industry supports this concept, as demonstrated in response to a specific question on the Applicability posed in a prior posting. Requirement R3 is a "peer review" type requirement that can result in the inclusion of the Transmission Planner in a process to review models which result in issues requiring collaboration. However, as owner of the model, the requirement is structured such that the Generator Owner is both responsible and has the final say in collaboration regarding model issues.**
Response: Thank you for your comment. Please see responses above.		
Texas Reliability Entity		1) Applicability: The applicable Facility requirements should be the same for every Standard in this Project! **The applicability of MOD-026 is carefully selected in an attempt to balance the need for verified models with the cost and effort required. The size requirements are selected to assure that 80% of the generation MVA represented has verified models. Also, the effective and implementation dates for the current drafts of MOD-026 and MOD-027 (dynamic model verification standards) are effectively the same.** 2) Section 4.2 should reference the Bulk Electric System definition for generation facilities or Transmission Planner requirements whichever is more inclusive. At a minimum, the BES definition should be used without differences for each interconnection.

Organization	Yes or No	Question 5 Comment
		Based upon your comments and others, the SDT replaced references to the BPS with references to the BES which is the NERC defined term. 3) Effective Dates: Ten years is too long of an implementation period and should be shortened. The reliability implications of not validating responses within the models are significant. More emphasis (a shorter time frame) should be given to correcting model errors that may lead to (or have led to) improper planning of the system based on the current model results. **The purpose of the initial 10-year implementation period is to give industry sufficient time to perform verification on required units with limited resources to perform the verification activities. The SDT believes that 10 years is a reasonable re-verification period. The standard does include requirements that obligate the Generator Owner to possibly re-verify the model before 10 years upon the occurrence of certain activities, including a change in equipment expected to modify the output of the equipment. The proposed 10-year re-verification period is also supported by an overwhelming majority of comments received from the industry.** 4) The SDT should consider moving the "Consideration for Early Compliance" criteria from Attachment 1 into the Effective Dates section. **The SDT has reformatted Attachment 1 for improved clarity. The consideration for early compliance could be included in section 5, "Effective Date", but we believe the flow of the standard is best if the early compliance information appears in Attachment 1 with the other clarifying criteria.** 5) Regarding Requirements R3 and R4: The inclusion of "or a plan" extends the timeframe associated with getting good modeling data to the TP. What does the Transmission Planner do in the interim? Who is responsible for the use of the unusable or invalid data? Does the unusable or invalid data get used at all (do the plants need to disconnect until "usable" data is provided)? **The draft standard realizes that upon recognition of an issue with the model, the**

Organization	Yes or No	Question 5 Comment
		investigation of the issue and ultimately the implementation of the solution does take time. Both parties will be motivated to resolve the model issue as quickly as possible. Thus, in practicality, the process does require time as it does currently today. The decision on what model to use for dynamic studies in the interim would be made by the Transmission Planner, ideally after consultation with the Generator Owner. 6) Regarding VSLs for R1, R3, R4, R5 and R6: The numbers of days stated in the Severe VSLs need to be reconsidered. For example, in the Severe VSL for R1, no VSL applies if the performance occurs on day 181. **Based on your comment, the SDT has revised the verbiage for the Severe VSL for Requirement R1 to "The Transmission Planner failed to provide the instructions and data to the Generator Owner within 180 calendar days of receiving a request."** 7) Regarding VSL R5: There is reference to Subpart(s) 5.2 and 5.3 in the High and Severe VSL text, but there are no corresponding subparts in the Standard. **Based on your comment, the SDT has revised the verbiage for the High VSL to not include any references to the sub bullets in Requirement R5, and revised the verbiage for the Severe VSL to include " OR The Generator Owner written response failed to indicate one of the sub bullets of Requirement R5."** 8) Regarding Attachment 1: The allowed time to provide usable verified models is far too long. For example, as written there could be a gap of almost two years between the time a TP learns that a model is "unusable" and the time the GO has to provide a verified model. **The SDT drafted the standard recognizing the model verification requires expertise and calendar time. Regarding the specific example offered, the SDT believes that the vast majority of the time, issues regarding model usability will be resolved very quickly. Typical issues include scaling issues, model data typos, incorrect per unit calculations, etc. Typically, a model that is found to be not**

Organization	Yes or No	Question 5 Comment
		useable does not result in the model having to be re-verified. In the interim, after an initial consultation with the Generator Owner, the Transmission Planner may choose to use the prior model. **Also, in part as a goal to further simplify and streamline the Periodicity Table (Attachment 1), the maximum amount of time between the Transmission Planner learns and notifies the Generator Owner that a model is "unusable" and (assuming the Generator Owner decides to verify the model) when the Generator Owner transmits a re-verified model is decreased to 1 year 90 days. (instead of 1 year 270 days as proposed in the previous posting).** 9) In Attachment 1, change "356 days" to "365 calendar days" in the third line of the table for consistency. **The typo error correction has been made.**
Response: Thank you for your comment. Please see responses above.		
Ingleside Cogeneration LP		1. Ingleside Cogeneration LP cannot agree with the change in the applicability section of MOD-026-1, which references generation connected to the "bulk power system" rather than the NERC-defined term "Bulk Electric System". This bypasses the express intent of the NERC Glossary to carefully describe concepts which otherwise can be unevenly applied at the discretion of Regional audit teams. In fact, this action ignores the work output of Project 2010-17 "Definition of the Bulk Electric System" which was carefully crafted by the entire industry in response to FERC Docket RR09-6-000 - which was issued to eliminate exactly these kinds of ambiguities. **Based upon your comments and others, the SDT replaced references to the BPS with references to the BES which is the NERC defined term.** 2. What could possibly be a technical justification for including generators below that included in the Applicability Section. Without this in the Standard, it leaves

Organization	Yes or No	Question 5 Comment
		it open to whatever the PC is inlinded to do. If you have a "catch all" requirement, you need to have a specific set of technical requirements to limit the PC's discretion. **The reference to Planning Coordinator has been changed to Transmission Planner to be consistent with the Applicability section of the standard. The technical justification for a request is described in a footnote reference in the standard (see section 4.2.4) – in summary, the TP must demonstrate that the simulated unit or plant response does not match the measured unit or plant response.** 3. Registered Entities below the individual unit thresholds of 100MVA, 75MVA, and 50MVA do not need to be modeled unless there is technical justification. This is a significant burden on small generators. Small generators should only be required to provide model verification where the PC can show justification through a set of criteria. **The SDT believes that smaller units that meet NERC registry criteria connected to BES system can have a significant role in the stable operation of the grid – especially when in aggregate they meet or exceed the plant thresholds in the standard.**
Response: Thank you for your comment. Please see responses above.		
We Energies		a. In Section A3. reference is made to Bulk Electric System (BES) reliability. Then, in Section A4, there are repeated references to the "bulk power system" (BPS). Please clarify the distinction, and why the standard needs to refer to both the BES and the BPS. We believe all references should be to the BES. The use of "bulk power system" could possibly lead to the inclusion of generating units in the Applicability which are not connected to the BES, and should not be subject to this standard. **Based upon your comments and others, the SDT replaced references to the BPS with references to the BES which is the NERC defined term.**

Organization	Yes or No	Question 5 Comment
		b. In Requirement R1, instead of the TP providing "instructions", the standard should require the TP to simply "provide" the model data and the list of acceptable models, block diagrams, etc, to the GO upon request. The TP already has the expertise with these models and the dynamics software applications, and has easy access to the necessary information. Since the Generator Owners in most cases will not have access to the dynamics software and associated libraries, it would be more efficient to have the Transmission Planner provide the information (list of acceptable models, block diagrams/data, and existing in-use model data) instead of instructing the Generator Owner how to obtain it. **The software manufacturers have indicated that they will make accommodations so that generator owners without software licenses can receive the block diagrams and data sheets. Transmission Planners ordinarily have license agreements that do not permit them to provide the block diagrams and data sheets directly to the generator owner.** c. In Requirement R2.2, the GO is responsible to provide a verified aggregate model for multiple generating units rated less than 20 MVA. This will be an unreasonable burden on the GO, which typically does not have the modeling experience or the need to develop these equivalent models. The requirement should be more flexible to allow the GO the option to provide the same unit-specific data that is required for units rated 20 MVA or higher, or else to make the requirement applicable to both the GO and TP to allow them to work together to develop a suitable aggregate model. **Requirement R2 Part 2.2 has been re-worded and merged into Part 2.1. The new verbiage makes it clear that the entity performing the model verification has flexibility regarding if the model should be represented by individual unit or plant aggregate models or any combination therein as dictated by the specific situation.** **The genesis of this language around aggregated models was to address Variable Energy Resources (wind and large PV solar plants) where the standard practice is to use a single aggregated generator and collector model to represent all wind turbines or solar inverters in a plant with like technology. Aggregated models for**

Organization	Yes or No	Question 5 Comment
		renewable energy plants are available either from the OEM or via WECC's generic models and there shouldn't be an issue obtaining at least one of them. d. In R2.1.1, the GO is required to provide documentation that the generator model response matches the recorded response for a voltage excursion. Since the GO often does not have the capability to run dynamic studies, how will it obtain the "model response" for comparing to the recorded response? We suggest that this requirement be modified to require that the GO "provide the recorded response for a voltage excursion". As presently written, R2.1.1. can only be required of the TP. **The SDT has assigned responsibility for model verification to the Generator Owner and has received support for this proposal from the vast majority of industry. Generator Owners have access to the equipment, along with access to the equipment's Original Equipment Manufacturer for assistance with technical issues. Historically, the Transmission Planner and Generator Owner entities used to work for the same company, but in today's functional model environment, Transmission Planners could easily work for a different company than the generation entity. As such, the stated access advantages for the generation entity do not transfer to the Transmission Planner. The draft standard does not require the generator entity to perform dynamic simulations to determine Bulk Electric System limits. The generator entity is responsible for ensuring that the excitation system model response matches the response from a recorded voltage excursion. This can be accomplished through software that is much simpler than full dynamic simulation software utilized by Transmission Planners for assessing BES limits. Finally, agreements between the Transmission Planner and the Generator Owner can be arranged for the Transmission Planning entity to perform portions or all of the model verification process however responsibility for model verification remains with the Generator Owner.** Further thought and guidance needs to be given to this matter, as well as the availability and type of recording equipment needed to capture the voltage data as required in R2.1.1. There needs to be a recognition that the Transmission Planner

Organization	Yes or No	Question 5 Comment
		and Generator Owner will need to work cooperatively on this. The goal is good, but this standard is not nearly developed enough to be a useful standard. **Recording equipment needed to capture voltage data is widely available. The SDT does recognize that expertise in performing model verification is limited, and that entities will need time to either hire consultants to perform the verification or develop the expertise in house – thus the staged ten year Implementation Plan.**
Response: Thank you for your comment. Please see responses above.		
PPL Electric Utilities and PPL Supply NERC Registered Organizations		a. Independent generators provide model data to the TP/TOP and TO, who then run their models, but we do not ourselves have means of running dynamic models or representing within the model the system we connect-to. **The draft standard does not require the generator entity to perform dynamic simulations to determine Bulk Electric System limits. The generator entity is responsible for ensuring that the excitation system model response matches the response from a recorded voltage excursion. This can be accomplished through software that is much simpler than full dynamic simulation software utilized by Transmission Planners for assessing BES limits.** R2.1 1 should require the TP, not GOs, to run models and develop the referenced documentation (or, if the result is not suitable, open a dialogue per R3). The same comment applies for R2.2. **The SDT has assigned responsibility for model verification to the Generator Owner and has received support for this proposal from the vast majority of industry. Generator Owners have access to the equipment, along with access to the equipment's Original Equipment Manufacturer for assistance with technical issues. Historically, the Transmission Planner and Generator Owner entities used to work for the same company, but in today's functional model environment, Transmission Planners could easily work for a different company than the generation entity. As such, the stated access advantages for the generation entity do not transfer to the**

Organization	Yes or No	Question 5 Comment
		Transmission Planner. Finally, agreements between the Transmission Planner and the Generator Owner can be arranged for the Transmission Planning entity to perform portions or all of the model verification process however responsibility for model verification remains with the Generator Owner. b. There is presently no definition of the voltage excursion magnitude and intensity or the recording instrumentation sampling rate required for a valid verification event, nor are there any specifics regarding how closely the model must match the recorded response. **The SDT consciously avoided definitions of how tests are performed as well as quality of match between model and test to avoid risk of being over-prescriptive and too restrictive. The focus is solely on "what" is required, not "how" it's done. Ultimately, the Generator Owner and their testing and model validation entities are left to determine the appropriate tests and responses to validate models against, as well as determining how well the model represents the as-installed equipment.** The references in MOD-026 provide guidance but not necessarily NERC pass/fail criteria, especially since Transmission Planners may differ in their preferences. Perceived shortcomings in these respects would presumably trigger the Transmission Planner expression of concern described in R3, but it would be better to establish the rules up-front rather than addressing the matter only after a GO has attempted to comply with MOD-026. It was stated in the 7/29/11 webinar that a signal-to-noise ratio of at least 5:1 is needed for a meaningful validation, but this criterion is not included in the draft standard. **Again, the focus is solely on "what" is required, not "how" it's done. Ultimately, the Generator Owner and their testing and model validation entities are left to determine the appropriate tests and responses to validate models against, as well as determining how well the model represents the as-installed equipment.** c. We suggest replacing "rotational inertia" in R2.1.3 with "inertia constant (H)," the

Organization	Yes or No	Question 5 Comment
		rotational inertia divided by MVA rating, since this is the parameter of interest for stability studies. **In mentioning the rotational inertia, the SDT is providing examples of the types of data included to help understanding, and did not intend to specify the base that should be used in providing the data. The standards attempt to specify what is required, and hence do not provide the details regarding the data to be provided. However, for clarity, the term "inertia" in sub part 2.1.3. was modified to "total rotational inertia" as some industry commenters expressed concern that reference to "inertia" only would lead to submittal of an inertia constant reflective only of the generator, as opposed to all of the mass attached to the shaft.** d. The 4/6/10-year periods specified in paras. 5.1.1-5.1.4 and 5.2.1-5.2.4 on pp. 3-4 of MOD-026-1 should provide for existing plants enough time to catch a disturbance of sufficient magnitude for verification purposes; but the one-year allowance in row 3 on p.15 for plants that are new or have replaced controls equipment may prove inadequate, especially since (per comment 5b above) we don't currently know what sort of transient is needed. At least a four-year window should be granted for the initial verification. It is also unclear how one decides up-front the applicability of this standard to a new facility. The past-years test of para. 4.2 cannot be used; and a unit anticipated to have less than a 5% capacity factor may prove otherwise depending on market conditions or other factors. In any event the one-year verification limit for new and modified units is inadequate if it takes longer than this amount of time just to determine whether or not MOD-026-1 is applicable. **The SDT believes that a new excitation control system will be tested during commissioning and the test data will be adequate to comply with this standard. Whether or not a new unit may have a capacity factor of greater than 5%, it should still be commissioned with initial testing of the excitation control system. If additional time is needed to create a model from the test data, the SDT believes that 1 year is adequate. The standard requires each new unit to be modeled within one year.**

Organization	Yes or No	Question 5 Comment
		e. The use of the undefined term “technically justified request” in R5 is unclear. Does this term apply only if a model fails to meet the requirements of R6.1-R6.3, or can there be other reasons? Further, the 90 day time period should not begin until both parties fully understand the “technically justified request.” **The technical justification for a request is described in Footnote 2 of the current draft of the standard. The technical justification request in Requirement R5 is intended to perform a model review for any unit/plant not included in the applicability section of the standard. The 90 day grace period in Requirement R5 is intended for the Generator Owner to perform a review and submit a written response to Transmission Planner’s request. The 90 days grace period is not intended for Generator Owner to perform model verification.** f. The means by which a walk-down would lead to identification of model parameters in the second bull-dot of R.5.2 is not understood. **The text has been modified and the expression “walk down” was replaced by “on-site review” of the equipment.**
Response: Thank you for your comment. Please see responses above.		
Independent Electricity System Operator		a. Requirement R2.1: We continue to disagree with the phrase “models acceptable to the Transmission Planners” as it is a potential source of dispute between the TP and the GO. Requirement R1 already asks the TP to provide instructions and model data to its requesting GO but makes no reference to “acceptability”. To avoid potential disputes, we suggest that R2.1 be reworded to:R2.1. Perform verifications using one or more models provided by the Transmission Planner in R1, that include(s) the following information: **In the current draft, bullet one in Requirement R1 makes provisions for the Transmission Planner to provide instructions for the Generator Owner to acquire models that are acceptable to the Transmission Planner. The SDT believes that the subsequent phrase in Requirement 2 which reads “perform verification using one**

Organization	Yes or No	Question 5 Comment
		or more models acceptable to the Transmission Planner" sufficiently specifies the link to Requirement R1 bullet one. b. We continue to disagree with Parts R6.1 to R6.3 which set the criteria for usable model. The stipulated criteria may not be accomplished even if the GO provides an accurate excitation control system and plant volt/var control function model, especially if such devices are new for which there are no previous simulations to benchmark with. **The SDT believes that excitation systems and other closed-loop control systems in a power plant (barred some mal-function or failure) are commissioned to provide stable and properly damped response. Thus, validated simulation models should exhibit a similar response and that can be easily assessed using simulations as those described in Part 6.1 to Part 6.3. On the other hand, a model that does not exhibit a stable and properly damped response to these simulations described in Part 6.1 to Part 6.3 is probably not representing the actual behavior of the equipment and this discrepancy should be addressed before the model is accepted and deemed usable.** A computer model may fail to initialize due to reasons other than inaccuracy in the submitted excitation control system and plant volt/var control function model itself, and a no-disturbance simulation may not result in the excitation control system and plant volt/var control system model exhibiting positive damping due to other system parameters. System damping is affected by many other dynamic performance contributors such as other generators, system topology, power flow levels, voltage levels, excitation system and power system stabilizer settings, etc. **The models can be tested, as described in Part 6.1 to Part 6.3, based on a machine vs. infinite bus simulation model. As such, the influence of other models is removed. On the other hand, if a simulation model fails to initialize, it might indicate issues with limits and/or per unit scales and these issues should be addressed before the model can be considered approved or usable.**

Organization	Yes or No	Question 5 Comment
		In short, having an accurate excitation control system and plant volt/var control function model does not necessary guarantee or equate to meeting the conditions stipulated in the three parts. We suggest this requirement be removed. **The Part 6.1 to Part 6.3 are related to the usability of the models by the end-users (entities carrying out system simulations) and are not exactly related to the validity of the models. The SDT believes that the models should be not only valid models, but also usable models.**
Response: Thank you for your comment. Please see responses above.		
Duke Energy		o R2, 2.1.3 - Please revise to specify total inertia. Total unit inertia should be given to include all coupled rotating elements. The way this is currently worded, it could lead generators to only provide the generator H values. **The SDT has modified the term to include "total" rotational inertia as suggested.** o R2, 2.2 - Insert the phrase "or individual unit" after the word "aggregate". **Requirement R2 Part 2.2 has been re-worded and merged into Part 2.1. The new verbiage makes it clear that the entity performing the model verification has flexibility regarding if the model should be represented by individual unit or plant aggregate models or any combination therein as dictated by the specific situation.** o Page 15, Equivalent applicable unit - Identically designed generation units are identical in control response, independent of site location. New techniques for validation eliminate the impact of the grid on the validation efforts. Thus, credit for sister unit validations should be available independent of the location of a unit or connected voltage. **The SDT notes the general agreement among industry with using the proxy unit approach. The SDT respectfully maintains that the "same physical location" requirement is necessary since it provides a strong indication of similarity of equipment and settings (which could be verified by the same field personnel during**

Organization	Yes or No	Question 5 Comment
		a single site review). For example, a GO/GOP could own/operate otherwise similar equipment physically located in vastly different geographic locations with substantially different Reliability Coordinator or Transmission Operator requirements (e.g. requirement for PSS in-service). To ensure all GO/GOP equipment meets standard intent, the SDT maintains the "same physical location" requirement is necessary.
Response: Thank you for your comment. Please see responses above.		
American Transmission Company, LLC		ATC recommends that the SDT give consideration to the following:1. In Requirements, R1, bullet 2 - change the wording to be more similar to bullet 1, "obtain model library block diagrams and/or data sheets that are acceptable to the Transmission Planner for use in dynamic simulations". Software manufacturer model library block diagrams and data sheets are usually proprietary and most Generator Owners do not own the license to receive them. As in the more general wording bullet 1, requiring instructions to simply obtain acceptable diagrams and data sheets, allows the Transmission Planner to provide instructions for obtaining either public (IEEE standard) or proprietary diagrams and data sheets depending on the Generator Owner licenses or lack of licenses. **The standard drafting team has revised the wording of Requirement R1 bullet two. Also, it should be noted that the software manufacturers have indicated that they will make accommodations so that generator owners without software licenses can receive the block diagrams and data sheets. Transmission planners ordinarily have license agreements that do not permit them to provide the block diagrams and data sheets directly to the generator owner.** 2. In Event Triggering Verification Table, Item 6, Cell 1 - fix typographical error of ". . . system event did not "did not" match . . ." **The typographical error has been corrected.**

Organization	Yes or No	Question 5 Comment
Response: Thank you for your comment. Please see responses above.		
ERCOT		1: Requirement R2 and voltage ride through curve in the PRC-024 Attachment 2 are applicable to the voltage at point of interconnection to the Bulk Electric System (BES). However, in requirement R2.1 "When operating within 95 percent to 105 percent of rated generator terminal voltage and during the transmission system operating conditions defined in PRC-024 Attachment 2, with the following clarifications:" The clarification is needed for R2.1 that describes how the generator terminal voltage will affect the applicability to this requirement. **The clarification phrase has been removed and Requirement R2 has been restructured to provide more clarity around when it is acceptable for the unit to trip.** 2: In the attachment 1 and attachment 2, it is not clear if a unit can be allowed to trip instantaneously under extreme high voltage or high/low frequency occurred during and post disturbance period. For example, the physical limitation requires a wind farm to trip the turbine instantaneously when voltage is above 1.25 pu. If there is a short duration of overvoltage, 1.3pu for 0.15 second, during and post disturbance period that cause the wind farm trip the turbines, does this wind farm violate the requirement as stated in attachment 2 that requires the wind farm to remain in service for 0.2 second when voltage is above 1.2 pu? **Tripping of a unit or plant is allowed anywhere outside of the curves. The table in attachment 2 has been revised and now has an entry that allows for instantaneous tripping when the voltage is greater than or equal to 1.20 pu.**
Response: Thank you for your comment. Please see responses above.		
Cowltiz PUD		Cowlitz PUD respectfully disagrees with the use of the statutory term bulk[-]power system in the applicability section of any reliability standard. This term is not

Organization	Yes or No	Question 5 Comment
		adequately defined to be used anywhere excepting arguments as to whether a proposed standard falls within the jurisdiction of the Federal Power Act of 2005. Use of the statutory term will hamper any future efforts to revise the Statement of Compliance Registry Criteria. The Bulk Electric System is a subset of the bulk-power system. If the intent of the SDT is to include any generation of stated MVA name plate capacity connected to a "transmission system" operated at an undefined voltage, the result will be to defeat work being done to technically justify exclusion of certain bulk-power system facilities which have no substantial impact on Reliability. If however, the intent of the SDT is to follow the Statement of Compliance Registry Criteria and imply that the "BPS" is equal to the BES, it is preferable to specify generation connection voltage than use BPS. Cowlitz agrees that non-BES generation may need to be included in this standard's applicability section (as users of the BES), however specific generation that a particular GO may own which by itself would not have required registration of the entity should not be inadvertently included in the applicability of this standard.
Response: We appreciate your thoughtful comments. Based upon your comments and others, the SDT replaced references to the BPS with references to the BES which is the NERC defined term.		
FirstEnergy Corp		FirstEnergy would like to make the following comments on this standard: 1) Under the Applicability section 4.2.1.2, the use if the term "common bus" should be clarified as either the low-side or high-side of the GSU. **The SDT team believes that the consistent use of the term "directly connected to the Bulk Electric System" in the current draft of the standard makes it clear that it is referring to the high side of GSUs of 115 kV or greater.** 2) Footnote 1a on Page 2, says that "... the generator excitation control system includes the generator, exciter, voltage regulator and power system stabilizer."

Organization	Yes or No	Question 5 Comment
		While we understand that the excitation system supplies the generator field, there is a separate Model for the Generator (typically GENROU). We suggest omitting the word generator from the footnote to avoid confusion. **The SDT believes that the generator is an integral part of the voltage/reactive power control loop and thus an essential part to the validation of the excitation control system response. As such, there is no separate Standard regarding the validation of the generator model, so the SDT believes there is no conflict or confusion regarding the validation of the generator model.** 3) Suggest rewording 2.1 to begin with, "Provide models acceptable to the Transmission Planner, including verified parameters ...", rather than "Perform verifications ...". The GO provides information on applicable models as well as the parameters. The TP actually runs the models to determine system impact. **The SDT has assigned responsibility for model verification to the Generator Owner and has received support for this proposal from the vast majority of industry. Generator Owners have access to the equipment, along with access to the equipment's Original Equipment Manufacturer for assistance with technical issues. Historically, the Transmission Planner and Generator Owner entities used to work for the same company, but in today's functional model environment, Transmission Planners could easily work for a different company than the generation entity. As such, the stated access advantages for the generation entity do not transfer to the Transmission Planner.** 4) Requirement 2.1.1 requires "Documentation demonstrating the applicable unit's model response matches the recorded response for a voltage excursion at the applicable unit's point of interconnections from either a staged test or a measured system disturbance. O Please define or qualify the term "matches". This is a subjective term, subject to interpretation of results; i.e., what % error is considered "matching". **The SDT consciously avoided definitions of how tests are performed as well as**

Organization	Yes or No	Question 5 Comment
		quality of match between model and test to avoid risk of being over-prescriptive and too restrictive. The focus is solely on "what" is required, not "how" it's done. Ultimately, the Generator Owner and their testing and model validation entities are left to determine the appropriate tests and responses to validate models against, as well as determining how well the model represents the as-installed equipment. oRefers to recorded response "... at the applicable unit's point of interconnection ...". This should be reworded to "at generator terminals". An excitation system controls to the generator terminals since this is where Voltage and Current inputs to the AVR originate. Further, this is where measurements are taken during dynamic testing. **Specific reference to point of connection is removed from Requirement R 2, Part 2.1.1. Language has been modified to: "Documentation demonstrating the applicable unit's model response matches the recorded response for a voltage excursion from either a staged test or a measured system disturbance."** o"a measured system disturbance" is not practical for a GO, and should be eliminated. DME is owned by the TO, and do not have access to results of disturbances. **The intent of this language is to allow GO's to use recorded data (if they have it) from a known system event as a means to validate an exciter or volt/var control model against. Ultimately, the usability of this or any data to validate a model against is at the discretion of the GO and their testing and model validation entities.**
Response: Thank you for your comment. Please see responses above.		
American Electric Power		For section 4.2 we suggest the term "bulk power system" be replaced with "Bulk Electric System". BES is currently being defined, while bulk power system currently does not have a definition and thus is ambiguous.

Organization	Yes or No	Question 5 Comment
		Based upon your comments and others, the SDT replaced references to the BPS with references to the BES which is the NERC defined term. In the second bullet of 4.2.1.2, one of the words “comprised” or “consisting” needs to be removed as they are redundant. Also, we are confused by the bullets in 4.2.1.2 which should be re-worded to clarify the intent. For example, would diesel generators at a larger facility be in scope of this requirement? Furthermore, the qualifier between the two bullets should be “or” rather than “and”. **The section was re-written to provide clarity and in the process, the word “comprised” was deleted. With the new language, the qualifier between the bullets is correct.** For the effective date, we recommend not mixing years and quarters. Instead, we recommend that the total number of quarters be used, otherwise it is unclear if the effective date is the quarter following the year or the quarter at the end of that year. **The effective date is specified using standard language that is well known and understood.** Throughout the standard, “generator excitation control system and plant volt/var control function model” should have an “or” rather than an “and”. **The SDT implemented your suggestion.** The second footnote in requirement 4 could be interpreted to be all-inclusive. Please check the numbering of all footnotes and the pages that those footnotes reference. References should only be made to footnotes on the same page as the referring number. **The SDT has made the aforementioned corrections.**
Response: Thank you for your comment. Please see responses above.		
Indiana Municipal Power		IMPA believes that the reference of “bulk power system” should be replaced with

Organization	Yes or No	Question 5 Comment
Agency		Bulk Electric System throughout the standard. Bulk power system is used in the Compliance Registry, but it is not a NERC defined term. FERC even agrees that bulk power system goes beyond the Bulk Electric System (FERC Order 693). **Based upon your comments and others, the SDT replaced references to the BPS with references to the BES which is the NERC defined term.** IMPA is troubled by the requirement in R2.1.1 that requires a voltage excursion from a staged test or a measured system disturbance. Are there an ample supply of contractors or consultants that can perform such a test? What is the risk to a unit to perform the staged test? **A staged test to obtain data to verify excitation control system models does not typically involve an actual BES voltage excursion. A stage test typically involves injecting a step change signal into the unit's voltage regulator – which makes the voltage regulator "think" that a voltage excursion has occurred. Usually a laptop PC can be used to record the resulting staged testing data. There has been ample experience in industry with safely and effectively using a staged test.**
Response: Thank you for your comment. Please see responses above.		
Los Angeles Department of Water and Power		LADWP supports the language under Attachment 1, "Consideration for Early Compliance".
Response: Response: Thank you for your comment.		
Manitoba Hydro		Manitoba Hydro is voting negative for the following reasons: 1 - Implementation time frames - the implementation plans/effective dates for the standards MOD-025, MOD-026, MOD-027, and PRC-019 in Project 2007-09 should be the same to reduce unnecessary outages and to maximize the productivity of site visits. Manitoba Hydro suggests that the implementation plan for MOD-026 be applied to MOD-025, MOD-027 and PRC-019.

Organization	Yes or No	Question 5 Comment
		MOD-024 and MOD-025 have now been combined. The verification of steady state MW and MVAR capabilities would be accomplished by test which is distinctly different than the activities required for verification of excitation control systems. Also, the verification of steady state MW and MVAR capabilities would be accomplished without taking the unit out of service. Personnel involved in steady state MW and MVAR capabilities will almost certainly be different than personnel involved in the verification of excitation control systems. Also, the verification of excitation control systems per the current draft of MOD-026 will almost always be ten years, whereas the periodicity of steady state MW and MVAR capabilities per the current draft of MOD-025 is only five years. MOD-012 and MOD-013 are simply data submittal standards as opposed to data verification standards. Also, the effective and implementation dates for the current drafts of MOD-026 and MOD-027 (dynamic model verification standards) are effectively the same. 2 - R5 'walk down' - the requirement of a 'walk down' of equipment in R5 is unclear. Manitoba Hydro suggests that the wording be revised to 'based on an onsite review of the equipment. **The text has been modified and the expression "walk down" was replaced by "on-site review" of the equipment.** '3 - Data Retention - The data retention requirements are too uncertain for two reasons. First, the requirement to "provide other evidence" if the evidence retention period specified is shorter than the time since the last audit introduces uncertainty because a responsible entity has no means of knowing if or when an audit may occur of the relevant standard. Secondly, it is unclear what 'other evidence', besides the specified evidence in the Measures, an entity may be asked to provide to demonstrate it was compliant for the full time period since their last audit. **Entities need to be able to demonstrate that they are compliant with the standard, regardless of the date of the last audit. The drafting team used the boilerplate language endorsed by the Standards Committee.**

Organization	Yes or No	Question 5 Comment
		Manitoba Hydro also suggests that synchronous condensers be included in MOD-026. **The GVSDT asked stakeholders if they believed that synchronous condensers should be applicable under MOD-026. The majority of commenters believe that synchronous condensers should not be included in MOD-026. Synchronous condensers are not currently addressed in the NERC Registry Criteria. On an MVA capacity basis, the penetration of synchronous condensers in North America is extremely low, with many units owned by Transmission Owners. As such, the peer review draft requirements would not make sense. The SDT decided that, with the current structure of the Compliance Registry Criteria, if there is a need to develop a reliability standard to model the expected behavior of dynamic voltage devices typically owned by Transmission entities, then a more appropriate strategy is to include synchronous condensers along with other Transmission system dynamic reactive devices (such as SVCs, STATCOMs, etc.) into a separate SAR. The GVSDT will closely monitor BES SDT efforts to define BES and the correlation of BES elements with the ERO Statement of Compliance Registry Criteria, and make appropriate adjustment as necessary to the Applicability of MOD-026-1 regarding the treatment of synchronous condensers.**
Response: Thank you for your comment. Please see responses above.		
Entergy Services		MOD-026-1 R2.1.1 is:2.1.1. Documentation demonstrating the applicable unit's model response matches the recorded response for a voltage excursion at the applicable unit's POINT OF INTERCONNECTION from either a staged test or a measured system disturbance. We recommend the POINT OF INTERCONNECTION be changed to GENERATOR TERMINALS.
Response: Thank you for your comment. Specific reference to point of connection is removed from Requirement R2 Part 2.1.1. Language has been modified to: "Documentation demonstrating the applicable unit's model response matches the recorded response for a voltage excursion from either a staged test or a measured system disturbance."		

Organization	Yes or No	Question 5 Comment
Progress Energy		Our AFFIRMATIVE vote is conditional upon the "Clean" version being voted on. There are major differences between the Red-line and clean version in Section 5 "Effective Date". The Clean version 5.1.3 requires 50 % where as Red-line version has 100 %
Response: Thank you for your comment. The clean version is the appropriate version to reference if there are any differences between the clean and red line versions.		
MRO NSRF		Please give consideration to the following suggestions from the MRO NSRF: 1. In Requirements, R1, bullet 2 - change the wording to be more similar to bullet 1, “obtain model library block diagrams and/or data sheets that are acceptable to the Transmission Planner for use in dynamic simulations”. Software manufacturer model library block diagrams and data sheets are usually proprietary and most Generator Owners do not own the license to receive them. As in the more general wording bullet 1, requiring instructions to simply obtain acceptable diagrams and data sheets allows the Transmission Planner to provide instructions for obtaining either public (IEEE standard) or proprietary diagrams and data sheets depending on the Generator Owner licenses or lack of licenses. **The standard drafting team has revised the wording of Requirement R1 bullet two. Also, it should be noted that the software manufacturers have indicated that they will make accommodations so that generator owners without software licenses can receive the block diagrams and data sheets. Transmission Planners ordinarily have license agreements that do not permit them to provide the block diagrams and data sheets directly to the generator owner.** 2. In Event Triggering Verification Table, Item 6, Cell 1 - fix typographical error of “. . . system event did not did not match . . .” **The typographical error has been corrected.** 3. Please restructure requirements and evidence to allow for posted instructions and model data to meet compliance for appropriate requirements such as R1,R2, etc...

Organization	Yes or No	Question 5 Comment
		Response: The SDT apologizes but we could not determine your question. 4. In the second bullet item under Applicability Section 4.2.1.2, recommend the drafting team remove the word "consisting" and add the word "solely" to avoid confusion. Section 4.2.1.2 would instead read "Each generating plant / Facility comprised consisting solely of ...". **Section 4.2.2 of the standard applicability has been revised and the word "consisting" has been deleted.** 5. Recommend the capacity factor test in Applicability Section 4.2 be revised to state: "Applicable units or plants with an average capacity factor greater than 5 percent ..." As currently drafted, it is unclear as to whether all units, applicable or not, are included in the calculation of the Capacity Factor (CF). In cases where an entity has a plant with one 60 MVA unit and three 15 MVA units, the units less than 20 MVA would not be applicable per the criteria in MOD-026-1. However, would all units still be factored into the CF calculation? **The capacity factor statement in section 4.2 is the first qualifying statement for applicability of all units. Any unit that does not meet the capacity factor qualifier is not included in the standard. Any unit that does meet the capacity factor qualifier is then subjected to the next qualifiers of MVA rating and connection to the BES. The SDT does not believe that the use of the word "applicable" in the capacity factor qualifier would clarify the standard.** 6. Requirement R6.3 specifies "a disturbance simulation results in .... exhibiting positive damping". Guidance is needed as to what is considered acceptable positive damping. **The SDT believes that excitation systems and other closed-loop control systems in a power plant (barred some mal-function or failure) are commissioned to provide stable and properly damped response. Thus, validated simulation models should exhibit a similar response and that can be easily assessed using simulations as those described in Part 6.1 to Part 6.3. On the other hand, a model that does not**

Organization	Yes or No	Question 5 Comment
		exhibit a stable and properly damped response to these simulations described in Part 6.1 to Part 6.3 is probably not representing the actual behavior of the equipment and this discrepancy should be addressed before the model is accepted and deemed usable. It should be noted that Part 6.1 to Part 6.3 are related to the usability of these validated models in system studies, not exactly with the validation. 7. R6 has two periods at the end of the paragraph just before [Violation Risk Factor ...] **This has been corrected in this revision.** 8. In the applicability section 4.2, the undefined term bulk power system is used. To avoid confusion regarding the applicability, it is recommended the defined term Bulk Electric System be used. **Based upon your comments and others, the SDT replaced references to the BPS with references to the BES which is the NERC defined term.**
Response: Thank you for your comment. Please see responses above.		
ReliabilityFirst		ReliabilityFirst abstains on the MOD-026-1 ballot and offers the following comments for consideration: 1. Facilities a. What is the rationale/justification for the size qualification for applicable units (i.e. greater than 100 MVA)? ReliabilityFirst believes all generating units connected to the BES and referenced in the NERC Statement of Compliance Registry Criteria should be included within this standard. **As discussed in the Comment Form with the first posting of the draft MOD-026 standard, the SDT considered the extent of the facilities to be verified and how to reflect this in the "applicability" of this proposed standard. As a basis, the SDT recognized that the excitation system models and model data are already collected through the processes identified in MOD-012 and MOD-013. These models and data should, with few exceptions, already result in a quality**

Organization	Yes or No	Question 5 Comment
		dynamics database. However, as confirmed through the Field Test, performing the activities specified in the draft standard is expected to result in an improvement of the accuracy of the exciter models used in dynamic simulations. Utilizing engineering judgment, based in part on recent entity experiences in verifying excitation system models, the SDT is proposing to require verification of excitation systems associated with 80% or greater of the connected MVA per Interconnection. Therefore, specific MVA thresholds corresponding to 80% of connected MVA or greater for each Interconnection are proposed. The SDT further believes that a minimum unit interconnection of >100 kV, consistent with the Compliance Registry Guidelines, is appropriate. Finally, the SDT believes that the standard should apply to units with a capacity factor such that they are on-line 1000 hours or greater a year. The SDT believes that these three applicability thresholds will result in substantial accuracy improvement to the excitation models and associated Reliability based limits determined by dynamic simulations, while not unduly mandating costly and time consuming verification efforts. The SDT asked a specific question on the Comment Form regarding the proposed applicability, and the response to the question reflected Industry concurrence with this approach. 2. Requirement R1 a. For the purposes of NERC standards, "bullets points" are to be considered "OR" statement. ReliabilityFirst believes all the "bullets points" in R1 are required and should renumbered into sub-parts (i.e. 1.1, 1.2, 1.3) **The SDT believes that these bullet points are "OR" statements, at least to the sense that a Generation Owner might not have requested all three items listed in the bullets. The requirement is meant to be that the TP should provide the information requested by the GO.** 3. Requirement R5a. ReliabilityFirst is unclear on the meaning of the term "walk down of the equipment" in the second bullet? ReliabilityFirst request further clarification of the term "walk down of the equipment?"

Organization	Yes or No	Question 5 Comment
		The text has been modified and the expression "walk down" was replaced by "on-site review" of the equipment. 4. Requirement R6a. ReliabilityFirst requests further clarification on the term "initializes" as referenced in Subpart 6.1. Is this in the context of excitation control system and plant volt/var control function model initialization within a PSSE application? **The SDT wants to reiterate that model usability is a different issue than model validation. The objective of Part 6.1 to Part 6.3 is to assess the usability of the models in system simulations (e.g. PSS/E, PSLF or whatever simulation tool being used). The tests listed in these requirements are expected to be typically performed when a new model is incorporated to the simulation database.** 5. Section G. References. ReliabilityFirst recommends removing the references in Reference Section G and place it into a reference type document. Even though this good information, it is not needed in a Reliability Standard. **The SDT believes the references are useful to some users and should be provided in the most helpful location. In some cases, references are included in a NERC standard instead of moving them to a separate document.** 6. VSL Requirement R2a. Requirement R2 contains a sub-part 2.2 which is not mentioned in the corresponding Violation Severity Level (VSL). ReliabilityFirst recommends including a VSL covering Subpart 2.2. Here is an example of a "lower" VSL: "For plants that are comprised of units that have a gross nameplate rating of less than 20 MVA in Requirement R2, Subpart 2.2, the Generator provided the Transmission Planner verified models, using plant aggregate model(s), that omitted one of the six Parts identified in Requirement R2, Subparts 2.1.1 through 2.1.6." **Requirement R2, Part 2.2 has been re-worded and merged into Part 2.1. The new verbiage makes it clear that the entity performing the model verification has flexibility regarding if the model should be represented by individual unit or**

Organization	Yes or No	Question 5 Comment
		plant aggregate models or any combination therein as dictated by the specific situation. A VSL does exist in the current draft for Part 2.1. 7. VSL Requirement R5 a. The VSL for “High” and “Severe” mention Subparts 5.2 and 5.3 though there are no associated subparts referenced in Requirement R5 (there are only 2 bullet points). ReliabilityFirst recommends removing the references to Subparts 5.2 and 5.3. **Based on your comment, the SDT has revised the verbiage for the High VSL to not include any references to the sub bullets in Requirement R5, and revised the verbiage for the Severe VSL to include “ OR The Generator Owner’s written response failed to include one of the sub bullets of Requirement R5”** 8. VSL Requirement R6a. R6 requires the Transmission Planners to “...notify the Generator Owner within 90 calendar days... “, while the corresponding VSL states “The Transmission Planner provided a written response to the Generator Owner indicating...” **The reference to the required time frame in the VSL is included.** Based on the FERC Guideline #3 "Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement," ReliabilityFirst recommends the following as an example of the “Lower” VSL: “The Transmission Planner notified the Generator Owner indicating whether the model is useable or not useable; including a technical description if the model is not useable, more than 90 calendar days but less than 120 calendar days of receiving verified model information. (R6)” **The SDT believes that all of the relevant information is addressed in an acceptable format in the current version of the VSL.**
Response: Thank you for your comment. Please see responses above.		
Florida Municipal Power Agency		The applicability refers to the “bulk power system”, e.g., “4.2.1.1 Individual generating unit greater than 100 MVA (gross nameplate rating) directly connected to

Organization	Yes or No	Question 5 Comment
		the bulk power system". The term "bulk-power system" should not be used in the standards as it is ambiguous and should be replaced with "Bulk Electric System". We do not understand how the Applicability of 4.2.1.2 means. **Based upon your comments and others, the SDT replaced references to the BPS with references to the BES which is the NERC defined term.** We suggest making the language clearer.R2.1.1 should only apply if a system disturbance actually happens and should not require a staged test. A staged test could threaten the reliability of the BES more than inaccuracy of an excitation system model. **A staged test to obtain data to verify excitation control system models does not typically involve an actual BES voltage excursion. A staged test typically involves injecting a step change signal into the unit's voltage regulator – which makes the voltage regulator "think" that a voltage excursion has occurred. Usually a laptop PC can be used to record the resulting staged testing data. There has been ample experience in industry with safely and effectively using a staged test.** R4 should specifically exclude temporary changes, e.g., generator AVR settings are often changed when the unit is started or shut-down, if the AVR is planned out of service, etc., we believe the intent of the standard is only to communicate more permanent changes and not temporary changes. **Changes in operating mode (auto/manual, PSS on/off, etc.) do not trigger the need to provide a revised model or re-verification as described in Requirement 5. The following sentence has been added to Footnote 4 in the current draft of the standard to clarify the intent: "Automatic changes in settings that occur due to changes in operating mode do not apply to Requirement 5".** R5 is ambiguous. What is technically justified? Who gets to decide what is technically qualified? **The technical justification for a request is described in Footnote 2 of the current**

Organization	Yes or No	Question 5 Comment
		draft of the standard.
Response: Thank you for your comment. Please see responses above.		
City of Vero Beach		The applicability refers to the "bulk power system", e.g., "4.2.1.1 Individual generating unit greater than 100 MVA (gross nameplate rating) directly connected to the bulk power system". The term "bulk-power system" should not be used in the standards as it is ambiguous and should be replaced with "Bulk Electric System". We do not understand how the Applicability of 4.2.1.2 means. **Based upon your comments and others, the SDT replaced references to the BPS with references to the BES which is the NERC defined term.** We suggest making the language clearer.R2.1.1 should only apply if a system disturbance actually happens and should not require a staged test. A staged test could threaten the reliability of the BES more than inaccuracy of an excitation system model. **A staged test to obtain data to verify excitation control system models does not typically involve an actual BES voltage excursion. A staged test typically involves injecting a step change signal into the unit's voltage regulator – which makes the voltage regulator "think" that a voltage excursion has occurred. Usually a laptop PC can be used to record the resulting staged testing data. There has been ample experience in industry with safely and effectively using a staged test.** R4 should specifically exclude temporary changes, e.g., generator AVR settings are often changed when the unit is started or shut-down, if the AVR is planned out of service, etc., we believe the intent of the standard is only to communicate more permanent changes and not temporary changes. **Changes in operating mode (auto/manual, PSS on/off, etc.) do not trigger the need to provide a revised model or re-verification as described in Requirement 5. The following sentence has been added to Footnote 6 to clarify the intent: "Automatic changes in settings that occur due to changes in operating mode do not apply to**

Organization	Yes or No	Question 5 Comment
		Requirement R5". R5 is ambiguous. What is technically justified? Who gets to decide what is technically qualified? **The technical justification for a request is described in Footnote 2 of the current draft of the standard.**
Response: Thank you for your comment. Please see responses above.		
Dynegy		The division of responsibility (between GO and TP) in the task of 'verifying' the model should be revisited. Some GOs have neither the modeling expertise nor the software for this task. TPs typically have more experience running these types of models. We believe a more appropriate division of responsibility is to have the GO supply the field data from the response test and let the TP run and 'verify' the models. This would also eliminate the question of what constitutes a 'verified' model, i.e., how good is good enough.
Response: Thank you for your comment. The SDT considered who should be the owner of the model and asked Industry during the first posting. Generator Owners have access to the equipment, along with access to the equipment's Original Equipment Manufacturer for assistance with technical issues. Historically, the Transmission Planner and Generator Owner entities used to work for the same company, but in today's functional model environment, Transmission Planners could easily work for a different company than the generation entity. As such, the stated access advantages for the generation entity do not transfer to the Transmission Planner. For all of these reasons, the SDT believes that the Generator Owner is the appropriate entity to perform model verification activities. Finally, as the owner of the model, the peer review Requirement R3 clearly states that the Generator Owner has the final say for any technical discussions regarding the model. Finally, the Generator Owner could pursue entering an agreement with the Transmission Planner to perform portions or all of model verification. However, the Generator Owner would still be responsible from a compliance perspective.		
Western Electricity		The introduction to this comment form indicates that "The typographical errors in R2.1.1 language has been corrected to clearly state expectation that, "The unit or

Organization	Yes or No	Question 5 Comment
Coordinating Council		plant's model response matches the recorded response for a voltage excursion at the generator or plant point of Interconnection..." However, the versions posted for review (clean and redline) do not indicate that the "unit or plan's model..." They say the "applicable unit's model response matches..." There is no reference to plants in part 2.1.1
Response: Thank you for your comment. In the Applicability section 4.2 (Facilities), the first sentence reads "For the purpose of this standard, the following Facilities are considered…."applicable units" Units or plants that meet the following ….." . As such, references in the standard to "applicable units" includes units and plants. A reference to an "applicable unit" is included in part 2.1.1		
Austin Energy		The standard drafting team may consider adding the sentences in footnotes 2 & 3 directly to section 4.2 Facilities to avoid potentially unnecessary complexity. Also in section 4.2 Facilities, the term bulk power system (BPS), not BES is used. Would use of BES instead of BPS remove the need for footnote 2 without changing the overall intent of the SDT?
Response: We appreciate your thoughtful comments. Based upon your comments and others, the SDT replaced references to the BPS with references to the BES which is the NERC defined term. The SDT also removed Footnote 2. The SDT believes that the standard is more readable by placing the information pertaining to capacity factor in the footnote.		
Consolidated Edison Co. of NY, Inc.		Use of terms Bulk Electric System (BES) in the purpose and bulk power system in the Applicability section should be reconciled. NERC is standardizing on the term Bulk Electric System (BES). **Based upon your comments and others, the SDT replaced references to the BPS with references to the BES which is the NERC defined term.**

Organization	Yes or No	Question 5 Comment
		Requirement 2: o R2.1.1: requires that model results must "match" results from field testing. This language implies that there is zero tolerance which is unreasonable. There should be some stipulated allowed tolerance band. We suggest that a tolerance is a specific value based on per unit. For example, the model and actual response shall match within a tolerance of .02 per unit of the buss voltage being controlled. **The draft standard states "what is required" but not "how to accomplish what is required". The SDT considered ways to quantify a method for evaluating how well the equipment's measured response matches the model's predicted response. However, since a generally accepted technique or criteria for making this quantitative assessment does not exist, the SDT believes that the peer review process incorporated into the standard will ensure model quality. The SDT believes all entities involved with the peer review process have common purpose to develop an accurate excitation control system model.** o The units "point of interconnection" is open to interpretation and could create compliance uncertainty. Almost all generator excitation systems control the generator terminal voltage (low side of the GSU) while the term "point of interconnection" may be interpreted as on the substation bus (high side of the GSU). A suggestion is use the following: at the buss controlled by the generator excitation system. **Specific reference to point of connection is removed from Requirement R2, Part 2.1.1. Language has been modified to: "Documentation demonstrating the applicable unit's model response matches the recorded response for a voltage excursion from either a staged test or a measured system disturbance."** The Applicability Section of the Standard, Section 4.2 permits exclusion of generators with a low capacity factor (< 5%). Why should the Standard allow an exemption for low capacity factor units? The objective of the Standard is to develop good excitation models for dynamics simulations, which are often conducted under high

Organization	Yes or No	Question 5 Comment
		load conditions. At higher loads, these lower capacity factor units are frequently needed and operating. Therefore the Standard should apply to even lower capacity factor units. **The increase in excitation control system model verification is expected to result in improved accuracy of stability based security assessments. The SDT does not believe un-verified data is necessarily inaccurate or that the overall stability of the system is sensitive to that data. The excitation information from the generating units with a 5% capacity factor or less, as provided per standards MOD-012 and MOD-013, is included in the models used to analyze the system under various conditions. Even if these low capacity factor generating units are verified, the accuracy of the simulation is not guaranteed because there are other significant assumptions involved in simulation results, such as load models. As such, the verified models do not provide absolute accuracy under operating conditions other than those conditions for which verification is performed.** Tables following Attachment 1: the purpose of these tables is not clear, they are not referenced in the Requirements. **The periodicity information included in Attachment 1 is referenced in Requirement 2, "...in accordance with the periodicity specified in MOD-026 Attachment 1". The attachment table format is being used because the SDT believes that it is the clearest way to present the periodicity information.** Note, there is an entire page of technical references included in the Standard (section G). It is not clear why this is necessary, as the references are described as "beyond the scope of this Standard". **The references are industry documents related to excitation systems. They are provided as a courtesy only because the SDT believes they will be helpful to some users. The referenced documents are not required reading nor are they required for compliance with the standard.**

Organization	Yes or No	Question 5 Comment
Response: Thank you for your comment. Please see responses above.		
Northeast Power Coordinating Council		Use of the terms Bulk Electric System (BES) in the Purpose and bulk power system in the Facilities Section should be reconciled. NERC is standardizing on the term Bulk Electric System (BES). **Based upon your comments and others, the SDT replaced references to the BPS with references to the BES which is the NERC defined term.** In the Applicability Section under the Introduction, the bullets under 4.2.1.2 are unnecessary. The wording of 4.2.1.2 already covers what the bullets detail. **The SDT has refined section 4.2.1.2 of the Facilities section under** **Applicability to provide added clarity.** Regarding Requirement 2: o R2.1.1: requires that model results must "match" results from field testing. This language implies that there is zero tolerance which is unreasonable. There should be a stipulated allowable tolerance band. Suggest that a tolerance be a specific value based on per unit. For example, the model and actual response shall match within a tolerance of .02 per unit of the bus voltage being controlled. o R2.1.1: A unit's "point of interconnection" is open to interpretation and could create compliance uncertainty. Almost all generator excitation systems control the generator terminal voltage (low side of the GSU) while the term "point of interconnection" may be interpreted as on the substation bus (high side of the GSU). A suggestion is use the following: at the bus controlled by the generator excitation system. **Specific reference to point of interconnection is removed from Requirement R2 Part 2.1.1. Language has been modified to: "Documentation demonstrating the applicable unit's model response matches the recorded response for a voltage excursion from either a staged test or a measured system disturbance."**

Organization	Yes or No	Question 5 Comment
		Tables following Attachment 1: the purpose of these tables is not clear, they are not referenced in the Requirements. **The periodicity information included in Attachment 1 is referenced in Requirement 2, "...in accordance with the periodicity specified in MOD-026 Attachment 1". The attachment table format is being used because the SDT believes that it is the clearest way to present the periodicity information.** Why are the References listed in Section G included? They are described as being "beyond the scope of this Standard". **The references are industry documents related to excitation systems. They are provided as a courtesy only because the SDT believes they will be helpful to some users. The referenced documents are not required reading nor are they required for compliance with the standard.** The language for R4 should be reworded as follows: "R4. Each Generator Owner shall provide revised model data or plans to perform model verification7 (in accordance with Requirement R2) to its Transmission Planner within 180 calendar days of prior to making changes to the excitation control system and plant volt/var control function that alter the equipment response8 characteristic." **The SDT drafted the standard recognizing the model verification requires expertise and calendar time. The model cannot be verified until the actual equipment is installed. While 180 days is the maximum time period that can be utilized to be deemed compliant, it should be recognized that in the vast majority of cases, the personnel that implement the excitation control and plant volt/var control function modifications would also perform testing of the new equipment including staged tests leading to a new model. As such, it would be expected that the final model would be submitted well before the 180 days afforded for compliance.** The way the language is currently written, the generator has to provide its revised model data or plans to perform model verification within 180 days of making the change. For up to 180 days after a change has been made the correct data still may

Organization	Yes or No	Question 5 Comment
		not have been made available to the Transmission Planner. This could have a significant impact on reliability. **The SDT drafted the standard recognizing the model verification requires expertise and calendar time. 180 days is the maximum time period that can be utilized to be deemed compliant. It is expected that all entities will strive to verify the model as quickly as practical.** The suggested rewording addresses this possibility. The suggested language would be in line with FERC approved language that is currently part of ISO Tariffs. What is the definition of Gross Nameplate Rating as used in the Standard? **The gross nameplate rating in the applicability of the standard is not capitalized. The gross nameplate rating refers to generator nameplate ratings.**
Response: Thank you for your comment. Please see responses above.		
Southern Company		We agree that the collection of preliminary excitation control system model data from the equipment manufacturer is outside the scope of this standard. Also, any pre-COD staged testing to collect equipment responses to be used to verify the model can be required via Interconnection Agreements. It is understood that any equipment responses collected through pre-COD staged testing with final equipment settings in place that is subsequently used for model verification per the Requirements in the standard would result in fulfilling the requirements for model verification for the next 10 years per the Periodicity Table or until a special circumstance occurs leading to an earlier model re-verification as detailed in Requirements R3, R4, R5, or R5. The limitation to allow sisterhood for only those units at the same physical location should be extended to all identical units for the same GO/GOP - a sister is a sister is a sister. The GO should be allowed to take credit if he can show that the physical location is not a factor in the comparison.

Organization	Yes or No	Question 5 Comment
		The SDT notes the general agreement among industry with using the proxy unit approach. The SDT respectfully maintains that the "same physical location" requirement is necessary since it provides a strong indication of similarity of equipment and settings (which could be verified by the same field personnel during a single site walk down). For example, a GO/GOP could own/operate otherwise similar equipment physically located in vastly different geographic locations with substantially different Reliability Coordinator or Transmission Operator requirements (e.g. requirement for PSS in-service). To ensure all GO/GOP equipment meets standard intent, the SDT maintains the "same physical location" requirement is necessary. In section 4.2.1.1, and other places, we don't understand the use of "bulk power system" -shouldn't this be "Bulk Electric System". **Based upon your comments and others, the SDT replaced references to the BPS with references to the BES which is the NERC defined term.** In 4.2.1.2, second bullet, eliminate the word "comprised" as it is redundant with "consisting". The same redundant use of "comprised" is in section 4.2.2.2 and 4.2.3.2, second bullet. **Section 4.2.2 of the Facilities section under** **Applicability has been revised and the word "comprised" has been deleted.** In R2.1.4, the intended information is not clear - the closed loop voltage regulator part is not needed - it is part of the previous wording. In R2.2, replace "For plants" with "For applicable plants". Please add "where applicable" each time the "plant volt/var control" is used. **The SDT believes that the "closed loop voltage regulator" verbiage is needed to convey technical intent. Please note that at the beginning of the "Facilities" section, there is a phrase "For the purpose of this standard, the following Facilities are considered, "applicable units".**

Organization	Yes or No	Question 5 Comment
		Due to R5, the Planning Coordinator should be listed in the 4.1 Functional Entitles. **The reference to Planning Coordinator has been changed to Transmission Planner to be consistent with the Applicability section of the standard and to conform to NERC functional model.** R5 is confusing - the bullet items list what the GO response should include, but the sentence is written such that the list is what the model review must include. **The main body of the requirement includes the phrase right before the bullets "….that includes one of the following" which re-affirms that the one of the bullets is necessary.** In R2.1.1, please insert "or voltage at the generator terminal" to "at unit's point of interconnection". **Specific reference to point of connection is removed from Requirement R2 Part 2.1.1. Language has been modified to: "Documentation demonstrating the applicable unit's model response matches the recorded response for a voltage excursion from either a staged test or a measured system disturbance."**
Response: Thank you for your comment. Please see responses above.		
ACES Power Marketing Standards Collaborators		We continue to believe that this standard is overly administrative by memorializing the interactions between the Generator Owner, Transmission Planner and Planning Coordinator that occur to model the generator's excitation system. Most of the requirements are purely administrative and present compliance risk to the registered owners without commensurate reliability benefit. Addition of administrative requirements acts contrary to the recent efforts of FERC and NERC to eliminate compliance backlogs created by violations of requirements that present no reliability risk or benefits. This is the purpose of the FFT process that NERC initiated and FERC recently approved. Interestingly, within the approval order, FERC even suggested that these types of requirements need to be eliminated. Only two requirements are really needed to accomplish the purpose of this standard. They are: one

Organization	Yes or No	Question 5 Comment
		requirement for the Generator Owner to perform the test and one for the Transmission Planner to verify the model is accurate. Requirement R3 highlights the overly administrative nature of the standard and the problem with attempting to memorialize the cooperation that must occur between the Generator Owner and Transmission Planner to model the generator's excitation and volt/VAr control functions accurately. Requirement R3 allows a Generator Owner to simply respond with a technical basis for leaving its model intact which does not solve the Transmission Planner's model issue. Thus, this requirement does nothing for reliability because modeling problems cannot be left unsolved. It should be struck. **Requirement R3 is a "peer review" type requirement to ensure cooperation between the Generator Owner and the Transmission Planner. The SDT believes peer review is an essential part of the model verification process since the peer review provides the Transmission Planner an opportunity to review the data and identify problems or errors with information provided. The SDT believes that all entities will be equally motivated to resolve model issues. This process was over whelming supported by Industry based on their responses in prior postings.** We are not convinced Requirement R4 is needed. **Requirement 4 specifies the need for model verification due to changes to the excitation control system and plant volt/var control function that alter the equipment response characteristic. Without Requirement R4, there would be no trigger between the standard 10 year periodicity to update the model to reflect changes to the excitation system.** The situation of providing model updates when changes are made to the covered control systems is already covered in Attachment 1. Since Attachment 1 is referenced in Requirement R2, why is this additional Requirement R4 needed? If Requirement R4 is needed, we are assuming the drafting team did not think this situation was covered in Requirement R2. If this is the case, at the very least, Requirement R4 should reference Attachment 1. Otherwise, Attachment 1 would

Organization	Yes or No	Question 5 Comment
		not ever apply to the situation of applicable control system changes. **Requirement R4 specifies the need for model verification due to changes to the excitation control system and plant volt/var control function that alter the equipment response characteristic. Attachment 1 addresses the required periodicity and acceptable time delays to remain compliant.** For Requirement R5, there is no clarity for how soon the Generator Owner has to address the model concerns communicated by the Planning Coordinator. If the Generator Owner has the unit in its 10 year plan to test their generation fleet's control systems, they could simply communicate that plan which might be much longer than the Planning Coordinator intended. The drafting team needs to provide more guidance on whether the Generation Owner is expected to accelerate their plans for the unit in question by the Planning Coordinator and by how much. **The intent of the Requirement R5 is for Transmission Planners to use technical justification for validating models for units that meet NERC registry criteria but did not meet applicability threshold of the standard. The Generator Owner has 90 days from the receipt of a request to review and respond to the Transmission Planner's request. If the need for validation is agreed by Generator Owner, the Generator Owner has one calendar year from the date of submitted verification plan to complete validation.** For Requirement R5, who decides if the request is technically justified? Could the Generator Owner simply choose not to respond because they do not believe the request is technically justified? **The technical justification for a request is described in Footnote 4 on page 4 of the standard. However, Generator Owner can in writing challenge any findings of the Transmission Planner within 90 days of the request.** In the Background Information section of the comments, the drafting team indicated that the "standard is drafted to provide the proper cost/benefit balance for performing generator verification". Since the summaries of field test results posted

Organization	Yes or No	Question 5 Comment
		with the second draft of the SAR indicate the costs of these tests could range from $5,000 to $50,000 for a single unit and that does not even include opportunity costs from lost energy sales should the test cause the unit to trip, we believe it would be helpful for the drafting team to provide information on the cost/benefit that was discussed in the Background Information section of the comment form in the next posting. **The stance of the SDT concerning the proper cost/benefit balance was a result of the field test initiated by the Phase III-IV SDT. The field test involved participants from 4 regions including WECC, SERC, ERCOT, and MRO, and was conducted in 2006 to the summer of 2007. The final report is available on the NERC website. At the final face to face meeting of the Field Test, it was concluded by those in attendance that performing the activities specified in the draft standard is expected to result in an improvement of the accuracy of the exciter models used in dynamic simulations – but at the same time, everyone recognized that there is a monetary cost associated with verifying the models. The SDT believes that these applicability thresholds proposed in the draft standard is in support of the desire of the field test participants in that model verification will result in substantial accuracy improvement to the excitation models and associated Reliability based limits determined by dynamic simulations, while not unduly mandating costly and time consuming verification efforts. Also, it should be noted that industry experience has proven that the possibility of a unit trip during these tests is extremely low. If ambient monitoring is utilized, the risk is even lower as the collection of data is entirely passive.** The response to our comments regarding consideration for early compliance from the last posting was not satisfactory. In our comments we stated that we appreciated the drafting team's consideration to allow for early compliance based on past tests. However, we stated concerns regarding how to demonstrate this compliance because a registered entity was not required to retain documentation and may not be able to prove they completed a test. The drafting team responded that demonstration of compliance was beyond the scope of the drafting team. While

Organization	Yes or No	Question 5 Comment
		we agree demonstration of compliance for specific companies and situations are likely beyond the scope, demonstration of compliance in general is never beyond the scope. Drafting teams must write standard requirements with which can be complied. Given that the issue of evidence retention from before the effective date of the standard was one of the key subjects in the High-level review conducted by NERC for CAN-0008 recently at the request of the Trade Associations, we suggest the drafting team should consult the appropriate NERC subject matter experts to determine how to avoid these similar issues with this draft standard. **The verbiage for consideration for early compliance is, in part: "The Generator Owner has a verified model that is compliant with the applicable regional policies, guidelines or criteria existing at the time of model verification". The SDT believes that this conveys the intent that documentation required by those "regional policies, guidelines or criteria existing at the time of model verification" would constitute sufficient proof for early compliance.** Sections 4.2.1.2, 4.2.2.2, and 4.2.3.2 are confusing and potentially contradictory. First, these sections state that they apply to each generating plant/Facility greater than 100, 75 and 50 MVA respectively. Then, the second bullet under each of these sections applies to generating plant/Facility. How can there be a plant within a plant? **The SDT has removed the term "Facility from applicability section of the standard, except one time to clarify the use of the term "applicable units" throughout the standard.** With the first bullet, it appears the intent is to include generating units 20 MVA and greater within generating plants meeting the 100, 75, or 50 MVA thresholds, respectively. However, the second bullet really confuses us because it appears to bring in everything below 20 MVA which is not covered in the first bullet. These sections are further confused by the fact that they potentially apply a different threshold for individual generating units than section 4.2.1.1, 4.2.2.1, and 4.2.3.1

Organization	Yes or No	Question 5 Comment
		which apply to individual generating units. For example, 4.2.2.1 applies a 75 MVA threshold to an individual generating unit and then the first bullet of section 4.2.2.2 applies a 20 MVA unit threshold because it defines a generating plant/Facility as including one or more units. Using plant/Facility confuses the matter further. **The SDT has refined the aforementioned sections in the Applicability section to address your stated concerns.** The NERC Glossary of Terms uses a generator as an example of a Facility. In the second bullet under each segment, it appears the discussion is totally focused on a plant but despite the use of the singular Facility. **The SDT has removed the term "Facility from applicability section of the standard, except one time to clarify the use of the term "applicable units" throughout the standard.** The VRFs simply do not meet the NERC definitions for anything greater than Lower. Requirements R2 and R6 are written with Medium VRFs. All other requirements have Lower VRFs. Neither Requirement R2 nor R6 could be construed as affecting the electrical state or capability of the Bulk Electric System or the ability to monitor, control or restore it. Per NERC definition of Medium VRF, these are prerequisites for meeting a Medium VRF. For Requirement R1, the VRF justification for FERC Guideline 5 refers to the requirement having a high risk objective. This is not consistent with a Lower VRF. We agree with the Lower VRF and recommend removing the "high risk objective" language. **The language in the VRF Guidelines document for a Medium VRF is:** **Medium Risk Requirement** **A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under**

Organization	Yes or No	Question 5 Comment
		emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition. **The language in the VRF Guidelines document for a Lower VRF is:** **Lower Risk Requirement** **A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.** **Requirement 2 requires that the Generator Owner "provide, for each of its applicable units, a verified generator excitation control system and plant volt/var control function model…" Model verification is not an administrative task. It requires physical verification of actual system responses. R6 requires the Transmission Planner to notify the Generator Owner whether or not the model that was provided is useable. This links directly with the verification process and has an equal impact to the validity of the model.** All of the measurements use language that sounds like it is creating a new a requirement and is not consistent with language used in any other NERC standard. They all use "must include".

Organization	Yes or No	Question 5 Comment
		The SDT believes the measures support requirements by identifying what evidence or types of evidence could be used to show that an entity is compliant with the requirement. It should be noted that this is consistent with NERC guidelines and support documentation for drafting Standards. It is more typical to use “shall demonstrate”, “shall make available”, etc. These measurements should be made consistent with other NERC standards. All evidence requirements for proof of transmission should be dropped as they go above and beyond basic evidence requirements. **The SDT believes the measures support requirements by identifying what evidence or types of evidence could be used to show that an entity is compliant with the requirement. It should be noted that this is consistent with NERC guidelines and support documentation for drafting Standards.** Some examples of the proof include dated postal receipts, dated confirmation of facsimile, etc. When is a dated and signed letter not sufficient proof? Must it also be sent by registered mail? Furthermore, any of the proofs of transmission do not prove anything other than something was transmitted. They do not prove the evidence was transmitted. For example, a confirmation report will not prove anything other than some fax was sent. Even dated and time stamped email proves only that the email was sent. It does not prove it was received. **The examples were offered as such: these are examples. The SDT understands that the different regions and different entities will have their specific protocols for the requirements associated with NERC Standards. As such, these methods and examples are just to illustrate the flow of information, as the SDT perceives it. These methods and examples are not part of the Requirements, but listed in the Measures. Once again, the methods listed in the Measures are for reference, but are not intended to be an exhaustive and comprehensive list of the possible ways in which this could be implemented.** The Compliance Enforcement Authority section is not the latest approved language

Organization	Yes or No	Question 5 Comment
		being used by NERC. In the data retention section, there is no length of time given for how long a Generation Owner must retain information for Requirement R2 and its associated measurement. **The data retention section for Requirement R2 requires that they keep the latest model verification evidence.** The High and Severe VSLs for Requirement R5 need to be updated. They still refer to Subparts 5.2 and 5.3. The Subparts have been changed to a bulleted list which means they are options. Thus, missing one and meeting the other is full compliance and not partial compliance as the VSLs suggest. **Based on your comment, the SDT has revised the verbiage for the High VSL to not include any references to the sub bullets in Requirement R5, and revised the verbiage for the Severe VSL to include " OR The Generator Owner written response failed to indicate one of the sub bullets of Requirement R5."** We suggest the drafting team write a brief paragraph at the beginning of the Reference section to explain the inclusion of the References. Currently, it states that those references contain technical information that is out of scope of the standard. If so, what is the purpose of including them? We are not against including them but just believe a short explanation for their inclusion is necessary. **The references are industry documents related to excitation systems. They are provided as a courtesy only because the SDT believes they will be helpful to some users. The referenced documents are not required reading nor are they required for compliance with the standard. The statement used to introduce the references is consistent with that used in other standards.** The verification periodicity for row 3 in Attachment 1 needs to be updated from 356 days to 365 days. Furthermore, the drafting team should consider using a year to account for leap years. Otherwise, every four years we are shifting the compliance date up by one calendar day. **We have corrected the typographical error to say "365 days." The SDT believes**

Organization	Yes or No	Question 5 Comment
		that the use of "365 days" instead of "one year" is more appropriate and consistent with the use of "180 days" elsewhere in the standard.
Response: Thank you for your comment. Please see responses above.		
PSEG		We have these additional comments: a. The exclusion of synchronous condensers (and other reactive devices) in MOD-026-1 per the rationale provided in the Background (with which we agree) states "Synchronous condensers are not currently addressed in the NERC Registry Criteria" However, companion standards under Project 2007-09 (MOD-025-2 and PRC-019-1) are applicable to synchronous condensers. The GVSDT should address this inconsistency. **The SDT believes that MOD-026 is different from the other standards with respect to synchronous condensers due to the complex interaction required between the Transmission Planner and the Generator Owner, and thus believes it better to wait for efforts by others to define where synchronous condensers fit in the functional model.** b. The entire section 4.2 has language that includes "directly connected to the bulk power system." The BES is a subset of the BPS (per Order 743), and the GVSDT should consult with the SDT for Project 2010-17 - Definition of BES - to develop alternate language that instead refers to the BES. **Based upon your comments and others, the SDT replaced references to the BPS with references to the BES which is the NERC defined term.**
Response: Thank you for your comment. Please see responses above.		
ISO New England Inc		We suggest that the language for R4 be made more clear and state as follows."R4. Each Generator Owner shall provide revised model data or plans to perform model verification5 (in accordance with Requirement R2) to its Transmission Planner 180

Organization	Yes or No	Question 5 Comment
		calendar days prior to making changes to the excitation control system and plant volt/var control function that alter the equipment response6characteristic. The way the language is currently written, the generator merely has to provide its plans for model verification. This means that 6 months after a change has been made, the correct data still may not have been made available to the Transmission Planning. This could have a significant impact on reliability. The suggested language would be in line with FERC approved language that is currently part of ISO Tariffs.
Response: The SDT thanks you for your comment. The SDT drafted the standard recognizing the model verification requires expertise and calendar time. The time frames mentioned in the comment are the maximum time periods that can be utilized to be deemed compliant. It is expected that all entities will strive to verify the model as quickly as practical. The model representing the new equipment cannot be verified until the new equipment is installed. Also, this standard addresses model verification, not the submittal of preliminary design models.		
Southern California Edison Company		While an active closed-loop voltage regulation function is useful in distinguishing transient voltage and frequency responses within mere cycles or seconds of perturbations, a similar requirement should be added to MOD-026-1 to require variable generators who were exempted from the standard by the condition added to Attachment 1 to provide similar plant voltage/var control, design, and test data to the Transmission Planner. The automatic switching of capacitor banks and reactor banks can play a role in maintaining the voltage stability of the system.
Response: The SDT thanks you for your comment. The intent was not to give an exemption to any unit or plant that has a closed loop voltage regulation function. If a plant has a device that provides dynamic voltage regulation (such as a STATCOM, DVAR or SVC, and perhaps automatically controlled capacitors commonly found in Renewable Plants), these devices should be included in the model and should be validated. If the automatically controlled (mechanically switched) capacitor bank is in whole or a part of the primary dynamic volt/var response of the plant, it should be modeled and validated. Both PSS/e and PSLF have standard library models to represent automatically switched capacitor banks (SWSHNT in PSS/e and MSC1 in PSLF). Ultimately, the local		

Organization	Yes or No	Question 5 Comment
interconnection requirements should be used to determine if the automatically controlled capacitor banks are a primary means for dynamic volt/var regulation within any particular application. Based on review of a plant's application requirements, the testing /validation entity should determine if the automatic capacitor bank should be validated. Please reference Row 6 of Attachment 1 of the current draft of the standard.		
Exelon Corp.		Draft MOD-026-1 R.2.1 requires that the Generator Owner perform verifications subject to include certain information as specified in sub requirements 2.1.1 through 2.1.6. R 2.1.1 requires that the unit model response is matched to the recorded response for a voltage excursion at the "point of interconnection". For certain generating units the "point of interconnection" is on the high voltage side of the main power transformer (i.e., the switchyard disconnect switch). Because of this, the model would have to consider the impact of the main power transformer, auxiliary transformer, and auxiliary transformer loads all of which are not part of the generator/excitation system model. The Standard should be revised to state the response of interest is at the generator terminals and not at the "point of interconnection." **Specific reference to point of connection is removed from Requirement R2 Part 2.1.1. Language has been modified to: "Documentation demonstrating the applicable unit's model response matches the recorded response for a voltage excursion from either a staged test or a measured system disturbance."** Typically individual synchronous machines have generator excitation control systems and do not have volt/var control systems. The text "and / or" or "as applicable" should be added to all references to "volt/var model" in the Standard and the associated attachments. **Based on your and other industry comments, the SDT modified the phrase "generator excitation control system and plant volt/var control functions" to "generator excitation control system or plant volt/var control functions" to recognize that the use of the phrase "or" is technically correct the vast majority of the time.**

Organization	Yes or No	Question 5 Comment
		With respect to the SDTs response to Exelon's comment regarding the lack of acceptance criteria (refer to MOD-026-1 Consideration of Comments dated 2-23-12 pp 89-90), the following statements by the SDT need to be more clearly articulated within the body of the Standard. **"It should be noted that the standard is written so that the Generator Owner "owns' the model, and as such, even with the peer review process described, the Generator Owner has final say on the voltage excursion used, including sampling rate, for model verification as well as determining if the equipment recorded response satisfactorily matches the model's predicted response."** The current draft (draft 3) of MOD-026-1 R.3 requires that a Generator Owner provide a written response to its Transmission Planner if the Transmission Planner deems the functional model is not "usable", if there are technical concerns with the verification documentation, or if the model response did not match an actual event. This written response is to contain either plans for performing model verification, model changes or a technical basis for maintaining the current model. It appears from the comments of the SDT (see question 3 above) that the Generator Owner has final say on the model; however, if the opinion of the Transmission Planner differs from that of the Generator Owner there is the potential for a disagreement between the two entities. Given the potential for a dispute to occur and the lack of an "acceptance criteria" the SDT should consider adding in a provision for dispute resolution between the parties or clearly delineate that the GO has the final say. **The SDT believes that the draft Requirement clearly conveys that the GO has the final say as the draft standard does not list any additional processes. The SDT also believes that both parties will be equally motivated to resolve any technical issues with the model.**
Response: Thank you for your comment. Please see responses above.

Puget Sound Energy		None

PRC-024 Overall Summary Consideration: The GVSDT received valuable feedback from stakeholders regarding improvements to the standard. Many of the suggested edits were incorporated into the revised standard.

A slight majority of stakeholders were in agreement with the approach taken for Requirement R4. Of the stakeholders who did not agree with the approach, the reasons most often cited were that such estimates would not provide any reliability benefit, the estimates are difficult to calculate, and the time period allowed to respond to a request for an estimate (60 days) is too short. The SDT modified the structure of the requirement to clarify the intent and the limits of what entities could request a performance estimate, but did not change the time period allowed to respond.

A large majority of stakeholders indicated that they did not agree that it is technically achievable for new generation to meet the performance required in Requirement R5. The most common reason stated was that Attachment 1 did not correctly specify the WECC region underfrequency tripping limits. Other objections cited by more than one responder were that the curves in Attachments 1 and 2 are too stringent, that significant R&D work needs to be done on the design of a plant to meet the requirement, and that the cost of building such a plant would be too high with little corresponding gain in grid reliability. The SDT corrected the error in the Attachment 1 underfrequency curve and data table for the Western Interconnection. The SDT did not make any substantive changes to Requirement R5 since the SDT did not feel stakeholders presented valid arguments that the requirement could not be achieved technically, given that similar requirements are already in effect in other parts of the world.

Other specific revisions to the standard are:

- **The wording in Requirement R1 was revised for clarity, Part 1.1 (rate of change of frequency) was removed and new Parts 1.2 and 1.3 were added for consistency with Requirement R2 at the request of several stakeholders.**
- **Minor changes in the wording in Requirement R2 were made to improve clarity at the request of several stakeholders.**
- **The structure of Requirement R4 was modified and minor wording changes were made to improve clarity at the request of several stakeholders, though no changes were made to the intent of the requirement.**
- **Part 5.1 and Subpart 5.1.1 were incorporated into the body of Requirement R5 so that the remaining Parts of this requirement describe exceptions (i.e. allowances to trip).**
- **Minor wording changes were made at the request of multiple stakeholders to clarify wording in Parts 5.1 – 5.6 of Requirement R5.**

- **The allowable time to respond to a request for generator protection settings in Requirement R6 was increased from 30 days to 60 days at the request of several stakeholders.**
- **The Violation Risk Factors for Requirements R1, R2, and R5 were changed from High to Medium at the request of several stakeholders.**
- **Minor wording changes were made to Measures M3, M4, and M5 were made for clarity at the request of several stakeholders.**
- **The time frame referenced in Measure M6 was modified to correlate with the change made in Requirement R6.**
- **The wording in the Data Retention section was revised at the request of one stakeholder and now reflects the wording used in other recently-approved standards.**
- **Minor changes were made in the VSL's for Requirements R1, R2, R3, and R4 to add clarity or correct errors mentioned by several stakeholders.**
- **The wording in the Severe VSL for Requirement R5 was revised to add a reference to Parts 5.1 – 5.6 and the tardiness levels in the Requirement R6 VSL's were revised to reflect the change in the requirement.**
- **The underfrequency curve for the Western Interconnection and corresponding data table were corrected in Attachment 1 at the request of many stakeholders in the WECC region.**
- **Curves for the ERCOT Interconnection and a corresponding data table were added to Attachment 1 at the request of ERCOT.**
- **The term "base voltage" was replaced with "nominal operating voltage" in Clarification #1 to Attachment 2 at the request of several stakeholders.**
- **Minor wording changes were also made to Clarifications #2, and #5 to better convey the intent of the SDT in response to questions presented by several stakeholders.**

6. **Requirement R4 has been added for owners of existing units or generating plant/facilities to provide an estimate of the performance of the units during frequency and voltage excursions. This information is intended to provide Transmission Planners with information useful in performing planning studies. Do you agree with this approach? If not please explain and provide alternative language.**

Summary Consideration: A slight majority of stakeholders were in agreement with the approach taken for Requirement R4. Of the stakeholders who did not agree with the approach, the reasons most often cited were that such estimates would not provide any reliability benefit, the estimates are difficult to calculate, and the time period allowed to respond to a request for an estimate (60 days) is too short. The SDT modified the structure of the requirement to clarify the intent and the limits of what entities could request in a performance estimate, but did not change the time period allowed to respond.

Organization	Yes or No	Question 6 Comment
Independent Electricity System Operator	Negative	Requirement R4 asks owners of existing units or generating plant/facilities to provide an estimate of the performance of the units during frequency and voltage excursions. This estimate is difficult to provide with sound technical basis, and may not contribute to any more valid assessment of a generator's expected performance than a TP's conservative assumptions drawn from available information already provided by the GO and the standard's Attachments 1 and 2. In brief, this requirement does not appear to provide any reliability benefit at all.
Response: Thank you for your comments. The SDT appreciates your position, but was charged with meeting the recommendations of FERC Order 693 and the 2003 Blackout Report. Requirement R4 attempts to address a portion of the recommendation to provide better information to Transmission Planners regarding the performance of generating facilities during frequency and voltage excursions. This requirement is written such that the information is only provided if it is requested by a planner. If the planner does not believe the information received would be of any value, it is permissible to not make the request. The draft standard has been modified to clarify that, "Detailed unit performance studies are not required to develop the estimate."		
Oncor Electric Delivery	Negative	In a deregulated market, the Balancing Authority (BA) and Planning Authority (PA) are in the best position to provide a more strategic look at gathering this type of information and ensuring the necessary broad distribution. As a result, the receiving

Organization	Yes or No	Question 6 Comment
		of modeling data from a Generator Owner (GO) should be the responsibility of the PA or the BA and not the Transmission Planner or Transmission Operator. This approach provides a single clearinghouse for generator data, ensuring accuracy and consistency, from the GO which then can accessed by any impacted Registered Entities.
Response: Thank you for your comments. Planning Authority is no longer used in the current NERC Functional Model; the functions are now assigned to the Planning Coordinator, which is included in Requirement R4. The SDT believes that the Balancing Authority typically does not do long-term planning studies, but if the BA were interested in the performance estimate, he could work with the Transmission Operator or Transmission Planner to obtain the information.		
Wisconsin Electric Power Co., Wisconsin Electric Power Marketing	Negative	Requirement R4 is not reasonable since it is difficult to provide any meaningful estimate of performance during frequency excursions. **The SDT appreciates your position, but was charged with meeting the recommendations of FERC Order 693 and the 2003 Blackout Report. Requirement R4 attempts to address a portion of the recommendation to provide better information to Transmission Planners regarding the performance of generating facilities during frequency and voltage excursions. This requirement is written such that the information is only provided if it is requested by a planner. If the planner does not believe the information received would be of any value, it is permissible to not make the request. In addition, the SDT does not require Generator Owners to do extensive dynamic simulations to determine performance. The draft standard has been modified to clarify that, "Detailed unit performance studies are not required to develop the estimate." The SDT believes the Generator Owner could identify the most likely piece of equipment to fail to ride through (whether from contactor dropout or other mechanism) and estimate the time between that event and a generator trip due to the resulting process upset.** Also, the No Trip curve in Attachment 2 needs further clarity, especially when the Generator Owner has voltage relaying that is connected to VT's on the low-side of the GSU. **The SDT agrees that generator protection normally senses the voltage at the**

Organization	Yes or No	Question 6 Comment
		generator terminals. Because there are many configurations of the connections of the generators to the transmission systems, it is not practical to develop a single voltage curve defined at the generator terminals that equates to the voltage caused by an event on the transmission system. Each Generator Owner will have to determine how the transmission system event affects his specific generating units. This approach is consistent with FERC Order 661-A and other international grid standards that are in effect.
Response: Thank you for your comments. Please see the responses to your specific comments above.		
Wisconsin Energy Corp.	Negative	PRC-024-1: Requirement R4 is not reasonable since it is difficult to provide any meaningful estimate of performance during frequency excursions. The SDT appreciates your position, but was charged with meeting the recommendations of FERC Order 693 and the 2003 Blackout Report. Requirement R4 attempts to address a portion of the recommendation to provide better information to Transmission Planners regarding the performance of generating facilities during frequency and voltage excursions. 		the generators to the transmission systems, it is not practical to develop a single voltage curve defined at the generator terminals that equates to the voltage caused by an event on the transmission system. Each Generator Owner will have to determine how the transmission system event affects his specific generating units. This approach is consistent with FERC Order 661-A and other international grid standards that are in effect.
Response: Thank you for your comments. Please see the responses to your specific comments above.		
Texas Reliability Entity	No	Most existing facilities are likely not designed to a frequency or voltage ride-through standard, and a useful estimate may be very difficult for owners to provide. Generator Operators may be able to document "known" equipment limitations. There are probably many examples of unknown equipment limitations, simply because a plant may not have experienced a fault condition that could expose the limitation.
Response: Thank you for your comments. The SDT agrees that most existing facilities are not designed to ride through a voltage excursion created by a three-phase fault at the plant substation. The SDT believes the Generator Owner could identify the most likely piece of equipment to fail to ride through (whether from contactor drop out or other mechanism) and estimate the time between that event and a generator trip due to the resulting process upset. The SDT was charged with meeting the recommendations of FERC Order 693 and the 2003 Blackout Report. Requirement R4 attempts to address a portion of the recommendation to provide better information to Transmission Planners regarding the performance of generating facilities during frequency and voltage excursions. This requirement is written such that the information is only provided if it is requested by a planner. If the planner does not believe the information received would be of any value, it is permissible to not make the request. In addition, the draft standard has been modified to clarify that, "Detailed unit performance studies are not required to develop the estimate."		
Exelon Corp.	No	The Frequency/Voltage Excursions should be limited to those listed in the standard, this should be explicitly stated in the requirement. 60 calendar days is an unreasonable amount of time to perform a study of this magnitude, suggest increasing the amount of time perform this study.

Organization	Yes or No	Question 6 Comment
Response: Thank you for your comments. The SDT believes there is value in allowing the estimate of performance for a voltage excursion specific to particular facilities (which would be less stringent than the curves in Attachment 2). The SDT does not require Generator Owners to do extensive dynamic simulations to determine performance. The draft standard has been modified to clarify that, "Detailed unit performance studies are not required to develop the estimate." The SDT believes the Generator Owner could identify the most likely piece of equipment to fail to ride through (whether from contactor dropout or other mechanism) and estimate the time between that event and a generator trip due to the resulting process upset.		
ACES Power Marketing Standards Collaborators	No	This requirement will essentially be redundant with standards MOD-026 and MOD-027. MOD-026 already requires the Generator Owner to verify its excitation and volt/VAr control systems. MOD-027 already requires the Generator Owner to verify its frequency response and its turbine/governor, load control and active power/frequency control models.
Response: Thank you for your comments. The SDT disagrees that this requirement is redundant with MOD-026 and MOD-027. Those standards require Generator Owners to verify the response of the excitation system (MOD-026) and frequency control system (MOD-027) to disturbances, but do not address the ability of a generating unit to ride through excursions.		
MRO NSRF	No	Since most existing facilities are likely not designed to a frequency or voltage ride-through standard, the estimate may be very difficult for owners to provide. Staged testing would not be practical for making this determination and engineering analysis may not have the accuracy to make it useful for use by Transmission Planners.
Response: Thank you for your comments. The SDT agrees that most existing facilities are not designed to ride through a voltage excursion created by a three phase fault at the plant substation. The SDT does not require Generator Owners to do extensive dynamic simulations or staged testing to determine performance. The draft standard has been modified to clarify that, "Detailed unit performance studies are not required to develop the estimate." The SDT believes the Generator Owner could identify the most likely piece of equipment to fail to ride through (whether from contactor dropout or other mechanism) and estimate the time between that event and a generator trip due to the resulting process upset. The SDT was charged with meeting the recommendations of FERC Order 693 and the 2003 Blackout Report. Requirement R4 attempts to address a portion of the recommendation to provide better information to Transmission Planners regarding the performance of generating facilities during frequency and voltage excursions. This requirement is written such that the information is only provided if it is requested by a		

Organization	Yes or No	Question 6 Comment
planner. If the planner does not believe the information received would be of any value, it is permissible to not make the request.		
PPL Electric Utilities and PPL Supply NERC Registered Organizations	No	Independent generators provide model data to the TP/TOP and TO, who then run their models, but we do not ourselves have means of predicting responses to voltage and frequency excursions. This is especially the case when one must, per R4.1, engage in the phenomenal complexity of calculating the transient performance of auxiliary buses and identifying the short-term drop-out thresholds of the multitudinous pieces of equipment they power. The references in R4.1 and 4.2 to experience, actual event histories or sound engineering judgment as alternatives to a computer model are not helpful, because meaningful assessments can be made only if one has relevant data (i.e. high-speed records of past disturbances, at HV, MV and LV voltage levels) and issue a PV. Further on the subject of complexity, there are a variety of aux bus configurations possible for our multiple-unit plants, any one of which could be deemed normal depending on circumstances. Having to check every aux bus configuration for every units-running combination would be unduly burdensome, even if it were possible. The fact that R4 cites “Frequency/Voltage Excursions” (apparently meaning simultaneous deviations of these parameters), while R5 is careful to refer to “frequency excursion or voltage excursion,” adds confusion. Another concern is that the boundary conditions for the above-described analysis are presently undefined, with the standard invoking instead a “dynamic simulation provided by the Transmission Planner.” For the reasons stated above, the proposed requirement R.4 should be eliminated.
Response: Thank you for your comments. The SDT did not intend that the Generator Owner have to estimate performance during simultaneous voltage and frequency excursions and has revised the wording in Requirement R4 to say, “…frequency or voltage excursion…” The SDT does not require Generator Owners to do extensive dynamic simulations to determine performance. The draft standard has been modified to clarify that, “Detailed unit performance studies are not required to develop the estimate.” The SDT believes the Generator Owner could identify the most likely piece of equipment to fail to ride through (whether from contactor drop out or other mechanism) and estimate the time between that event and a generator trip due to the resulting process upset. The SDT was charged with meeting the recommendations of FERC Order 693 and the 2003 Blackout Report. Requirement R4 attempts to address a portion of the recommendation to provide better information to Transmission Planners		

Organization	Yes or No	Question 6 Comment
regarding the performance of generating facilities during frequency and voltage excursions.		
Luminant Power	No	An estimate of the time that a unit would remain on-line during or following a voltage or frequency event described by a Transmission Planner would be difficult if not impossible considering the complexity of the auxiliary system and would result in little value to the Transmission Planner. There is no known methodology to provide a consistent estimation or calculation of the value. Luminant recommends that the requirement be removed from the standard.
Response: Thank you for your comments. The SDT does not require Generator Owners to do extensive dynamic simulations to determine performance. The draft standard has been modified to clarify that, "Detailed unit performance studies are not required to develop the estimate." The SDT believes the Generator Owner could identify the most likely piece of equipment to fail to ride through (whether from contactor drop out or other mechanism) and estimate the time between that event and a generator trip due to the resulting process upset. The SDT was charged with meeting the recommendations of FERC Order 693 and the 2003 Blackout Report. Requirement R4 attempts to address a portion of the recommendation to provide better information to Transmission Planners regarding the performance of generating facilities during frequency and voltage excursions.		
Arizona Public Service Company	No	This type of data is not going to result into any more accurate simulation than the existing methodology which does not include this data. There are many other inaccuracies involved in modeling and scenario planning for islanding studies. It is a misconception that just by having more complex modeling will improve accuracy and thus reliability.
Response: Thank you for your comments. The SDT appreciates your position, but was charged with meeting the recommendations of FERC Order 693 and the 2003 Blackout Report. Requirement R4 attempts to address a portion of the recommendation to provide better information to Transmission Planners regarding the performance of generating facilities during frequency and voltage excursions. This requirement is written such that the information is only provided if it requested by a planner. If the planner does not believe the information received would be of any value, it is permissible to not make the request.		
Southern Company	No	We cannot agree with the approach of Requirement R4 due to the uncertainty about how to estimate the performance of "each" plant system, sub-system, or

Organization	Yes or No	Question 6 Comment
		component that could cause the unit to trip for the voltage excursion profile of Attachment 2. For most units, this estimate may vary from a few cycles (examples: dropout of low voltage motor contactors or an auxiliary control relay) to up to 1-2 seconds (examples: tripping of boiler controls or medium voltage motors). Determination of a more accurate time estimate would require detailed dynamic analysis, which would entail significant engineering study and involve assumptions and judgment based on experience. Data from actual event histories, if available, would likely not match all points of the Attachment 2 time-voltage profile. The voltage excursion profile needed for an evaluation would be the voltages present on the generator bus and plant distribution system auxiliary buses rather than at the point of interconnect. Without detailed analysis, only a rough estimate could be made which would probably be of limited value for transmission system analyses. A conservative approach would be the "go/no-go" approach and identify those units that are likely to trip for a specified voltage excursion. For the current requirements stated in R4, the 60 day time requirement would be a significant challenge for a GO to meet for a single unit. For GOs who have a large number of units and limited engineering resources, the 3-year phase-in period will be impractical to establish on many units the estimated performance of "each" plant system, sub-system, and component that could trip. Bottom line is, the concept may seem simple enough in principle, but these requirements cannot be practically met. We believe the scope of the standard should be limited to identification of the protection function trips per R1, R2, R3, and R6 only.
Response: Thank you for your comments. The SDT does not require Generator Owners to do extensive dynamic simulations to determine performance. The draft standard has been modified to clarify that, "Detailed unit performance studies are not required to develop the estimate." The SDT believes the Generator Owner could identify the most likely piece of equipment to fail to ride through (whether from contactor drop out or other mechanism) and estimate the time between that event and a generator trip due to the resulting process upset (similar to the go/no go methodology suggested). While it is possible that a Transmission Planner could request a performance estimate for all of a Generator Owner's units over the implementation period (which has been revised from three years to five years), the SDT feels the Transmission Planner would be more likely to only request the information for generators more critical to system stability. The SDT was charged with meeting the recommendations of FERC		

Organization	Yes or No	Question 6 Comment
Order 693 and the 2003 Blackout Report. Requirement R4 attempts to address a portion of the recommendation to provide better information to Transmission Planners regarding the performance of generating facilities during frequency and voltage excursions.		
AECI	No	My concern with this requirement is that if a GO provides an estimate of how long they believe that the unit can ride out the event, then what will happen if they do not make this target? Will the GO be held responsible for not making this time? Due to this concern how accurate are these times that are provided by the GO going to be and how much will be a built in cushion?
Response: Thank you for your comments. There is no language in Requirement R4, Measure M4, or the associated VSL that indicates there would be any penalty to the Generator Owner if an excursion occurred and a generating unit did not perform as estimated.		
We Energies	No	It is very difficult to estimate generator performance during frequency or voltage excursions, especially frequency, and the best efforts to provide an estimate may not provide a meaningful result. It is proposed that the TO or TP could achieve the objective better by tracking transmission system voltage/frequency events that could have resulted in abnormal voltages at generating stations, and work cooperatively with the GO informally to determine the generator performance.
Response: Thank you for your comments. The SDT does not require Generator Owners to do extensive dynamic simulations. The process suggested in your comment would be one method of estimating the generating unit performance. The draft standard has been modified to clarify that, "Detailed unit performance studies are not required to develop the estimate."		
Manitoba Hydro	No	More detail is required in R4 to ensure that the Transmission Planner can model behavior before and after the disturbance. Information should be provided on how long the unit should take to ramp back to full power following a voltage or frequency excursion that doesn't cause the unit to trip.
Response: Thank you for your comments. The SDT believes it the uncertainties involved in trying to determine generator outputs		

Organization	Yes or No	Question 6 Comment
and ramp rates would not improve grid reliability.		
Independent Electricity System Operator	No	As indicated in our previous comment, we do not support having a requirement to obtain such an estimate. First of all, the requirement does not distinguish whether it applies to units that are equipped with frequency/voltage protective relays or otherwise. Secondly, the intent of providing the suggested estimate is to allow Transmission Planners to apply valid or supported assumptions in their planning studies. Given the requirements in Attachments 1 and 2 and Requirement R3 and the information already received, a TP can apply the following relevant assumptions to its planning studies: i. For units that are equipped with frequency/voltage protective relays, the GO's submitted relay settings will determine when the units will trip;ii. For units that are NOT equipped with frequency/voltage protective relays, the units are conservatively assumed to trip when the simulated frequency/voltage goes outside the bounds of Attachments 1 and 2. We do not see what other estimates that can be more relevant and valid than the above. We see that there may be some value in providing these estimates but only in the case of generators not equipped with frequency/voltage protective relays where tripping takes place beyond the no-trip zones of Attachments 1 and 2. For this information to be useful however, the generator's behavior must be predictable. While it may facilitate some "what-if" analysis, it is not clear that using this information would be more valid than applying the conservative assumption "b" above. We cannot envisage a Transmission Planner to use this additional information if this information cannot be ascertained to be more valid. In short, we do not believe provision of this estimate will provide any more valid assessment of a generator's expected performance than a TP's conservative assumptions drawn from available information already provided by the GO and Attachments 1 and 2. The estimate does not provide any reliability benefit at all.We suggest the SDT remove this requirement altogether.
Response: Thank you for your comments. The SDT appreciates your position, but was charged with meeting the recommendations of FERC Order 693 and the 2003 Blackout Report. Requirement R4 attempts to address a portion of the recommendation to provide better information to Transmission Planners regarding the performance of generating facilities during		

Organization	Yes or No	Question 6 Comment
frequency and voltage excursions. This requirement is written such that the information is only provided if it requested by a planner. If the planner does not believe the information received would be of any value, it is permissible to not make the request.		
Ingleside Cogeneration LP	No	Ingleside Cogeneration believes that this is an open-ended requirement that allows multiple planning and operations entities - not just Transmission Planners - to require complex assessments completely at their discretion. There is no allowance for the availability of GO resources nor any need for the requestor to provide a reliability justification. Furthermore, we would like to point out that the modeling validation requirements of MOD-027-1 (frequency) and MOD-026-1 (voltage) must, by definition, include the impact of protective relay settings. This means that a need for an estimate of performance is not necessary as real performance data will always be available. In addition, these Standards already allow recourse for a re-validation if Transmission Planners cannot reconcile their models with actual generator performance.
Response: Thank you for your comments. The SDT does not require Generator Owners to do extensive dynamic simulations to determine performance. The draft standard has been modified to clarify that, "Detailed unit performance studies are not required to develop the estimate." The SDT disagrees that MOD-026 and MOD-027 evaluate voltage and frequency protection functions. Those standards require Generator Owners to verify the response of the excitation system (MOD-026) and frequency control system (MOD-027) to disturbances, but do not address the ability of generator protection or a generating unit to ride through excursions.		
Luminant Energy	No	An estimate of the time that a unit would remain on-line during or following a voltage or frequency event described by a Transmission Planner would be difficult if not impossible considering the complexity of the auxiliary system and would result in little value to the Transmission Planner. There is no known methodology to provide a consistent estimation or calculation of the value. Luminant recommends that the requirement be removed from the standard.
Response: Thank you for your comments. The SDT does not require Generator Owners to do extensive dynamic simulations to determine performance. The draft standard has been modified to clarify that, "Detailed unit performance studies are not required		

Organization	Yes or No	Question 6 Comment
to develop the estimate." The SDT believes the Generator Owner could identify the most likely piece of equipment to fail to ride through (whether from contactor drop out or other mechanism) and estimate the time between that event and a generator trip due to the resulting process upset (similar to the go/no go methodology suggested). The SDT was charged with meeting the recommendations of FERC Order 693 and the 2003 Blackout Report. Requirement R4 attempts to address a portion of the recommendation to provide better information to Transmission Planners regarding the performance of generating facilities during frequency and voltage excursions. The SDT cannot remove the requirement without replacing it with another method of giving the Transmission Planner the necessary information.		
Duke Energy	No	Generator Owners don't currently have the capability to provide this information, and will need time to obtain the capability and perform the studies. Requirement R4 should be removed from Effective Date sections 5.1, 5.2 and 5.3 because one, two or three years is insufficient time. R4 should have its own effective date section specifying an effective date of the first day of the first calendar quarter five years following applicable regulatory approval; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter five years following Board of Trustees adoption. Requirement R4 should also be revised to allow the Generator Owner 180 days (instead of 60 days) to respond to a request and provide an estimate of a unit's performance during frequency/voltage excursions.
Response: Thank you for your comments. The SDT does not require Generator Owners to do extensive dynamic simulations to determine performance so has not extended the time period for responding to a request for the estimate. The draft standard has been modified to clarify that, "Detailed unit performance studies are not required to develop the estimate." The SDT agrees with the suggestion to change the implementation period to five years.		
Ameren	No	At the end of R4.2, we suggest to add "the Transmission Planner's voltage recovery characteristic from R2 part 2.1.1" since that may well have bearing on the estimate. We understand the reasons for such studies, but we ask the GVSDT to consider the fact that more than 60 days may be needed to estimate generating unit performance especially the first time it is done for each unit. As long as this applies only to generator frequency and voltage protective relaying (and not to station auxiliaries)

Organization	Yes or No	Question 6 Comment
		developing these estimates in the time frame mentioned earlier is achievable.
Response: Thank you for your comments. The standard has been modified to require the requesting entity to provide a "…frequency or voltage excursion defined by the voltage or frequency profile at the point of interconnection described by dynamic simulation provided by the requestor (Reliability Coordinator, Planning Coordinator, Transmission Operator or Transmission Planner that monitors or models the associated generating unit)." The SDT does not require Generator Owners to do extensive dynamic simulations to determine performance, so has not extended the time period for responding to a request for the estimate. The draft standard has been modified to clarify that, "Detailed unit performance studies are not required to develop the estimate."		
Cowltiz PUD	No	Cowlitz is only concerned with the 60-day response time. The responding entity should be given some leeway to negotiate a delivery time if the 60-day response is not feasible. Otherwise, substandard estimates will be provided to avoid violation of the standard.
Response: Thank you for your comments. The SDT does not require Generator Owners to do extensive dynamic simulations to determine performance so has not extended the time period for responding to a request for the estimate. The SDT agrees with many commenters that it is not realistic to provide an extremely precise estimate. The quality of the estimate is not specified in the requirement, measure, or associated VSL. The draft standard has been modified to clarify that, "Detailed unit performance studies are not required to develop the estimate."		
Indiana Municipal Power Agency	No	IMPA does not agree that there would be any gain in reliability by requiring Generator Owners to give an estimate on the performance of a unit or the overall plant during a frequency or voltage excursion. Will such a request include specific parameters that would be expected on the system to narrow down this imposition of an estimate upon the Generator Owner? Will Generator Owners be capable of providing an estimate that may be required under this item? In addition, the Transmission Planner is to provide the dynamic simulation of the voltage and frequency profile at the point of interconnection. There is no guidance in the Standard as to how often or what means will be used to submit the (new) profile(s) to the GO - will it be annually, seasonally or?? IMPA also has concerns with attempting

Organization	Yes or No	Question 6 Comment
		to accurately predict the ride-thru capabilities of a generating unit/plant on a consistent basis. As an example, if the unit/plant was operating during an extreme and prolonged period of heat and humidity it's characteristics and ability to ride thru a frequency and/or voltage event will be different than if running during the opposite - extreme cold and wind. Many of the unit/plant auxiliary systems may be located in areas that are not climate controlled and it would be extremely difficult to consistently predicte how they will react during temperature extremes.
Response: Thank you for your comments. As you note in the comment, the standard requires the requestor to specify the voltage or frequency excursion for which the Generator Owner is to provide an estimate of the time duration the generator unit will remain connected. The SDT does not require Generator Owners to do extensive dynamic simulations to determine performance, so has not extended the time period for responding to a request for the estimate. The SDT agrees with many commenters that it is not realistic to provide a precise estimate. The draft standard has been modified to clarify that, "Detailed unit performance studies are not required to develop the estimate." The SDT believes the Generator Owner could identify the most likely piece of equipment to fail to ride through (whether from contactor drop out or other mechanism) and estimate the time between that event and a generator trip due to the resulting process upset. While the requirement does not limit the number of requests that may be submitted by a Reliability Coordinator, Planning Coordinator, Transmission Operator, or Transmission Planner, it also does not prevent the Generator Owner from responding with the same estimate to each request.		
Pepco Holdings Inc. & Affiliates	Yes	Agree in principle with attempting to quantify the ability of the unit (including affect on plant auxiliary systems) to remain connected during voltage and frequency excursions. However, the present wording of this requirement may not result in sufficient information to fully model the performance of the unit in dynamic studies. It may be more constructive to request a modified set of voltage and frequency ride through curves (similar to Attachments 1 & 2) that represent the Generator Owner's best estimate of a no trip zone for each unit, taking into account the performance of plant auxiliary systems, as well as any other protection / control setting, or operational limitation, that would prevent the unit from remaining on line within the no-trip zone as defined in Attachments 1 & 2. This would provide the Transmission Planner with sufficient information to fully model the anticipated performance of the

Organization	Yes or No	Question 6 Comment
		unit in their dynamic studies.
Response: Thank you for your comments. The SDT believes that requiring the Generator Owner to produce a set of curves that define successful performance would require more resources and would not provide any more useful information than the approach currently defined in Requirement R4. The draft standard has been modified to clarify that, "Detailed unit performance studies are not required to develop the estimate."		
Xcel Energy	Yes	We agree that the current wording (which removes the requirement to provide a probability of ride through) is an adequate means of achieving the reliability goal.
Response: Thank you for your comments.		
American Electric Power	Yes	AEP agrees with this approach for Attachment 1 only. We also have the following comments about the reference to Attachment 2 in R4. The reliability advantage to be gained from the inclusion of Attachment 2 is unclear, unprecedented and potentially costly. With respect to Attachment 1, any information that a GO can provide about a potential for their unit to trip within the no-trip zone of Attachment 1 will assist the Planning Coordinator in devising a UFLS program for their area, which they are obligated to do under PRC-006-1. A successfully designed UFLS program depends on knowing whether or not generation would trip prior to operation of all stages of UFLS. If it is known that a generator could trip prior to all stages of UFLS, apart from protection settings that would be reported to them under R1 of this standard, the PC ought to know that. Of course, we understand that a GO would not be held accountable under R4 for unknown factors that may result in tripping of their unit within the no-trip zone of Attachment 1. Attachment 1 should be referenced because it would be difficult for the TP to come up with simulation results that would adequately convey in a comprehensive fashion the coordination that should take place between UFLS and generation tripping apart from Attachment 1. We also believe reference to Attachment 1 is necessary for consistency in the application of R4 throughout an interconnection. We therefore conclude that it is desirable for overall reliability purposes to reference Attachment 1 in R4. We also point out that

Organization	Yes or No	Question 6 Comment
		curves of the nature of those in Attachment 1 have long existed as guidelines for generation performance during frequency excursions in each of the reliability regions. GOs are familiar with these types of curves, and generating units have been designed with these guidelines in mind. With respect to Attachment 2 being referenced in R4, the reliability advantage is not as clear, but we ask the SDT to consider again that it may be difficult for the TP to come up with simulation results that would adequately convey in a comprehensive fashion the possible voltage excursion events that a generating unit may be subject to, and for which it may be desirable to know whether or not a given generating unit would be able to ride through that disturbance. Reference to Attachment 2 may be desirable for, again, consistency in the application of R4 throughout an interconnection. However, in contrast to frequency, voltage is a local quantity and so it is not as critical to system reliability that GOs report voltage excursion trips within the no-trip zone of Attachment 2. The translation of the no-trip zone of Attachment 2 to internal generating plant voltages that would need to be determined is not straightforward, though that translation would need to be made by a GO regardless of whether they would receive point-of-interconnection voltage simulations from a TP or be directed to Attachment 2. We conclude that reference to Attachment 2 in R4 may have reliability benefits that the SDT may want to consider, but we do not believe reference to Attachment 2 is as essential as reference to Attachment 1.If the SDT did not include reference to Attachment 2, that should not have a bearing on the reference to Attachment 1. We assert that, because of the different characteristics of frequency and voltage, it would not be inconsistent to reference Attachment 1 but not Attachment 2.

Response: Thank you for your comments. The SDT agrees that it will be easier for a Generator Owner to estimate generating unit performance for a frequency excursion than to estimate performance for a voltage excursion. The SDT does not require Generator Owners to do extensive dynamic simulations to determine performance. The draft standard has been modified to clarify that, "Detailed unit performance studies are not required to develop the estimate." For a voltage excursion, the SDT believes the Generator Owner could identify the most likely piece of equipment to fail to ride through (whether from contactor drop out or

Organization	Yes or No	Question 6 Comment
other mechanism) and estimate the time between that event and a generator trip due to the resulting process upset.		
Western Electricity Coordinating Council		I am unsure of the intent of the phrase "estimate of the performance of the units during frequency and voltage excursions." Is this intended to mean that the owners should estimate whether or not the unit will stay connected, or provide some estimate of the unit's dynamic performance and response to an event? I also don't understand the purpose of this requirement. If models already exist and are available to the Transmission Planners, then the owners should be validating the model. As part of the validatio process the owners should be able to tell the Transmission Planner what the performance will be. Is this for units for which models have not been validated?
Response: Thank you for your comments. The wording in Requirement R4 has been revised so that it now states, "…the time duration the existing unit or generating plant or generating Facility will remain connected (considering performance of the auxiliary systems as well as the generator) as a result of a frequency excursion or voltage excursion…" It is only an estimate of if the unit is expected to ride through the event or to trip. There is no connection between this requirement and the verification of excitation response or frequency response models as defined in Standards MOD-026 and MOD-027.

7. **Requirement R5 requires a Generator Owner's new unit or generating plant/facility to be able to stay on line when exposed to point-of-interconnection frequency or voltage excursions depicted in the curves of Attachment 1 and Attachment 2. Do you believe this requirement is technically achievable for new units or generating plant/facilities? Please provide comments supporting your answer. Please provide along with your comment, what you believe the timeframe is needed to implement this requirement.**

Summary Consideration: A large majority of stakeholders indicated that they did not agree that it is technically achievable for new generation to meet the performance required in Requirement R5. The most common reason stated was that Attachment 1 did not correctly specify the WECC region underfrequency tripping limits. Other objections cited by more than one responder were that the curves in Attachments 1 and 2 are too stringent, that significant R&D work needs to be done on the design of a plant to meet the requirement, and that the cost of building such a plant would be too high with little corresponding gain in grid reliability. The SDT corrected the error in the Attachment 1 underfrequency curve and data table for the Western Interconnection. The SDT did not make any substantive changes to Requirement R5 since the SDT did not feel stakeholders presented valid arguments that the requirement could not be achieved technically, given that similar requirements are already in effect in other parts of the world. The SDT did not feel objections to the cost or lack of reliability benefit could be considered as overriding FERC Order 693.

Organization	Yes or No	Question 7 Comment
Avista Corp.	Negative	The curve depicting the "no trip zone" for WECC in Attachment A is not consistent with the overfrequency and underfrequency requirements of the WECC Coordinated Off-Nominal Frequency Load Shedding Plan (Plan). A step is missing in the curve for the underfrequency requirements. The table representing the points on the "no trip zone" curve for WECC is also missing the same step as the plot. Additionally the presentation of the information in the table is confusing. As presented, the table specifies a time range of staying connected for selected specific frequencies. The table should specify a specific time for staying connected for frequency ranges. For example, as currently depicted in the table, a generator would need to stay connected up to 0.75 seconds (or between 0 and 0.75 seconds) at 57.0 Hz. The WECC Plan allows for instantaneous trips at 57.0 Hz. Further, the WECC Plan requires the generator to stay connected for 45 cycles (0.75 seconds) for frequencies greater than 57.0 Hz. but less than or equal to 57.3 Hz. This is not accurately reflected in the Table. The plot in Attachment A and the associated tables must be corrected to accurately

Organization	Yes or No	Question 7 Comment
		reflect the requirements of the WECC Coordinated Off-Nominal Frequency Load Shedding Plan.
Response: Thank you for your comments. The WECC curve in Attachment 1 has been corrected per the 25 Nov 1997 WECC Coordinated Off Nominal Frequency Load Shedding Plan document. The table of associated values for the WECC region has also been corrected.		
Balancing Authority of Northern California	Negative	Regarding Attachment for the “OFF NOMINAL FREQUENCY CAPABILITY CURVE” o The WECC ONFLS plan vs. the PRC-024 plan do not match for the low-frequency duration. Please refer to the submitted WECC Comments. o Regarding the PRC-024 Attachment I curves, the multiple regional frequency curve overlay is quite busy and difficult to discern. Please consider posting separate curves for the various interconnection. o It is unclear whether or not frequency events that fall on the “line” allow for the generator to trip. For instance the WECC Off-Nominal Frequency Plan allow for instantaneous trip for frequency excursions f ? 57.0 Hz. Please identifying the allowable trip-time values for each interconnection table at the given time delay.
Response: Thank you for your comments. The WECC curve in Attachment 1 has been corrected per the 25 Nov 1997 WECC Coordinated Off Nominal Frequency Load Shedding Plan document. The table of associated values for the WECC region has also been corrected.		
BrightSource Energy, Inc. 		WECC Coordinated Off-Nominal Frequency Load Shedding Plan."
Response: Thank you for your comments. The WECC curve in Attachment 1 has been corrected per the 25 Nov 1997 WECC Coordinated Off Nominal Frequency Load Shedding Plan document. The table of associated values for the WECC region has also been corrected.		
City of Redding	Negative	Regarding Attachment for the "OFF NOMINAL FREQUENCY CAPABILITY CURVE" - The WECC ONFLS plan vs. the PRC-024 plan do not match for the low-frequency duration. - Suggest to separate out the drawings for the various interconnection curves so they are not all on one graph. - Formally state that the "line" in the graph is not included in the No Trip Zone. Currently, the only way to know whether the "line" is in or out is this note on the graph. WECC formally indicates it in their table with the "<" signs.
Response: Thank you for your comments. The WECC curve in Attachment 1 has been corrected per the 25 Nov 1997 WECC Coordinated Off Nominal Frequency Load Shedding Plan document. The table of associated values for the WECC region has also been corrected. The note on the graph of Attachment 1 formally states that the No Trip Zone excludes the boundary line.		
Clark Public Utilities	Negative	I have voted negative because the PRC-024 criteria for generator frequency ride through and generator voltage ride through are not consistent with current WECC practices and proposals. Regarding frequency, WECC has had its Off Nominal Frequency Plan in place for many years. In addition, Reliability Standard Project WECC-0065 is proposed regional generator frequency ride through plan. Both of those plans use a long existing frequency ride through schedule. PRC-024 as proposed has a frequency ride through that neglects one of the low frequency points in the WECC plans. The 58.4 Hz setpoint (missing in PRC-024) avoids a low frequency area will result in damage to combustion turbines. PRC-024-1 must have a WECC low frequency ride through as follow: 57.0 HZ (0 - 0.75); 57.3 HZ (0.75 - 7.5); 57.8 Hz (7.5 - 30); 58.4 Hz (30 - 180); 59.4 Hz (>180). The overfrequency setpoints in PRC-024 are consistent with WECC practices. **The WECC curve in Attachment 1 has been corrected per the 25 Nov 1997 WECC Coordinated Off Nominal Frequency Load Shedding Plan document. The table of associated values for the WECC region has**

Organization	Yes or No	Question 7 Comment
		also been corrected. Additionally, the voltage ride through is confusing. In WECC, generators are supposed to be able to run continuously from 1.10 pu to 0.9 pu. I urge the STD to look at the work in the now terminated WECC-060 standards project (see the document entitled The Technical Basis for the New WECC Voltage Ride). The PRC-024 curve point data table seems to indicate that instantaneous trips are not allowed for 1.20 pu overvoltage. There is no reason for not allowing an instantaneous trip at this high of voltage. The generator will probably trip on overexcitation at this level anyway. The table needs to be informative enough so that if the data points were plotted, the expected curve would result. Looking at the curves it appears the table should read as follows for overvoltage. 1.05 pu (no trip); 1.10 pu (1.0 - 600.0); 1.15 pu (0.5 - 1.0); 1.175 pu (0.2 - 0.5); 1.20 pu (0 - 0.2). To avoid confusion the undervoltage criteria should read as follows. 0.95 pu (no trip); 0.90 pu (2.0 - 600.0); 0.75 pu (2.0 - 3.0), 0.65 pu (0.3 - 2.0); 0.45 pu (0.15 - 0.3); 0.00 pu (0.15). **The SDT acknowledges that certain regions may have more stringent voltage requirements, but does not believe that the standard should require the entire continent to meet the most stringent requirements. The data table for Attachment 2 has been reformatted to make the information clearer**
Response: Thank you for your comments. Please see the responses to your specific comments above.		
Colorado Springs Utilities	Negative	The curve depicting the “no trip zone” in Attachment A is not consistent with the overfrequency and underfrequency requirements of the WECC Coordinated Off-Nominal Frequency Load Shedding Plan (Plan). Response: Thank you for your comments. The WECC curve in Attachment 1 has been corrected per the 25 Nov 1997 WECC Coordinated Off Nominal Frequency Load Shedding Plan document. The table of associated values for the WECC region has also been corrected.		
Consumers Energy	Negative	"Related to undervoltage criteria, the 18 cycle at 45% of generator voltage would put a great deal of strain on the plant auxiliary systems and that may not be something these systems are able to withstand. The same would be true of a fault that produces 65% voltage at the generator terminals for 2 seconds. These comments relate specifically to Consumers Energy. However, it is likely that many others have similar equipment and would have the same issues. Please also note that the proposed standard does not align with ANSI C37.102, IEEE Guide for AC Generator Protection or with the NERC Technical Reference Document entitled Power Plant and Transmission System Protection Coordination." My vote is the same on the non-binding poll.
Response: Thank you for your comments. Please note that the voltage levels specified in Attachment 2 are at the point of interconnection to the transmission system. They would not correlate directly with the auxiliary bus voltages, especially if the auxiliaries are unit-connected. The SDT does not believe this proposed standard is in conflict with either the IEEE or the NERC documents cited. Please inform the SDT of the specifics of your concerns.		
MEAG Power	Negative	Regarding Attachment for the "OFF NOMINAL FREQUENCY CAPABILITY CURVE" o The WECC ONFLS plan vs. the PRC-024 plan do not match for the low-frequency duration. o We'd like them to separate out the drawings for the various interconnection curves so they are not all on one graph. o Formally state that the "line" in the graph is not included in the No Trip Zone. Response: Thank you for your comments. The WECC curve in Attachment 1 has been corrected per the 25 Nov 1997 WECC Coordinated Off Nominal Frequency Load Shedding Plan document. The table of associated values for the WECC region has also been corrected. The note on the graph of Attachment 1 formally states that the No Trip Zone excludes the boundary line.		
Seattle City Light	Negative	A) Regarding Attachment for the "OFF NOMINAL FREQUENCY CAPABILITY CURVE" o The WECC ONFLS plan vs. the PRC-024 plan do not match for the low-frequency duration. o Please separate out the drawings for the various interconnection curves so they are not all on one graph. It is difficult to read as presented. o Formally state in the standard that the "line" in the graph is not included in the No Trip Zone. Currently, the only way to know whether the "line" is in or out is a note on the graph. B) Regarding timing of various proposed activities: o Clarify the time given to Generator Owners to document all the equipment limitation that prevents compliance with the proposed Requirements R1 and R2, in reference to Requirement R3. o Provide a timeline on when to communicate the removal of a documented limitation if it takes more than 30 days to remove or repair the limitation after it is identified. (R3.1 requires the communication within 30 days of the identifying the limitation, but the repair or removal could take longer than 30 days, depending what the causes for the limitation are.)
Response: Thank you for your comments. The WECC curve in Attachment 1 has been corrected per the 25 Nov 1997 WECC Coordinated Off Nominal Frequency Load Shedding Plan document. The table of associated values for the WECC region has also been corrected. The note on the graph of Attachment 1 formally states that the No Trip Zone excludes the boundary line.		

Organization	Yes or No	Question 7 Comment
Northeast Power Coordinating Council	No	The exception in 5.2 should not be allowed. Each generating unit that is registered based on the NERC Registry Criteria as a single unit, or as part of a generating facility, should comply with PRC-024 without exception. Simultaneous loss of 10 percent of the generators at a number of installations could introduce severe reliability concerns. This standard allows loopholes which undermine reliability. **Part 5.2 gives an allowance for loss of up to 10% of units at a site with many small units, which is analogous to a runback in power on a single larger unit. The SDT does not agree that the exceptions written unduly compromise reliability.** Suggest revising Requirement 5.6 from "may retroactively grant a temporary exemption" to "may grant a retroactive temporary exemption". **The SDT agrees and has made the suggested revision.** The magnitude of voltage excursions at the point of interconnection may be different from the generator terminals where generator relays receive their voltage inputs. **The SDT agrees that the voltage at the point of interconnection to the transmission system will almost always be different than the voltage at the generator terminals. It is not practical to define the generator terminal voltage for an event on the transmission system considering all of the different configurations of generators and transformers. Each Generator Owner will have to evaluate the designs for his particular equipment.**
Response: Thank you for your comments. Please see the responses to your specific comments above.		
Exelon Corp.	No	It should be noted that even if a relay is not set to operate according to the curves in the attachments, a minute deviation will exist in the operation of the relay, and as such, a protection system may operate in what the SDT has deemed the "no trip zone." If a relay operates in that zone, then an entity will technically be out of compliance with this standard even though it set its protection system correctly as per the standard. An allowable tolerance needs to be included in the requirements in order to capture real world conditions.

Organization	Yes or No	Question 7 Comment
Response: Thank you for your comments. Relays that are known to drift from their settings should either be calibrated more frequently or set such that a tolerance is built into the relay setting so that the drift will not cross the "no trip zone" boundary.		
Texas Reliability Entity	No	While it is technically feasible to set generator protective relays to meet the intent of this Standard, there are technical limitations that may prevent manufacturers from achieving it, especially if the term "generating plant" includes auxiliary equipment within the plant that is required for the generator to continue to operate. The standard needs to clarify if and how the limitations of auxiliary equipment are to be addressed in connection with applicable generating facilities.
Response: Thank you for your comments. NERC standards do not specify how reliability goals are to be accomplished. There are already similar requirements in effect in parts of Europe and Asia. The implementation schedule for Requirement R5 allows six years before the requirement goes into effect in order to allow North American engineers to determine optimal methods for accomplishing the goal.		
ACES Power Marketing Standards Collaborators	No	It is not clear to us why this requirement is needed given the many tariffs that already exist to govern interconnection requests. These tariffs already have well established facility connection requirements. If the requirement persists, we believe it actually belongs in the FAC-001 standard which establishes facility connection requirements for new facilities including generators. While we believe that this requirement is probably technically achievable in most cases, there should be exceptions available. It looks like Part 5.3 will allow the Transmission Planner to offer these exceptions. However, this does not consider that the Transmission Planner in many cases (especially organized markets) is not the entity evaluating interconnection requests. Thus, the Planning Coordinator should be allowed to grant exceptions in those situations as well. **The SDT was charged with meeting the recommendations of FERC Order 693 and the 2003 Blackout Report. The SDT does not agree that placing the requirement in an Interconnection Agreement would achieve the desired performance goal.** The need to supply the bases for the estimate in Part 4.2 is not clear, offers no

Organization	Yes or No	Question 7 Comment
		reliability benefit and is administrative in nature. Of the three bases listed, (experience, actual event histories, or sound engineering judgment) what will the RC, PC, TOP, or TP do with the bases? Will they decide the bases are invalid and substitute their own judgment? If so, what is the purpose of getting an estimate from the Generation Owner anyway? It appears to be a documentation requirement that offers no reliability benefit or even information for which the recipient of the information could take action. **The SDT agrees and has removed the wording that required the Generator Owner to supply the basis for the estimate to the requesting entity.**
Response: Thank you for your comments. Please see the responses to your specific comments above.		
Puget Sound Energy	No	Steam units appear to have very tight frequency requirements, and the damage is cumulative. In order to protect the prime mover, after several under frequency operations the units may need to immediately trip offline.
Response: Thank you for your comments. A number of regions in North America already require operation to underfrequency levels more stringent than those described in this standard. Manufacturers are able to build turbines to meet these requirements. If a particular unit has experienced cumulative damage to the extent it can no longer meet Requirement R5, the Generator Owner may request an exemption from the Reliability Coordinator per Part 5.5. The RC can determine if there is more reliability gain to the grid by having the unit operational with a risk that it may not remain connected during an excursion.		
MRO NSRF	No	A Standard cannot tell us what or how a generator needs to be built. Section 215 of the Federal Powers Act "(i) Savings Provisions, (2) This section does not authorize the ERO or the Commission to order the construction of additional generation or transmission capacity or to set and enforce compliance with standards for adequacy or safety of electric facilities or services". We believe that R5 is directing "GO's to design, build and maintain new unit..." and is in violation to the Federal Power Act as stated above. **This requirement does not specify what equipment a generation facility needs to install. It does specify how it is to perform under certain conditions. The requirement does not indicate that a Generator Owner has to build**

Organization	Yes or No	Question 7 Comment
		anything at all, so the cited section of the Federal Power Act does not apply. It is true that a new plant that trips due to an excursion as defined in this standard would be out of compliance (with certain caveats as described in Parts 5.1 – 5.7). Since there are already similar grid requirements in effect in parts of Europe and Asia, the SDT believes it is possible to build a plant to meet Requirement 5 without a need for "future technology." The question was posed to ascertain if anybody is aware of valid technical reasons why it cannot be done with existing technology. There are many factors that a Generator Owner must consider when making a decision to build a new facility. Regulatory compliance may be one factor. As R5 is written, if an entity builds a new unit and it trips for a voltage or excursion event within the parameters of Attachment 1 and 2, the entity is non compliant. **The SDT agrees that this interpretation is correct. However, per Requirement R5, Part 5.5, the Generator Owner could ask the Reliability Coordinator for a retroactive exemption if he determines how to address the limitation that caused the unit to trip.** This Requirement seems to be based on future technology that does not exist today. The SDT should state that the parameters of Attachment 1 and 2 "should" prevent a unit from tripping. R5 is written as an absolute and may reduce a new unit from being built. With the risk of non compliance being $1 million per day, it is easier and less risky not to even build a new unit. **There are already similar requirements in effect in parts of Europe and Asia, so the SDT does not believe meeting the reliability goal will require "future technology." Evaluation of risks and rewards has always been a part of determining when and where to build generating resources.**
Response: Thank you for your comments. Please see the responses to your specific comments above.		
PPL Electric Utilities and PPL Supply NERC Registered Organizations	No	It is possible for new facilities to buy steam turbines that permit operation in accordance with Att.1. We cannot confirm that it is possible to do so for all fossil unit sizes or generation unit types, however, and recommend that question 7 above be put to OEMs. This is particularly the case for gas turbine engines, for which the

Organization	Yes or No	Question 7 Comment
		limiting factor may be surge avoidance rather than resonance margins. Note also that such units may auto-unload at abnormal frequencies. This action may not provide the grid ride-out capability wanted, despite satisfying R5's no-trip requirement. The general acceptability stated above for steam turbines bears clarification, however, because OEM guidelines for off-frequency operation typically have a lifetime basis. That is, each transient results in cumulative fatigue damage. The frequency curves of PRC-024-1 are consequently not acceptable for an unstable grid that often swings to the max-specified deviations, and a statement should be added to this standard to the effect that the no-trip zones of Att. 1 apply for frequency excursions to the extremes no more frequently than once per decade. **A number of regions in North America already require operation to underfrequency levels more stringent than those described in this standard. Manufacturers are able to build turbines to meet these requirements. If a particular unit has experienced cumulative damage to the extent it can no longer meet Requirement R5, the Generator Owner may request an exemption from the Reliability Coordinator per Part 5.5. The RC can determine if there is more reliability gain to the grid by having the unit operational with a risk that it may not remain connected during an excursion.** Att. 2 presents a problem in that the deviation location is specified to be the point of interconnection, but GOs are being asked to confirm that all MV and LV devices required to maintain the unit on-line will not drop-out. An excursion to -10% voltage on the 230 kV span would correspond to -10% on the LV and MV systems only for theoretically ideal transformers, and the actual transient at critical loads may be greater. It would not be possible in any event to get OEMs to guarantee that the auxiliary equipment they supply will not drop-out for the Att. 2 excursions of 10 minutes at -10% voltage, 2 sec at -35% or 0.2 sec at -55%. The industry standard on this subject is ANSI C84.1, which stipulates voltage boundaries of +/- 5% for continuous operation and +/- 10% for emergency operation of no specified duration. If NERC feels that the criteria of Att. 2 are important for BES reliability they should start by asking the appropriate ANSI and IEEE committees to revise their standards

Organization	Yes or No	Question 7 Comment
		accordingly. We cannot support PRC-024-1 until its criteria become the nationally-accepted norm, because we otherwise would be making a commitment that it is impossible to fulfill. **The SDT agrees that studies will need to be done to design generating units (especially their auxiliary systems) to be able to ride through the types of transmission system voltage excursions defined in this standard. Since similar requirements are already in effect in parts of Europe and Asia, the SDT believes it is technically feasible. ANSI C84.1 sets standards for steady-state operating voltages and does not apply to voltage transients.**
Response: Thank you for your comments. Please see the responses to your specific comments above.		
Luminant Power	No	Although this requirement may be achieveable, it is highly probably that as the unit ages, components will begin deteriate such that they will not be able to ride through severe voltage or frequency excursions. For example, Luminant has done testing of 480v contactors that when purchased new exhibit a drop out voltage level but over time, the drop out level will deteriate to a level. Since there is no method for determining when to replace equipment susceptible to voltage ride through criteria, this requirement is not auditable for the maintain requirement. The "maintain" requirement should be removed. The cost of meeting this requirement could potentially discourage new generation. Overall, requirement R5 provides little benefit to the reliability of the BES, and Luminant recommends that this requirement be removed.
Response: Thank you for your comments. The SDT is charged with meeting the reliability recommendations of FERC Order 693 and the 2003 Northeast Blackout Report. Maintenance is required for most equipment to ensure reliable operation. Contactor coils may have to be supplied from a source isolated from transmission system voltage excursions to ensure their reliable operation.		
Progress Energy	No	Progress Energy has a concern associated with the voltage ride through curve referenced in R5 (Attachment 2). The concern is not about setting the relay protection to ride through this transient or the generators capability of riding through

Organization	Yes or No	Question 7 Comment
		such a transient but of the physical capability associated with the large pumps and motors in the auxiliary equipment that would be subjected to this transient. A lot has to do with the size of the motors at the 4160 or 6900 volt level and the control relays at the 480 volt level. After 9 cycles at zero voltage the phase of the motor decay voltage and the incoming line voltage of the large motors may have shifted significantly causing large currents to be drawn when the voltage is restored to the motor. This could cause significant cyclical torques on motor shafts that can damage the shaft over time. Also the control contactors for most 480 volt control circuits do not hold in for less than 60 -70 % voltage. The capability of UPS systems are not sufficient to power the large motors being discussed and it may not be feasible to UPS all the plant 480 volt control circuitry. (We wouldn't be concerned with 480 if we thought we would lose higher voltage equip...) To implement this requirement as presently worded appears to be impractical and could prevent building of any new generating facilities at reasonable cost. **The SDT agrees that shaft torques on large motors is something that needs to be considered in designing the auxiliary system, but that is a concern for existing plants as well unless they have high speed under voltage bus tripping. Presumably, a new facility designed to ride through the voltage excursion described in the standard would include means of mitigating some of the effects of the excursion (e.g. unit-connected auxiliary transformers) which would reduce the shock on motor shafts. The SDT does not believe it would be necessary to carry the 480 V auxiliary loads on a UPS system. It would be sufficient to power the contactor coils with a UPS or from DC to ensure that they don't drop out on an excursion. Similar voltage ride through requirements are already in effect in parts of Europe and Asia so it appears that it is possible to design facilities to achieve the required performance.** There needs to be some ability to deviate for the specific requirements of the voltage curve in Attachment 2 if it can be show that the fault clearing time for the bulk electric system that the unit is connected to is different than the specific voltage requirements of Attachment 2 or there needs to be some more specific wording excluding the auxiliary equipment from the requirements of this voltage curve**. Part**

Organization	Yes or No	Question 7 Comment
		5.3 of Requirement R5 allows the Generator Owner to use the site-specific voltage recovery characteristic provided by the Transmission Planner for that site. Attachment 2 gives engineers and manufacturers the outer bounds of what might have to be met when designing equipment and facilities for multiple locations.
Response: Thank you for your comments. Please see the responses to your specific comments above.		
Tennessee Valley Authority GO/GOP	No	There are specific areas within the no-trip zone curves in attachments 1 & 2 that would violate nuclear safety limits, which are controlled by the NRC. Also, the turbines of large steam-turbine units may be exposed to unsafe operating conditions within the no-trip zone of the frequency curve.
Response: Thank you for your comments. Requirement R5 does not apply to existing plants (nuclear or otherwise). Existing plants with documented technical limitations (including nuclear safety considerations) may obtain an exemption from portions of the No Trip Zones defined in the standard through the process described in Requirement R3.		
Arizona Public Service Company	No	Yes, the requirement is technically achievable. However there is a problem with measure and how compliance may enforce it. Generating units trip for many other reasons other than frequency and voltage excursions. The meaure, as written, will require a GO to prove that the unit(s) did not trip due to frequency or voltage excursion which may be impossible to prove. Even if it finds other reasons, it may be hard to prove that frequency and voltage excursion did not contribute to that other reason. Thus, a GO may be non-compliant unless for each unit trip it can clearly prove that the frequency and voltage excursion did not contribute to trip, which may be impossible to prove.
Response: Thank you for your comments. The SDT believes it is general practice for Generator Owners to investigate and determine the cause of all generating unit trips. Recording unit speed (for synchronous units) or system frequency does not seem overly burdensome. Determining local transmission system voltage may require coordination with the Transmission Operator in some cases, but is not unachievable. This requirement would necessitate adding a step to a trip investigation to evaluate this information to determine if there was an excursion at the time of the trip.		

Organization	Yes or No	Question 7 Comment
PacifiCorp	No	While PacifiCorp has no concerns with this Requirement R5 as applied to new units or generating plant/facilities meeting the point of interconnection frequency excursion performance depicted in Attachment 1 (for the corrected WECC curve), PacifiCorp believes that new units or generating plant/facilities should meet the voltage excursions performance depicted in Attachment 2; however, ultimately it will be up to generator manufacturers to implement necessary facility changes to withstand the voltage excursions.
Response: Thank you for your comments. The SDT appreciates the support for the reliability goals. We would add that it will require changes in auxiliary system configuration and equipment as well as the turbine and generator manufacturers' inputs to achieve the goal		
Southern Company	No	We recommend R5 be eliminated. New plants should be subjected to the same requirements as existing plants. The design of plant systems, sub-systems, and components are based on industry technical standards (ANSI, IEEE, ASME, etc.). Establishment of new NERC plant performance requirements must be coordinated with the industry through those standard processes. We believe significant R&D will be required to achieve significant new plant design requirements that can be used to revise the industry technical standards and that plant, system, and equipment designers and builders can meet. The scope of systems and components that must be addressed includes, but is not limited to, turbine generators, transformers, feed pump systems/controls, boiler control systems, reactor protection systems, emergency diesel generators, AC motors, pumps, fans, AC motor contactors, auxiliary relays, etc. In addition, significant costs will be incurred by the industry that we believe demand further justification.
Response: Thank you for your comments. The implementation schedule calls for six years beyond approval of the standard before Requirement R5 goes into effect. The SDT believes this is enough time to develop the required designs. Similar grid requirements are already in effect in parts of Europe and Asia so it appears to the SDT that existing technology exists to meet the requirements of this standard.		

Organization	Yes or No	Question 7 Comment
AECI	No	In my opinion, there needs to a definition of what is considered to be a new plant. Many plants are being built that were actually plants and projects that started 10 years ago. I do not believe that those plants should be included.
Response: Thank you for your comments. The SDT believes that Footnotes 2 and 4 provide a clear definition of "existing" plants and "new" plants. Plants that are already in the design or construction stages are not considered "new" plants.		
American Electric Power	No	AEP believes that the requirement for new units and plants to not trip within the no-trip zone of Attachment 1 is reasonable, and has precedence in existing reliability region guidelines.To not trip within the no-trip zone of the Attachment 2 is another matter. AEP believes Attachment 2 is inappropriate as a requirement on conventional generation for the following reasons:(1) It has not been found necessary to impose such a requirement as Attachment 2 on conventional generation in the past and we question why this should be proposed now. The appearance of such graphs seems to have been in response to the performance of wind farms that tripped off-line by protective relays when minor fault disturbances occurred on the transmission system. Attachment 2 may thus be an appropriate requirement for wind turbine generators and other non-conventional generation. We ask the SDT why such a requirement now needs to be imposed on conventional generation. If this is being done solely for the standard to appear technology neutral, it does not remove the fact that a new, unnecessary, and possibly onerous requirement is being imposed. **The SDT is charged with implementing the reliability improvement recommendations from FERC Order 693 and the 2003 Northeast Blackout Report. The SDT is working under the assumption that when industry approved the SAR for this project it agreed that the standard provided a reliability gain.** (2) Application of Attachment 2 to conventional generation is not straightforward because of the need to translate point-of-interconnection voltage to plant or unit internal voltage, particularly in the time period following fault removal (.15 seconds). Conventional synchronous generators have a substantial capability to control the voltage they are subjected to during a system disturbance (unlike most wind farms)

Organization	Yes or No	Question 7 Comment
		and whose critical auxiliary systems are usually (and should be) served from the generator bus (low side of GSU) and are thus shielded to some degree by the GSU impedance from voltage excursions on the transmission system. **The SDT agrees that it will require engineering studies when designing new generating units to determine the effect of the transmission system voltage excursion on the generator terminals and on the various auxiliary bus voltages taking into consideration the configuration of the various transformers. The SDT does not believe this is unachievable.** (3) Back in 2005, FERC Order 661-A contained a requirement for wind farms to ride through point-of-interconnection faults up to 9 cycles as determined by the actual fault clearing time at the interconnection station. The final order was thought to be sufficient to ensure wind farm fault ride-through by intervening parties including NERC and AWEA without the need for a graph along the lines of Attachment 2. Justification for the content of the final order was that all generation would be treated equitably. Why does the SDT now think it necessary to impose Attachment 2 on new generation? It would seem that deference to TPL standards for the types of transmission system disturbances where stability should be maintained should continue to be an acceptable ride-through criterion for all types of generation. Reference to Attachment 2 in R5 should thus be replaced by a requirement for all generation to ride through normally cleared 3-phase or unbalanced faults at the POI not to exceed 9 cycles. **If the Transmission Planner for a new generation facility can provide the voltage profile for that specific site, then per Part 5.2 the Generator Owner can design his new facility to ride through that profile even if it is less stringent (i.e. uses faster clearing and faster voltage recovery) than Attachment 2. The voltage envelope described in Attachment 2 provides equipment OEM's with an outer boundary on the voltage stress they have to design for.** (4) We do not know the incremental cost to comply with Attachment 2 under R5; however, we believe that it could be very costly to design and build synchronous generating units that would, with a high degree of confidence, remain on-line for any and all disturbances whose POI voltage falls within the no-trip zone. Attachment 2

Organization	Yes or No	Question 7 Comment
		would also be a new requirement without historical precedent and the SDT has not stated how reliability would be improved. With uncertain reliability benefits and uncertain and potentially high incremental costs to comply, we do not think the SDT is in a position to impose this requirement.For these reasons, we believe that reference to Attachment 2 in R5 should be removed. **There are similar voltage ride through requirements already in effect in parts of Europe and Asia. The SDT is charged with implementing the reliability improvement recommendations from FERC Order 693 and the 2003 Northeast Blackout Report. The SDT agrees that generating units designed and built to meet Requirement R5 will be more costly than those that cannot meet this reliability goal. The SDT is not in a position to place a monetary value on the consequent reliability gain. The SDT is working under the assumption that when industry approved the SAR for this project it agreed that the standard provided a reliability gain.**
Response: Thank you for your comments. Please see the responses to your specific comments above.		
Luminant Energy	No	Although this requirement may be achieveable, it is highly probably that as the unit ages, components will begin deteriate such that they will not be able to ride through severe voltage or frequency excursions. For example, Luminant has done testing of 480v contactors that when purchased new exhibit a drop out voltage level but over time, the drop out level will deteriate to a level. Since there is no method for determining when to replace equipment susceptible to voltage ride through criteria, this requirement is not auditable for the maintain requirement. The "maintain" requirement should be removed. The cost of meeting this requirement could potentially discourage new generation. Overall, requirement R5 provides little benefit to the reliability of the BES, and Luminant recommends that this requirement be removed.
Response: Thank you for your comments. The SDT is charged with meeting the reliability recommendations of FERC Order 693 and the 2003 Northeast Blackout Report. Maintenance is required for most equipment to ensure reliable operation. Organization	Yes or No	Question 7 Comment
operation.		
Duke Energy	No	The proposed bands should be considered by new plant designers and incorporated into their design basis if feasible. Specific criteria have not been provided in new plant design guidance provided by EPRI Utility Requirements Document (URD) nor in other industry standards used by new plant designers. The frequency band was considered for some new plant design basis and no concerns were identified. It's not clear if all or even most of the designers for other nuclear/fossil designs have considered this.The proposed voltage band has caused many concerns and probably is not achievable for existing or new steam plants because electrically powered equipment (motors, MCC components, contactors, etc.) has been and is normally designed for proper operation as follows:The normal voltage boundaries have been specified to be for the steady-state operating conditions based on the ANSI C84.1-2006 “American National Standard for Electric Power Systems and Equipment - Voltage Ratings (60Hz)”as follows:a. Normal Conditions: Â±5% Continuous Durationb. Emergency Conditions: Â±10% not specified DurationThese Criteria are currently widely used in practice and can be complied with by all types of new generating plants designed with an in-plant voltage regulation capability. In connection with these criteria, all new equipment, both on the transmission system and in new generation plants must be chosen in order to be able to operate and withstand these voltage excursions.For transients, the above should be applied for conditions lasting more than one second. Transient conditions lasting more than one second, can be more severe and the equipment can still ride through it. A design solution to address severely degraded voltage lasting more than one second is to utilize expensive voltage regulation devices, normally not utilized at power generation plants. This standard shouldn’t dictate a solution to the situation where a generator goes offline due to low voltage on the transmission system, because in many cases the generator going offline may not be a problem for the overall transmission system. In situations where it is a problem, a collaborative effort between the Transmission Planner and the Generator Owner would be the best approach (see AREVA white paper that has been provided to the SDT).An R&D effort

Organization	Yes or No	Question 7 Comment
		should be considered to investigate steam plant ride through capabilities if a criteria is needed.
Response: Thank you for your comments. The voltage profile described in Attachment 2 is specified at the transmission system. This cannot be directly applied to the auxiliary system buses unless the Generator Owner insists on using substation-connected auxiliary transformers. Operating the auxiliaries from unit-connected transformers would provide a much better voltage profile to the equipment. As noted, ANSI C84.1 applies to steady state voltages. This standard does not state that any transient condition lasting longer than one second is defined as steady state. In IEEE 1159 a long duration variation is defined as being longer than one minute. The SDT is charged with implementing recommendations from FERC Order 693 and the 2003 Northeast Blackout Report. The implementation schedule calls for six years beyond approval of the standard before Requirement R5 goes into effect. The SDT believes this is enough time to develop the required designs. Similar grid requirements are already in effect in parts of Europe and Asia so it appears to the SDT that existing technology exists to meet the requirements of this standard.		
Ameren	No	(1) We understand this to include generating plant auxiliary load based on the GVSDT reply to our draft 2 comments. If still is the case, please clarify and explicitly insert “including its auxiliary systems” after generating plant so that all GO understand it. **The SDT agrees and has added “(including auxiliary systems)” to the wording in the requirement.** (2) Many 480V class contactors drop out in the 70% to 80% voltage range, so we doubt they’ll ride through the 2 to 3 second portion of the voltage excursion. The middle portion of your voltage excursion curve is more stringent than the CBEMA and SEMI curves, both of which recover to 80% in 0.5 sec. Transmission system protection in our system will clear faults faster than the proposed voltage excursion curve, thus in effect yielding a voltage recovery curve with shorter durations for the voltages specified. We would ask the GVSDT to consider what we feel is a more realistic approach of designing a new generating facility to the Transmission Planner’s voltage recovery characteristic allowed for in R2 part 2.1.1 is achievable now. What was the basis on which the proposed voltage excursion curve developed? **The curves cited in your comments specify voltages at the equipment. The voltages specified in Attachment 2 of the standard are at the high side of the generator step-**

Organization	Yes or No	Question 7 Comment
		up transformer. A new generation facility would have to be designed such that contactor coils and delicate electronic equipment are isolated from the full extent of a transmission system voltage excursion. If the Transmission Planner for a new generation facility can provide the voltage profile for that specific site, then per Part 5.3 the Generator Owner can design his new facility to ride through that profile even if it is less stringent (i.e. uses faster clearing and faster voltage recovery) than Attachment 2. The voltage envelope described in Attachment 2 was developed from studies in WECC and SERC of multiple fault scenarios and their recovery characteristics. It is similar to the envelope described in FERC Order 661-A that wind units already are required to meet and to grid requirements already in effect in parts of Europe and Asia.
Response: Thank you for your comments. Please see the responses to your specific comments above.		
Southern California Edison Company	No	The language in the requirement is acceptable, but the frequency curve identified for generators is too restrictive for hydro facilities, which are often dispatched to provide VAR and voltage support. SCE's hydro generation plants operate at very low RPM, which provides them with the ability to operate safely above (60-78 Hz) and below (<58 Hz) the frequency curves in Attachment 1 and Attachment 2, respectively. As a transmission operator, SCE applies this flexibility in its hydro generation plants to compensate for system instabilities resulting from VAR and voltage excursions. In addition, SCE's employs its hydro plants to support system restoration.
Response: Thank you for your comments. The SDT is not clear on your response. It appears that you want hydro units to be able to operate below 57.0 Hz and/or above 61.7 Hz that are the boundaries for the WECC interconnection. The standard does not require that any generators trip if the frequency goes outside of the No Trip Zone defined in Attachment 1, it only prevents tripping within the No Trip Zone.		
Cowltiz PUD	No	Cowlitz supports Clark County PUD's position. Please verify the following: The problem is that PRC-024 skips a frequency step in the low frequency operating area. The generator frequency ride through of Attachment 1 is inconsistent with the

Organization	Yes or No	Question 7 Comment
		current WECC Off Nominal Frequency plan and the frequency ride through in the proposed WECC-0065 regional criteria. The PRC-024 ride through could cause a combustion turbine to operate at 58 Hz for a duration that would cause damage to the turbine blades. The current WECC ONF ride through avoids this.
Response: Thank you for your comments. The WECC curve in Attachment 1 has been corrected per the 25 Nov 1997 WECC Coordinated Off Nominal Frequency Load Shedding Plan document. The table of associated values for the WECC region has also been corrected.		
Indiana Municipal Power Agency	No	Is the technology to meet this requirement even currently available to a newly built generating facility? To force such a requirement on newly built generating facilities at this time, one is speculating that the technology will be available. Can we risk reliability of the gird on such speculation (Generator Owners not building generating facilities because they cannot meet this requirement)? What if the technology is not available? IMPA believes that this standard will be reviewed by NERC in five years or sooner and at the time the SDT can revisit this possible requirement to see if the technology to keep a generating facility on line during a voltage or frequency excursion has been proven. Or a condition could be added that says new units shall be designed and built with the frequency and voltage excursion equipment if it is the industry standard, readily and commercially available and comes at competitive market prices.
Response: Thank you for your comments. The implementation schedule calls for six years beyond approval of the standard before Requirement R5 goes into effect. The SDT believes this is enough time to develop the required designs. Similar grid requirements are already in effect in parts of Europe and Asia so it appears to the SDT that existing technology exists to meet the requirements of this standard.		
Pepco Holdings Inc. & Affiliates	Yes	Yes, it is possible to design a new facility to operate within the requirements identified in this standard. However, it may require specification of equipment with higher than normal overvoltage capabilities. Also, significant analyses would have to be conducted on the behavior of plant control systems (exciter controls, boiler

Organization	Yes or No	Question 7 Comment
		controls, etc.), as well as equipment connected to auxiliary busses (including low voltage motor contactors) to ensure that all systems are designed with appropriate ride-through capabilities.
Response: Thank you for your comments. The SDT agrees with your position.		
ISO New England Inc	Yes	The exception in 5.2 should not be allowed. Each generating unit that is registered based on the NERC Registry Criteria as a single unit, or as part of a generating facility, should comply with PRC-024 without exception. Simultaneous loss of 10 percent of the generators at a number of installations could introduce severe reliability concerns. This standard appears to allow loopholes which undermine reliability.
Response: Thank you for your comments. Part 5.2 (now 5.1) gives an allowance for loss of up to 10% of units at a site with many small units which is analogous to a runback in power on a single larger unit. The SDT does not believe the exceptions written in Requirement R5 unduly compromise reliability.		
Xcel Energy	Yes	We believe the requirement is technically achievable, but question whether the additional cost to design and build plants to meet this goal is the most effective way to spend money to increase grid reliability.
Response: Thank you for your comments.		
Ingleside Cogeneration LP	Yes	In our view, the time frame allotted to accommodate PRC-024-1's frequency and voltage ride-through specifications for new generating facilities is reasonable.
Response: Thank you for your comments.		
GenOn Energy	Yes	Conditionally yes; unconditionally no. It is achievable for any plant with a modern AVR and unit connected auxiliaries. Problems arises for unique circumstances that may require auxiliaries that are not unit connected (directly connected to transmission systems). Existing plants orginally designed with unit connected

Organization	Yes or No	Question 7 Comment
		auxiliaries have been forced to extend auxilary power feeds directly from transmission level voltages.It is believed that transmission system performance better than Attachment 2 is available at the majority of locations, and therefore, it is not necessarily appropriate to make this the design criteria for every future generating station.
Response: Thank you for your comments. Requirement R5 does not apply to existing plants. Part 5.3 of Requirement R5 allows the Generator Owner to design to a less stringent voltage profile (e.g. a profile with faster clearing and faster recovery) if the Transmission Planner can provide the profile for the specific site in question. Attachment 2 provides the outer bounds that may be used by engineers and manufacturers to determine the limits of what they may be required to withstand.		
American Wind Energy Association	Yes	Yes, the feedback we have received from wind turbine manufacturers is that, if such a standard were not applied retroactively and were implemented with a grace period extending at least several years into the future, wind plants would be able to meet these requirements.
Response: Thank you for your comments. The implementation for Requirement R5 is set at six years past approval of the standard. Requirement R5 applies only to "new" plants (as defined in Footnotes 2 and 4) and does not apply retroactively to existing plants.

Georgia Transmission Corporation		Don't know
Los Angeles Department of Water and Power		LADWP does not have comments on this question at this time.

8. Do you have any other comment, not expressed in questions above, for the GVSDT regarding PRC-024-1?

Summary Consideration: The Effective Date section was modified for Requirements R1, R2, R3, R4, and R6 to reflect a five-year implementation at the request of several stakeholders. The wording in Requirement R1 was revised for clarity, Part 1.1 (rate of change of frequency) was removed and new Parts 1.2 and 1.3 were added for consistency with Requirement R2 at the request of several stakeholders. Minor changes in the wording in Requirement R2 were made to improve clarity at the request of several stakeholders. The structure of Requirement R4 was modified and minor wording changes were made to improve clarity at the request of several stakeholders, though no changes were made to the intent of the requirement. Part 5.1 and Subpart 5.1.1 were incorporated into the body of Requirement R5 so that the remaining Parts of this requirement describe exceptions (i.e. allowances to trip). Minor wording changes were made at the request of multiple stakeholders to clarify wording in Parts 5.1 – 5.6 of Requirement R5. The allowable time to respond to a request for generator protection settings in Requirement R6 was increased from 30 days to 60 days at the request of several stakeholders. The Violation Risk Factors for Requirements R1, R2, and R5 were changed from High to Medium at the request of several stakeholders. Minor wording changes were made to Measures M3, M4, and M5 were made for clarity at the request of several stakeholders. The time frame referenced in Measure M6 was modified to correlate with the change made in Requirement R6. The wording in the Data Retention section was revised at the request of one stakeholder and now reflects the wording used in other recently-approved standards. Minor changes were made in the VSL's for Requirements R1, R2, R3, and R4 to add clarity or correct errors mentioned by several stakeholders. The wording in the Severe VSL for Requirement R5 was revised to add a reference to Parts 5.1 – 5.6 and the tardiness levels in the Requirement R6 VSL's were revised to reflect the change in the requirement. The underfrequency curve for the Western Interconnection and corresponding data table were corrected in Attachment 1 at the request of many stakeholders in the WECC region. Curves for the ERCOT Interconnection and a corresponding data table were added to Attachment 1 at the request of ERCOT. The term "base voltage" was replaced with "nominal operating voltage" in Clarification #1 to Attachment 2 at the request of several stakeholders. Minor wording changes were also made to Clarifications #2, and #5 to better convey the intent of the SDT in response to questions presented by several stakeholders.

Organization	Yes or No	Question 8 Comment
Southern Company		Yes: 1) We respectfully disagree with the SDT's response to our prior comment related to maintaining the safety of the reactor core at nuclear plants for voltage or frequency transients. The intent of our comments is to ensure that application of this standard to nuclear units is coordinated per the requirements of NUC-001.

Organization	Yes or No	Question 8 Comment
		Employing any changes to the grid frequency and voltage ride-through requirements may impact the licensing and design basis of nuclear facilities. NUC-001-1 requires coordination between Nuclear Plant Generator Operators and Transmission Entities for the purpose of ensuring nuclear plant safe operation and shutdown. This is achieved through development of Nuclear Plant Interface Requirements (NPIRs) for each nuclear unit that are based on plant-specific Nuclear Plant Licensing Requirements (NPLRs) and Bulk Electric System requirements that have been mutually agreed to by the Nuclear Plant Generator Operator and the applicable Transmission Entities. The NPLRs are requirements included in the design basis of the nuclear plant and statutorily mandated for the operation of the plant, including nuclear power plant licensing requirements for 1) Off-site power supply to enable safe shutdown of the plant during an electric system or plant event; and 2) Avoiding preventable challenges to nuclear safety as a result of an electric system disturbance or transient condition is important. It is essential that this process be followed closely in attempting to apply any new grid frequency and voltage requirements that are more extreme than those currently addressed in each plant's licensing and design basis. The safety of nuclear power plants is of paramount importance. **The SDT respectfully disagrees that this standard is in conflict with the requirements of NUC-001. Requirement R4.3 of NUC-001 acknowledges that it is not always possible to operate the transmission system to meet the requirements of a particular site's NPIR. The Reliability Coordinator is an applicable entity to the NUC-001 standard, and as such can be involved in granting an exemption (per PRC-024 part 5.6) to any new nuclear facility that cannot meet the ride-through requirements of Requirement R5 because of a conflict with the facility's NPIR if the Reliability Coordinator agrees there is a reliability benefit to allowing the facility to operate with a greater risk of tripping during a frequency or voltage excursion. Existing nuclear facilities can get an exemption from portions of the no trip zones defined in Attachments 1 and 2 through the process defined in Requirement R3 based on the regulatory nuclear safety requirements.** 2) R1, R2, and R3 state "each" non-protection system equipment limitation. This

Organization	Yes or No	Question 8 Comment
		should be clarified to state "each non-protection system equipment limitation associated with the applicable protection function." **The SDT agrees and has removed the term "non-protection system equipment limitation" from Requirements R1, R2, and R3.** 3) Event monitoring equipment required by M5 will be a significant burden on GOs to only prove a negative. We believe M5 should be removed from the standard, because the benefits gained do not justify the costs. **The SDT does not agree that event monitoring equipment poses a significant burden compared to the cost of a new generating unit.**
Response: Thank you for your comments. Please see the responses to your specific comments above.		
Ameren		(1)Under Applicability it should state that 'all existing generators meeting registry criteria' and also 'new generating units that will meet the registry criteria.' **The SDT feels that the applicable generators owned by a "Generator Owner" is clearly stated in the Registry Criteria and that no further clarification is required.** (2)Please modify the Effective Date and Implementation Plan to provide a five year phase-in to match that of the companion PRC-019-1. Generator voltage protective relaying must be reviewed in both these standards, and we believe that doing so on the same schedule will yield a better coordinated result and less confusion. Each of these standards will consume valuable resource time and the efficiency of reviewing each generator concurrently will improve BES reliability **The SDT agrees and has changed the implementation period, relative to Requirements R1, R2, R3, R4 and R6, of PRC-024-1 to match that of PRC-019.** (3)Please add 'R1, 1.3 If clearing a system fault necessitates disconnecting a generator, then this action is acceptable within the "no trip zone".' This affords the same practical reality recognized for voltage excursions. **The SDT agrees so that there is consistency between Requirements R1 and R2. Part 1.2 has been added in the current revision.**

Organization	Yes or No	Question 8 Comment
		(4)Please be clearer regarding the Voltage Ride-Through curve. Attachment 2 Voltage Ride-Through Curve Clarification #2 could be interpreted to imply that the curve is based on three phase faults. But the inclusion of #5 states that phase-to-ground or phase-to-phase voltages (minimum or maximum as appropriate) are assumed. Of course, for a three phase fault the each phase's voltage is equal. So we interpret #5 to mean that the actual fault type to be simulated should match the Transmission Planning criteria, which for example may be double or single line to ground faults with delayed clearing. We recommend to the GVSDT to align this with the TPL standards, which use three phase fault or single line to ground fault with Normal Clearing, but only single line to ground fault with Delayed Clearing. We would appreciate an example or in depth explanation to tie these together. Please annotate Attachment 2 with references to R2 and clarifications on page 18. **Clarification #2 to Attachment 2 has been modified with an added statement saying "The curves apply to voltage excursions regardless of the type of initiating event." The SDT believes it is not realistic to design generating units to be able to withstand zero voltage at the point of interconnection to the transmission system for extended time periods. None of the other grid standards for generator ride through that the SDT reviewed contain requirements to ride through delayed clearing.** (5)Delete 'or generating plant' from R1, R2, and R3 to be clear that the generating plant auxiliary loads are not subject to these requirements. Alternatively, restate R3 as "...that prevents a generator frequency or voltage protective relay generating unit or generating plant, from meeting the criteria in Requirements R1 or R2 including study results, experience from an actual event, or manufacturer's advisory" to be consistent with R1 and R2. **The SDT agrees and has removed the words "or generating plant" from the Requirements. The wording of R1 and R2 has been changed to indicate that the relaying included in the scope of R1, R2, and R3 are generator voltage relays and generator frequency relays, both of which trip the unit when they operate**. (6)At the end of Requirement R4.2, please add "the Transmission Planner's voltage recovery characteristic from R2 part 2.1.1" since that may well have bearing on the estimate. **Since it is not a requirement for the Transmission Planner to provide the**

Organization	Yes or No	Question 8 Comment
		voltage profile defined in Part 2.1.1. (now Part 2.2), the SDT does not believe it can be required to provide this information in Requirement R4. (7)From our perspective, Requirement R5 doesn't make sense for a newly designed generator. We would suggest the GVSDT to realign M5 to be prospective and to require the GO to provide design basis evidence appropriate for the stage of design of new generators. In early conception stages, the GO would request the Transmission Planner's frequency and voltage excursions. Then the GO would design the generator train and auxiliary system to ride through, and if infeasible, request technical exceptions. Late in the design process the generator frequency and voltage protective trip settings would be determined; it would be appropriate at that time to provide them R6 requests for future system studies. **The SDT appreciates this suggestion, but in discussions with the US regulatory agency regarding this approach, they indicated it could only be used in addition to the performance requirement, not in lieu of performance. The SDT does not believe it would increase grid reliability to require Generator Owners to do both.** (8)For Requirement R6 we oppose providing this specific information to all these functional entities, given that they are getting the R4 estimate of performance during such excursions. **The information would only be given to the entity that requested the information. The number of entities who are allowed to request the information is restricted to those named in Requirement R6. The performance estimate requested in Requirement R4 is different in that it must consider the performance of the entire generating unit including auxiliaries, not just the protection system.** (9)If R6 is retained, please make the following changes: (a) We strongly prefer a reporting of exceptions to the standards frequency and voltage excursion ride-through curves rather than reporting all these relay settings. Use PRC-006-1 Attachment 1 page 28 of that standard for frequency reporting. Develop a similar envelope for voltage reporting. If a Transmission Planner's voltage recovery characteristic allowed for in R2 part 2.1.1 differs that should be provided for the

Organization	Yes or No	Question 8 Comment
		generators in their area. Generator Owners would then report exceptions. (b)Insert "frequency and voltage" between generator and protection in the first line.(c)Delete "and within 30 calendar days of any change to those trip settings," because this creates an open ended obligation on the GO. **The SDT assumes that the requestor would only ask for settings for the protection functions that are modeled for stability or UFLS performance. Typically, most generator protection functions are not included in these models. However, in order to predict the generators' behavior accurately, the entity creating the model must know the settings for all of the modeled protection functions, not just those that do not meet Requirements R1 or R2. Following such a request only changes to the settings that have been requested would need to be reported. The SDT has added the words "…unless otherwise directed" so that the requestor can indicate that future changes do not have to be reported (as may be the case for a one-time study that will not be repeated).** (10)We would suggest the GVSDT to not capitalize frequency and voltage excursions as they are no longer defined terms. **The SDT agrees and has made the suggested changes.** (11)We suggest the GVSDT to replace the time-based or binary VSL for R1, R2, R3, R4 and R6 with a VSL in terms of the GO % of MWh produced for the time period of violation. This better characterizes the risk to BES reliability. We propose <5% for Lower, 5 to 10% for Moderate, 10 to 15% for High, and >15% for Severe. As presently proposed a generator with no operating hours could cause a GO to incur a Severe violation though it posed no risk to the BES. **The SDT discussed this approach with NERC earlier in the drafting process and was told it is not an acceptable method of structuring a VSL.** (12)From our perspective, the VSL for R5 doesn't make sense for a newly designed generator. We suggest, a time-based VSL with x days late in providing R4 or R6 type information. . In this regard, we propose to the GVSDT 30 days late for Lower, 31 to 60 days late for Moderate, 61 to 90 days late for High, and >90 days for Severe. **The**

Organization	Yes or No	Question 8 Comment
		SDT does not see how a tardiness structure would apply to a performance requirement. (13)PRC-024-1, R2.1 states that generator terminal voltage refers to Attachment 2. However, in R2 itself, footnote 3 states that voltage excursion applies to point of interconnection, meaning the GSU high-side. We suggest the SDT resolve this discrepancy. **Requirement R2, part 2.1 states that Attachment 2 applies to conditions on the transmission system when the generator is operating within 95% to 105% of its rated voltage. The SDT does not see a discrepancy.** (14)Attachment 2 should include footnote similar to footnote 3 provided for R2. **The SDT does not believe it is necessary to insert duplicate footnotes.**
Response: Thank you for your comments. Please see the responses to individual comments above.		
Pepco Holdings Inc. & Affiliates		1) If it is critical to the reliability of the BES to not have generators trip off line for voltage excursions associated with close in three phase faults, then it is equally as important to have them remain on-line for single line to ground faults, which are much more common. During a phase to ground fault at the point of interconnection the faulted phase voltage collapses to zero but the unfaulted RMS phase to ground voltages could rise as high as 80% of the RMS line to line voltage for an effectively grounded system (with a coefficient of grounding = 80%). This is well in excess of the 1.2 p.u. overvoltage requirement presently shown in Attachment 2. As such, for the unit to ride through phase to ground faults at the point of interconnection then the short time 1.2 p.u. overvoltage threshold at the point of interconnection needs to be raised above 0.8 x 1.73 = 1.38 p.u.. In summary, the overvoltage portion of the curve in Attachment 2 should be modified to require the unit to stay connected with a 138% phase to ground overvoltage appearing at the point of interconnection for up to the expected clearing time of a Zone 1 phase to ground fault. **The SDT agrees that the phase to ground voltage can rise to the level noted in your comment during single phase to ground faults. The SDT has modified Clarification #5 to remove the words "…phase to ground…" If only the phase-to-phase voltages are evaluated,**

Organization	Yes or No	Question 8 Comment
		then the limit can remain at 1.2 p.u. voltage. 2) The standard should make clear whether the no-trip zone shown in Attachments 1 and 2 includes the boundary curves themselves. **There is a text box in the middle of the graph that specifically states that the no trip zone does not include the lines. The SDT does not believe any further explanation is necessary.** 3) To add clarity and avoid confusion, the ordinate of the graph in Attachment 2 should be labeled Per-unit RMS Voltage Measured at the Point of Interconnection. **Clarification #5 to Attachment 2 has been modified to include the term "RMS."** 4) The current language in Item #1 of the "Voltage Ride-Through Curve Clarifications," which appears on the last page of the standard, may cause problems for generator interconnections on the 500kV system. Most transmission Planners use "nominal" transmission system voltage levels as the "base voltage" in their system models. These are the same "nominal" system voltages specified in ANSI C84.1. In most cases, C84.1 shows the maximum allowable system voltage as 105% of nominal, with the exception of 500kV. For 500kV systems the maximum system voltage is 550kV, and it is routine to operate the transmission system above 525kV (105% of nominal). If the "base voltage" at the point of interconnection used in planning studies is 500kV but the system is normally operated above 105%, then the generation protective systems must be capable of maintaining operation with the continuous voltage at the point of interconnection above 105% of "nominal" (at least for 500kV systems). This being the case the voltage base in Attachment 2 for 500kV systems will by necessity have to be something other the "nominal base voltage" used by the Transmission Planner in their system models. Perhaps this could be addressed by re-wording Item #1 to read "1. The per unit voltage base for these curves is to be specified by the Transmission Planner at the point of interconnection to the Bulk Electric System (BES)." By removing the reference to "the base voltage used in the system models by the Transmission Planner" it eliminates the conflict mentioned above. On the other hand it now requires the Transmission Planner to provide this "other than nominal base voltage for 500kV systems" to the Generator Owners. **Since some 500**

Organization	Yes or No	Question 8 Comment
		kV systems may not operate in the same manner as yours, the SDT would prefer not to specify different ranges for particular voltage classes. In order to address your concern, the SDT has modified Clarification #1 to Attachment 2 by removing the words "base voltage" and "in the system models" and has replaced them with "nominal operating voltage specified by the Transmission Planner." The SDT believes this will address the different operating criteria used in different regions. 5) The word "crest" should be removed from Item #5 of the "Voltage Ride-Through Curve Clarifications," which appears on the last page of the standard . The voltages referred to in this standard are all per-unit "RMS" voltages, not "peak" or "crest" voltages. **The word "crest" is necessary for equipment manufacturers to know what the limits are that they must meet in designing equipment to meet the requirements of this standard. Under normal operating conditions per unit crest and per unit RMS are the same, but during high voltage excursions, magnetic saturation creates differences.** 6) Typically unit connected generator protection packages, which include frequency and voltage protective elements, are supplied by voltage transformers connected on the terminals of the generator rather than on the high side of the generator step-up (GSU) transformer. For frequency elements, the frequency at the terminals of the generator is the same as on the high side of the GSU transformer. So comparison of frequency protective element set points can be made directly with Attachment 1. However, this is not true for voltage. The generator terminal voltage could be higher, or lower, than the system voltage on the high side of the GSU transformer depending on the voltage drop across the transformer, which varies depending on the generator real power output and whether the generator is supplying or absorbing reactive power. Since this standard requires the generation to remain connected for specific voltage criteria as measured at the point of interconnection, but the voltage sensing protection is connected to the generator terminals, some technical guidance (with specific examples) must be provided to allow the Generator Owner to properly translate these voltage criteria to the voltages seen by the protective relays on the terminals of the generator. Otherwise an incorrect evaluation may result. It is

Organization	Yes or No	Question 8 Comment
		recommended that a Technical Reference Document similar to the "Power Plant and Transmission System Protection Coordination" document developed by the NERC System Protection and Control Subcommittee be produced, or the above mentioned document revised, to provide illustrative examples of how to apply the Attachment 2 POI voltage criteria to voltage sensing protective elements connected to the terminals of the generator. **There are text books that cover the necessary calculations. Clarification #6 to Attachment 2 provides guidance to the conditions to be used when doing the evaluation.**
Response: Thank you for your comments. Please see the responses to your specific comments above.		
Texas Reliability Entity		1) Purpose Statement: If we correctly understand the intent, the second comma should be removed. **The SDT agrees and has removed the comma.** 2) Does the SDT want to consider any specific requirements regarding generators that are connected as synchronous condensers, and is it the intent of the standard to cover this operating mode? **The SDT considered including synchronous condensers as applicable facilities for this standard. The SDT determined that it is not necessary to include synchronous condensers because frequency transients within the scope of this standard are not a serious concern for synchronous condensers, and most synchronous condensers do not have the auxiliary systems that would cause a condenser to trip under the voltage transients defined in this standard.** 3) All requirements: Need to clarify the phrase "generating unit or generating plant". Does the "generating plant" phrase imply that the frequency and voltage setting criteria also applies to plant auxiliary equipment (referenced in R4)? In ERCOT, we have seen multiple instances where close-in faults have created low voltage conditions which caused auxiliary equipment to trip (boiler feed pumps, baghouse fans, etc.) which in turn caused a unit runback and trip. If the intent of this standard is to also cover plant auxiliary equipment, then this needs to be very clearly stated in the Applicability section and/or in the Requirements. **The SDT agrees and has removed the words "or generating plant" from the Requirements. The wording of**

Organization	Yes or No	Question 8 Comment
		R1 and R2 has been changed to indicate that the relaying included in the scope of R1, R2, and R3 are generator voltage relays and generator frequency relays, both of which trip the unit when they operate. 4) R1 and R2: The SDT may want to consider adding Volts per Hertz criteria. For example: ERCOT region criteria currently states a generator must remain connected if Volts/Hertz is less than 105% of generator design voltage and frequency, and also if Volts/Hertz is less than 116% of generator design voltage and frequency for less than 1.5 seconds. **The V/Hz relaying applicability is addressed in Footnote 1. R1 and R2 apply to situations where a unit is tripped by generator frequency relaying or voltage relaying.** 5) R1: Need to add "or generating plant" to end of R1. **The SDT has removed the words "or generating plant" from Requirements R1 and R2 at the suggestion of other commenters, so it is no longer necessary to add it to the end of Requirement R1 for consistency.** 6) R2: Need to specify that the undervoltage "no trip zone" applies to both single-phase and three-phase voltage excursions. **Clarification #2 to Attachment 2 has been modified with an added statement saying, "The curves apply to voltage excursions regardless of the type of initiating event."** 7) R2.1.2 and 2.1.3 need to include the phrase "generating unit or generating plant" versus "generator" to be inclusive of a plant site and provide consistency throughout Standard. **The SDT agrees. The standard has been revised to use the words "generating unit."** 8) R1 and R2 Exclusions: The SDT may want to consider these additional exclusions: a. A generating unit may trip by frequency or voltage protection while a unit is being brought on or off-line, if the trip does not result in the loss of generation to the system.b. A generation unit may trip by frequency or voltage protection if the unit is being operated below its Low Sustained Limit (LSL), where LSL is defined as the limit established by the Generator Operator that describes the minimum sustained energy

Organization	Yes or No	Question 8 Comment
		production capability of the generator.c. A generator unit may trip by frequency or voltage protection if the unit is being operated in a "Test" status and is not under AGC control. **The SDT disagrees that these exclusions are needed in Requirements R1 and R2. These two requirements specify how generator protection is to be set, which does not change for different operating conditions. There are similar exceptions written into Requirement R5, which is a performance requirement, to cover these situations for plants designed and built after the standard is approved and this requirement is implemented.** 9) R3: Generator Operators should be required to document "known" equipment limitations. There are probably many examples of unknown equipment limitations, simply because a plant may not have experienced a fault condition that could expose the limitation. Also need to clearly state if this requirement (i.e. due to the phrase "generating plant") also applies to plant auxiliary equipment, which would require the GO to provide extensive review and documentation on all of their plant auxiliary systems as well. **The SDT agrees and has added the word "known" to Requirement R3.** 10) R5: Need to clearly state if this requirement applies to plant auxiliary equipment. **The SDT agrees and has added "(including auxiliary systems)" to Requirement R5.** 11) In 5.2, insert "nameplate" after "aggregate" to be consistent with R5.1.1. **The SDT agrees and has added the word "nameplate," as suggested.** 12) R5 Exceptions: The SDT may want to consider these additional exceptions: (a) A generating unit may trip by frequency or voltage protection while a unit is being brought on or off-line, if the trip does not result in the loss of generation to the system. (b) A generator unit may trip by frequency or voltage protection if the unit is being operated in a "Test" status and is not under AGC control. **The SDT believes that the first suggested exception is already covered under part 5.1 (now part of the main body of the requirement). The SDT is not sure why AGC status is of issue since many base loaded units do not run on AGC, but if it would cause certain units to become unstable during an excursion such that it was about to lose synchronism,**

Organization	Yes or No	Question 8 Comment
		then part 5.6 would apply. 13) In Measures M1 and M2: See comment 3 above regarding the use of the phrase “generating plant”. Is it the intent of these measures to also cover frequency and voltage setting sheets for plant auxiliary equipment protection systems? **No. Requirement R1 specifically says, “generator frequency protective relaying” and Requirement R2 specifically says, “generator voltage protective relaying.” The auxiliary equipment protection systems are not in the scope of these requirements.** 14) In Requirement R4, Measures M4 and M5, and some VSLs: Remove capitalization of “Frequency/Voltage Excursions” and similar terms (e.g. Frequency Excursion), which are not formally defined in this standard nor in the NERC glossary. **The capitalization has been removed as suggested.** 15) VSLs for R1, R2, and R3: What is the SDT’s intent regarding a GO that has set its relays per R1 and R2, and has no documented equipment limitations per R3, but still experiences a unit trip within the one of the “no trip” zones in Attachment 1? Is that intended to be a violation of this standard? There is not a VSL for this situation. The VSL for R5 contemplates a violation for tripping in the no-trip zone, but it only covers “new” generation units, and there is not a similar VSL for existing units. **For existing generating units, a trip during a frequency or voltage excursion for reasons other than operation of the generator protection is *not* a violation. For that reason, it is not covered in the VSL’s. Requirement R5 is only applicable to “new” units (as defined in the standard). The standard does not contain an equivalent performance requirement for “existing” units, hence there is no such VSL.** 16) VSL for R1 and R2: The term “technical” should be replaced with “equipment” to be consistent with the Requirements. Need to replace “generator” with “generating unit or generating plant” to be consistent with the Requirements. **The SDT agrees that the word “technical” should be replaced with “equipment” and has made the suggested revision. The word “generator” has been replaced with “generating unit” since that wording is now used in Requirements R1 and R2.**

Organization	Yes or No	Question 8 Comment
		17) VSL for R2: Language should be similar to VSL for R1 with respect to "activated to trip" phrase and to be consistent with the Requirement itself. Suggest replacing "conditions" with "criteria" to be consistent with VSL for R1. **The SDT agrees and has changed the wording in the VSL for Requirement R2 as suggested.** 18) VSL for R3 and R4: What VSL applies if the communication occurs on day 61? It looks like the answer is "none." **The SDT agrees and has revised the number used in the Severe level of the VSL accordingly.** 19) VSL for R3: See comment 9 regarding requirement R3 above. The requirement and VSL should only apply to "known" equipment limitations. **The SDT agrees and has added the word "known" to the VSL.** 20) VSL for R4: Consider changing "unit's performance" to "unit's or plant's performance." **The wording in Requirement R4 refers to "generating unit" so the SDT did not change the wording in the associated VSL.** 21) VSL for R6: Remove the phrase "or limitations," because R3 discusses limitations and the reporting thereof and it is out of place here. **The SDT agrees and has removed the words "or limitations" from the VSL** 22) Attachment 1- Change "Texas Interconnection" to "ERCOT Interconnection". **The labels on Attachment 1 and the associated data tables have been changed as suggested.** 23) Regarding the Voltage Ride-Through Curve Clarifications: The reference to a generation facility's "point of interconnection to the Bulk Electric System" is incorrect, because the generation facility is itself part of the BES. We assume this is intended to refer to the point of interconnection between the generation facility and the transmission facility, and the text should be modified accordingly. **The SDT appreciates your position, but declines to change the wording because other commenters have expressed concern when the term Bulk Electric System is not used.**

Organization	Yes or No	Question 8 Comment
Response: Thank you for your comments. Please see the responses to your specific comments above.		
PacifiCorp	Negative	1. PacifiCorp does not support the addition of the term "bulk power system" to Section 4.2.2.1 of the "Applicability" section. The term is ambiguous and, in this context, fails to provide the clarity afforded by either the previous language ("at greater than or equal to 100 kV") or the defined term of "Bulk Electric System." PacifiCorp suggests maintaining the existing applicability language, including the "directly connected" qualifier so that the sentence reads as follows: "Individual generating unit greater than 75 MVA (gross nameplate rating) directly connected to the point of interconnection at greater than or equal to 100 kV." **It appears to the SDT that this comment refers to MOD-026, not PRC-024. Please see the response provided to this same comment in Question 5.** 2. PacifiCorp believes that the second bullet under Section 4.2.2.2 of the "Applicability" section introduces confusion for registered entities. If we correctly understand the intent of the GVSDT, then please consider the following language to replace the two existing bullets: o "Each individual generating unit greater than 20 MVA (gross nameplate rating), plus an aggregate model for the other generating units of less than 20 MVA at the plant/Facility; and o Where there are no individual generating units greater than 20 MVA in a plant/Facility with total generation greater than 75 MVA (gross aggregate rating), an aggregate model for the generating units of less than 20 MVA." **It appears to the SDT that this comment refers to MOD-026, not PRC-024. Please see the response provided to this same comment in Question 5.** 3. PacifiCorp agrees that the addition of sub-Requirement 2.2 is a good clarification, but believe that the language could be further clarified to remove unnecessary confusion by amending the sub-Requirement as follows: "For generating plants/Facilities with total generation greater than the thresholds established in the Applicability section of this standard that are comprised of units that have gross nameplate rating of less than 20 MVA, each Generator Owner shall perform its verification using plant aggregate model(s) that include the information required by

Organization	Yes or No	Question 8 Comment
		Requirement sub-parts 2.1.1 through 2.1.6." **It appears to the SDT that this comment refers to MOD-026, not PRC-024. Please see the response provided to this same comment in Question 5.**
Response: Thank you for your comments. Please see the responses to your specific comments above.		
Luminant Power		1. Requirement R1 and R2 discuss generator frequency and voltage relaying to be set such that they do not trip within the "no trip zone" of Attachement 1 and 2 respectively. Luminant believes that these requirements should only apply to relays that use frequency or voltage sensing only. Impedance, and voltage controlled over-current relays should not be included since they are part of the Generator Loadability and AVR Control standards. Relays using both voltage and frequency should not be part of the standard. Alternately, if volts per hertz relays are included, Luminant recommends that an additional requirement R2.2 be added to take in consideration volts per hertz relays. R2.2 would become "Generator volts per hertz relaying shall not cause a unit trip for conditions that are less than 116% of generator rated design voltage and frequency and last for less than 1.5 seconds." For footnote 1, individual curves would have to be listed for each protective relay function, as the Attachement 1 curve is for voltage relays only. **The SDT feels that the list of relaying included in Footnote 1 needs to be considered in the scope of this standard, as they will be just as effective as voltage only and frequency only relays in tripping the unit during frequency or voltage excursions described by Attachments 1 and 2. V/Hz characteristics from applicable IEEE standards were considered. Clarification #4 to Attachment 2 states: "The curves depicted assume system frequency is 60 Hertz. Adjust the magnitude of the high voltage curve in proportion to deviations of frequency below normal."** 2. R3 is an administrative requirement that provides little or no benefit to the BES. Luminant recommends that the requirement be removed, and Requirements R1 and R2 should be modified to delete the reference to R3 as follows; " ... unless the generator owner has identified an equipment limitation ..." **The SDT agrees that Requirement R3 is basically administrative, but ensures the limitations (and associated changes in**

Organization	Yes or No	Question 8 Comment
		protection settings that affect the performance of a generating unit during a frequency or voltage excursion) are communicated to the appropriate planning and operating entities so that its performance can be correctly modeled. 3. R6 should be at a minimum of 90 days due to some entities have a large number of generating units. **The SDT agrees that an increase in the amount of time allowed for response is warranted. The SDT has changed the time period from 30 days to 60 days.** 4. Overall, this standard should address voltage and frequency relay settings only. **The SDT is charged with implementing the reliability improvement recommendations from FERC Order 693 and the 2003 Northeast Blackout Report which requires that the standard address performance.**
Response: Thank you for your comments. Please see the responses to your specific comments above.

We Energies		a. Most generator voltage relaying is supplied from generator voltage transformers on the low-voltage side of the generator step-up transformer (GSU). It is necessary to provide the information needed for the Generator Owner to relate relay settings on the low-side of the GSU to the No Trip characteristic in Attachment 2, which is based on voltages on the GSU high-side. **The SDT agrees that generator protection normally senses the voltage at the generator terminals. Because there are many**

Organization	Yes or No	Question 8 Comment
		configurations of the connections of the generators to the transmission systems, it is not practical to develop a single voltage curve defined at the generator terminals that equates to the voltage caused by an event on the transmission system. Each Generator Owner will have to determine how the transmission system event affects his specific generating units. This approach is consistent with FERC Order 661-A and other international grid standards that are in effect. b. In Attachment 2, please clarify whether the No Trip zone includes the lines, similar to what was done in Attachment 1. **The no trip zone as depicted on the graph does include the lines (it is not permissible to trip if the voltage at the POI reaches 0.0 pu or if the continuous operating voltage is at 0.95 pu or 1.05 pu). The SDT expects that protection settings will be calculated to provide some margin from the absolute numbers on the curve (translated appropriately to the generator voltage level that the protection senses).**
Response: Thank you for your comments. Please see the responses to your specific comments above.		
PPL Electric Utilities and PPL Supply NERC Registered Organizations		a. A standard-specific definition of the word “plant” is needed, restricting applicability to NERC-registered generators. A plant consisting of two 750 MW fossil units and a standby 10 MW diesel generator, for example, should not have to model the diesel unit’s behavior. **Individual generators and plants are not “registered” with NERC. The Applicability section states that the standard is applicable to Generator Owners. As such, all generating facilities that fall within the definition of the Registry Criteria fall within the scope of this standard.** b. Clarity is needed for the expression, “it does not trip,” in R1 and R2. Does this mean that the protective relaying does not trip, or that the unit does not trip? In the latter case do the requirements pertain only to interlocks, or do they also cover disturbances that may result in a trip? Such differentiations were clearly spelled-out in the PRC-005-2 draft currently out for voting, and they are needed here also. What seems at first to be relay-setting requirements may in fact also incorporate aux equipment drop-out, invoking for existing equipment the concerns stated above in

Organization	Yes or No	Question 8 Comment
		response to question 7 (with regard to designing a standard based on a technology for which vendors may not guaranty performance). **The wording of R1 (and R2) has been modified and, hopefully, clarifies the intent. The intention is that the relaying operate to trip the unit only when conditions are such that the frequency vs time characteristic (or voltage in R2) presented to the relay are described by the area outside of the "no trip zone" of Attachment 1 (2 for R2). It does not matter if the protection trips the generator directly or through a lockout relay or other auxiliary device.**
Response: Thank you for your comments. Please see the responses to your specific comments above.		
Independent Electricity System Operator		a. Requirement R1: We believe the words "or generating plant" are missing at the end of R1 since the requirement addresses frequency protection relay settings for new or existing generating unit and generating plant. **The SDT has removed the words "or generating plant" from all of Requirement R1 for consistency in wording.** b. Requirement 4: In the last posting, we commented that:"We do not support the requirement to provide an estimate of the performance of the units during frequency and voltage excursions. First of all, the requirement does not distinguish whether it applies to units that are equipped with frequency/voltage protective relays or otherwise. Secondly, the intent of providing the suggested estimate is to allow Transmission Planners to apply valid or supported assumptions in their planning studies. Given the requirements in Attachments 1 and 2, and Requirement R3, the TPs can apply the following relevant assumptions: (i) For units that are equipped with frequency/voltage protective relays, the GO's submitted relay settings will determine when the units will trip; (ii) For units that are NOT equipped with frequency/voltage protective relays, the units are conservatively assumed to trip when the simulated frequency/voltage goes outside the bounds of Attachments 1 and 2. We do not see what other estimates that can be more relevant and valid than the above. We see that there may be some value in providing these estimates but only in the case of generators not equipped with frequency/voltage protective relays where tripping

Organization	Yes or No	Question 8 Comment
		takes place beyond the no-trip zones of Attachments 1 and 2. For this information to be useful however, the generator's behavior must be predictable. While it may facilitate some "what-if" analysis, it is not clear that using this information would be better than the conservative assumption "b" above. How does the SDT envisage that the Transmission Planner will use this additional information if it cannot be relied upon? The SDT responded that "The "estimate of performance in 25% increments" portion of the requirement has been removed. The SDT agrees that it would not improve reliability." We do not agree that removing the 20% increment part goes far enough to achieve a good quality standard. In our view, based in argument put forth in our previous comments, the whole requirement does not add any value to reliability. We again suggest the SDT to remove this requirement altogether." **The SDT appreciates your position but was charged with meeting the recommendations of FERC Order 693 and the 2003 Blackout Report. Requirement R4 attempts to address a portion of the recommendation to provide better information to Transmission Planners regarding the performance of generating facilities during frequency and voltage excursions. This requirement is written such that the information is only provided if it requested by a planner. If the planner does not believe the information received would be of any value, it is permissible to not make the request.** c. Requirement R4.1, last sentence "If the Generator Owner expects the existing unit, generating plant will remain connected.....". We believe the "," before "generating plant" should read "or". **The SDT agrees that the wording was incorrect. Requirement R4 has been significantly modified and the intent of Parts 4.1 and 4.2 incorporated into the body of the requirement.** d. The proposed implementation plan for both standards conflicts with Ontario regulatory practice respecting the effective date of implementing approved standards. It is suggested that this conflict be removed by appending to each of the sentences in Section A5, after "following applicable regulatory approval", of the two standards to the following effect:", or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities." **The phrase "following**

Organization	Yes or No	Question 8 Comment
		applicable regulatory authority" includes regulatory bodies from Canadian provinces requiring regulatory body approval. For clarity, the SDT modified the Implementation section and expanded the implementation description to more clearly show effective dates for those areas requiring regulatory approval and those areas that do not require regulatory approval.
Response: Thank you for your comments. Please see the responses to your specific comments above.		
American Transmission Company, LLC		ATC recommends the SDT give consideration to the following:1. In Requirements R2 - the text refers to "non-protection system equipment" but this terminology is not defined. ATC recommends that the SDT provide some definition/description and perhaps a list of this type of equipment in a footnote to improve clarity. **The SDT agrees that this term was confusing. The term has been removed from Requirement R2 and the wording in Requirement R3 has been modified to more clearly indicate that limitations of the protection system do not qualify as a reason for exemption from portions of the no trip zones defined in Attachments 1 and 2.** 2. In Requirements, R3 - ATC recommends that the SDT add the requirement that the GO provides the expected duration of the limitation, if it is known. **In general, the SDT believes these limitations are permanent due to equipment design or regulatory considerations. The Reliability Coordinator, Planning Coordinator, Transmission Operator, or Transmission Planner may certainly inquire if they believe the Generator Owner is describing a temporary limitation.**
Response: Thank you for your comments. Please see the responses to your specific comments above.		
ACES Power Marketing Standards Collaborators		Because NERC has made clear that standards are enforced against the BPS and not the BES, the applicability section should be modified to state clearly that it applies to Facilities that are part of the BES. Otherwise small generators that do not affect reliability could be impacted by these standards. NERC enforcement has made this clear in response to comments on CAN-0016 that the CIP-001 standard applied only to the BES. They stated clearly: "According to Section 39 of the Energy Policy Act of

Organization	Yes or No	Question 8 Comment
		2005, NERC defines the Interconnected Power Grid as the Bulk Power System. Unless otherwise restricted by a standard, it is applicable to the BPS." **There is no mention of either BPS or BES in the Applicability section of this standard. The term "Bulk Electric System" is used within the Clarifications to Attachment 2.** Use of "new or existing" as a description for the generators in Requirements R1, R2 and R5 is confusing. What exactly constitutes new and why is it relevant? The requirements are performance requirements that apply to in-service generators so how does new help explain this further? The footnote in Requirement R5 only further confuses the situation since it is not included in Requirements R1 and R2. Part of the confusion likely centers around Requirement R5 applying to maintaining new generators frequency and voltage excursion performance as well as designing and building it. If "maintain" was removed from Requirement R5, we believe "new" could be removed from Requirement R1 and R2 and they essentially become the maintenance requirements. **The SDT agrees and has removed the words "new or existing" from both R1 and R2 and has revised Footnote 4 in Requirement R5** Furthermore, "new and existing" is not used consistently within other requirements such as Requirement R4. It is not obvious why it would not apply to Requirement R4 it if applies to Requirements R1 and R2. **The words "new and existing" were not used in Requirement R4. This requirement applies only to "existing" units because "new" units are expected to perform per Requirement R5.** Neither Requirement R1 nor R2 state within the main body of the requirement that the Parts are intended to be exceptions to the requirement. For clarity, there should be a statement (i.e. except when the Parts 1.1 and 1.2 are met) within the requirement that makes this clear. **The SDT agrees and has added wording identical to that in Requirement R2 to clarify that the sub parts are intended to be exceptions.** For Requirements R1 and R2, it is not clear if the sub-parts are the only reasons that allow for exceptions if other equipment limitations exceptions are allowed. Other equipment limitations should be allowed, and these requirements should be clarified to allow them. **It is stated in both Requirements R1 and R2 that equipment**

Organization	Yes or No	Question 8 Comment
		limitations (documented and communicated per Requirement R3) will allow tripping within portions of the no trip zones in Attachments 1 and 2. These statements have been moved into the sub parts of the two requirements for clarity. As written, Requirement R5 appears to be assumed to apply to a new generator in perpetuity. We draw this conclusion from the inclusion of "maintain" in the requirement. We think it makes more sense to have this requirement apply only to designing and building a new unit and then have the requirements that apply to existing units apply to the maintenance of the new units once they are established. The standard does not appear to allow "new" generating units to have frequency and voltage excursion performance limited by equipment. It should allow "new" equipment as it experiences normal wear and tear as well as damage for any other reasons to document its equipment limited frequency and voltage performance and communicate it similar to Requirements R1 through R3. Otherwise, a Geneator Operator with a "new" generator that has damaged equipment will be forced between operating the unit in a limited manner providing reliability support to the BES and possibly in violation of this standard or taking a forced outage to avoid violating the standard and experiencing escalated penalties for knowingly violating the standard. **The intent of Requirement R5 is to apply to "new" plants in perpetuity as you have described. If equipment aging or other conditions develop that clearly limit the generating plant's ability to ride through excursions and the owner is faced with performing maintenance that would not otherwise be needed in order to regain ride-through performance, Part 5.5 allows the Reliability Coordinator to grant an exemption if the RC believes the reliability improvement from having the generator operating or available outweighs the risk that it may not ride through an excursion.** We do not believe that Reliability Coordinator is the proper entity to grant a temporary exemption in Part 5.6. Rather, it is the Planning Coordinator that should grant the exemption. Furthermore, this is not consistent with other requirements such as Parts 2.1 and 2.1.1 that specify the Transmission Planner grant the exemption. Of course, Part 5.6 would not be necessary if Requirement R5 did not

Organization	Yes or No	Question 8 Comment
		deal with maintaining the unit and allowed the other requirements that apply to existing units to address maintenance. **It is the Reliability Coordinator that is responsible for the reliability of the transmission system, not the Planning Coordinator.** We do not believe the VRFs for Requirements R1, R2 and R5 warrant High VRFs. The BES is already operated within each BA and TOP for the loss of a single unit. Tripping of a generator due to a frequency or voltage excursion is an uncommon event that is already planned for. It is highly unlikely that tripping of such a generator or even several generators will lead to instability, system separation or cascading which is required for the VRF to be High. Furthermore, by setting the VRF to High, this increases the potential that every single unit outage could become subject to a Compliance Violation Investigation which is simply not necessary. **The SDT agrees and has changed the VRF's for these three requirements to Medium.**
Response: Thank you for your comments. Please see the responses to your specific comments above.		
ERCOT		Comment 1: In the Applicability section, it is not clear in 4.2.3.2 which units/plants are required to meet this standard. For example, a generating plant that is greater than 75 MVA and consisted of 75 1MW generating units, is this generating plant required to meet MOD-026-1? Another example, a generating plant that is greater than 75 MVA and consisted of one 45MVA generating unit and two 15MVA generating unit, is only the 45MVA generating unit required to meet MOD-026-1?
Response: Thank you for your comments. Your comment refers to MOD-026. The SDT has refined Section 4.2.2 of the MOD-026 standard applicability to clarify that all units in a plant that meet the applicability are to be verified. Units that are less than 20 MVA can be verified utilizing either individual or aggregate model(s)		
Georgia Transmission Corporation		Comment on R6, Severe VSL.Time limit is within 60 calendar days, however the time limit for R3, R4 and R5 state 61 calendar days.Wording for Severe VSL for R3, R4, R5 and R6 should have the same time limitations of either "...within 61 calendar days" or revised so that the documentation was"communicated greater than 60 calendar

Organization	Yes or No	Question 8 Comment
		days....”.
Response: Thank you for your comments. The SDT agrees. The Severe VSL for Requirement R6 has been revised to address the issue you presented.		
Ingleside Cogeneration LP		Ingleside Cogeneration LP fully supports the goal to standardize voltage and frequency ride-through settings. In addition, we recognize the benefit to provide accurate generator modeling information and perform regular performance validations to system planners. However, such activities come at a price and compete for the same resources needed to support BES reliability in other ways.Furthermore, there is a cost to develop new PRC-024-1 compliant generation technologies - or to harden existing ones. This may improve reliability over the longer term, but could delay or even rule out the deployment of promising capabilities early on. These are all considerations that we know that the project team is aware of, but we will continue to point out the hidden costs of compliance wherever we believe that a justification of its advantages is not immediately obvious.
Response: Thank you for your comments. The SDT agrees that designing, building, and maintaining a generating facility to meet the performance requirement of Requirement R5 will be more expensive than building one without that capability. For this reason, the SDT is limiting the scope of the requirement to new facilities, with a six-year implementation schedule to allow designs to be developed, and is not requiring existing generating facilities to have to redesign and rebuild to accomplish the same level of performance.		
ISO New England Inc		ISO New England has comments on Requirement R2 and R3:R2Although the time duration is acceptable ISO-NE does not agree with the band shown. The band is shown as 0.95 p.u to 1.05 p.u at the point of interconnection. Parts of the New England system have not been designed to maintain steady state operation within this band. The band needs to be expanded to 0.90 pu to 1.05 pu. We also believe there are a number of other parts of the system outside of New England which would have similar concerns. Failure to make this change means that it is acceptable for generators to trip during steady state operation of the system on “low” voltage.

Organization	Yes or No	Question 8 Comment
		Unanticipated tripping of generators under steady state conditions could lead to significant reliability concerns on the system. **The voltage band applies to the point of interconnection of an operating generator. Other portions of a transmission system may be at significantly different voltages, but that would not give the generator an excuse to trip. If it is necessary to have an expanded band of normal operating voltage for a particular region, it can be mandated through a regional standard without imposing the same requirements on the entire continent.** R3The ISO would like to reiterate its previous comment that R3 is a significant concern. In the event that a generator has a piece of equipment which prevents it from meeting the requirements of R1 and R2, such as a motor contactor which drops out on voltages in the "No Trip Zone", there is no requirement to correct the issue. Instead, the generator must only document the limitation. This completely undermines the intent of this standard. There is no point to setting undervoltage relays to meet the curve if other equipment is still going to trip the plant. This standard appears to simply documenting system concerns rather than identifying and correcting them. **Requirements R1 and R2 apply to generator protection, not to the auxiliary systems. An "existing" generating facility may trip during a frequency or voltage excursion due to upsets caused by events on the auxiliary system (such as the cited contactor drop out). Requirement R4 is included in the standard to allow planning entities to obtain an estimate of such performance from the Generator Owner so the facilities can be appropriately modeled. The SDT does not believe it is realistic to require all "existing" generating facilities to be rebuilt to ensure performance to the level of Requirement R5.**
Response: Thank you for your comments. Please see the responses to your specific comments above.		
Los Angeles Department of Water and Power		LADWP supports the following comment below:"The curve depicting the "no trip zone" for WECC in Attachment A is not consistent with the overfrequency and underfrequency requirements of the WECC Coordinated Off-Nominal Frequency Load Shedding Plan (Plan). A step is missing in the curve for the underfrequency

Organization	Yes or No	Question 8 Comment
		requirements. The table representing the points on the "no trip zone" curve for WECC is also missing the same step as the plot. Additionally the presentation of the information in the table is confusing. As presented, the table specifies a time range of staying connected for selected specific frequencies. The table should specify a specific time for staying connected for frequency ranges. For example, as currently depicted in the table, a generator would need to stay connected up to 0.75 seconds (or between 0 and 0.75 seconds) at 57.0 Hz. The WECC Plan allows for instantaneous trips at 57.0 Hz. Further, the WECC Plan requires the generator to stay connected for 45 cycles (0.75 seconds) for frequencies greater than 57.0 Hz. but less than or equal to 57.3 Hz. This is not accurately reflected in the Table. The plot in Attachment A and the associated tables must be corrected to accurately reflect the requirements of the WECC Coordinated Off-Nominal Frequency Load Shedding Plan."
Response: Thank you for your comments. The WECC curve in Attachment 1 has been corrected per the 25 Nov 1997 WECC Coordinated Off Nominal Frequency Load Shedding Plan document. The table of associated values for the WECC region has also been corrected.		
Lakeland Electric	Negative	LAK is a member of FMPA, please refer to their comments.
Manitoba Hydro		Manitoba Hydro is voting negative for the following reasons:1 - R1 - the facility interconnection document required through FAC-001 should supersede Attachment 1 in order to best address local area issues. R1 should be revised to specify this. **The SDT was charged with creating continent-wide requirements for frequency and voltage excursions and believes that consistency will not occur if various Transmission Service Providers apply various "no trip zones." Requirement R1, therefore, should not be dictated by FAC-001.** 2 - NERC IVGTF Task Force Document - the SDT should consider the recommendations from the NERC IVGTF Task Force 1.3 document. Specifically, the recommendations regarding clarifying the potential coordination issues between TPL-001 and PRC-024, clearly defining performance requirements for unbalanced and

Organization	Yes or No	Question 8 Comment
		balanced faults, and defining the performance required during and after disturbances and making clear and unambiguous statements as to what remaining "connected" entails (i.e. how much real power is expected to be delivered post disturbance and how long until the normal pre-disturbance power can delivered) should be considered. **The SDT reviewed the NERC IVGTF Task Force 1.3 document. Changes in the wording to Clarifications#2 and #5 to Attachment 2 have been made that address the concern with unbalanced and balanced faults. At this point, the SDT does not have a technical basis for defining requirements for performance during and after disturbances. Section 3.5.3 of the IVGTF document states, "A detailed power recovery characteristic for variable generators is not necessary to be specified in a standard."** 3 - Low Voltage Ride Through clarification - more information is required on the low voltage ride through curve. The GO should be required to provide unit outputs and ramp rates for the different voltage transitions and levels on the ride-through curve. **The SDT believes it the uncertainties involved in trying to determine generator outputs and ramp rates would not improve grid reliability.** 4 - Data Retention - The data retention requirements are too uncertain for two reasons. First, the requirement to "provide other evidence" if the evidence retention period specified is shorter than the time since the last audit introduces uncertainty because a responsible entity has no means of knowing if or when an audit may occur of the relevant standard. Secondly, it is unclear what 'other evidence', besides the specified evidence in the Measures, an entity may be asked to provide to demonstrate it was compliant for the full time period since their last audit. **The SDT agrees and has modified the wording in the Data Retention section of the standard to match that being used in other recently-approved NERC standards.**

Beaches Energy Services	Negative	R2 - point of interconnection is confusing. We recommend putting the footnote into body of requirements and replace "point of interconnection" with "high side of GSU or collector bus" **The SDT believes Footnote 3 clearly explains the meaning of "point of Interconnection," as used in this standard.** R3.1, the second bullet, should be clarified to explain that the equipment replaced is plural, meaning all equipment causing a limitation would need to be replaced, e.g., if one piece of equipment was replaced, but another stil causes a limitation, the "grandfathering" of existing equipment lmimtations should still be in place. **The SDT does not intend the "equipment" to necessarily be plural. For that reason, the SDT said, "The equipment…" instead of "All equipment…" If there are multiple pieces of equipment that are causing limitations, only those that are replaced as a result of an upgrade would have to be designed to meet the full range of the no trip zones in Attachments 1 and 2.** R1 and R2 are inconsistent with R5, bullet 5.2. R1 and R2 provide no exceptions for a new plant/wind farm/solar farm, R5 bullet 5.2 does. **There are no exceptions for "new" facilities in Requirements R1 and R2 because "new" facilities are expected to meet the performance requirements of Requirement R5. Part 5.2 (now 5.1) does allow up to 10% of a facility consisting of multiple small units to trip which is analogous to a power runback of a single large generator.** R6 is ambiguous as to whether or not any time any protection settings are changed, whether or not they violate the curves, the entity has to notify and provide the settings. It should be limited to only generators that violate the curves. Or is it that all trip settings of all generators are intended to be modeled? We would think that we

Organization	Yes or No	Question 8 Comment
		do not need to model the generator trip settings for those that meet the curves because the UFLS program is supposed to prevent us from reaching those curves. Hence, we should only need to model the trip settings of those generators that do not meet the curves. **The SDT assumes that the requestor would only ask for settings for the protection functions that are modeled for stability or UFLS performance. Typically, most generator protection functions are not included in these models. However, in order to predict the generators' behavior accurately, the entity creating the model must know the settings for all of the modeled protection functions, not just those that do not meet Requirements R1 or R2. Following such a request, only changes to the settings that have been requested would need to be reported. The SDT has added the words "unless otherwise directed" so that the requestor can indicate that future changes do not have to be reported (as may be the case for a one-time study that will not be repeated).**
Response: Thank you for your comments. Please see the responses to specific comments above.		
American Electric Power		R2 is very "wordy", essentially a single run-on sentence which references yet additional material in its two footnotes, making it difficult to follow. This could be made more clear with the usage of bulleted items.R2.1.1 through R2.1.4 could be and perhaps should be R2.2 through R2.5. **The SDT agrees that Requirement R2 could be improved and has shortened the initial sentence by moving the reference to Requirement R3 to Part 2.6 and has restructured the other Parts as suggested.** R3: We recommend adding "known" to R3 such as "...shall document each known equipment limitation..." to make clear that a GO is not responsible for a cause they are not aware of. **The SDT has added the word "known" as for clarity as suggested, although the SDT believes the Generator Owner would not set its protection inside the no trip zone because of "unknown" limitations.** R3: The second point under R3 causes the limitation to expire with rating increases. Is a 10percent or more rating increase a realistic scenario and common enough to justify attention?10 percent seems arbitrary and this provision could pose a

Organization	Yes or No	Question 8 Comment
		hindrance to rating increasesthat may supply other reliability benefits. It may be advisable to remove this point. **The SDT agrees that ten percent is an arbitrary number. The SDT feels that if a Generator Owner is making enough of an investment in a facility to achieve a ten percent increase in rating, then any limitations caused by the equipment being upgraded should be eliminated. If AEP can provide a technical justification for a different number the SDT would be very interested.** R4.1 should include the Planning Coordinator in addition to the TP because the PC is responsible for UFLS coordination and assessment in PRC-006-1. **Requirement R4 has been extensively revised. It should be clearer now that the Planning Coordinator is one of the entities allowed to request the performance estimate from the Generator Owner.** R5.2 should be removed because of its obvious partiality toward wind farms. **Part 5.2 (now 5.1) gives an allowance for loss of up to 10% of units at a site with many small units which is analogous to a runback in power on a single larger unit.** R5.6 needs to include coordination with the Planning Coordinator because of the PC's responsibilities with respect to automatic UFLS. This should also perhaps include coordination with the Transmission Planner for exceptions on voltage excursion ride-through. **Both the Planning Coordinator and Transmission Planner are allowed to request a performance estimate from a Generator Owner in Requirement R4. The SDT believes this gives these entities access to the pertinent information.**
Response: Thank you for your comments. Please see the responses to your specific comments above.		
Florida Municipal Power Agency		R3.1, the second bullet, should be clarified to explain that the equipment replaced is plural, meaning all equipment causing a limitation would need to be replaced, e.g., if one piece of equipment was replaced, but another stil causes a limitation, the “grandfathering” of existing equipment lmimtations should still be in place. **The SDT does not intend the “equipment” to necessarily be plural. For that reason, the SDT**

Organization	Yes or No	Question 8 Comment
		said, "The equipment…" instead of "All equipment…" If there are multiple pieces of equipment that are causing limitations, only those that are replaced as a result of an upgrade would have to be specified to meet the full range of the no trip zones in Attachments 1 and 2. R1 and R2 are inconsistent with R5, bullet 5.2. R1 and R2 provide no exceptions for a new plant/wind farm/solar farm, R5 bullet 5.2 does. **There are no exceptions for "new" facilities in Requirements R1 and R2 because "new" facilities are expected to meet the performance requirements of Requirement R5. Part 5.2 (now 5.1) does allow up to 10% of a facility consisting of multiple small units to trip which is analogous to a power runback of a single large generator.** R6 is ambiguous as to whether or not any time any protection settings are changed, whether or not they violate the curves, the entity has to notify and provide the settings. It should be limited to only generators that violate the curves. Or is it that all trip settings of all generators are intended to be modeled? We would think that we do not need to model the generator trip settings for those that meet the curves because the UFLS program is supposed to prevent us from reaching those curves. Hence, we should only need to model the trip settings of those generators that do not meet the curves. **The SDT assumes that the requestor would only ask for settings for the protection functions that are modeled for stability or UFLS performance. Response: Thank you for your comments. Please see the responses to your specific comments above.		
Atlantic City Electric Company	Negative	Refer to comments submitted by Pepco Holdings Inc and Affiliates.
ReliabilityFirst		ReliabilityFirst votes in the affirmative for the the PRC-024-1 standard because the standard further enhances reliability by ensuring that generating units remain connected during frequency excursions. Even though ReliabilityFirst votes in the affirmative, we offer the following comments for consideration:1. Requirement R5 and associated Subpart 5.1a. ReliabilityFirst believes there is a potential conflict and seeks clarification on the choice of words between Requirement R5 and associated Subparts 5.1 and 5.1.1. Requirement R5 begins by stating "Each Generator Owner shall design, build, and maintain its new unit or new generating plant..." which lends itself more to the "planning" type stages while Subpart 5.1 states "When the generating unit or generating plant is operating at or above the minimum sustainable generation threshold" which lends itself to actual "operation" of the unit. ReliabilityFirst questions how the conditions in Subpart 5.1 and 5.1.1 can be utilized if the actual "operation" of the unit has yet to be observed since Requirement R5 is dealing with the design stages of a new unit? **The SDT believes the design, construction, and maintenance of a generating facility are the key elements in assuring that the facility is able to remain connected to the grid during the excursions defined in the standard. There is really nothing that can be done operationally to prevent a generator from tripping if it has not been designed, built,**

Organization	Yes or No	Question 8 Comment
		and maintained correctly. There are, however, certain operating regimes (e.g. start-up and shut-down) when generating units are much less stable and less capable of remaining connected during an excursion. The SDT believes there is not a large reliability risk to allow a generator to trip if it is in this condition when an excursion occurs given the short term nature of operation in these regimes. 2. Requirement R6 a. ReliabilityFirst request further clarity regarding whether the parenthetical, "(that monitors or models the associated unit)," is associated with all the requesting entities listed in Requirement R6 (RC, PC, TOP, and TP) or just the TP. **The parenthetical refers to all four of the named entities.** 3. VSL Requirement R5 a. Requirement R5 states "Each Generator Owner shall design, build, and maintain its new unit or new generating plant so that it will not trip due to a frequency excursion or voltage excursion." The VSL states "The Generator Owner's generator tripped due to a Frequency Excursion within the no-trip parameters set forth in attachment 1". Based on the FERC Guideline #3 "Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement," the language in the requirement is not consistent with the associated VSL. It is not a violation of Requirement R5 if the generator tripped offline within the no-trip parameters, rather it is a violation if the GO failed to design, build, and maintain its new unit or new generating plant so that it will not trip due to a frequency excursion or voltage excursion. ReliabilityFirst recommends the following language for the "High" VSL, "The Generator Owner failed to design, build, and maintain its new unit or new generating plant so that it will not trip during a frequency excursion within the no-trip parameters set forth in Attachment 1. OR The Generator Owner failed to design, build, and maintain its new unit or new generating plant so that it will not trip during a voltage excursion within the no-trip parameters set forth in Attachment 1. **The VSL relates to Measure M5. The Measure relates to how the entity demonstrates that they have designed, built, and maintained the generating unit so that it does not trip during an excursion. Requirement R5 is written as a performance requirement. The words "design, build, and maintain" give the Generator Owners guidance as to how to achieve the performance**

Organization	Yes or No	Question 8 Comment
		objective. b. ReliabilityFirst also noted there is no mention of the Subparts 1.1 through 1.7 in the VSL (ReliabilityFirst understands that these are “Conditions and Exceptions” but they should somehow be incorporated into the VSLs. **VSL’s only apply when a violation of the requirement occurs. Parts 5.1 – 5.7 (now 5.1 – 5.6) are part of the requirement.**
Response: Thank you for your comments. Please see the responses to your specific comments above.		
Gulf Power Company	Negative	See comments submitted via the electronic comments form by Antonio Grayson.
Dairyland Power Coop.	Negative	See MRO NSRF comments. In addition: The VSL must match the requirements of the standard. VSL R4 indicates a different calendar schedule than that of requirement R4. Requirement R4 indicates 60 calendar days after receipt of written request to provide information. VSL R4 indicates levels of severity less than 60 calendar days. **The SDT agrees and has revised the wording in the Requirement R4 VSL to address the issue.** Requirement R6 states "Each Generator Owner shall provide its generator protection trip settings to the...". Trip settings is open to interpretation. Please clarify what is meant by the term "trip settings", is meant to provide all trip settings or just specific trip settings. **The requesting entity will specify which protective functions he is modeling for which the trip settings (as opposed to settings that may be set to alarm only) must be reported. In this standard “trip” means disconnecting the generator from the transmission system.**
Response: Thank you for your comments. Please see the responses to your specific comments above.		
U.S. Army Corps of Engineers	Negative	See MRO/NSRF comments
Occidental Chemical	Negative	See submitted comments on behalf of Ingleside Cogeneration LP

Organization	Yes or No	Question 8 Comment
GenOn Energy		Thank you to the SDT for you efforts to produce a quality standards.R3 should be worded in a similar manner to R4. "The Generator Owner shall document the estimated equipment limitations..." The problem with a requirement like R3, is that documenting "each" equipment limitation on older facilities will contain uncertainties and unknowns. **The SDT has added the word "known" to qualify the equipment limitations for clarity, although the SDT does not see why a Generator Owner would set the protection system to operate inside the no trip zones due to unknown limitations.** The implementation schedule for the requirements will be more efficient if the schedule is aligned with the PRC-019 schedule rather than having the two similar efforts on different tracks. **The SDT agrees and has changed the implementation period, relative to Requirements R1, R2, R3, R4 and R6, of PRC-024-1 to match that of PRC-019.**
Response: Thank you for your comments. Please see the responses to your specific comments above.		
Alberta Electric System Operator		The AESO does not support the changes made to the Curve Details, in the Voltage Ride-Through Curve Clarifications section of the standard, in particular the use of the term "base voltage" . In many parts of the Alberta transmission system the maximum normal operating voltages are significantly higher than 1.05pu of than the "base voltage" used in studies. The system has been studied, planned and designed around these higher voltages. For example; in a study the base (nominal) voltage is chosen to be one per unit (1.0 pu) equals 240 kV but in the study area typical operating voltages are 256 kV (1.07 pu) and can be as high as 1.10 pu.
Response: Thank you for your comments. The SDT has modified Clarification #1 to Attachment 2 by removing the words "base voltage" and "in the system models" and has replaced them with "nominal operating voltage" (specified by the Transmission Planner). The SDT believes this will address the different operating criteria used in different regions.		
Western Electricity		The Attachment depicting the No Trip Zone for frequency excursions for the WECC

Organization	Yes or No	Question 8 Comment
Coordinating Council		Interconnection is incorrect. It is missing one of the steps from the materials provided to the drafting team in July. The table is also missing a step. This must be corrected. In my opinion, the table identifying the High and Low Frequency Duration information is hard to interpret. As depicted, the table appears to be giving a range of time that a generator must stay interconnected at a specific frequency. I am not familiar with the requirements in other regions, but in WECC, we have specified a specific time that a generator must stay interconnected for a frequency range. In looking at the WECC table included int he draft standard I would not be able to discern how long a generator had to stay interconnected if the frequency were at 59.0 Hz. Similarly, I have the same problem with the information in the tables for the other interconnections. After discussions with drafting team representatives, an suggested revision for the format of the tables has been proveded to the drafting team for consideration.Even with the inclusion of the (not including the lines) statement on the No Trip Zone plot, it is still difficult to determine minute specifications from the plot. Depending on the quality of the diagram and the thickness of the line, there will still be the potential for debate. I believe a solution is to indicate the plot is for illusrative purposes only, and the specifics are provided in the tables. With the suggested format changes provided to the drafting team, there should be no room for speculation.Whether the Off-Nominal Frequency Capability Curve is used for illustrative purposes as suggested above, or for specifying details, it is difficult to view as presented. One option would be to provide three individual plots, one for each interconnection, and include them all as Attachment 2. This way you could still refer to Attachment A in Requirement R2, and perhaps add language such as "appropriate plot in Attachment 2" to the requirement.
Response: Thank you for your comments. The WECC curve in Attachment 1 has been corrected per the 25 Nov 1997 WECC Coordinated Off Nominal Frequency Load Shedding Plan document. The table of associated values for the WECC region has also been corrected.		
California Independent		The California Independent System Operator Corporation has adopted tariff requirements for generator frequency and voltage ride through capabilities that

Organization	Yes or No	Question 8 Comment
System Operator		apply to synchronous generators as well as requirements for generator frequency and voltage ride through capabilities that apply to asynchronous generators. As written, the requirements of draft PRC-024-1 apply to both synchronous and asynchronous generators. The ISO requests that the Generator Verification Standard Drafting Team confirm this reading of draft PRC-024-1, and suggests making this clarification in PRC-024-1 as well.
Response: Thank you for your comments. Under "Generator Owner" the Registry Criteria makes no distinction between synchronous and asynchronous generators. The SDT intends for both synchronous and asynchronous generators to be included as implied in the Registry Criteria and therefore made no specific distinction.		
Bonneville Power Administration		The curve depicting the "no trip zone" for WECC in Attachment A is not consistent with the overfrequency and underfrequency requirements of the WECC Coordinated Off-Nominal Frequency Load Shedding Plan (Plan). A step is missing in the curve for the underfrequency requirements. The table representing the points on the "no trip zone" curve for WECC is also missing the same step as the plot. Additionally the presentation of the information in the table is confusing. As presented, the table specifies a time range of staying connected for selected specific frequencies. The table should specify a specific time for staying connected for frequency ranges. For example, as currently depicted in the table, a generator would need to stay connected up to 0.75 seconds (or between 0 and 0.75 seconds) at 57.0 Hz. The WECC Plan allows for instantaneous trips at 57.0 Hz. Further, the WECC Plan requires the generator to stay connected for 45 cycles (0.75 seconds) for frequencies greater than 57.0 Hz. but less than or equal to 57.3 Hz. This is not accurately reflected in the Table. The plot in Attachment A and the associated tables must be corrected to accurately reflect the requirements of the WECC Coordinated Off-Nominal Frequency Load Shedding Plan.
Response: Thank you for your comments. The WECC curve in Attachment 1 has been corrected per the 25 Nov 1997 WECC Coordinated Off Nominal Frequency Load Shedding Plan document. The table of associated values for the WECC region has also		

Organization	Yes or No	Question 8 Comment
been corrected.		
Consolidated Edison Co. of NY, Inc.		The definition of the terms Frequency Excursion and Voltage Excursion were deleted.All references to these terms should now be lower case. Measures M4 and M5 continue to carry the prior wording and need to be revised to use lower case terms.
Response: Thank you for your comments. The capitalization has been removed as suggested.		
Northeast Power Coordinating Council		The definitions of the terms Frequency Excursion and Voltage Excursion were deleted. All references to these terms should be lower case. Measures M4 and M5 continue to carry the prior wording and need to be revised to use the lower case terms. **The capitalization has been removed as suggested.** Regarding requirement R2, the time duration is acceptable. However, the band is shown as 0.95 per unit to 1.05 per unit at the point of interconnection, and there are areas of the power system that have not been designed to maintain steady state operation within this band. The band needs to be expanded to 0.90 per unit to 1.05 per unit. Failure to make this change means that it would be acceptable for generators to trip during steady state operation of the system on “low” voltage. Unanticipated and unncecessary tripping of generators under steady state conditions could lead to significant reliability concerns on the system. **The voltage band applies to the point of interconnection of an operating generator. Presumably, the generator would be holding that voltage within the scheduled voltage band provided by the Transmission Operator per VAR-001. Other portions of a transmission system may be at significantly different voltages, but that would not give the generator an excuse to trip. If it is necessary to have an expanded band of normal operating voltage for a particular region, it can be mandated through a regional standard without imposing the same requirements on the entire continent.** The PTs connected to the high voltage terminals of the GSU may not be used as a

Organization	Yes or No	Question 8 Comment
		source for generator protective relaying. Generator protective relays may be connected to the generator output terminals for their source of potential. The wording of R2 should incorporate generator terminals in addition to point of interconnection. **The SDT agrees that generator protection normally senses the voltage at the generator terminals. Because there are many configurations of the connections of the generators to the transmission systems, it is not practical to develop a single voltage curve defined at the generator terminals that equates to the voltage caused by an event on the transmission system. Each Generator Owner will have to determine how the transmission system event affects his specific generating units. This approach is consistent with FERC Order 661A and other international grid standards that are in effect.** Regarding R3, in the event that a generator has a piece of equipment which prevents it from meeting the requirements of R1 and R2, such as a motor contactor which drops out on voltages in the "No Trip Zone", there is no requirement to correct the issue. The generator must only document the limitation. This completely undermines the intent of this standard. It is counterproductive to set undervoltage relays to meet the curve if other equipment is still going to trip the plant for those same conditions. This standard appears to simply document system concerns rather than identify and correct them. **Requirements R1 and R2 apply to generator protection, not to the auxiliary systems. An "existing" generating facility may, indeed, trip during a frequency or voltage excursion due to upsets caused by events on the auxiliary system (such as the cited contactor drop out). Requirement R4 is included in the standard to allow planning entities to obtain an estimate of such performance from the Generator Owner so the facilities can be appropriately modeled. The SDT does not believe it is realistic to require all "existing" generating facilities to be rebuilt to ensure performance to the level of Requirement R5.** Under Requirement R5, 5.5 (exception) is unnecessary. It does not have to be stated that a generating unit or generating plant may trip if clearing a system fault necessitates disconnecting the generating unit or generating plant. **The SDT agrees that it is self-evident from a technical perspective, but is included for completeness**

Organization	Yes or No	Question 8 Comment
		for compliance auditing purposes.
Response: Thank you for your comments. Please see the responses to your specific comments above.		
Duke Energy		The frequency and voltage ride-through curves are at the point of interconnection. Conditions inside a generating plant will depend upon how the generator responds to the transient. Models will have to be built and validated against plant-specific auxiliary equipment performance expectations.
Response: Thank you for your comments. The SDT assumes this comment is in reference to Requirement R4. The SDT does not require Generator Owners to do extensive dynamic simulations to determine performance. The SDT believes the Generator Owner could identify the most likely piece of equipment to fail to ride through (whether from contactor drop out or other mechanism) and estimate the time between that event and a generator trip due to the resulting process upset.		
MRO NSRF		The MRO NSRF believes that an entity having to attest to the fact that a generating unit or plant did not trip offers no foreseeable benefit to reliability. As currently stated, Measure M5 could be interpreted to mean that an entity would need to provide a letter of attestation each day or month a generating unit or plant were to function as intended. The MRO NSRF recommends the drafting team either remove this statement or else rephrase the Measure to avoid the expectation that entities verify normal operation. **The SDT agrees with your comment and has removed the wording that requires the attestation as evidence.** Additionally, as frequency excursion and voltage excursion are not NERC-defined terms nor terms to be defined as part of this project, recommend the terms be placed in lowercase letters to maintain consistency with the Requirement. M5. Each Generator Owner shall have evidence, such as dated unit output records, trip investigation reports or disturbance monitoring records, showing that each unit trip did not result from a FfrequencyEexcursion or VvoltageEexcursion as specified in Requirement R5, or evidence that a listed exception applied, or provide an attestation that the generating unit or generating plant did not trip. **The SDT agrees**

Organization	Yes or No	Question 8 Comment
		with your comment. The capitalization has been removed as suggested. Please give consideration to the following suggestions:1. In Requirements R2 - the text refers to “non-protection system equipment” but this terminology is not defined. Provide some definition/description and perhaps a list of this type of equipment in a footnote to improve clarity. **The SDT has removed the term “non-protection system” from the wording in Requirement R2. In Requirement R3 the parenthetical has been revised so that it reads “(excluding limitations that are caused by generator frequency and voltage protective relays).”** 2. In Requirements, R3 - add the requirement that the GO provides the expected duration of the limitation, if it is known. . **In general, the SDT believes these limitations are permanent due to equipment design or regulatory considerations. The Reliability Coordinator, Planning Coordinator, Transmission Operator, or Transmission Planner may certainly inquire if they believe the Generator Owner is describing a temporary limitation.** 3. Request MOD-026 and MOD-027 be verified for redundancy with PRC-024.In the applicability section the only reference is to Generator Owner. It is recommended the applicability section include a statement that the affected units are only those that are a part of the Bulk Electric System. **The SDT does not believe MOD-026 or MOD-027 are redundant with PRC-024. The MOD standards require model validations where PRC-024 is a generator protective relaying setting and generator performance standard. The SDT feels that the applicable generators owned by a “Generator Owner” is clearly stated in the Registry Criteria and that no further clarification is required.**
Response: Thank you for your comments. Please see the responses to your specific comments above.		
Kansas City Power & Light Co.	Negative	The proposed change to requirement 1.1 will allow for generator trips in operating conditions involving automatic load shedding action and increase the risk of taking the interconnection into a black out condition.

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 8 Comment</th></tr>
<tr><td colspan="3">Response: Thank you for your comments. The allowance to trip for a specific rate of change of frequency that was specified in Requirement R1, Part 1.1 was provided so that any relaying added to protect from “Aurora” events would be allowed to trip the unit. The SDT investigated several major grid separation events and found that the rate of change of frequency during these events did not approach the 2.5 Hz/sec specified in the standard. However, it appears to the SDT that including the rate of change of frequency criterion in Requirement R1 is confusing industry and that “Aurora” protection is among the functions allowed to trip a generator due to impending or actual loss of synchronism or stability (Part 1.2 – now 1.1) and removed the rate of change of frequency criterion.</td></tr>
<tr><td>Public Utility District No. 1 of Lewis County</td><td>Negative</td><td>The standard does not list a minimum size generator that this standard applies to. Our utility has one plant with two small generators. The plant is near a project 10 times our size. We do not have the monitoring equipment to run this frequency or voltage testing. Therefore we must hire the work done. We get little or no benefit from the testing and money spent. Suggest the standard state a minimum generator size of 100 MVA that verification is required.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. The SDT feels that the applicable generators owned by a “Generator Owner” is clearly stated in the Registry Criteria and that no further clarification is required.</td></tr>
<tr><td>Southern California Edison Company</td><td></td><td>The standard should allow for wider regional variances - for example, WECC allows lower frequency and voltage excursions.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. The WECC curve in Attachment 1 has been corrected per the 25 Nov 2007 WECC Coordinated Off Nominal Frequency Load Shedding Plan document. The table of associated values for the WECC region has also been corrected.</td></tr>
<tr><td>Northern Indiana Public Service Co.</td><td>Negative</td><td>There is a concern about inconsistencies between the Standards and Appendices</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. The SDT cannot address your concern without knowing the specifics of the inconsistencies to which you refer. Standard PRC-024 does not have any Appendices.</td></tr>

Organization	Yes or No	Question 8 Comment
Indiana Municipal Power Agency		This standard should concentrate on being a relay standard because it is not practical to include equipment limitations (excluding generator frequency and voltage protective relay equipment) that might trip the generating unit or generating plant offline. Just to figure out what the equipment limitations are at a generating plant an entity would have to perform a complete analysis and stability study on the generating plant including all auxiliary systems. If an entity cannot do this within it's organization, it will have to hire a contractor and/or outside consultant to inventory, test, and model the unit/plant. This type of analysis will be expensive and will come without any guarantees from the contractor that all the equipment limitations have been noted or discovered. In addition to the initial testing that a unit/plant will require to meet this standard, an entity will have to perform some type of routine testing and maintenance program in this area to ensure equipment characteristics have not changed enough to become a plant limitation (heat and age changes equipment characteristics). Based on this standard, entities will have to have equipment tested and built to certain specifications that will allow it to ride through a voltage and/or frequency excursion which will increase equipment and maintenance costs and could potentially limit equipment suppliers. One has to wonder if all of this cost will guarantee an increase in BES reliability that makes it worth paying for the work and equipment that will be needed for compliance (with the chance that the plant will still trip offline). In how many past instances has what this standard is trying to protect against been a proven issue? **The SDT agrees that studies will have to be done to design generating units (especially their auxiliary systems) to be able to ride through the types of transmission system voltage excursions defined in this standard. Since similar requirements are already in effect in parts of Europe and Asia, the SDT believes it is technically feasible.** There term "power conversion control equipmen"t is not defined and will allow entities to apply this term to different equipment which may or may not be correct. The SDT should take the time to define it now and not allow a CAN to define it. **There are a lot of terms that are not defined in the standard. The SDT prefers to refrain from adding definitions unless it is clear there is widespread confusion. You were**

Organization	Yes or No	Question 8 Comment
		the only entity to comment on this term. In this standard it refers to the electronics associated with asynchronous generator technologies. Measure five (M5) is currently written so that it appears that an entity will have to purchase a Digital Fault Recorder(s) for the unit/plant in order to produce the evidence needed to show a unit tripped offline (i.e. frequency rate of change greater than 2.5 Hz/sec) outside of the "no trip" zone. IMPA does not agree with this philosophy since the cost to purchase and install DFR's can be costly, especially to smaller entities. **Measure M5 does not require the purchase of any particular type of equipment. There are protective relays and voltage regulators with oscillographic recording capability. The Transmission Owner may already have a fault recorder in the substation. This requirement only applies to new units following a six-year implementation period to give time to budget for and design equipment to meet the requirement. In the event that it is determined that a fault recorder is the best option and does not exist in the substation the SDT believes the cost of adding a DFR as a percentage of the cost of building a new unit to be very small.** Why is 5.2 allowed for new units but not existing units**? Existing units are only required to set their protection systems such that they won't operate during an excursion as defined in the standard, but still may trip due to process upsets caused by the excursion. Requirement R5, however, does require new units to be designed to remain connected despite any process upsets. A generating unit may experience a power runback (which is allowed) and Part 5.2 (now 5.1) gives a facility with multiple small units an analogous allowance.** In 5.6, what makes the Mitigation Plan acceptable? Who needs to approve or make the Mitigation Plan acceptable. Where is the Mitigation Plan defined? IMPA believes the word "acceptable" should be removed. **The Reliability Coordinator has the discretion to determine if the plan to address the limitation that is submitted by a Generator Owner is acceptable. The SDT believes Part 5.6 (now 5.5) is worded correctly.**

Organization	Yes or No	Question 8 Comment
Response: Thank you for your comments. Please see the responses to your specific comments above.		
PSEG		We have these additional comments:a. In Part 4.1 of R4, the first sentence has this proposed change, indicated by capilatization: "An estimate of the time duration the existing generating unit or generating plant will remain connected (considering performance of the auxiliary systems as well as the generator) as a result of a frequency excursion or a voltage excursion defined by the voltage or frequency profile at the point of interconnection [deleted "described by"] THAT WAS DEVELOPED FROM A dynamic simulation provided by the Transmission Planner. **The SDT agrees and has revised the wording in Requirement R4.** b. M5 is confusing. M5 states "Each Generator Owner shall have evidence, such as dated unit output records, trip investigation reports or disturbance monitoring records, showing that each unit trip did not result from a Frequency Excursion or Voltage Excursion as specified in Requirement R5, or evidence that a listed exception applied, or provide an attestation that the generating unit or generating plant did not trip."i. Frequency Excursion and Voltage Excursion are capitalized terms - the previous version's defined terms were supposed to be removed. **The SDT agrees with your comment. The capitalization has been removed as suggested.** ii. While is appears that an "attestation that the generating unit or generating plant did not trip" is only required for a unit or plant that remained on line during a frequency or voltage excursion, the language should be made clearer. **The SDT agrees with your comment. The language referring to attestations has been removed.** iii. We suggest that the GVSDT consider rewording M5 to clearly state what trips should be reported, whether non-trips that occur during frequency and voltage excursions are to be reported, and what supporting evidence (or attestations) is required for each reported item. A table may be the best way to display this. **Measure M5 does not reference reporting non-trips during an excursion. Thus these events do not need to be reported. By default, the generating unit is compliant if it did not trip, whether there was an excursion or not.**

Organization	Yes or No	Question 8 Comment
		Finally, M5 should be developed to produce the VSL metric for R5. **The SDT believes that the VSL does cover both the Requirement its associated Measure.** c. The previously defined terms "Frequency Excursion" and "Voltage Excursion" were to be removed from this draft; however they are used in R4 and in the VSL table. The GVSDT should search the standard for all such usage and correct it. **The capitalization has been removed as suggested.**
Response: Thank you for your comments. Please see the responses to your specific comments above.		
Gainesville Regional Utilities	Negative	We support FMPA's position on this matter.
Southwest Power Pool Standards Development Team		We would suggest revision of M5 to read. Also since the two terms Frequency Excursion and Voltage Excursion are no longer to be defined by this project we would ask that you use the lower case for these terms in the standard. M5. Each Generator Owner shall have evidence, such as dated unit output records, trip investigation reports or disturbance monitoring records, showing that each unit trip did not result from a frequency excursion or voltage excursion as specified in Requirement R5, or evidence that a listed exception applied.
Response: Thank you for your comments. The capitalization has been removed and reference to the attestation that the unit did not trip has been removed as suggested.		
PacifiCorp		While PacifiCorp has no concerns with this Requirement R5 as applied to new units or generating plant/facilities meeting the point of interconnection frequency excursion performance depicted in Attachment 1 (for the corrected WECC curve), PacifiCorp believes that new units or generating plant/facilities should meet the voltage excursions performance depicted in Attachment 2; however, ultimately it will be up to generator manufacturers to implement necessary facility changes to withstand the voltage excursions.
Response: Thank you for your comments. The SDT appreciates the support for the reliability goals. We would add that it will		

Organization	Yes or No	Question 8 Comment
require changes in auxiliary system configuration and equipment as well as the turbine and generator manufacturers' inputs to achieve the goal.		
Exelon Corp.		The Off Normal Frequency Capability Curve should consist of separate tables for each Interconnect to make it easier to read. **There are already separate data tables for each curve on Attachment 1. The SDT does not believe adding more graphs would add clarification.** Exelon still feels that Footnote 1 belongs in the Applicability section of the standard. Suggest that the Applicability section be revised to state "GO shall set applicable protective relaying so as not to impact R1.1, R1.2, R1.3, R1.5 unless exempted by non-protection system equipment limitations per the exclusion criteria. **The SDT respectfully disagrees. In PRC-024-1, Footnote 1 is intended for clarification purposes only to make it clear that the standard does not force the GO to install voltage or protective relays if they are not already installed on its unit(s).** It should be noted that even if a relay is not set to operate according to the curves in the attachments, a minute deviation will exist in the operation of the relay, and as such, a protection system may operate in what the SDT has deemed the "no trip zone." If a relay operates in that zone, then an entity will technically be out of compliance with this standard even though it set its protection system correctly as per the standard. An allowable tolerance needs to be included in the requirements in order to capture real world conditions. **Relays that are known to drift from their settings should either be calibrated more frequently or set such that a tolerance is built into the relay setting so that the drift will not cross the "no trip zone" boundary.**
Response: Thank you for your comments. Please see the responses to your specific comments above.		

END OF REPORT

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. SAR posted for comment (April 20–May 21, 2007).
2. Revised SAR and response to comments posted.
3. Revised SAR and response to comments approved by SC (June 14, 2007).
4. SDT appointed (August 18, 2007).
5. First Draft of MOD-024-2 was posted for comment January 18 – February 18, 2010. MOD-024-2 was later combined with MOD-025-1 to form MOD-025-2.
6. Posted first draft of standard for a 30 day comment period June 15 –July 15, 2011

Proposed Action Plan and Description of Current Draft:

This is the second draft of the proposed standard including Time Horizons, Data Retention, Violation Risk Factors, and Violation Severity Levels; and is being submitted for a 45-day concurrent formal comment period and initial ballot.

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Develop responses to comments and develop second version draft standard.	July 2011 – February 2012
2. Post response to comments and conduct a formal 45 day comment period with concurrent initial ballot for the revised standard.	March - April 2012
3. Develop responses to ballot comments.	April - June 2012
4. Post response to comments and conduct successive ballot.	June 2012
5. Develop responses to ballot comments.	June - July 2012
6. Post responses to comments and conduct recirculation ballot.	August 2012
7. BOT adoption.	September 2012
8. File with regulatory authorities.	November 2012

A. Introduction

1. **Title:** Verification and Data Reporting of Generator Real and Reactive Power Capability and Synchronous Condenser Reactive Power Capability

2. **Number:** MOD-025-2

3. **Purpose:** To ensure accurate information on generator gross and net Real and Reactive Power capability and synchronous condenser Reactive Power capability is available for planning models used to assess Bulk Electric System (BES) reliability.

4. **Applicability:**

4.1. Functional entities

4.1.1 Generator Owner

4.1.2 Transmission Owner with synchronous condenser

4.2. Facilities:

For the purpose of this standard, the term, "applicable Facility" shall mean any one of the following:

4.2.1 Individual generating unit greater than 20 MVA (gross nameplate rating) directly connected to the bulk power system.

4.2.2 Synchronous condenser greater than 20 MVA (gross nameplate rating) directly connected to the bulk power system.

4.2.3 Generating plant/Facility greater than 75 MVA (gross aggregate nameplate rating) directly connected to the bulk power system.

5. **Effective Date:**

5.1. In those jurisdictions where regulatory approval is required:

5.1.1 By the first day of the first calendar quarter, one calendar year following applicable regulatory approval, each Generator Owner and Transmission Owner shall have verified at least 20 percent of its applicable Facilities.

5.1.2 By the first day of the first calendar quarter, two calendar years following applicable regulatory approval, each Generator Owner and Transmission Owner shall have verified at least 40 percent of its applicable Facilities.

5.1.3 By the first day of the first calendar quarter, three calendar years following applicable regulatory approval, each Generator Owner and Transmission Owner shall have verified at least 60 percent of its applicable Facilities.

5.1.4 By the first day of the first calendar quarter, four calendar years following applicable regulatory approval, each Generator Owner and Transmission Owner shall have verified at least 80 percent of its applicable Facilities.

5.1.5 By the first day of the first calendar quarter, five calendar years following applicable regulatory approval, each Generator Owner and Transmission Owner shall have verified 100 percent of its applicable Facilities.

5.2. In those jurisdictions where regulatory approval is not required:

5.2.1 By the first day of the first calendar quarter, one calendar year following Board of Trustees approval, each Generator Owner and Transmission Owner shall have verified at least 20 percent of its applicable Facilities.

5.2.2 By the first day of the first calendar quarter, two calendar years following Board of Trustees approval, each Generator Owner and Transmission Owner shall have verified at least 40 percent of its applicable Facilities.

5.2.3 By the first day of the first calendar quarter, three calendar years following Board of Trustees approval, each Generator Owner and Transmission Owner shall have verified at least 60 percent of its applicable Facilities.

5.2.4 By the first day of the first calendar quarter, four calendar years following Board of Trustees approval, each Generator Owner and Transmission Owner shall have verified at least 80 percent of its applicable Facilities.

5.2.5 By the first day of the first calendar quarter, five calendar years following Board of Trustees approval, each Generator Owner and Transmission Owner shall have verified 100 percent of its applicable Facilities.

5.3. Wind Farm Verification - If an entity has two wind sites, and verification of one site is complete, the entity is 50% complete regardless of the number of turbines at each site.

B. Requirements

R1. Each Generator Owner shall provide its Transmission Planner with verification of the Real Power capability of its applicable Facilities as follows: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

1.1. Verify the Real Power capability of its generating units in accordance with Attachment 1.

1.2. Submit a completed Attachment 2 (or a form containing the same information as identified in Attachment 2) to its Transmission Planner within 90 calendar days of either the date the data is recorded for a staged test or the date the data is selected for verification using historical operational data.

R2. Each Generator Owner shall provide its Transmission Planner with verification of the Reactive Power capability of its applicable Facilities as follows: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

2.1. Verify the Reactive Power capability of its generating units and the Reactive Power capability of its synchronous condenser units in accordance with Attachment 1.

2.2. Submit a completed Attachment 2 (or a form containing the same information as identified in Attachment 2) to its Transmission Planner within 90 calendar days of either the date the data is recorded for a staged test or the date the data is selected for verification using historical operational data.

R3. Each Transmission Owner shall provide its Transmission Planner with verification of the Reactive Power capability of its applicable Facilities as follows: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

3.1. Verify the Reactive Power capability of its synchronous condenser units in accordance with Attachment 1.

3.2. Submit a completed Attachment 2 (or a form containing the same information as identified in Attachment 2) to its Transmission Planner within 90 calendar days of either the date the data is recorded for a staged test or the date the data is selected for verification using historical operational data

C. Measures

M1. Each Generator Owner will have evidence that it performed the verification, such as a completed Attachment 2 or the Generator Owner form with the same information, and will have evidence that it submitted the information and a correction for ambient conditions, if requested, within 90 days to its Transmission Planner; such as dated electronic mail messages, mail receipts, or dated information collected and used to complete attachments, in accordance with Requirement R1.

M2. Each Generator Owner will have evidence that it performed the verification, such as a completed Attachment 2 or the Generator Owner form with the same information, and will have evidence that it submitted the information within 90 days to its Transmission

Planner; such as dated electronic mail messages, mail receipts, or dated information collected and used to complete attachments, in accordance with Requirement R2.

M3. Each Transmission Owner will have evidence that it performed the verification, such as a completed Attachment 2 or the Transmission Owner form with equivalent information, and will have evidence that it submitted the information within 90 days to its Transmission Planner; such as dated electronic mail messages, mail receipts, or dated information collected and used to complete attachments, in accordance with Requirement R3.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

Regional Entity

1.2. Evidence Retention

The following evidence retention periods identify a period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention specified below is shorter than the time since the last compliance audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Generator Owner and Transmission Owner shall each keep the latest data and evidence to show compliance as identified below, and the previous set of evidence if updated since the last compliance audit unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

- The Generator Owner shall retain the latest MOD-025 Attachment 2 and the data behind Attachment 2 or Generator Owner form with equivalent information and submittal evidence for Requirements R1 and R2, Measures M1 and M2 for the time period since the last compliance audit.
- The Transmission Owner shall retain the latest MOD-025 Attachment 2 and the data behind Attachment 2 or Transmission Owner form with equivalent information and submittal evidence for Requirement R3, Measure M3 for the time period since the last compliance audit.

If a Generator Owner or Transmission Owner is found noncompliant, it shall keep information related to the noncompliance until found compliant or for the time specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes

Compliance Audit

Self-Certification

Spot Checking

Compliance Investigation

Self-Reporting

Complaint

1.4. Additional Compliance Information

None

Version 2	TBD	Revised per SAR for Project 2007-09 and combined with MOD-024-1	TBD

MOD-025 Attachment 1 – Verification of Generator Real and Reactive Power Capability and Synchronous Condenser Reactive Power Capability

Periodicity for conducting a new verification:

The periodicity for performing Real and Reactive Power capability verification is as follows:

1. For staged verification; verify each applicable Facility at least every five years (with no more than 66 calendar months between verifications), or within 12 calendar months of the discovery of a change that is expected to affect its Real Power or Reactive Power capability by more than 10 percent of the last reported verified capability and is expected to last more than six months.
2. For verification using operational data; verify each applicable Facility at least every five years (with no more than 66 calendar months between verifications), or within 12 calendar months following the discovery that its Real Power or Reactive Power capability has changed by more than 10 percent of the last reported verified capability and is expected to last more than six months. If data for different points is recorded on different days, designate the earliest of those dates as the verification date, and report that date as the verification date on MOD-025, Attachment 2 for periodicity purposes.
3. For either verification method, verify each new applicable Facility within 12 calendar months of its commercial operation date.

It is intended that Real Power testing be performed at the same time as full Load Reactive Power testing, however separate testing is allowed for this standard. For synchronous condensers, perform only the Reactive Power capability verifications as specified below. If an applicable Facility is operated in synchronous condenser mode as well as generation mode, the unit should be verified in both modes.

Verification specifications for applicable Facilities:

1. For generating units of 20 MVA or less that are part of a plant greater than 75 MVA in aggregate, record data either on an individual unit basis or as a group. Perform verification individually for every generating unit or synchronous condenser greater than 20 MVA (gross nameplate rating).

2. Verify with all auxiliary equipment needed for expected normal operation in service for both the Real Power and Reactive Power capability verification. Perform verification with the automatic voltage regulator in service for the Reactive Power capability verification (see Note 3 if the automatic voltage regulator is not available). Operational data from within the two years prior to the verification date is acceptable for the verification of either the Real Power or the Reactive Power capability, as long as that operational data meets the criteria in 2.1 through 2.5 below and is at least 90 percent of a previously staged test that demonstrated at least 50 percent of the capability shown on the associated D-curve. If the previously staged test was unduly restricted by unusual generation or equipment limitations (e.g., capacitor or reactor banks out of service), then the next verification shall be by another staged test, not operational data:

2.1. Verify Real Power capability, Reactive Power capability over-excited (lagging) and Reactive Power capability under-excited (leading) of all applicable Facilities at the applicable Facilities' normal (not emergency) expected maximum Real Power at the time of the verifications. Verify variable generating units, such as wind, solar, and run of river hydro, at the maximum Real Power output the variable resource can provide at the time of the verification. Perform verification of Reactive Power capability of wind turbines and photovoltaic inverters with at least 90 percent of the wind turbines or photovoltaic inverters at a site on-line. If verification of wind turbines or photovoltaic inverter Facility cannot be accomplished meeting the 90 percent threshold, document the reasons the threshold was not met and test to the full capability at the time of the test. Retest the facility within six months of being able to reach the 90 percent threshold. Maintain, as steady as practical, Real and Reactive Power output during verifications.

2.2. Verify Reactive Power capability of all Applicable Facilities, other than wind and photovoltaic, for maximum overexcited (lagging) and under-excited (leading) reactive capability at the minimum Real Power output at which they are normally expected to operate. Nuclear Units are not required to perform Reactive Power verification at minimum Real Power output.

2.3. Conduct the maximum Real Power and over-excited Reactive Power verifications required in 2.1 for a minimum of one continuous hour.

2.4. Collect the under-excited Reactive Power capability verification data identified in 2.1 and 2.2, and the over-excited Reactive Power capability verification data identified in 2.2 as soon as a limit is reached.

2.5. For hydrogen-cooled generators, perform the verification at normal operating hydrogen pressure.

2.6. Collect the Generator Step-Up (GSU) transformer losses if the verification measurements are taken from the high side of the GSU transformer.

3. Record the following data for the verifications specified above:

3.1. The value of the gross Real and Reactive Power generating capabilities at the end of the verification period.

3.2. The voltage schedule provided by the Transmission Operator.

3.3. The voltage at the high and low side of the GSU and/or system Interconnection transformer(s) at the end of the verification period. If only one of these values is metered, the other may be calculated.

3.4. The ambient conditions, if applicable, at the end of the verification period the Generator Owner requires to perform corrections to Real Power for different ambient conditions such as:

- Ambient air temperature

- Relative humidity
- Cooling water temperature

3.5. The date and time of the verification period, including start and end time in hours and minutes.

3.6. The existing GSU and/or system Interconnection transformer(s) tap setting.

3.7. The GSU transformer losses if the verification measurements were taken from the high side of the GSU transformer.

3.8. Whether the test data is a result of a staged test or if it is operational data.

4. Develop a simplified key one-line diagram (refer to MOD-025, Attachment 2) showing sources of auxiliary Real and Reactive Power and associated system connections for each unit verified. Include GSU and/or system Interconnection and auxiliary transformers. Show Reactive Power flows, with directional arrows.

4.1. If metering does not exist to measure specific Reactive auxiliary Load(s), provide an engineering estimate and associated calculations.

Note 1: Under some transmission system conditions, the data points obtained by the MVAR verification required by the standard will not duplicate the manufacturer supplied thermal capability curve (D-curve). However, the verification required by the standard, even when conducted under these transmission system conditions, may uncover applicable Facility limitations; such as rotor thermal instability, improper tap settings, inaccurate AVR operation, etc., which could be further analyzed for resolution. Observe auxiliary bus voltage limits. The verified MVAR value obtained most likely will not be the value entered into the Transmission Planner’s database; nor is it likely this value will agree with data required to be submitted by MOD-010.

Note 2: While not required by the standard, it is desirable to perform engineering analyses to determine expected applicable Facility capabilities under less restrictive system voltages than those encountered during the verification. Even though this analysis will not verify the complete MVAR capability curve, it provides a reasonable estimate of applicable Facility capability that the Transmission Planner can use for modeling.

Note 3: It is desired that the automatic voltage regulator be in service when testing a generator’s reactive capability. If an automatic voltage regulator is not installed on the unit to be tested, or is not available at the time of the test, exercise extra caution not to exceed the operating limits of the generator.

Note 4: The verification is intended to define the limits of the unit’s capabilities. If a unit has no leading capability, then it should be reported with no leading capability; or the minimum lagging capability at which it can operate.

MOD-025 Attachment 2

One-line Diagram, Table, and Summary for Verification Information Reporting

Note: If the configuration of the applicable Facility does not lend itself to the use of the diagram, tables, or summaries for reporting the required information, changes may be made to this form, provided that all required information (identified in MOD-025, Attachment 1) is reported.

Company: **Reported By (name):**

Verification Data

Provide data by unit or Facility, as appropriate

Data Type	Data Recorded	Last Verification (Previous Data)
Gross Reactive Power Generating Capability (*Mvar)		
Aux Reactive Power (*Mvar)		
Net Reactive Power Capability (*Mvar) equals Gross Reactive Power Capability (*Mvar) minus Aux Reactive Power connected at the same bus (*Mvar) minus tertiary Reactive Power connected at the same bus(*Mvar)		
Gross Real Power Generating Capability (*MW)		N/A
Aux Real Power (*MW)		N/A
Net Real Power Capability (*MW) equals Gross Real Power Capability (*MW) minus Aux Real Power connected at the same bus (*MW) minus tertiary Real Power connected at the same bus(*MW)		N/A
* Note: Enter values at the end of the verification period.		
GSU losses (only required if verification measurements are taken on the high side of the GSU - Mvar)		

Summary of Verification

- Date of Verification _________,Verification Start Time _____, Verification End Time ______
- Scheduled Voltage _______________
- Transformer Tap Settings: GSU ______, Unit Aux _____, Station Aux _____, Other Aux _____
- Ambient conditions at the end of the verification period:

  Air temperature: _________

  Humidity: _________

  Cooling water temperature: _________

  Others as applicable: _________

- The recorded Mvar values were adjusted to rated generator voltage, where applicable.
- Generator hydrogen pressure (if applicable) ______________
- Date that data shown in last verification column in table above was taken ______________

Remarks :

Note: If the verification value did not reach the Thermal Capability Curve (D-Curve), describe the reason.

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps ~~-~~Completed:

1. SAR posted for comment (April 20–May 21, 2007).
2. Revised SAR and response to comments posted.
3. Revised SAR and response to comments approved by SC (June 14, 2007).
4. SDT appointed ~~on~~ (August 18, 2007).
5. First Draft of MOD-024-2 was posted for comment January 18 – February 18, 2010. MOD-024-2 was later combined with MOD-025-1 to form MOD-025-2.
6. Posted first draft of standard for a 30 day comment period June 15 –July 15, 2011

Proposed Action Plan and Description of Current Draft:

This is the ~~first~~second draft of the proposed ~~revision to this~~ standard including Time Horizons, Data Retention, Violation Risk Factors, and Violation Severity Levels~~. This first posting;~~ and is being submitted for a ~~30~~45-day concurrent formal comment period~~.~~ and initial ballot.

Future Development Plan:

Anticipated Actions	Anticipated Date
1. ~~Post first~~Develop responses to comments and develop second version draft ~~revision of~~ standard.	~~April-May~~July 2011 – February 2012
2. Post response to comments and ~~second version draft revision of~~conduct a formal 45 day comment period with concurrent initial ballot for the revised standard.	~~July – August 2011~~March - April 2012
3. ~~Post response to comments and request authorization~~Develop responses to ballot ~~the revised standard~~comments.	~~September - October 2011~~April - June 2012
4. ~~Conduct initial~~Post response to comments and conduct successive ballot.	~~November 2011~~June 2012
5. ~~Post response~~Develop responses to ballot comments.	~~December 2011~~June - July 2012
6. ~~Conduct~~Post responses to comments and conduct recirculation ballot.	~~January~~August 2012
7. BOT adoption.	~~February~~September 2012

8. File with regulatory authorities.	~~March~~November 2012

A. Introduction

1. **Title:** Verification and Data Reporting of Generator Real and Reactive Power Capability and Synchronous Condenser Reactive Power Capability

2. **Number:** MOD-025-2

3. **Purpose:** To ensure ~~that planning entities have~~ accurate information on generator gross and net Real and Reactive Power capability ~~data when assessing~~and synchronous condenser Reactive Power capability is available for planning models used to assess Bulk Electric System (BES) reliability.

4. **Applicability:**

   4.1. Functional entities

   4.1.1 Generator Owner

   4.1.2 Transmission Owner with synchronous condenser

   4.2. Facilities:

   For the purpose of this standard, the term, "applicable Facility" shall mean any one of the following:

   4.2.1 Individual generating unit ~~or synchronous condenser >~~greater than 20 MVA (gross nameplate rating) ~~in a generating Facility~~directly connected ~~at the point of interconnection at 100 kV or above~~to the bulk power system.

   ~~**4.2.1**~~**4.2.2** Synchronous condenser greater than 20 MVA (gross nameplate rating) directly connected to the bulk power system.

   ~~**4.2.2**~~**4.2.3** Generating plant/Facility ~~>~~greater than 75 MVA (gross aggregate nameplate rating) ~~and~~directly connected ~~at~~to the ~~point of interconnection at 100 kV or above~~bulk power system.

   ~~**4.2.3** Blackstart units, regardless of size that are included in a Transmission Operator's restoration plan.~~

5. **Effective Date:**

   5.1. In those jurisdictions where regulatory approval is required:

   5.1.1 By the first day of the first calendar quarter, one calendar year following applicable regulatory approval, each Generator Owner and Transmission Owner shall have verified at least 20~~%~~ percent of its applicable ~~units~~Facilities.

   5.1.2 By the first day of the first calendar quarter, two calendar years following applicable regulatory approval, each Generator Owner and Transmission Owner shall have verified at least 40~~%~~ percent of its applicable ~~units~~Facilities.

5.1.3 By the first day of the first calendar quarter, three calendar years following applicable regulatory approval, each Generator Owner and Transmission Owner shall have verified at least 60~~%~~ percent of its applicable ~~units~~Facilities.

5.1.4 By the first day of the first calendar quarter, four calendar years following applicable regulatory approval, each Generator Owner and Transmission Owner shall have verified at least 80~~%~~ percent of its applicable ~~units~~Facilities.

5.1.5 By the first day of the first calendar quarter, five calendar years following applicable regulatory approval, each Generator Owner and Transmission Owner shall have verified 100~~%~~ percent of its applicable ~~units~~Facilities.

5.2. In those jurisdictions where regulatory approval is not required:

5.2.1 By the first day of the first calendar quarter, one calendar year following Board of Trustees approval, each Generator Owner and Transmission Owner shall have verified at least 20~~%~~ percent of its applicable ~~units~~Facilities.

5.2.2 By the first day of the first calendar quarter, two calendar years following Board of Trustees approval, each Generator Owner and Transmission Owner shall have verified at least 40~~%~~ percent of its applicable ~~units~~Facilities.

5.2.3 By the first day of the first calendar quarter, three calendar years following Board of Trustees approval, each Generator Owner and Transmission Owner shall have verified at least 60~~%~~ percent of its applicable ~~units~~Facilities.

5.2.4 By the first day of the first calendar quarter, four calendar years following Board of Trustees approval, each Generator Owner and Transmission Owner shall have verified at least 80~~%~~ percent of its applicable ~~units~~Facilities.

5.2.5 By the first day of the first calendar quarter, five calendar years following Board of Trustees approval, each Generator Owner and Transmission Owner shall have verified 100~~%~~ percent of its applicable ~~units~~Facilities.

5.3. Wind Farm Verification - If an entity has two wind sites, and verification of one site is complete, the entity is 50% complete regardless of the number of turbines at each site.

B. Requirements

R1. Each Generator Owner shall provide its Transmission Planner with verification of the Real Power capability of its applicable Facilities as follows: *[Violation Risk Factor: ~~Lower~~Medium] [Time Horizon: Long-term Planning]*

1.1. Verify the Real ~~and~~Power capability of its generating units in accordance with Attachment 1.

1.2. Submit a completed Attachment 2 (or a form containing the same information as identified in Attachment 2) to its Transmission Planner within 90 calendar days of either the date the data is recorded for a staged test or the date the data is selected for verification using historical operational data.

R2. Each Generator Owner shall provide its Transmission Planner with verification of the Reactive Power capability of its applicable Facilities as follows: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

~~1.1.~~2.1. Verify the Reactive Power capability of its generating units and ~~shall verify~~ the Reactive Power capability of its synchronous condenser units in accordance with Attachment 1~~—~~.

~~1.2.~~ ~~Record the information on~~Submit a completed Attachment 2 (~~-~~or ~~on the Generator Owner's~~a form ~~that contains~~containing the same information as identified in Attachment 2~~);~~

~~1.3.~~2.2. ~~Submit~~) to its Transmission Planner within 90 calendar days of either the date the data is recorded ~~to its Transmission Planner~~for a staged test or the date the data is selected for verification using historical operational data.

~~R2.~~R3. Each Transmission Owner shall provide its Transmission Planner with verification of the Rective Power capability of its applicable Facilities as follows: *[Violation Risk Factor: ~~Lower~~Medium] [Time Horizon: Long-term Planning]*

~~2.1.~~3.1. Verify the Reactive Power capability of its synchronous condenser units in accordance with Attachment 1~~;~~.

~~2.2.~~ ~~Record the information on~~Submit a completed Attachment 2 (or ~~on the Transmission Owner's~~a form ~~that contains~~containing the same information as identified in Attachment 2)

~~2.3.~~3.2. ~~Submit~~ to its Transmission Planner within 90 calendar days of either the date the ~~verification to its Transmission Planner.~~ data is recorded for a staged test or the date the data is selected for verification using historical operational data

C. Measures

M1. Each Generator Owner ~~has~~will have evidence that it performed the verification, such as a completed ~~MOD-025~~ Attachment 2 or the Generator Owner form with ~~equivalent~~the same information, and ~~has~~will have evidence that it submitted the information~~,~~ and a correction for ambient conditions, if requested, within 90 days to its Transmission

Planner; such as dated electronic mail messages ~~or~~, mail receipts, or dated information collected and used to complete attachments, in accordance with Requirement R1.

M2. Each ~~Transmission~~Generator Owner ~~has~~will have evidence that it performed the verification, such as a completed ~~MOD-025~~ Attachment 2 or ~~Transmission~~ the Generator Owner form with ~~equivalent~~the same information, and ~~has~~will have evidence that it submitted the information~~,~~ within 90 days to its Transmission Planner; such as dated electronic mail messages ~~or~~, mail receipts, or dated information collected and used to complete attachments, in accordance with Requirement R2.

M3. Each Transmission Owner will have evidence that it performed the verification, such as a completed Attachment 2 or the Transmission Owner form with equivalent information, and will have evidence that it submitted the information within 90 days to its Transmission Planner; such as dated electronic mail messages, mail receipts, or dated information collected and used to complete attachments, in accordance with Requirement R3.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

Regional Entity

~~**Data**~~

1.2. Evidence Retention

The following evidence retention periods identify a period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention specified below is shorter than the time since the last compliance audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Generator Owner and Transmission Owner shall each keep the latest data ~~or~~and evidence to show compliance as identified below, and the previous set of evidence if updated since the last compliance audit unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

- The Generator Owner shall retain the latest MOD-025 Attachment 2 and the data behind Attachment 2 or Generator Owner form with equivalent information and submittal evidence for ~~Requirement 1, Measure 1~~Requirements R1 and R2, Measures M1 and M2 for the time period since the last compliance audit.
- The Transmission Owner shall retain the latest MOD-025 Attachment 2 and the data behind Attachment 2 or Transmission Owner form with equivalent information and submittal evidence for Requirement ~~2~~R3, Measure ~~2~~M3 for the time period since the last compliance audit.

If a Generator Owner or Transmission Owner is found ~~non-compliant~~noncompliant, it shall keep information related to the ~~non-compliance~~noncompliance until found compliant or for the time specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes

Compliance ~~Audits~~Audit

Self-~~Certifications~~Certification

Spot Checking

Compliance ~~Violation Investigations~~Investigation

Self-Reporting

~~Complaints~~

Complaint

1.4. Additional Compliance Information

None

2. Violation Severity Levels

R #	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The Generator Owner verified and recorded the Real ~~and Reactive~~ Power capability of its applicable generating unit ~~or applicable synchronous condenser~~, but submitted the data to its Transmission Planner more than 90 calendar days, but within ~~100~~120 calendar days, from the date of verification by staged test or the date of the historical operating data that was ~~recorded~~selected for verification. OR The Generator Owner verified the Real Power capability and submitted the data but was missing 1 to 33 percent of the data.	The Generator Owner verified and recorded the Real ~~and Reactive~~ Power capability of its applicable generating unit ~~or applicable synchronous condenser~~, but submitted the data to its Transmission Planner more than ~~100~~120 calendar days, but within ~~110~~150 calendar days, from the of verification by staged test or the date ~~the~~of the historical operating data that was ~~recorded~~selected for verification. OR The Generator Owner verified the Real Power capability and submitted the data but was missing 33 to 66 percent of the data.	The Generator Owner verified and recorded the Real ~~and Reactive~~ Power capability of its applicable generating unit ~~or applicable synchronous condenser~~, but submitted the data to its Transmission Planner more than ~~110~~150 calendar days, but within ~~120~~180 calendar days, of the date of verification by staged test or the date of the historical operating data that was ~~recorded~~selected for verification. Version History

Version	Date	Action	Change Tracking
Version 1	12/1/2005	1. Changed tabs in footer. 2. Removed comma after 2004 in “Development Steps Completed,” #1. 3. Changed incorrect use of certain hyphens (-) to “en dash” (–) and “em dash (—).” 4. Added “periods” to items where appropriate. 5. Changed apostrophes to “smart” symbols. 6. Changed “Timeframe” to “Time Frame” in item D, 1.2. 7. Lower cased all instances of “regional” in section D.3. 8. Removed the word “less” after 94% in section 3.4. Level 4.	01/20/06
Version 2	TBD	Revised per SAR for Project 2007-09 and combined with MOD-024-1	TBD

MOD-025 ~~-~~Attachment 1 – Verification of Generator Real and Reactive Power Capability and Synchronous Condenser Reactive Power Capability

~~For units of less than 20 MVA~~

Periodicity for conducting a new verification:

The periodicity for performing Real and Reactive Power capability verification is as follows:

1. For staged verification; verify each applicable Facility at least every five years (with no more than 66 calendar months between verifications), or within 12 calendar months of the discovery of a change that is expected to affect its Real Power or Reactive Power capability by more than 10 percent of the last reported verified capability and is expected to last more than six months.
2. For verification using operational data; verify each applicable Facility at least every five years (with no more than 66 calendar months between verifications), or within 12 calendar months following the discovery that its Real Power or Reactive Power capability has changed by more than 10 percent of the last reported verified capability and is expected to last more than six months. If data for different points is recorded on different days, designate the earliest of those dates as the verification date, and report that date as the verification date on MOD-025, Attachment 2 for periodicity purposes.
3. For either verification method, verify each new applicable Facility within 12 calendar months of its commercial operation date.

It is intended that Real Power testing be performed at the same time as full Load Reactive Power testing, however separate testing is allowed for this standard. For synchronous condensers, perform only the Reactive Power capability verifications as specified below. If an applicable Facility is operated in synchronous condenser mode as well as generation mode, the unit should be verified in both modes.

Verification specifications for applicable Facilities:

1. For generating units of 20 MVA or less that are part of a plant greater than 75 MVA in aggregate, record data either on an individual unit basis or as a group. Perform verification individually for every generating unit or synchronous condenser greater than 20 MVA (gross nameplate rating).

2. ~~Perform verification~~Verify with all auxiliary equipment needed for expected normal operation in service for both the Real Power and Reactive Power capability verification~~, and~~. Perform verification with the automatic voltage regulator in service for the Reactive Power capability verification~~.~~ (see Note 3 if the automatic voltage regulator is not available). Operational data from within the ~~year~~two years prior to the verification date is acceptable for the verification of either the Real Power or the Reactive Power capability, as long as ~~it~~that operational data meets the criteria in 2.1 through 2.5 below and is ~~within 20% of the expected value:~~at least 90 percent of a previously staged test that demonstrated at least 50 percent of the capability shown on the associated D-curve. If the previously staged test was unduly restricted by unusual generation or equipment limitations (e.g., capacitor or reactor banks out of service), then the next verification shall be by another staged test, not operational data:

2.1. ~~Perform verification of~~Verify Real ~~and~~Power capability, Reactive Power capability ~~of all generating units at maximum~~ over-excited (lagging) and Reactive Power capability under-excited (leading) ~~reactive capability at rated gross~~ of all applicable Facilities at the applicable Facilities' normal (not emergency) expected maximum Real Power ~~capability~~[1] at the time of the verifications. Verify variable generating units, such as wind, solar, and run of river hydro, at the maximum Real Power output the variable resource can provide at the time of the verification. Perform verification of ~~reactive~~ Reactive Power capability of wind turbines and photovoltaic inverters with ~~ninety~~at least 90 percent of the wind turbines or photovoltaic inverters at a site on--line. If verification of wind turbines or photovoltaic inverter Facility cannot be accomplished meeting the 90 percent threshold, document the reasons the threshold was not met and test to the full capability at the time of the test. Retest the facility within six months of being able to reach the 90 percent threshold. Maintain, as steady as ~~possible~~practical, Real and Reactive Power output during ~~verification~~verifications.

2.2. Verify Reactive Power capability of all ~~generating units~~Applicable Facilities, other than wind and photovoltaic, for maximum overexcited (lagging) and under-excited (leading) reactive capability at the minimum Real Power output at which they ~~could~~are normally ~~be~~ expected to operate. Nuclear Units are not required to perform Reactive Power verification at minimum Real Power output.

2.3. Conduct the ~~rated~~maximum Real Power and ~~overexcited~~over-excited Reactive Power verifications required in 2.1 for a minimum of one continuous hour.

2.4. ~~Record~~Collect the under-excited ~~reactive~~Reactive Power capability verification data ~~required~~identified in 2.1 and 2.2, and the over-excited ~~reactive~~Reactive Power capability verification data ~~required~~identified in 2.2 as soon as a limit is reached.

2.5. For hydrogen-cooled generators, perform the verification at normal operating hydrogen pressure.

2.6. Collect the Generator Step-Up (GSU) transformer losses if the verification measurements are taken from the high side of the GSU transformer.

3. Record the following data for the ~~verification~~ verifications specified above:

3.1. The value of the gross Real and Reactive Power generating capabilities at the end of the verification period.

3.2. The voltage schedule provided by the Transmission Operator.

~~[1] The generating unit's normal expected maximum Real Power at the time of the verification.~~

3.3. The voltage at the high and low side of the ~~generator step-up~~GSU and/or system ~~interconnection~~Interconnection transformer(s) at the end of the verification period. If only one of these values is metered, the other may be calculated.

3.4. The ambient ~~air temperature~~conditions, if applicable, at the end of the verification period ~~and a correction factor, if any, to allow~~ the ~~Transmission~~Generator Owner requires to perform corrections to ~~correct the~~ Real Power ~~rating to a~~for different ambient conditions such as:

- Ambient air temperature
- Relative humidity
- ~~3.4.~~ Cooling water temperature ~~if needed.~~

3.5. The date and time of the verification period, including start and end time in hours and minutes.

3.6. The existing ~~generator step-up~~GSU and/or system ~~interconnection~~Interconnection transformer(s) tap setting.

3.7. The GSU transformer losses if the verification measurements were taken from the high side of the GSU transformer.

3.8. Whether the test data is a result of a staged test or if it is operational data.

4. Develop a simplified key one-line diagram (refer to MOD-025, Attachment 2) showing sources of auxiliary Real and Reactive Power and associated system connections for each unit verified. Include ~~generator step-up~~GSU and/or system ~~interconnection~~Interconnection and auxiliary transformers. Show Reactive Power flows, with directional arrows.

4.1. If metering does not exist to measure specific ~~reactive~~Reactive auxiliary ~~load~~Load(s), provide an engineering estimate and associated calculations.

~~5. The periodicity for performing Real and Reactive Power generating capability verification is as follows:~~

~~5.1. For staged verification; verify each generator and/or synchronous condenser or plant/facility at least every five years, (with no more than 66 calendar months between verifications), or within one year of the discovery of a change that is expected to affect its Real Power or Reactive Power capability by more than 10% of the last reported verified capability and is expected to last more than six months.~~

~~5.2. For verification using operational data; verify each generator and/or synchronous condenser or plant/facility at least every five years, within 66 calendar months between verifications, or within one year following the discovery of a change that is expected to affect its Real Power or Reactive Power capability by more than 10% of the last reported verified capability and is expected to last more than six months. If data for different points is recorded on different days, the Generator Owner shall designate one of the dates as the verification date, and report that date as the verification date on MOD-025- Attachment 2 for periodicity purposes.~~

~~5.3. For either verification method, new units shall be verified within one year of their commercial operation date.~~

Note 1: ~~The~~Under some transmission system conditions, the data points obtained by the MVAR verification required by the standard ~~may~~will not duplicate the manufacturer supplied thermal capability curve (D-curve~~) due to transmission system conditions.~~). However, the verification required by the standard~~ may be able to ~~, even when conducted under these transmission system conditions, may uncover ~~unit~~applicable Facility limitations; such as rotor thermal instability, improper tap settings, inaccurate AVR operation, etc~~.~~., which could be further analyzed for resolution. ~~For any verification limited by transmission system conditions, the~~Observe auxiliary bus voltage limits. The verified MVAR value obtained most likely will not be the value entered into the Transmission Planner's database; nor is it likely this value will agree with data required to be submitted by ~~the~~ MOD-010~~ standard~~.

Note 2: While not required by the standard, it is desirable to perform engineering ~~analysis~~analyses to determine expected ~~unit~~applicable Facility capabilities under less restrictive system ~~conditions~~voltages than those encountered during the verification. Even though this analysis will not verify the complete MVAR capability curve, it provides a reasonable estimate of ~~unit~~applicable Facility capability that the Transmission Planner can use for modeling.

Note 3: It is desired that the automatic voltage regulator be in service when testing a generator's reactive capability. If an automatic voltage regulator is not installed on the unit to be tested, or is not available at the time of the test, exercise extra caution not to exceed the operating limits of the generator.

Note 4: The verification is intended to define the limits of the unit's capabilities. If a unit has no leading capability, then it should be reported with no leading capability; or the minimum lagging capability at which it can operate.

MOD-025 Attachment 2

One-line Diagram, Table, and Summary for Verification Information Reporting

Note: If the configuration of the ~~generation facility~~applicable Facility does not lend itself to the use of the diagram, tables, or summaries for reporting the required information, changes may be made to this form, provided that all required information (identified in MOD-025 ~~Attachement,~~ Attachment 1) is reported.

Implementation Plan

Project 2007-09 Generator Verification

Implementation Plan for MOD-025-2, Verification and Data Reporting of Generator Real and Reactive Power Capability and Synchronous Condenser Reactive Power Capability

Approvals Required

MOD-025-2, Verification and Data Reporting of Generator Real and Reactive Power Capability and Synchronous Condenser Reactive Power Capability

Prerequisite Approvals

None

Revisions to Glossary Terms

None

Applicable Entities

Transmission Owner with synchronous condenser
Generator Owner

Facilities

- Individual generating unit greater than 20 MVA (gross nameplate rating) directly connected to the bulk power system.
- Synchronous condenser greater than 20 MVA (gross nameplate rating) directly connected to the bulk power system.
- Generating plant/facility > 75 MVA (gross aggregate nameplate rating) directly connected to the bulk power system.

Conforming Changes to Other Standards

None

Effective Dates

In those jurisdictions where regulatory approval is required:

- By the first day of the next calendar quarter, one calendar year following applicable regulatory approval each Generator Owner and Transmission Owner shall have verified at least 20 percent of its applicable units.

- By the first day of the next calendar quarter, two calendar years following applicable regulatory approval each Generator Owner and Transmission Owner shall have verified at least 40 percent of its applicable units.
- By the first day of the next calendar quarter, three calendar years following applicable regulatory approval each Generator Owner and Transmission Owner shall have verified at least 60 percent of its applicable units.
- By the first day of the next calendar quarter, four calendar years following applicable regulatory approval each Generator Owner and Transmission Owner shall have verified at least 80 percent of its applicable units.
- By the first day of the next calendar quarter, five calendar years following applicable regulatory approval each Generator Owner and Transmission Owner shall have verified 100 percent of its applicable units.

In those jurisdictions where regulatory approval is not required:

- By the first day of the next calendar quarter, one calendar year following Board of Trustees approval each Generator Owner and Transmission Owner shall have verified at least 20 percent of its applicable units.
- By the first day of the next calendar quarter, two calendar years following Board of Trustees approval each Generator Owner and Transmission Owner shall have verified at least 40 percent of its applicable units.
- By the first day of the next calendar quarter, three calendar years following Board of Trustees approval each Generator Owner and Transmission Owner shall have verified at least 60 percent of its applicable units.
- By the first day of the next calendar quarter, four calendar years following Board of Trustees approval each Generator Owner and Transmission Owner shall have verified at least 80 percent of its applicable units.
- By the first day of the next calendar quarter, five calendar years following Board of Trustees approval each Generator Owner and Transmission Owner shall have verified 100 percent of its applicable units.

The Implementation Plan phasing proposed is designed to allow large entities with dozens of units requiring verification an adequate amount of time to obtain resources and conduct testing to become fully compliant with standard requirements. The phase in period is set at five years with expectation at least 20 percent of an entities' applicable units will be verified annually with full compliance achieved by the end of the five year period. The 20 percent annual increment threshold was also selected to ensure that small entities with few units have incentive to become fully compliant in a timely manner and not delay verification of its applicable units until the fifth year of the phasing period.

Wind Farm Verification - If an entity has two wind sites, and verification of one site is complete, the entity is 50% complete regardless of the number of turbines at each site.

It is the intent of *ReliabilityFirst* to perform a review of both the MOD-024-RFC-01 and MOD-025-RFC-01 standards upon NERC Board of Trustees approval of the associated NERC MOD-025-2 standard. The purpose of the review would be to ensure that any duplicative requirements or any requirements which are less restrictive or do not add additional detail will be considered for retirement. The steps outlined in the *ReliabilityFirst* Reliability Standards Development Procedure will be followed for any such revisions or retirements.

Retirements

MOD-024-1 - Verification of Generator Gross and Net Real Power Capability and MOD-025-1 - Verification of Generator Gross and Net Reactive Power Capability should both be retired at midnight of the day immediately prior to the Effective Date of MOD-025-2 in the particular jurisdiction in which the new standard is becoming effective.

Retirements

MOD-024-1 - Verification of Generator Gross and Net Real Power Capability and MOD-025-1 - Verification of Generator Gross and Net Reactive Power Capability should both be retired at midnight of the day immediately prior to the Effective Date of MOD-025-2 in the particular jurisdiction in which the new standard is becoming effective.

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. SAR posted for comment (April 20–May 21, 2007).
2. Revised SAR and response to comments posted.
3. Revised SAR and response to comments approved by SC (June 14, 2007).
4. SDT appointed on (August 18, 2007).
5. Posted first draft of standard for a 30 day comment period June 15 –July 15, 2011

Proposed Action Plan and Description of Current Draft:

This is the second draft of the proposed standard including Time Horizons, Data Retention, Violation Risk Factors, and Violation Severity Levels; and is being submitted for a 45-day concurrent formal comment period and initial ballot.

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Develop responses to comments and develop second version draft standard.	July 2011 – February 2012
2. Post response to comments and conduct a formal 45 day comment period with concurrent initial ballot for the revised standard.	March - April 2012
3. Develop responses to ballot comments.	April - June 2012
4. Post response to comments and conduct successive ballot.	June - July 2012
5. Develop responses to ballot comments.	August - September 2012
6. Post responses to comments and conduct recirculation ballot.	October 2012
7. BOT adoption.	November 2012
8. File with regulatory authorities.	December 2012

A. Introduction

1. **Title:** Verification of Models and Data for Turbine/Governor and Load Control and Active Power/Frequency Control Functions
2. **Number:** MOD-027-1
3. **Purpose:** To verify that the turbine/governor and load control and active power/frequency control[1] model and the model parameters, used in dynamic simulations that assess Bulk Electric System (BES) reliability, that accurately represent generator unit real power response to system frequency variations.
4. **Applicability:**

4.1. Functional entities

4.1.1 Generator Owner

4.1.2 Transmission Planner

4.2. Facilities

For the purpose of this standard, the term “applicable Facility” is considered, “applicable units[2].” Units or plants with an average capacity[3] factor greater than 5 percent over the last three calendar years, beginning on January 1 and ending on December 31, that meet the following:

4.2.1 Generating units connected to the Eastern or Quebec Interconnections with the following characteristics:

- Individual generating unit greater than 100 MVA (gross nameplate rating) directly connected to the bulk power system.
- For each generating plant or generating Facility consisting of one or more units that are connected to the bulk power system at a common bus with total generation greater than 100 MVA (gross aggregate rating):
    - o Each individual generating unit greater than 20 MVA (gross nameplate rating); and
    - o Each generating plant or generating Facility consisting of individual generating units less than 20 MVA (gross nameplate ratings)

---

[1] Turbine/governor and load control and active power/frequency control:

a. Turbine/governor and load control applies to conventional synchronous generation.

b. Active power/frequency control applies to variable energy plants.

2 Applicable generating units do not include startup or standby units not normally connected to the grid.

3 Once a capacity factor exemption is declared by notifying the Transmission Planner, verification is not required for 10 calendar years from the date eligibility occurs. At the end of this 10 calendar year timeframe, the current average 3 year capacity factor (for years 8, 9, and 10) is examined to determine if the capacity factor exemption can be declared for the next 10 calendar year period. If not eligible for the capacity factor exemption, then model verification must be completed within one year of the date the capacity factor exemption expired with the 10 calendar year periodicity requirement reset based on the verification date. For the definition of capacity factor, refer to Appendix F of the GADS Data Reporting Instructions on the NERC website.

4.2.2 Generating units connected to the Western Interconnection with the following characteristics:

- Individual generating unit greater than 75 MVA (gross nameplate rating) directly connected to the bulk power system.
- For each generating plant or generating Facility consisting of one or more units that are connected to the bulk power system at a common bus with total generation greater than 75 MVA (gross aggregate rating):
    - Each individual generating unit greater than 20 MVA (gross nameplate rating); and
    - Each generating plant or generating Facility comprised consisting of individual generating units less than 20 MVA (gross nameplate ratings)

4.2.3 Generating units connected to the ERCOT Interconnection with the following characteristics:

- Individual generating unit greater than 50 MVA (gross nameplate rating) directly connected to the bulk power system.
- For each generating plant or generating Facility consisting of one or more units that are connected to the bulk power system at a common bus with total generation greater than 75 MVA (gross aggregate rating):
    - Each individual generating unit greater than 20 MVA (gross nameplate rating); and
    - Each generating plant or generating Facility comprised of individual generating units less than 20 MVA (gross nameplate ratings)

5. Effective Date:

5.1. In those jurisdictions where regulatory approval is required:

5.1.1 Each responsible entity shall ensure compliance with Requirements R1, and R3 through R5 by the first day of the first calendar quarter, three years following applicable regulatory approval.

5.1.2 Each Generator Owner shall ensure at least 25 percent of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2 by the first day of the first calendar quarter, three years following applicable regulatory approval.

5.1.3 Each Generator Owner shall ensure at least 50 percent of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2 by the first day of the first calendar quarter, five years following applicable regulatory approval.

5.1.4 Each Generator Owner shall ensure at least 75 percent of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2 by the first day of the first calendar quarter, seven years following applicable regulatory approval.

5.1.5 Each Generator Owner shall ensure at least 100 percent of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2 by the first day of the first calendar quarter, nine years following applicable regulatory approval.

5.2. In those jurisdictions where no regulatory approval is required:

5.2.1 Each responsible entity shall ensure compliance with Requirements R1, and R3 through R5 by the first day of the first calendar quarter, three years following Board of Trustees adoption.

5.2.2 Each Generator Owner shall ensure at least 25 percent of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2 by the first day of the first calendar quarter, three years following Board of Trustees adoption.

5.2.3 Each Generator Owner shall ensure at least 50 percent of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2 by the first day of the first calendar quarter, five years following Board of Trustees adoption.

5.2.4 Each Generator Owner shall ensure at least 75 percent of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2 by the first day of the first calendar quarter, seven years following Board of Trustees adoption.

5.2.5 Each Generator Owner shall ensure at least 100 percent of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2 by the first day of the first calendar quarter, nine years following Board of Trustees adoption.

B. Requirements

R1. Each Transmission Planner shall provide the following instructions and model data to its requesting Generator Owner within 90 calendar days of receiving a request for those instructions or model data: *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*

- Instructions on how to obtain the list of acceptable turbine/governor and load control and active power/frequency control system models for use in dynamic simulation.
- Instructions on how to obtain the Transmission Planner’s software manufacturer’s dynamic turbine/governor and load control and active power/frequency control system model library block diagrams and/or data sheets.

- Model data for any of the Generator Owner's existing unit or plant specific turbine/governor and load control and active power/frequency control system contained in the Transmission Planner's dynamic database from the current (in-use) model(s).

R2. Each Generator Owner shall provide, for each of its applicable units, a verified turbine/governor and load control and active power/frequency control model including documentation and data as specified in Parts 2.1 and 2.2, to its Transmission Planner (within 365 calendar days from the date that the response was recorded) in accordance with the periodicity specified in MOD-027 Attachment 1, to ensure modeling data is accurate for use in simulation software. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

2.1. Perform verification using one or more models acceptable to the Transmission Planner that include(s) the following information:

2.1.1. Documentation comparing the applicable unit's model response to the recorded response for either a frequency excursion from a system disturbance that meets Attachment 1 Criteria 1 with the unit on-line, a speed governor reference change with the unit on-line, or from a partial load rejection test[4].

2.1.2. Type of governor and load control and active power control/frequency control equipment.

2.1.3. A description of the turbine (e.g. for Hydro turbine - Kaplan, Francis, or Pelton; for steam turbine - boiler type, normal fuel type, and turbine type; for gas turbine - the type and manufacturer; for variable energy plant - type and manufacturer).

2.1.4. Model structure and data for turbine/governor and load control and active power/frequency control.

2.1.5. Representation of the real power response effects of outer loop controls (such as operator set point controls, and load control but excluding AGC control) that would override the governor response (including blocked or nonfunctioning governors or modes of operation that limit Frequency Response), if applicable.

2.2. For plants that are comprised of units that have a gross nameplate rating of less than 20 MVA, perform verification using plant aggregate model(s) that include the information required by Requirement sub-parts 2.1.1 through 2.1.5

R3. Each Generator Owner shall provide a written response to its Transmission Planner within 90 calendar days of receiving one of the following items for an applicable unit.

[4] Differences between the control mode tested and the final simulation model must be identified, particularly when analyzing load rejection data. Most controls change gains or have a set point runback which takes effect when the breaker opens. Load or set point controls will also not be in effect once the breaker opens. Some method of accounting for these differences must be presented if the final model is not validated from on load data under the normal operating conditions under which the model is expected to apply

The written response shall contain either the technical basis for maintaining the current model, or the model changes, or a plan to perform model verification[5] (in accordance with Requirement R2): *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*

- Written notification, from its Transmission Planner (in accordance with Requirement R5) that the turbine/governor and load control and active power/frequency control model is not “usable”, or
- Written comments from its Transmission Planner identifying technical concerns with the verification documentation related to the turbine/governor and load control and active power/frequency control model, or
- Written comments and supporting evidence from its Transmission Planner indicating that the predicted turbine/governor and load control and active power/frequency control response did not approximate the recorded response for three or more transmission system events.

R4. Each Generator Owner shall provide revised model data or plans to perform model verification[5] (in accordance with Requirement R2) for an applicable unit to its Transmission Planner within 180 calendar days of making changes to the turbine/governor and load control and active power/frequency control system that alter the equipment response characteristic[6]. *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*

R5. Each Transmission Planner shall notify the Generator Owner within 90 calendar days of receiving the turbine/governor and load control and active power/frequency control system verified model information whether the model is useable (meets the criteria specified in Parts 5.1 through 5.3) or is not usable; and shall include a technical description if the model is not useable. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

5.1. The turbine/governor and load control and active power/frequency control function model initializes to compute modeling data without error.

5.2. A no-disturbance simulation results in negligible transients.

5.3. For an otherwise stable simulation, a disturbance simulation results in the turbine/governor and load control and active power/frequency control model exhibiting positive damping.

C. Measures

M1. Evidence for Requirement R1 must include the transmitted instructions or data and dated evidence of transmission of requested instructions and data, such as dated

[5] If verification is performed, the 10 year period as outlined in Attachment 1 is reset.

[6] Control replacement or alteration including software alterations or plant digital control system addition or replacement, plant digital control system software alterations that alter droop, and/or dead band, and/or frequency response and/or a change in the frequency control mode (such as going from droop control to constant MW control, etc).

electronic mail messages, dated postal receipts, dated confirmation of facsimile transmission.

M2. Evidence for Requirement R2 must include, for each of the Generator Owner's applicable Facilities, the verification report showing that the turbine/governor and load control and active power/frequency control model was verified and dated evidence of transmission, ,such as a dated electronic mail messages, dated postal receipts, or dated confirmation of facsimile transmission as specified in Requirement R2.

M3. Evidence for Requirement R3 must include the Generator Owner's dated written response containing the information identified in Requirement R3 and dated evidence of transmittal, such as a dated electronic mail messages, dated postal receipts, or dated confirmation of facsimile transmission.

M4. Evidence for Requirement R4 must include, for each of the Generator Owner's Facilities for which system changes specified in Requirement R4 were made, dated revised model data or dated plans to perform a model verification and dated evidence of transmittal, such as dated electronic mail messages, dated postal receipts, or dated confirmation of facsimile transmittal.

M5. Evidence of Requirement R5 must include, for each model received, the dated response containing the information required in Parts 5.1 through 5.3 and dated evidence of transmittal, such as dated electronic mail messages, dated postal receipts, or dated confirmation of facsimile transmittal.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

Regional Entity

1.2. Data Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Generator Owner and Transmission Planner shall each keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

- The Transmission Planner shall retain the information/data request and provided response evidence of Requirements R1 and R5, Measures M1 and M5 for 3 calendar years from the date the document was provided.
- The Generator Owner shall retain the latest and previous turbine/governor and load control and active power/frequency control system model verification evidence of Requirement R2, Measure M2.

- The Generator Owner shall retain the information/data request and provided response evidence of Requirements R3, and R4 Measures M3 and M4 for 3 calendar years from the date the document was provided.

If a Generator Owner or Transmission Planner is found non-compliant, it shall keep information related to the non-compliance until mitigation is complete and approved or for the time specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes

Compliance Audit

Self-Certification

Spot Checking

Compliance Investigation

Self-Reporting

Complaint

1.4. Additional Compliance Information

None

2. Violation Severity Levels

R #	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The Transmission Planner provided the instructions and data to the Generator Owner more than 90 calendar days but less than or equal to 120 calendar days of receiving a request.	The Transmission Planner provided the instructions and data to the Generator Owner more than 120 calendar days but less than or equal to 150 calendar days of receiving a request.	The Transmission Planner provided the instructions and data to the Generator Owner more than 150 calendar days but less than or equal to 180 calendar days of receiving a request.	The Transmission Planner failed to provide the instructions and data to the Generator Owner within 181 calendar days of receiving a request.
R2	The Generator Owner provided its verified model(s) to its Transmission Planner after the periodicity timeframe specified in MOD-027 Attachment 1 but less than or equal to 30 calendar days late; OR The Generator Owner provided the Transmission Planner a verified model that omitted one of the five Parts identified in Requirement R2, Subparts 2.1.1, through 2.1.5.	The Generator Owner provided its verified model(s) to its Transmission Planner more than 30 calendar days but less than or equal to 60 calendar days late as specified by the periodicity timeframe in MOD-027 Attachment 1. OR The Generator Owner provided the Transmission Planner a verified model that omitted two of the five Parts identified in Requirement R2, Subparts 2.1.1, through 2.1.5.	The Generator Owner provided its verified model(s) to its Transmission Planner more than 60 calendar days but less than or equal to 90 calendar days late as specified by the periodicity timeframe in MOD-027 Attachment 1. OR The Generator Owner provided the Transmission Planner verified models that omitted three of the five Parts identified in Requirement R2, Subparts 2.1.1, through 2.1.5.	The Generator Owner provided its verified turbine/governor and load control and active power/frequency control model(s) more than 90 calendar days late or failed to provide the verified model(s) to its Transmission Planner in accordance with the periodicity specified in MOD-027 Attachment 1. OR The Generator Owner failed to use model(s) acceptable to the Transmission Planner as specified in Requirement R2, Subpart 2.1. OR The Generator Owner provided the Transmission Planner verified model(s) that omitted four or more of the five Parts identified in Requirement R2, Subparts 2.1.1, through 2.1.5.

R3	The Generator Owner provided a written response more than 90 calendar days but less than or equal to 120 calendar days of receiving written notice. (R3)	The Generator Owner provided a written response more than 120 calendar days but less than or equal to 150 calendar days of receiving written notice. (R3)	The Generator Owner provided a written response more than 150 calendar days but less than or equal to 180 calendar days of receiving written notice. (R3)	The Generator Owner failed to provide a written response within 181 calendar days of receiving notice as specified in Requirement R3. OR The Generator Owner’s written response was provided within 181 calendar days of receiving written notice. However the Generator Owner's written response failed to contain either the technical basis for maintaining the current model, or a list of future model changes, or a plan to perform another model verification.
R4	The Generator Owner provided revised model data or plans to perform model verification more than 180 calendar days but less than or equal to 210 calendar days of making changes to the turbine/governor and load control and active power/frequency control system that alter the equipment response characteristic. (R4)	The Generator Owner provided revised model data or plans to perform model verification more than 210 calendar days but less than or equal to 240 calendar days of making changes to the turbine/governor and load control and active power/frequency control system that alter the equipment response characteristic. (R4)	The Generator Owner provided revised model data or plans to perform model verification more than 240 calendar days but less than or equal to 270 calendar days of making changes to the turbine/governor and load control and active power/frequency control system that alter the equipment response characteristic. (R4)	The Generator Owner failed to provide revised model data or failed to provide plans to perform model verification within 271 calendar days of making changes to the turbine/governor and load control and active power/frequency control system that altered the equipment response characteristic as specified in Requirement R3.
R5	The Transmission Planner provided a written response to the Generator Owner indicating whether the model is useable or not useable (including a technical description if the model is not useable) more than 90 calendar days but less than 120 calendar days of receiving verified model information. (R5)	The Transmission Planner provided a written response to the Generator Owner indicating whether the model is useable or not useable (including a technical description if the model is not useable), more than 120 calendar days but less than 150 calendar days of receiving the verified model information. (R5)	The Transmission Planner provided a written response to the Generator Owner indicating whether the model is useable or not useable (including a technical description if the model is not useable) more than 150 calendar days but less than 180 calendar days of receiving the verified model information. (R5)	The Transmission Planner failed to provide a written response to the Generator Owner within 181 calendar days of receiving the verified model information as specified in Requirement R5. OR The Transmission Planner provided a written response without including

		OR The Transmission Planner provided a written response within 181 calendar days to the Generator Owner however the written response omitted confirmation for one of the specified model criteria listed in Requirement R5, Parts 5.1 through 5.3.	OR The Transmission Planner provided a written response within 181 calendar days to the Generator Owner however the written response omitted confirmation for two of the specified model criteria listed in Requirement R5, Parts 5.1 through 5.3.	confirmation of all specified model criteria listed in Requirement R5, Parts 5.1 through 5.3

E. Regional Variances

None.

MOD-027 Attachment 1

Turbine/Governor and Load Control and Active Power/Frequency Control Model Periodicity

Periodicity Determination Supporting Criteria
Criteria 1: Unit Model Verification Frequency Excursion Criteria: • ≥ 0.05 hertz deviation from scheduled frequency for the Eastern Interconnection with the applicable unit operating in a frequency responsive mode • ≥ 0.10 hertz deviation from scheduled frequency for the ERCOT and Western Interconnections with the applicable unit operating in a frequency responsive mode • ≥ 0.15 hertz deviation from scheduled frequency for the Quebec Interconnection with the applicable unit operating in a frequency responsive mode **Criteria 2: Establishing the Initial Ten Year Unit Verification Period Start Date:** **For each applicable unit, the initial start date is set to either of the 25 percent, 50 percent, 75 percent, or 100 percent Standard Implementation Effective Dates established for compliance in accordance with the nine calendar year transition period.** **Criteria 3: Establishing the Recurring Ten Year Unit Verification Period Start Date:** **The start date is the actual data collection date for the most recently performed applicable unit verification.** **Criteria 4: For the purpose of calculating the initial ten year unit verification period 25 percent, 50 percent, 75 percent or 100 percent threshold for generation fleet compliance, equivalent unit MVA is included (reference 4th row in the following table).** **Consideration for Early Compliance** **Existing turbine/governor and load control and active power/frequency control model verification is sufficient for demonstrating compliance for a ten year period from the actual verification date if either of the following applies:** • **The Generator Owner has a verified model that is compliant with the applicable regional policies, guidelines or criteria existing at the time of model verification.** • **The Generator Owner has an existing verified model that is compliant with the requirements of this standard.**

Event Triggering Verification	Verification Periodicity	Comments
Establishing the initial verification period (Criteria 2) for an applicable unit (Requirement R2)	Record unit Real Power response to the first frequency excursion event that meets Criteria 1 on or after the Standard Implementation Effective Date. OR Record unit Real Power response for an on-line speed governor reference change test or a partial load rejection test before or on the Standard Implementation Effective Date	Transmit the verified model and documentation and data to the Transmission Planner no more than 365 calendar days from the date that the response was recorded. Criteria 4 applies when calculating generation fleet compliance during the 9-year transition period
Subsequent verification for an existing applicable unit	Record unit Real Power response for a frequency excursion event that meets Criteria 1 within one year of the applicable unit's ten year anniversary date of the collection of the recorded unit Real Power response used for the current validation. OR Record unit Real Power response for an on-line speed governor reference change test or a partial load rejection test on or before the applicable unit's ten year anniversary date of the collection of the recorded unit Real Power response used for the current validation.	Transmit the verified model and documentation and data to the Transmission Planner no more than 365 calendar days from the date that the response was recorded.
Initial verification for a new applicable unit or for an existing applicable unit with new turbine/governor and load control or active power/frequency control equipment installed with settings final	Record unit Real Power response to the first frequency excursion event that meets Criteria 1	Transmit the verified model and documentation and data to the Transmission Planner no more than 365 calendar days from the date that

Event Triggering Verification	Verification Periodicity	Comments
(Requirement R2)	OR Record unit Real Power response for an on-line speed governor reference change test or a partial load rejection test no more than 365 calendar days from the commissioning date	the response was recorded.
Existing applicable unit that is equivalent to another operating unit(s) at the same physical location AND Each equivalent applicable unit has the same MVA nameplate rating. AND The nameplate rating is ≤ 350 MVA. AND Each equivalent applicable unit has identical applicable components and settings. AND The model for one of these equivalent applicable units has been verified. (Requirement R2)	Verify a different equivalent unit during each ten year verification period.	Document circumstance with a written statement and include with the verified model and documentation and data provided to the Transmission Provider for the verified equivalent unit. Criteria 4 applies when calculating generation fleet compliance during the 9-year transition period.
Existing applicable unit does not experience an acceptable frequency excursion event during the ten year unit verification period AND Neither an on-line speed governor reference test nor a partial load rejection test was performed. (Requirement R2)	Record unit Real Power response to the first frequency excursion event that meets Criteria 1after the ten year verification period	Document circumstance with a written statement. Transmit the verified model and documentation and data to the Transmission Planner no more than 365 calendar days from the date that the response was recorded.

Event Triggering Verification	Verification Periodicity	Comments
Existing applicable unit control system response is altered resulting in an alteration of the response of the turbine/governor and load control or active power/frequency control model AND The Generator Owner has submitted a verification plan. (Requirement R4)	Record unit Real Power response to the first frequency excursion event that meets Criteria 1. OR Record unit Real Power response for an on-line speed governor reference change test or a partial load rejection test no more than 365 calendar days from the date of the submitted verification plan.	Transmit the verified model and documentation and data to the Transmission Planner no more than 365 calendar days from the date that the response was recorded.
The Generator Owner receives written comments including dated electronic or hard copy evidence indicating that the recorded turbine/governor and load control or active power/frequency control response for three or more transmission system events did not match the predicted control system model response. AND The Generator Owner has submitted a verification plan. (Requirement R3)	Record unit Real Power response to the first frequency excursion event that meets Criteria 1. OR Record unit Real Power response for an on-line speed governor reference change test or a partial load rejection test no more than 365 calendar days from the date of the submitted verification plan	Transmit the verified model and documentation and data to the Transmission Planner no more than 365 calendar days from the date that the unit Real Power response was provided as part of the dated evidence.
The Generator Owner receives written comments detailing technical concerns with the Generator Owner's turbine/governor and load control and active power/frequency control model verification documentation. AND The Generator Owner has submitted a verification plan (Requirement R3)	Record unit Real Power response to the first frequency excursion event that meets Criteria 1. OR Record unit Real Power response for an on-line speed governor reference change test or a partial load rejection test no more than 365 calendar days from the date of the submitted verification plan	Transmit the verified model and documentation and data to the Transmission Planner no more than 365 calendar days from the date that the response was recorded.

Event Triggering Verification	Verification Periodicity	Comments
The Turbine/governor and load control and active power/frequency control model identified as unusable by the Transmission Planner. AND The Generator Owner has submitted a verification plan. (Requirement R3)	Record unit Real Power response to the first frequency excursion event that meets Criteria 1. OR Record unit Real Power response for an on-line speed governor reference change test or a partial load rejection test no more than 365 calendar days from the date that of the submitted verification plan	Transmit the verified model and documentation and data to the Transmission Planner no more than 365 calendar days from the date that the response was recorded.
New or existing applicable unit is not responsive to a frequency excursion event (The unit does not operate in a control mode, except during normal start up and shut down, that would result in a turbine/governor and load control or active power/frequency control mode response.) OR New or existing applicable unit has a disabled control system	Not required until responsive control mode operation for connected operations is established.	Document circumstance with a written statement. Perform verification per the periodicity specified in Row 3 for a “New Generating Unit” (or new equipment) once responsive control mode operation for connected operations is established.
New or existing applicable unit does not have an installed control system	Not required until unit has an installed control system	Document circumstance with a written statement. Perform verification per the periodicity specified in Row 3 for a “New Generating Unit” (or new equipment) once responsive control mode operation for connected operations is established.

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps ~~-~~Completed:

1. SAR posted for comment (April 20–May 21, 2007).
2. Revised SAR and response to comments posted.
3. Revised SAR and response to comments approved by SC (June 14, 2007).
4. SDT appointed on (August 18, 2007).
5. Posted first draft of standard for a 30 day comment period June 15 –July 15, 2011

Proposed Action Plan and Description of Current Draft:

This is the ~~first~~second draft of the ~~this~~proposed standard including Time Horizons, Data Retention, Violation Risk Factors, and Violation Severity Levels~~. This first posting~~; and is being submitted for a ~~30~~45-day concurrent formal comment period~~.~~ and initial ballot.

Future Development Plan:

Anticipated Actions	Anticipated Date
1. ~~Post first~~Develop responses to comments and develop second version draft ~~revision of~~ standard.	~~April-May~~July 2011 – February 2012
2. Post response to comments and ~~second version draft revision of~~conduct a formal 45 day comment period with concurrent initial ballot for the revised standard.	~~July – August 2011~~March - April 2012
3. ~~Post response to comments and request authorization~~Develop responses to ballot ~~the revised standard~~comments.	~~September - October 2011~~April - June 2012
4. ~~Conduct initial~~Post response to comments and conduct successive ballot.	~~November 2011~~June - July 2012
5. ~~Post response~~Develop responses to ballot comments.	~~December 2011~~August - September 2012
6. ~~Conduct~~Post responses to comments and conduct recirculation ballot.	~~January~~October 2012
7. BOT adoption.	~~February~~November 2012

8. File with regulatory authorities.	~~March~~December 2012

A. Introduction

1. Title: Verification of Models and Data for Turbine/Governor and Load Control ~~or~~and Active Power/Frequency Control ~~-~~Functions

2. Number: MOD-027-1

3. Purpose: To verify that the turbine/governor and ~~Load~~load control ~~or~~and active power/frequency control[1] model and the model parameters, used in dynamic ~~simulation~~simulations that assess Bulk Electric System (BES) reliability, that accurately represent generator unit real power response to system frequency variations.

4. Applicability:

4.1. Functional entities

4.1.1 Generator Owner

4.1.2 Transmission Planner

4.2. Facilities

For the purpose of this standard, the ~~following Facilities are~~term "applicable Facility" is considered, "applicable units[2]." Units or plants with an average capacity[3] factor greater than 5~~%~~ percent over the last three calendar years, beginning on January 1 and ending on December 31, that meet the following:

4.2.1 Generating units connected to the Eastern or Quebec Interconnections with the following characteristics:

- ~~Each~~Individual generating unit ~~with a~~ greater than 100 MVA (gross nameplate rating ~~greater than 100 MVA,~~) directly connected ~~at~~to the ~~point of interconnection[4] at greater than 100 kV~~bulk power system.
- For each generating plant or generating Facility consisting of one or more units that are connected to the bulk power system at a common bus with ~~a~~ total generation greater than 100 MVA (gross aggregate ~~nameplate~~ rating ~~greater than 100 MVA, connected at the same point of interconnection at greater than 100 kV:~~):

[1] Turbine/governor and ~~Load~~load control ~~or~~and active power/frequency control:

a. Turbine/governor and ~~Load~~load control applies to conventional synchronous generation.

b. Active power/frequency control applies to variable energy plants.

2 Applicable generating units do not include startup or standby units not normally connected to the grid.

[~~3~~]3 Once a capacity factor exemption is declared by notifying the Transmission Planner, verification is not required for 10 calendar years from the date eligibility occurs. At the end of this 10 calendar year timeframe, the current average 3 year capacity factor (for years 8, 9, and 10) is examined to determine if the capacity factor exemption can be declared for the next 10 calendar year period. If not eligible for the capacity factor exemption, then model verification must be completed within one year of the date the capacity factor exemption expired with the 10 calendar year periodicity requirement reset based on the verification date. For the definition of capacity factor, refer to Appendix F of the GADS Data Reporting Instructions on the NERC website.

[4] ~~The common transmission bus voltage level at which the generator step up transformer is connected.~~

- o Each individual generating unit ~~with a~~ greater than 20 MVA (gross nameplate rating ~~greater than 20 MVA;~~); and
- ~~o The remainder of the plant as an aggregate.~~
- o Each generating plant or generating Facility consisting of individual generating units less than 20 MVA (gross nameplate ratings)

4.2.2 Generating units connected to the Western Interconnection with the following characteristics:

- ~~Each~~Individual generating unit ~~with a~~ greater than 75 MVA (gross nameplate rating ~~greater than 75 MVA,~~) directly connected ~~at~~to the ~~point of interconnection[3] at greater than 100 kV~~bulk power system.
- For each generating plant or generating Facility consisting of one or more units that are connected to the bulk power system at a common bus with ~~a~~ total generation greater than 75 MVA (gross aggregate ~~nameplate~~ rating ~~greater than 75 MVA, connected at the same point of interconnection t greater than 100 kV:~~):
  - o -Each individual generating unit ~~with a gross nameplate~~ greater than 20 MVA~~;~~ (gross nameplate rating); and
  - ~~o The remainder of the plant as an aggregate.~~
  - o Each generating plant or generating Facility comprised consisting of individual generating units less than 20 MVA (gross nameplate ratings)

4.2.3 Generating units connected to the ERCOT Interconnection with the following characteristics:

- ~~Each~~Individual generating unit ~~with a~~ greater than 50 MVA (gross nameplate rating ~~of greater than 50 MVA,~~) directly connected ~~at~~to the ~~point of interconnection[3] with rating greater than 100 kV~~bulk power system.
- For each generating plant or generating Facility consisting of one or more units that are connected to the bulk power system at a common bus with ~~a~~ total generation greater than 75 MVA (gross aggregate ~~nameplate~~ rating ~~of greater than 75 MVA, connected at the same point of interconnection at greater than 100 kV:~~):
  - o Each individual generating unit ~~with a gross nameplate~~ greater than 20 MVA~~;~~ (gross nameplate rating); and
  - ~~o The remainder of the plant as an aggregate.~~
  - o Each generating plant or generating Facility comprised of individual generating units less than 20 MVA (gross nameplate ratings)

5. Effective Date:

5.1. In those jurisdictions where regulatory approval is required:

5.1.1 ~~By~~Each responsible entity shall ensure compliance with Requirements R1, and R3 through R5 by the first day of the first calendar quarter, three years following applicable regulatory approval~~:~~.

- **5.1.2** ~~At~~Each Generator Owner shall ensure at least 25~~%~~ percent of ~~each Generator Owner's~~its applicable units per Interconnection on an MVA basis are compliant with Requirement R2 by the first day of the first calendar quarter, three years following applicable regulatory approval.

  - ~~100% compliant with Requirements R1, and R3 through R5.~~

~~5.1.2~~**5.1.3** ~~By~~Each Generator Owner shall ensure at least 50 percent of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2 by the first day of the first calendar quarter, five years following applicable regulatory approval~~:~~.

- ~~At least 50% of each~~Each Generator ~~Owner's~~Owner shall ensure at least 75 percent of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2~~.~~

~~5.1.3~~**5.1.4** ~~By~~ by the first day of the first calendar quarter, seven years following applicable regulatory approval~~:~~.

- ~~At least 75% of each~~Each Generator ~~Owner's~~Owner shall ensure at least 100 percent of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2~~.~~

~~5.1.4~~ ~~By~~ by the first day of the first calendar quarter, nine years following applicable regulatory approval~~:~~

- **5.1.5** ~~100% of each Generator Owner's applicable units compliant with Requirement R2~~.

5.2. In those jurisdictions where no regulatory approval is required:

5.2.1 ~~By~~Each responsible entity shall ensure compliance with Requirements R1, and R3 through R5 by the first day of the first calendar quarter, three years following Board of Trustees adoption~~:~~.

- **5.2.2** ~~At~~Each Generator Owner shall ensure at least 25~~%~~ percent of ~~each Generator Owner's~~its applicable units per Interconnection on an MVA basis are compliant with Requirement R2 by the first day of the first calendar quarter, three years following Board of Trustees adoption.

  - ~~100% compliant with Requirements R1, and R3 through R5.~~

~~5.2.2~~**5.2.3** ~~By~~Each Generator Owner shall ensure at least 50 percent of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2 by the first day of the first calendar quarter, five years following Board of Trustees adoption~~:~~.

- ~~At least 50% of each~~Each Generator ~~Owner's~~Owner shall ensure at least 75 percent of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2~~.~~

~~5.2.3~~5.2.4 ~~By~~ by the first day of the first calendar quarter, seven years following Board of Trustees adoption~~:~~.

- ~~At least 75% of each~~Each Generator ~~Owner's~~Owner shall ensure at least 100 percent of its applicable units per Interconnection on an MVA basis are compliant with Requirement R2~~.~~

~~5.2.4~~5.2.5 ~~By~~ by the first day of the first calendar quarter, nine years following Board of Trustees adoption~~:~~.

- ~~100% of each Generator Owner's applicable units compliant with Requirement R2.~~

B. Requirements

R1. Each Transmission Planner shall provide ~~its Generator Owner with~~ the following instructions and model data to its requesting Generator Owner within ~~30~~90 calendar days of receiving a request ~~from its Generator Owner~~ for those instructions ~~and~~or model data: *[Violation Risk Factor: Lower] [Time Horizon: ~~Long-term~~Operations Planning]*

- Instructions on how to obtain the list of acceptable turbine/governor and ~~Load~~load control ~~or~~and active power/frequency control[1] system models for use in dynamic simulation.
- Instructions on how to obtain the Transmission Planner's software manufacturer's dynamic turbine/governor and ~~Load~~load control ~~or~~and active power/frequency control[1] system model library block diagrams and/or data sheets.
- ~~Any~~Model data for any of the Generator Owner's existing unit or plant specific turbine/governor and ~~Load~~load control ~~or~~and active power/frequency control[1] system ~~data~~ contained in the Transmission Planner's dynamic database from the current (in-use) model(s).

R2. Each Generator Owner shall provide, for each of its applicable units, a verified turbine/governor and ~~Load~~load control ~~or~~and active power/frequency control[1] model ~~(for each of its applicable Facilities)~~including documentation and data as specified in Parts 2.1 and 2.2, to its Transmission Planner (within 365 calendar days from the date that the response was recorded) in accordance with the periodicity specified in MOD-027 Attachment 1, to ensure modeling data is accurate for use in simulation software ~~subject to the following:~~. *[Violation Risk Factor: ~~Lower~~Medium] [Time Horizon: Long-term Planning]*

2.1. ~~Each Generator Owner shall perform its verifications with~~ Perform verification using one or more models acceptable to ~~its~~the Transmission Planner that ~~collectively~~ include(s) the following information:

2.1.1. Documentation ~~from the turbine/governor and Load control or active power/frequency control[1]~~comparing the applicable unit's model ~~verification activities including the on-line~~ response ~~compared~~ to the recorded response for either a frequency excursion from a system disturbance~~, or~~ that meets Attachment 1 Criteria 1 with the unit on-line, a ~~frequency~~ speed governor reference change~~.~~ with the unit on-line, or from a partial load rejection test[5].

2.1.2. Type of governor and ~~Load~~load control ~~or~~and active power control/frequency control equipment.

2.1.3. A description of the turbine (e.g. for Hydro turbine - Kaplan, Francis, or Pelton; for steam turbine - boiler type, normal fuel type, and turbine type; for gas turbine - the type and manufacturer; for variable energy plant - type and manufacturer).

2.1.4. ~~Turbine~~Model structure and data for turbine/governor and ~~Load~~load control ~~or~~and active power/frequency control~~[1] model structure and data~~.

2.1.5. Representation of the real power response effects of outer loop controls (such as operator set point controls, ~~Load~~and load control~~, etc.~~ but excluding AGC control) ~~which~~that would override the governor response (including blocked or nonfunctioning governors or modes of operation that limit Frequency Response), if applicable.

2.2. For plants that are comprised of units that have a gross nameplate rating of less than 20 MVA, perform verification using plant aggregate model(s) that include the information required by Requirement sub-parts 2.1.1 through 2.1.5
