Response: The NERC Functional Model Technical Document identifies the BA as the entity that manages and deploys Frequency Response. This is because a BA controls the amount and distribution of spinning reserves and also has some control over interruptible resources. This is similar to the relationship between the TOP and voltage control. Even though the TOP may not own generators or capacitor banks, the TOP is still responsible for controlling voltage within limits.

The industry-approved Standards Authorization Request (SAR) for BAL-003 did not include a performance obligation for generators. The drafting team is obliged to stay within the bounds of its SAR.

There are two primary reasons the SAR did not apply a performance obligation on generators. First, there are thousands of generators in North America. It would be many times more costly and difficult to implement a standard that measures all generators and verifies performance is properly calculated. Secondly, given the fact that there presently is sufficient frequency response in all Interconnections, the value of implementing a performance obligation on generators at this time would not outweigh the effort and cost.

Again, the drafting team cannot include requirements beyond the bounds of its SAR. If the commenter(s) believes there is a

| Organization | Yes or No | Question 10 Comment |
| :--- | :--- | :--- |

need for a generator performance obligation, they are encouraged to submit a SAR to that effect.
Attachments that are referenced within a Requirement are mandatory and enforceable.
The SDT has been instructed to include a "reliability outcome" within the requirements. The SDT will forward your concerns about the wording to the Standards Committee Quality Review group for consideration.

| Avista Corp. | Negative | This standard should be designed for each interconnection explicitly rather than one <br> size fits all. Frequency is an interconnection issue and response is driven by the <br> interconnection's topology. One size does not fit all for interconnections. This |
| :--- | :--- | :--- |

| Organization | Yes or No | Question 10 Comment |
| :--- | :--- | :--- |
|  |  | standard should be designed around the explicit needs of each interconnection. <br> Reducing frequency bias obligation is detrimental to reliability. It seems that <br> Lowering the Minimum Frequency Bias Setting from 1\% to .8\% will result in a lower <br> response, which in turn will lower the natural frequency response. Over time it <br> seems this pattern would lead to poorer response. |

Response: The SDT believes that an Interconnection has the capability to request a variance (especially one that is more restrictive), however the SDT has tried to prevent the need for variances by respecting the individuality of each of the Interconnections in setting Interconnection Frequency Excursion Threshold Values, Interconnection Frequency Response Obligations and the Frequency Bias Setting Minimums as noted in Attachment A.
Early research by Nathan Cohn ${ }^{5}$ on interconnected power system operations found that control is optimum if a BA's Bias Setting is equal to its natural Frequency Response. If there were to be a difference between the two values, it is preferable to be slightly over-biased.

The drafting team has proposed to bring Bias Setting and natural Frequency Response more in line. The process to do this is outlined in a Procedure developed by the SDT which replaces Attachment B. The Procedure manages a "go slow" approach to making this happen and includes checks to confirm there are not unexpected influences injected into the CPS-related calculations. Based on concerns raised by the industry, the drafting team has modified the Procedure to make the initial minimum Bias Setting $0.9 \%$ of peak and has included a provision that the ERO will evaluate the impact caused by a change in minimum Bias Setting. The evaluation will look at both frequency performance and impact on CPS-related compliance calculations.

| Beaches Energy Services; City <br> of Bartow, Florida; Tampa <br> Electric Co. | Negative | We thank the SDT for their hard work and diligence in moving this Project forward. <br> However, I have some concerns that cause me to not support the standard in its <br> current form. In general, I believe that there has not been sufficient prudency review <br> for the standard, especially R1, to justify a performance based standard around a <br> Frequency Response Measure. <br> I also believe that the proposed standard does not meet the intent of the Final SAR |
| :--- | :--- | :--- |

[^63]| Organization | Yes or No | Question 10 Comment |
| :---: | :---: | :---: |
|  |  | or Supplemental SAR. The "Final SAR" was to develop methods by which a performance based standard would eventually be developed. The Final SAR states: "The proposed standard's intent is to collect data needed to accurately model existing Frequency Response. There is evidence of continuing decline in Frequency Response in the three Interconnections over the past 10 years, but no confirmed reason for the apparent decline. The proposed standard requires entities to provide data so that Frequency Response in each of the Interconnections can be modeled, and the reasons for the decline in Frequency Response can be identified. Once the reasons for the decline in Frequency Response are confirmed, requirements can be written to control Frequency Response to within defined reliability parameters." BAL-003-1 is beyond the scope of this "Final SAR". For instance, "the reasons for the decline in Frequency Response" were not confirmed to our knowledge; and the field trial is not completed to our knowledge. The Supplemental SAR adds to the scope of the Final SAR: "To provide a minimum Frequency Response Obligation for the Balancing Authority to achieve, methods to obtain Frequency Response and provide a consistent method for calculating the Frequency Bias Setting for a Balancing Authority. In addition, the standard will specify the optimal periodicity of Frequency Response surveys." Please note that the Standards Development Roadmap does not confirm whether this Supplemental SAR was ever approved; hence, I question whether this is actually part of the scope of the SDT. Be that as it may, the Supplemental SAR does not eliminate the pre-requisite contained in the Final SAR to determine the reasons for the decline in frequency response and confirm them before establishing "defined reliability parameters". In addition, the standard does not meet the scope requirements of the Supplemental SAR. |
| Response: The SDT is responding to FERC Directives from Order 693 as well as the FERC Order dated March 18, 2010 which mandated development of a standard addressing the Order 693 directives within six months. FERC later granted an extension to provide a standard addressing these issues by the end of May 2012. <br> The SDT agrees that the original SAR was strictly for data collection. However, a supplemental SAR was developed to address the FERC March 18, 2010 Order and was subsequently approved by the industry. |  |  |

3 - The SDT adjusted the event selection Criteria to address concerns related to response driving frequency back to the pre-event level during the $B$ value measurement period. We believe that this adjustment addresses your concern.
4 - The SDT has a section in the Background Document addressing methods of obtaining Frequency Response.
The drafting team believes the following are valid methods of obtaining Frequency Response:

- Regulation services.
- Contractual service. The drafting team has developed an approach to obtain a contractual share of Frequency Response from Adjacent Balancing Authorities. See FRS Form 1. While the final rules with regard to contractual services are being defined, the current expectation is that the ERO and the associated Region(s) should be notified beforehand and that the service be at least 6 months in duration.
- Through a tariff (e.g. Frequency Response and regulation service).
- From generators through an interconnection agreement.
- Contract with an internal resource or Loads (The drafting team encourages the development of a NAESB business practice for Frequency Response service for linear (droop) and stepped (e.g. LaaR in Texas) response).

Since NERC standards should not prescribe or preclude any particular market related service, BAs and FRSGs may use whatever is most appropriate for their situation.
5 - The NERC Functional Model Technical Document identifies the BA as the entity that manages and deploys Frequency Response. This is because a BA controls the amount and distribution of spinning reserves and also has some control over interruptible resources. This is similar to the relationship between the TOP and voltage control. Even though the TOP may not own generators or capacitor banks, the TOP is still responsible for controlling voltage within limits.
The industry-approved Standards Authorization Request (SAR) for BAL-003 did not include a performance obligation for generators. The drafting team is obliged to stay within the bounds of its SAR.

There are two primary reasons the SAR did not apply a performance obligation on generators. First, there are thousands of generators in North America. It would be many times more costly and difficult to implement a standard that measures all generators and verifies performance is properly calculated. Secondly, given the fact that there presently is sufficient frequency response in all Interconnections, the value of implementing a performance obligation on generators at this time would not

If the commenter(s) believes there is a need <br> for a generator performance obligation, they are encouraged to submit a SAR to that effect. <br> 6 - The SDT agrees with you comment. <br> Additional minor issues <br> The Forms will be put on a NERC website and announced once the standard is approved. <br> The definition no longer reference FRS Form 1. <br> Independent Electricity <br> System Operator <br> NegativeThe complete IESO's comments on the revised standard are provided through the <br> electronic comment form. The summary below highlights IESO's major concerns with <br> the revised standard: <br> 1)The definition for Frequency Response Measure (FRM): The proposed FRM <br> definition: "The median of all the Frequency Response observations reported <br> annually on FRS Form 1" is problematic. It references an FRS Form 1 which is not <br> included in the definition itself but is in fact an attachment to the standard. In the <br> current NERC Glossary of Terms, there is no such precedence that a definition must <br> rely on the requirements or details in a standard for completeness. Also, it is very <br> cumbersome that when changes are made to FRS Form 1, the definition must be <br> posted for industry comment and balloting, and vice versa. When other standards <br> begin using the term, there will be cross references betwen standards. This further <br> complicates the update/maintenance problem without any appreciable value. (See <br> complete comment in Section Q1 in the electronic comment form)   <br> 2)Attachment A: Attachment A should include only the event selection process and   <br> calculations associated with the requirements, including an explanation of what is   <br> necessary if variable Frequency Bias Settings are implemented. If other   <br> "requirements" need to be specified, such as the reporting time frame stipulated on   <br> page 3 of Attachment A, they should be moved to the standard itself but not   <br> imbedded in an attachment. (See complete comment in Section Q6 in the electronic   |
| :--- |

| Organization | Yes or No | Question 10 Comment |
| :--- | :--- | :--- |
|  |  | comment form) <br> 3)The expanded FRS Form 1 and the addition of a Form 2 ask for data entry that is <br> excessive and whose value has not been demonstrated. (See complete comment in <br> Section Q9 in the electronic comment form) |

Response: 1) The SDT has modified the definition to no longer reference FRS Form 1. The definition now reads "The median of all the Frequency Response observations reported annually by Balancing Authorities for frequency events specified by the ERO. This will be calculated as MW/0.1Hz."
2) The intent of Attachment $A$ is to describe the process that will be used. There is no intent to require a filing on a certain date and to have the BA prove to the auditor that a filing was made on that date. Rather the requirement is to have an FRM that provides at least the response required of a BA based on it's FRO and provide a high-level overview of the mechanical parts of the process. The drafting team has modified the Requirements and Attachments to address the concerns raised by the comments that indicated requirements were in the Attachments. In order to explain the process, the drafting team believes the information needs to be attached to the standard such that it cannot be changed without input from the industry.
3) The SDT points out that there are no additional data requirements. It is possible that you are seeing more spreadsheets due to them being unhidden.

Form 2 is a separate stand-alone workbook. Form 1 does have a worksheet labeled "BA Form 2 Event Data" that will contain the single event data from each of the BA's Form 2s. Two additional worksheets were added to Form 1 and several worksheets were deleted. The "Time Zone Ref" worksheet was added to allow the BA to enter the time zone of its data and have the spreadsheet calculate the local time of the event from the UTC time. This was added for the convenience of the BA in collecting the correct data for each event and does not require additional data from the BA. The second worksheet added was a worksheet that displays graphs of frequency for each event and the $t(0)$ selected correctly. This was added to aid the BA with data collection and the selection of $t(0)$ since this seemed to be one of the biggest problems during the first phase of the field trial. This graph worksheet does not require the BA to do anything. It is not used in the analysis and can be deleted. Deleting this worksheet will greatly reduce the size of Form 1. None of the data requirements on Form 1 or Form 2 have changed from previous versions. The absolute minimum data needed for this standard is the date/time, frequency and NAI in columns A, B and C of the "Data" worksheet in Form 2. Columns D through I have been totally optional and can be left blank. Column J is the Bias setting in the ACE equation and is important to BA's that utilize Variable Bias. Column K, BA Load, was added by the drafting team in the beginning to see if Load Dampening could be measured as this has been done for several years on one Interconnection. Column I of the

| Organization | Yes or No | Question 10 Comment |
| :---: | :---: | :---: |
| "Data" worksheet is the only optional data that the BA should use when it is the contingent BA during any of the events evaluated. Utilizing this data will allow the BA's SEFRD to be calculated correctly and give the BA a full sample set for the annual median calculation. Form 2 is necessary to standardize the measurement process on all Interconnections. You are free to hide any analytical worksheets on Form 1 and Form 2. You can do this on your "master" Form 2 and then build each Form 2 for each event using this master. These additional worksheets are available for BAs to utilize if they find that their performance is below the FRO and will aid the analysis of the contributing causes. |  |  |
| ISO New England, Inc. | Negative | ISO New England will not vote to approve the standard because it fails to place requirements on generators to provide frequency response. There are four substantive problems: <br> 1 • Using 59.6 Hz as an Eastern Interconnection UFLS instead of an actual value of either 59.5 Hz or 59.7 Hz <br> 2 - Using installed capacity in determining the Frequency Response Obligation <br> 3 - The sampling interval needs to be tuned on a per Interconnection basis to support HQTE's characteristics <br> 4- Do not advocate the use of supplemental regulation as a method of procuring frequency response <br> Additionally, the SDT must decide on what the purpose of this standard is. If it is to respond to Order 693 then the standard misses the point of defining how often to run Frequency Response Surveys; it does not crisply define the "Interconnection" obligations. If the SDT does want to focus on performance then the issue of who is the default provider must be addressed. As the IRC has noted previously, all BAs do not own the service providers. To create standards that apply to entities that are dependent on other function entities to comply with a standard requirement is of great concern. |

Response: 1 - Florida sees a greater change in frequency for a given contingency than for a comparable event elsewhere in the East. This is the reason for their higher first step of UFLS in Florida. Having all Eastern Interconnection Balancing Authorities carry extra frequency responsive reserves to protect against a target minimum frequency of 59.7 Hz would not protect Florida against a

Organization
Yes or No

## Question 10 Comment

contingency inside Florida, but would require the other BAs in the East to continuously carry about 4000 MW of frequency responsive reserves to protect against a false trip in Florida if frequency fell below 59.7 Hz but over 59.5 Hz . This is a contingency on the order of 7,000 MW or more. The drafting team compromised and gave the entire Interconnection an obligation based on 59.96 Hz .

2 - The SDT has modified both the Background Document and Attachment A to be consistent. The calculation uses "historical data" to circumvent the problem you have described.
3 - The SDT adjusted the event selection Criteria to address concerns related to response driving frequency back to the pre-event level during the B value measurement period. We believe that this adjustment addresses your concern.

4 - The SDT has a section in the Background Document addressing methods of obtaining Frequency Response.
The drafting team believes the following are valid methods of obtaining Frequency Response:

- Regulation services.
- Contractual service. The drafting team has developed an approach to obtain a contractual share of Frequency Response from Adjacent Balancing Authorities. See FRS Form 1. While the final rules with regard to contractual services are being defined, the current expectation is that the ERO and the associated Region(s) should be notified beforehand and that the service be at least 6 months in duration.
- Through a tariff (e.g. Frequency Response and regulation service).
- From generators through an interconnection agreement.
- Contract with an internal resource or Loads (The drafting team encourages the development of a NAESB business practice for Frequency Response service for linear (droop) and stepped (e.g. LaaR in Texas) response).

Since NERC standards should not prescribe or preclude any particular market related service, BAs and FRSGs may use whatever is most appropriate for their situation.

The NERC Functional Model Technical Document identifies the BA as the entity that manages and deploys Frequency Response. This is because a BA controls the amount and distribution of spinning reserves and also has some control over interruptible resources. This is similar to the relationship between the TOP and voltage control. Even though the TOP may not own generators or capacitor banks, the TOP is still responsible for controlling voltage within limits.

| Organization | Yes or No | Question 10 Comment |
| :--- | :--- | :--- |

The industry-approved Standards Authorization Request (SAR) for BAL-003 did not include a performance obligation for generators. The drafting team is obliged to stay within the bounds of its SAR.
There are two primary reasons the SAR did not apply a performance obligation on generators. First, there are thousands of generators in North America. It would be many times more costly and difficult to implement a standard that measures all generators and verifies performance is properly calculated. Secondly, given the fact that there presently is sufficient frequency response in all Interconnections, the value of implementing a performance obligation on generators at this time would not outweigh the effort and cost.
Again, the drafting team cannot include requirements beyond the bounds of its SAR. If the commenter(s) believes there is a need for a generator performance obligation, they are encouraged to submit a SAR to that effect.
6 - The SDT agrees with you comment.
Additional minor issues
The Forms will be put on a NERC website and announced once the standard is approved.
The definition no longer reference FRS Form 1.

| JEA | Negative | JEA is not comfortable with a performance based standard as written without more <br> field testing to ensure that net interchange is not skewed by load and generation <br> changes that are not a function of frequency. Since frequency response has <br> components from load and generation resources, and load is not controllable for the <br> most part, seems this standard should be directed at specific generator response <br> methods from the GO/GOP's. <br> This is a wide reaching standard. And, this is a performance standard (if it doesn't <br> perform as designed, it is a violation). Because of this, more testing needs to be <br> completed so we know the model is correct. We are not sure we know how to <br> ensure compliance. |
| :--- | :--- | :--- |
| Don't agree the standard needs to be performance based. |  |  |

| Organization | Yes or No | Question 10 Comment |
| :--- | :--- | :--- |

events addresses the concerns raised by the noise being inside a single event. The studies from the field trial show a convergence of the measurement after approximately 20 to 25 events.
The SDT is responding to FERC Directives from Order 693 as well as the FERC Order dated March 18, 2010 which mandated development of a standard addressing the Order 693 directives within six months. FERC later granted an extension to provide a standard addressing these issues by the end of May 2012.

| Kansas City Power \& Light Co. | Negative | The proposed Standard BAL-003-1 does not consider the real time operating <br> conditions under which this standard should apply. There are no considerations for <br> the complexities introduced by capacity energy agreements between BA's nor <br> consideration of the differing level of Interconnection Frequency Response needed <br> at times of minimum interconnection load conditions and interconnection peak load <br> conditions. |
| :--- | :--- | :--- |

Response: The method for determining the FRO is based upon the determination of the largest contingency that could occur at any time and does not vary based upon time of day or system conditions. Since the largest contingency could occur at any time, the minimum Frequency Response Obligation necessary to manage the contingency will not be dependent upon the differing conditions that can occur during different times of the day like those referred to in the question.

| Lakeland Electric | Negative | In general; here has not been sufficient prudency review for the standard, especially <br> R1, to justify a performance based standard around a Frequency Response Measure. <br> Refer to comments submitted by FMPA on LAK behalf. |
| :--- | :--- | :--- |

Response: The SDT is responding to FERC Directives from Order 693 as well as the FERC Order dated March 18, 2010 which mandated development of a standard addressing the Order 693 directives within six months. FERC later granted an extension to provide a standard addressing these issues by the end of May 2012.

Please refer to the SDT response to the comments received from FMPA in the earlier questions.

| Liberty Electric Power LLC | Negative | Voting no due to SDT addressing FERC directives with attachments instead of in the <br> standard requirements. |
| :--- | :--- | :--- |
| Response: The SDT disagrees with your concern about addressing FERC directives within an attachment. If a requirement |  |  |

| Organization | Yes or No | Question 10 Comment |
| :---: | :---: | :---: |
| references specific performance in an Attachment, then the performance described in the Attachment is mandatory and enforceable. |  |  |
| Manitoba Hydro | Negative | The Applicability of BAL-003-1 should be clarified. Specifically, Section 1.2 should be changed from "Reserve Sharing Groups (where applicable)" to "Reserve Sharing Group whose intent includes meeting Frequency Response Obligations". <br> Regarding Data Retention: <br> 1. As the standard is currently drafted, both the BA and the RSG would be required to retain data or evidence to show compliance with requirements R1 and M1. It is unclear whether this is the intention, or whether it would be acceptable that just one or the other would maintain such records. <br> 2. In the first and second paragraph, the reference to 'three calendar years' should be specified to be the 'previous three calendar years'. <br> 3. In the third paragraph, it should be clarified who is required to keep information related to non compliance if the BA belongs to an RSG - the BA or the RSG or both. <br> 4. In the fourth paragraph, it should be clarified for what length of time the last audit records must be retained. |
| Response: The SDT has defined a new term "Frequency Response Sharing Group (FRSG)" because it believes that using the presently defined term "Reserve Sharing Group" could cause confusion. The new definition reads "A group whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply operating resources required to jointly meet the Frequency Response Obligations of its members." The SDT has modified the Background Document to further explain how an RSG (now FRSG) can be used to supply Frequency Response. |  |  |
| $1 \& 3$ - The SDT believes that the reporting entity would be the responsible entity to maintain records. The SDT also believes that once a BA has declared themselves as part of a FRSG then the FRSG would be the responsible entity to maintain records. |  |  |
| 2 - The SDT agrees with your second comment and has made this modification. |  |  |
| 4 - The last audit record should be kept until the next audit. |  |  |

| Organization | Yes or No | Question 10 Comment |
| :--- | :--- | :--- |
| New Brunswick Power <br> Transmission Corporation | Negative | The compliance burden should not fall on the BA as the provider of Frequency <br> Response (i.e. Primary Control response). In this case the BA per se has no assets, <br> moreover the primary response service providers have no obligations to provide the <br> service, thus the BA potentially could face a situation where there is no physical <br> service to be purchased but there is a mandated standard to comply with. The idea <br> of creating a Primary Response Market as some have proposed does not work <br> without an obligation on some entity to physically provide that service. |
| Response: The NERC Functional Model Technical Document identifies the BA as the entity that manages and deploys Frequency <br> Response. This is because a BA controls the amount and distribution of spinning reserves and also has some control over <br> interruptible resources. This is similar to the relationship between the TOP and voltage control. Even though the TOP may not |  |  |

of frequency responsive reserves to protect against a false trip in Florida if frequency fell below 59.7 Hz but over 59.5 Hz . This is a contingency on the order of $7,000 \mathrm{MW}$ or more. The drafting team compromised and gave the entire Interconnection an obligation based on 59.96 Hz .
2 - The SDT has modified both the Background Document and Attachment A to be consistent. The calculation uses "historical data" to circumvent the problem you have described.

3 - The SDT adjusted the event selection Criteria to address concerns related to response driving frequency back to the pre-event level during the B value measurement period. We believe that this adjustment addresses your concern.

4 - The SDT has a section in the Background Document addressing methods of obtaining Frequency Response.
The drafting team believes the following are valid methods of obtaining Frequency Response:

- Regulation services.
- Contractual service. The drafting team has developed an approach to obtain a contractual share of Frequency Response from Adjacent Balancing Authorities. See FRS Form 1. While the final rules with regard to contractual services are being defined, the current expectation is that the ERO and the associated Region(s) should be notified beforehand and that the service be at least 6 months in duration.
- Through a tariff (e.g. Frequency Response and regulation service).
- From generators through an interconnection agreement.
- Contract with an internal resource or Loads (The drafting team encourages the development of a NAESB business practice for Frequency Response service for linear (droop) and stepped (e.g. LaaR in Texas) response).

Since NERC standards should not prescribe or preclude any particular market related service, BAs and FRSGs may use whatever is most appropriate for their situation.

The NERC Functional Model Technical Document identifies the BA as the entity that manages and deploys Frequency Response. This is because a BA controls the amount and distribution of spinning reserves and also has some control over interruptible resources. This is similar to the relationship between the TOP and voltage control. Even though the TOP may not own generators or capacitor banks, the TOP is still responsible for controlling voltage within limits.

The industry-approved Standards Authorization Request (SAR) for BAL-003 did not include a performance obligation for

| Organization | Yes or No | Question 10 Comment |
| :--- | :--- | :--- |

generators. The drafting team is obliged to stay within the bounds of its SAR.
There are two primary reasons the SAR did not apply a performance obligation on generators. First, there are thousands of generators in North America. It would be many times more costly and difficult to implement a standard that measures all generators and verifies performance is properly calculated. Secondly, given the fact that there presently is sufficient frequency response in all Interconnections, the value of implementing a performance obligation on generators at this time would not outweigh the effort and cost.

Again, the drafting team cannot include requirements beyond the bounds of its SAR. If the commenter(s) believes there is a need for a generator performance obligation, they are encouraged to submit a SAR to that effect.

FRS Forms 1 and 2 will be Attached to the standard. The Forms will be put on a NERC website and announced once the standard is approved.
The definition no longer reference FRS Form 1.

- From generators through an interconnection agreement.
- Contract with an internal resource or Loads (The drafting team encourages the development of a NAESB business practice for Frequency Response service for linear (droop) and stepped (e.g. LaaR in Texas) response).

Since NERC standards should not prescribe or preclude any particular market related service, BAs and FRSGs may use whatever is most appropriate for their situation.

| South California Edison | Negative | SCE's "No" vote, like the WECC position, regarding Project 2007-12 is based on the |
| :--- | :--- | :--- |

| Organization | Yes or No | Question 10 Comment |
| :---: | :---: | :---: |
| Company |  | following five points: <br> 1) Clarification is needed whether there will/ will not be conflicts between proposed Requirement R3 and the requirements of FERC-approved regional reliability standard BAL-004-WECC-1 - Automatic Time Error Correction <br> 2) Confusion exists between Attachment A and the Background Document: <br> 2a) Attachment A states peak load allocation is based on "Projected" Peak Loads and Generation, versus <br> 2b) The Background Document which states it will use "historical" Peak Load and Generation. <br> 3) Reducing frequency bias obligation is detrimental to reliability. It seems that Lowering the Minimum Frequency Bias Setting from $1 \%$ to $.8 \%$ will result in a lower response, which in turn will lower the natural frequency response. Over time it seems this pattern would lead to poorer response. <br> 4) There is no clear statement of what is expected from the Balancing Authorities and whether or not there is a limit on that expectation. <br> 5) Why are there no requirements on governor installation, settings, and operation for a frequency response standard? |
| Response: 1) The SDT has removed Requirement R3. The SDT believes that this requirement is duplicative of BAL-005-0.1b Requirements R6 \& R7. <br> 2) The SDT has modified both the Background Document and Attachment A to be consistent. The calculation uses "historical data" to circumvent the problem you have described. <br> 3) Early research by Nathan Cohn ${ }^{6}$ on interconnected power system operations found that control is optimum if a BA's Bias Setting is equal to its natural Frequency Response. If there were to be a difference between the two values, it is preferable to be slightly over-biased. |  |  |

[^64]| Organization | Yes or No | Question 10 Comment |
| :--- | :--- | :--- |

The drafting team has proposed to bring Bias Setting and natural Frequency Response more in line. The process to do this is outlined in a Procedure developed by the SDT which replaces Attachment B. The Procedure manages a "go slow" approach to making this happen and includes checks to confirm there are not unexpected influences injected into the CPS-related calculations. Based on concerns raised by the industry, the drafting team has modified the Procedure to make the initial minimum Bias Setting $0.9 \%$ of peak and has included a provision that the ERO will evaluate the impact caused by a change in minimum Bias Setting. The evaluation will look at both frequency performance and impact on CPS-related compliance calculations.
4) The SDT understands your concern and has added language in Attachment A that caps the amount of Frequency Response that a BA will be required to provide
5) The NERC Functional Model Technical Document identifies the BA as the entity that manages and deploys Frequency Response. This is because a BA controls the amount and distribution of spinning reserves and also has some control over interruptible resources. This is similar to the relationship between the TOP and voltage control. Even though the TOP may not own generators or capacitor banks, the TOP is still responsible for controlling voltage within limits.

The industry-approved Standards Authorization Request (SAR) for BAL-003 did not include a performance obligation for generators. The drafting team is obliged to stay within the bounds of its SAR.
There are two primary reasons the SAR did not apply a performance obligation on generators. First, there are thousands of generators in North America. It would be many times more costly and difficult to implement a standard that measures all generators and verifies performance is properly calculated. Secondly, given the fact that there presently is sufficient frequency response in all Interconnections, the value of implementing a performance obligation on generators at this time would not outweigh the effort and cost.
Again, the drafting team cannot include requirements beyond the bounds of its SAR. If the commenter(s) believes there is a need for a generator performance obligation, they are encouraged to submit a SAR to that effect.

| Western Area Power <br> Administration | Negative | 1. Reducing frequency bias obligation is a detriment to reliability of interconnection <br> and the proposed standard aims to reduce the bias obligation from the current <br> minimum level of $1 \%$ load to $0.8 \%$ and subsequently to a lower percentage. <br> 2. The proposed standard is very confusing and complex in regard to data collection |
| :--- | :--- | :--- |

| Organization | Yes or No | Question 10 Comment |
| :---: | :---: | :---: |
|  |  | and compliance. <br> 3. The proposed standard is encompassing reserve sharing group (where applicable), why? What reserve sharing group operates AGC? <br> It is not clear whether the compliance period is monthly or yearly for R1 \& R5. <br> The issue of non-binding standard and whether it serves a purpose to go through complicated data submission and found in compliance or out of compliance without any consequences. |
| Response: 1. Early research by Nathan Cohn ${ }^{7}$ on interconnected power system operations found that control is optimum if a BA's Bias Setting is equal to its natural Frequency Response. If there were to be a difference between the two values, it is preferable to be slightly over-biased. |  |  |
| The drafting team has proposed to bring Bias Setting and natural Frequency Response more in line. The process to do this is outlined in a Procedure developed by the SDT which replaces Attachment B. | 3. The SDT has modified the Background Document to provide additional information and clarity. |  |  |
| 4. The SDT modified R1 so that it no longer applies to an RSG _ the SDT defined new term, "Frequency Response Sharing Group" to address stakeholder concerns that the RSG is not the correct entity. The definition of Frequency Response Sharing Group is: |  |  |
| A group whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply operating resources required to jointly meet the Frequency Response Obligations of its members. |  |  |
| 3. Requirement R1 is calculated on an annual basis. The SDT has removed Requirement R5 and combined it into Requirement R2 |  |  |

[^65]| Organization | Yes or No | Question 10 Comment |
| :--- | :--- | :--- | :--- | | and new Requirement R3. <br> The SDT made modifications to Attachment A to try to distinguish mandatory performance assigned to the BA from process steps <br> performed by the ERO. |  |  |
| :--- | :--- | :--- |
| Xcel Energy, Inc. | Negative | It is not clear if there is an upper limit to the amount of frequency response expected <br> of the Balancing Authorities under this standard. Except for Table 2 in Attachment A, <br> there is no discussion of an amount of FR expected on a total basis. Balancing <br> Authorities need to know for how many tenths of a hertz they are to respond so they <br> can determine how to plan to meet this requirement. The documents do not appear <br> to provide any boundary on the maximum amount of FR that a BA will provide, i.e. it <br> is not clear what will happen if an event occurs in the Eastern Interconnection that <br> causes the frequency to drop to less than 59.6 Hz (e.g. what if freq dips to 59.0? Is <br> the BA expected to provide a limitless amount of frequency response?). Also, is that <br> event excluded from the list used to calculate the Balancing Authorities' response or <br> is it included with an expectation that it counts the same as any other event. Without <br> a clear statement of what is expected, including whether there is a limit on that <br> expectation or not, the Balancing Authorities cannot know what is expected of them <br> and therefore cannot plan appropriately. |

| Organization | Yes or No | Question 10 Comment |
| :--- | :--- | :--- | :--- |
|  |  | the Balancing Authority's AGC system. <br> A link should be provided in the proposed standard to FRS Form 1. |
| Response: Florida sees a greater change in frequency for a given contingency than for a comparable event elsewhere in the East. <br> This is the reason for their higher first step of UFLS in Florida. ## Unofficial Comment Form <br> Frequency Response Technical Conferences

Please use the electronic comment form to submit comments on the Frequency Response Technical Conferences held on May 22, 2012 and May 24, 2012. These comments will be posted on the project webpage as part of the development record and considered by the FRSDT as it continues to develop BAL-003. Comments must be submitted by June 15, 2012. If you have questions please contact Darrel Richardson (email) or by telephone at (609) 613-1848.

## Background I nformation:

NERC recently held two technical conferences on Frequency Response. The first conference was held on May 22, 2012 in Arlington, VA and the second was held in Denver, Colorado on May 24, 2012. The purpose of these conferences was to obtain industry input on the development of a Frequency Response standard. The information provided in the conferences primarily dealt with the following three areas.

1. The work that has been done on the standard to date
2. Which Functional Entity should be responsible for Frequency Response.
3. How to measure Frequency Response

A complete set of presentations from the conferences can be found at the following link.

## http://www.nerc.com/filez/standards/Frequency Response-RF.html

NERC is requesting industry comments pertaining to the information provided in the conferences or suggestions for further consideration in the development of a Frequency Response standard. Please share your thoughts on the Technical Conference and the associated subject matter below.

## Enter All Comments in Simple Text Format.

1. Please provide any comments on the Technical Conference and associated subject matter in the comment area below.

#### Abstract

Individual Don Tench on Behalf of ENBALA ENBALA Power Networks I. INTRODUCTION ENBALA Power Networks (ENBALA) respectfully submits these comments in response to the North American Electric Reliability Corporation (NERC) Technical Conference on Frequency Response held in Arlington VA on May 22, 2012 and Denver CO on May 24, 2012. ENBALA rewards large electricity users for participation in the Smart Grid. The ENBALA Power Network enables industrial, commercial and municipal partners to be financially rewarded for the inherent flexibility of their electrical equipment. Resource partners incur no cost in connecting to this platform and receive payments for helping to bring continuous balance to the electricity system. The purpose of these conferences was to provide background on the development, and implementation of BAL-003-1 - Frequency Response Standard (FRS) and to explain the rationale and considerations for the Requirements and their associated compliance information as well as to solicit feedback from industry participants on the standard. ENBALA provides these comments in support of draft standard BAL-0031 II. BACKGROUND The requirement to continuously balance load and generation to maintain stable frequency is a critically important aspect of interconnected power system operation. Frequency Response is the characteristic of load and generation within Balancing Authorities and Interconnections that reacts or responds to changes in load-resource balance and resulting changes in system frequency. Primary Frequency Control is defined by NERC as those actions provided by the Interconnection to arrest and stabilize frequency in response to frequency deviations, typically caused by a significant system loss. Primary Control comes from mechanical inertia, followed by automatic generator governor response, load response (typically from motors), and other devices that provide an immediate response based on local (device-level) control systems. Primary Frequency Response (PFR) is the first stage of overall frequency control and is the response, which begins immediately, of resources and load to a locally sensed change in frequency to arrest that change in frequency. This is distinct from Secondary Frequency Control, defined to be those actions provided by an individual BA or its Reserve Sharing Group to correct the resource - load unbalance that created the original frequency deviation, which will restore both Scheduled Frequency and Primary Frequency Response. Secondary Control comes from automated dispatch from a centralized control system. The original Standards Authorization Request (SAR) to establish mandatory standards with respect to this critical requirement were established in BAL-003-0, finalized on June 30, 2007. In Order No. 693, the Federal Energy Regulatory Commission (FERC) directed additional changes to this standard. We interpret the objective of the FERC direction to be to establish concrete measures and allocation of Interconnection Frequency Response to ensure continued reliable operation III. COMMENTS Presentations and discussion at the conference provided the following understanding; - The system currently has enough PFR to operate reliably. The concern is that continuing decline could result in unreliability at a future date. The immediate concern is to ensure that the decline on the Eastern Interconnection is halted. - Approximately $30 \%$ of generators provide governor response and hence primary frequency control at any time in the Eastern and Western Interconnections. - Primary Frequency Response (PFR) should not be viewed as event driven but rather as continuous control. - The draft standard has been written to give the Balancing Authority (BA) responsibility to meet the standard. The main issue with this is a concern that BA's are being given responsibility but do not have the requisite authority to impose requirements on participants (eg. generators) to provide the PFR. The discussion at the conference focused almost exclusively on the ability of generators to supply PFR through governor action. This is not surprising given the fact that the interconnected power system is based on rotating machines (for the most part) and that speed governors are a necessary part of generator control systems and have been providing PFR for many years. However, there is growing evidence that some generation operators prefer not to provide this service as only a fraction of qenerators actually

provide PFR to the interconnection at any time. Many reasons were discussed that generators do not provide response, ranging from regulatory restrictions, environmental restrictions, and operation at full output, economic choices to make the plant more efficient, and physical constraints, among others. But in our opinion, all of these reasons come down to a fundamental consideration - the generators must sacrifice some efficiency to provide PFR. This is not a surprising outcome. Prior to electricity deregulation many 'ancillary services ' provided by generators were considered to be delivered at low or no cost. However, organized electricity markets have shown that these services have considerable value. Primary Frequency Response is another example. This is not to say that generators may not be the most effective way to provide the majority of PFR. However, generation resources may not be the least cost supplier of PFR. It is important to recognize that this service has a cost and different technologies are able to provide the service at different costs. These costs vary even amongst generation technologies. In addition, there are alternatives to providing all PFR from generation. ENBALA's experience in providing Secondary Frequency Control (SFC) to organized markets has shown that aggregated mid-sized commercial and industrial facilities can provide very high quality SFC, demonstrably better performance than the majority of generation. This technology can be extended to provide localized PFR as well. It is our opinion that PFR from load can be of higher 'quality' than that provided by generation. The ability of individual aggregated loads to increase or decrease nearly instantaneously in response to frequency provides an immediate stabilizing influence on frequency that works together with generator inertia to arrest frequency deviations more quickly than generation alone. Recent studies by California ISO identify that this response can be several times more valuable than slower generation response. Given the facts that; PFR is a valuable reliability service, the cost of providing PFR varies with technology, decisions must be made with respect to who will provide PFR, and alternatives exist to continuing with the provision of generator only PFR, we respectfully make the following suggestions; - The standard should continue as drafted and not limit the technology to provide PFR (eg. generators only) - PFR should be recognized as a reliability service in the same manner as other ancillary services. - The standard should apply to an entity like the BA, as drafted, that has defined responsibility for balancing load and generation Mechanisms should be developed to procure PFR sufficient to meet NERC standards, on an economic basis either through market or tariff provisions IV. CONCLUSION It is ENBALA's belief that unless the value of Primary Frequency Response can be made transparent to the marketplace, efficient alternatives will not be implemented and inefficient decisions with respect to existing technologies will be made leading to higher costs for consumers. Treatment of PFR as a market priced reliability service will allow the industry to determine the most efficient and effective way to provide necessary Frequency Response, independent of changes taking place in the supply mix of generation. Respectfully Submitted,

17-year NERC veteran's, long-standing active FRS drafting team contributor's, ex NERC Standards Committee member's, and Columbia-University-postgraduated statistician's expert comments on "Avoiding a Trifecta of Statistics Errors in the NERC Frequency Response Standard". Please review my 6 -slide powerpoint presentation downloadable at http://www.robertblohm.com/3FRSissues.pptx or http://www.robertblohm.com/3FRSissues.ppt and submitted but never posted for inclusion in the technical conference. The last 3 slides highlight the following 3 fundamental statistics errors in the FRS as drafted so far: (1) confusion of (the correct probabilistic measure of "largest contingency" consisting of) "largest event to occur at least as often as once in 10 years" with (the incorrect probabilistic measure of "largest contingency" consisting of) "largest event in the last 10 years" which may be the "largest event to occur at least as often as once in MUCH MORE THAN 10 years"; (2) sampling of frequency responses to events that is not true "random", "unbiased" or "stratified" sampling which requires samples that are distributed unevenly over time just like the population of responses to events is: every month or season of the year cannot be forced to have the same number of samples; otherwise what is being measured is not the population of responses to events, but something else (like responses to regular small operating errors that are the domain of CPS, not the FRS) with a probability density over time in the shape of a flat-top box; (3) use of a median measure of frequency-response performance, which is impossible for 3 reasons: because there is a practical infinity of possible Frequency Responsive Reserve Sharing Groups or overlap regulation arrangements, because use of the median incents the formation of those whose actual provision of
frequency response is over-represented by the median and would in that case deteriorate below the actual minimum amount required for system reliability, and because use of the median disincents the formation of those whose actual provision of of frequency response is under-represented by the median. The first 3 slides clarify the following 3 technical points: (1) the resistance of load to adjust to sudden change in generation output prompts frequency (but not generator output) to change and to thereby involuntarily change the load whose resistance to that adjustment prompts frequency to change even more and only until the sudden generation output change is reversed enough in order first to stop the frequency change and then begin to reverse the frequency change; [The involuntary load response/adjustment provides the energy used by generation inertia to immediately slow down frequency change until frequency response is deployed to stop and begin to reverse the frequency change as illustrated in this 4 -slide powerpoint presentation of 4 errors in the Cummings presentation's slide of frequency response
http://www.robertblohm.com/CummingsVsIllianLoadResponse.pptx or
http://www.robertblohm.com/CummingsVsIIlianLoadResponse.ppt . The 2 graphs depicted therein show that load response and inertia are inseparable and provide the entirety of frequency response during more than the initial half of the 5 or 6 second pre-arresting period, and this supports the next slide.] (2) the FRS is a standard for "system" frequency response (the 1st of NERC's 2 glossary definitions of "frequency response"), not for "equipment" frequency response (the 2nd of NERC's 2 glossary definitions of "frequency response"); the FRS is a BA-Response System Operation and Measurement Standard, not a Connection and Maintenance Standard for Individual Pieces of Equipment; in other words, all sharp large-enough tie-line and frequency changes of whatever kind for whatever reason are counted ("summed") and managed (and included in the probability density curve of frequency events and responses thereto), not just measurements of a construed pure machine response to one single imagined un-overlapped change (shorn of supposed "contaminants" of an idealized "equipment" reality non-existent at actual "system" level); (3) the probability density function of frequency events that are un-uniformly distributed over time governs the FRS and is different from the standard normal distribution of operating errors (that governs CPS) that are evenly distributed over time in a uniform distribution.

## Group

Dominion
Connie Lowe

## Dominion

Dominion agrees that resources other than generators could supply some limited frequency response, but believe that all resources providing reliability-related services should be subject to applicable NERC reliability standards. We also agree that relationships can exist between reliability and compensation, especially in organized markets. In order for generators to be able to respond to a low frequency event, they would need to operate slightly below their maximum output. The Balancing Authority is the entity best suited to make the determination of how to balance efficiency and reliability. There may be financial consequences for resources that do not meet their assigned schedule and we encourage further discussion of this with NAESB to determine whether this issue might be ripe for discussions and possible solutions from NERC (reliability) and NAESB (commercial/financial). As noted in the Duke presentation, alignment is also needed in the new NERC standards and Glossary of terms (clarification is needed on specific terms used by engineering vs. the Generator Operator) as it pertains to frequency response.

## MISO

The standard sets a rational backstop for reliability without forcing undue costs for undefined improvements in reliability. My primary concern is the reliability gap created for variable bias BAs. There is no discernible reason why a variable bias BA should ever have a bias less negative than say $30 \%$ of its FRO. The variable bias BA should also have an average annual bias at least $90 \%$ of its FRO. This can be managed through the year and still will be well less than the current obligation under BAL-003-0. Since there is no firm technical guidance on how variable bias is to be set, to leave this gap will cause a mass movement of BAs to report as variable bias entities. It will also leave the door open to gaming to artificially improve CPS and DCS and BAAL performance.

SPP Standards Review Group

## Robert Rhodes

Southwest Power Pool
Requirement 3 of the standard covers the use of variable bias. However, the requirement does not establish a minimum limit for variable bias. In order to prevent what could be perceived as a way to 'game' the requirement, we would suggest incorporating a minimum limit on variable bias that does not allow the value to be positive.

PSEG Comments on Project 2007-12 - Frequency Response A. SUMMARY OF COMMENTS 1. The standard drafting team (SDT) for Project 2007-12 has not explained how compliance with draft standard BAL-003-1 is achievable; therefore, a key goal of Order 693 has not been met. a. BAL-0031's objectives (from the project's web page) states "There is evidence of continuing decline in Frequency Response in the three Interconnections over the past 10 years, but no confirmed reason for the apparent decline." If one does not know why Frequency Response is declining, how can a BA ensure itself that it has sufficient Frequency Response in its area to meet its obligation? b. BAL-003-1 assigns Balancing Authorities (BAs) the requirement to meet a Frequency Response Obligation for their respective areas. However, BAs have no the authority to set requirements for suppliers of Frequency Response service: Generator Owners (GOs) as well as demand response resources. 2. Two existing standards (BAL-001-0.1a and BAL-002-0) also address Frequency Response. However, the pro forma Open Access Transmission Tariff (OATT) contained ancillary services associated with these standards prior to the standards being approved. a. The SDT needs to explain the relationship between BAL-001-0.1a, BAL-002-0, and draft standard BAL-003-1 since they all address an aspect of Frequency Response. b. BAL-003-1's objectives (from the project's web page) do not include a statement that having sufficient Frequency Response is necessary to arrest the frequency decline within the first seconds of a disturbance so that underfrequency load shedding (UFLS) is minimized. 3. There is no OATT ancillary service for the service in draft standard BAL-003-1. Unless commercial terms are established which define the relationship between BAs and Frequency Response providers, BAL-003-1 will not be implementable. Because commercial terms need to be defined in the OATT, we encourage NERC to work with FERC's Office of Energy Market Regulation and/or its Office of Energy Policy and Innovation to initiate proceeding with the goal of developing a new ancillary service Primary Frequency Response Service. 4. A plot of frequency versus time after the sudden loss of generation is only contained in presentations for the technical conferences, but a plot is not in any of BAL-003-1's documents. Such a plot is needed in the standard (or in an attachment to it) so that the familiar reference points - A, B, and C - can be used in the standard's documents. 5. With regard to setting the Frequency Response Obligation by Interconnections in BAL-003-1: a. How can two Interconnections (Eastern and Quebec), which are not Registered Entities, comply with the requirement in Attachment A to set a Frequency Response Obligation? b. The SDT should explain its rationale for choosing "the largest category C ( $N-2$ ) event identified" as the basis for setting an Interconnection's Frequency Response Obligation. 6. Project 2010-14-1 is related to Project 2007-10, and the two project teams should coordinate on these items: a. Both SDTs should put themselves in the position of a BA that must comply with R3 and all its subparts in draft standard BAL-012-1 and develop a hypothetical implementation plan for a BA to meet its Frequency Response Obligation. b. Both SDTs should work together to explain the relationship between Regulating Reserve, Contingency Reserve, and Frequency Response Reserve contained in BAL-012-1. B. REGULATORY BACKGROUND When FERC approved BAL-003-0 - Frequency Response and Bias - in Order 693, it issued NERC a directive in P. 375: ...the Commission directs the ERO to develop a modification to BAL-003-0 through the Reliability Standards development process that: ...(3) defines the necessary amount of Frequency Response needed for Reliable Operation for each balancing authority with methods of obtaining and measuring that the frequency response is achieved." The standard drafting team for Project 2007-12 is currently addressing all but one of the items in the Order 693 directive. See below: Order 693, P. 375 (3) Directive Addressed by SDT? 1. Define the necessary amount of Frequency Response for each BA Yes 2. Define methods of obtaining Frequency Response No 3. Define methods of measuring that Frequency Response is achieved Yes This second item is critical. "Methods" can describe technical options, but it can also describe process options. While the project's "Frequency Response Backaround Document" dated October 2011 has a section on "methods of obtainina Freauencv

Response" on p. 11, that section has six bullet points on the topic. The points are not integrated into a coherent approach that explains how compliance is achievable. Draft standard BAL-003-1 assigns BAs the requirement to meet a Frequency Response Obligation for their respective areas. However, BAs have no the authority to set requirements for suppliers of Frequency Response service: GOs as well as demand response resources. In addition, there are no OATT provisions that will compensate suppliers for the service BAs will ask them to provide. C. TECHNICAL COMMENTS 1. BAL-001-0.1a and BAL-002-0 NERC's Glossary defines of Frequency Response and Frequency Bias as follows: Frequency Response: (Equipment) The ability of a system or elements of the system to react or respond to a change in system frequency. (System) The sum of the change in demand, plus the change in generation, divided by the change in frequency, expressed in megawatts per 0.1 Hertz (MW/0.1 Hz). Frequency Bias: A value, usually expressed in $\mathrm{MW} / 0.1 \mathrm{~Hz}$, set into a Balancing Authority [Area Control Area] ACE algorithm that allows the Balancing Authority to contribute its frequency response to the Interconnection. Two existing standards are related to draft standard BAL-003-1. a. BAL-001-0.1a - Real Power Control Performance - addresses maintenance of frequency, within limits, by a BA in a steady-state (no disturbance) environment by measuring ACE. This requires BAs to have sufficient Regulating Reserve. The ACE equation includes a component for Frequency Bias. This component adjusts ACE when frequency deviates from 60 Hz , allowing a BA to contribute its Frequency Response to the Interconnection. In the OATT, this service is Schedule 3 - Regulation and Frequency Response. b. BAL-002-1- Disturbance Control Performance - requires BAs to provide sufficient Contingency Reserve so that ACE can be returned to its pre-disturbance level within 15 minutes. In the OATT, this service is incorporated into two schedules: Schedule 5 - Operating Reserve - Spinning Reserve Service and Schedule 6 - Operating Reserve - Supplemental Reserve Service. In both standards, the needed ancillary services were in the OATT PRIOR to the standards being approved. The reliability standards set performance requirements while the OATT sets the commercial structure for compensating providers. To meet the requirements of BAL-001-0.1a and BAL-002-1, BAs need Frequency Response (equipment) so that they have the "ability... to react or respond to a change in system frequency." Maintaining ACE is a Frequency Response service, but it is different from the type of service in draft standard BAL-003-1 and as described in the technical conference. The SDT should explain the relationship of all three standards since they all address an aspect of Frequency Response. 2. Draft BAL-003-1 Objectives The objectives of Project 2007-12 are excerpted below from its web page: Frequency Response, a measure of an Interconnection's ability to stabilize frequency immediately following the sudden loss of generation or load, is a critical component to the reliable operation of the bulk power system, particularly during disturbances and restoration. Failure to maintain frequency can disrupt the operation of equipment and initiate disconnection of power plant equipment to prevent them from being damaged, which could lead to wide-spread blackouts. THERE IS EVIDENCE OF CONTINUING DECLINE IN FREQUENCY RESPONSE IN THE THREE INTERCONNECTIONS OVER THE PAST 10 YEARS, BUT NO CONFIRMED REASON FOR THE APPARENT DECLINE (emphasis added). The proposed standard would set a minimum Frequency Response obligation for each Balancing Authority, provide a uniform calculation of Frequency Response and Frequency Bias Settings that transition to values closer to natural Frequency Response, and encourage coordinated AGC operation. This statement has two shortcomings. First, the emphasized sentence above is discouraging because if one does not know why Frequency Response is declining, how can a BA ensure itself that it has sufficient Frequency Response in its area to meet its obligation? The standard should describe how a BA might comply with its Frequency Response Obligation in an appendix. (See the comments in Section D below.) Second, it makes no mention that having sufficient Frequency Response is necessary TO ARREST FREQUENCY DECLINE WITHING THE FIRST SECONDS OF A DISTURBANCE SO THAT UNDERFREQUENCY LOAD SHEDDING (UFLS) IS MINI MIZED. 3. Graphics A plot of frequency versus time after the sudden loss of generation is only contained in the presentations for the technical conferences, not in any of BAL-003-1's documents. Such a plot is needed in the standard (or in an attachment to it) so that the familiar reference points - A, B, and C - can be used in the standard's documents. 4. Physical response to loss of generation The workshop did a good job in explaining what occurs physically within an Interconnection after generation is lost. Those are summarized below for the SDT to review for any misunderstanding. a. At point A (pre-disturbance), an unspecified amount of generation is lost. b. Between point A and point C (the frequency nadir), several changes occur: i. Due to the loss of generation, load is greater than generation, and in response to this imbalance, generators "slow down" and frequency drops. Each generator's loss of speed releases power to serve the load, albeit at a reduced frequency. Generators with areater mass are preferred since thev have more stored rotatina power to release. Freauencv

Bias setting in each BA's ACE equation allows this power to flow into the Interconnection. ii. Load is also reduced when frequency is reduced because loads such as motors slow down also and consume less power. Load reduction aids in arresting frequency decline. However, unless the frequency decline triggers the first UFLS step, no connected is lost. iii. Generator governors begin to respond. A generator's governor that can increase output when frequency declines provided certain characteristics are met. 1) The generator must be operating below its maximum capacity that can be achieved under automatic (i.e. non-operator intervention) operation. A generator with a 100 MW capacity and operating at 80 MW has "head room" to respond while the same generator operating at 100 MW cannot. 2) The governor's "dead band," which defines a range (+/-) of frequency changes that do not activate the governor, must not be so wide so as to effectively disable the governor from responding to frequency changes during a disturbance. 3) The governor cannot be overridden by "outer loop controls" on the generator. These controls countermand the governor's response, keeping the generator's output level unchanged. Governor response is the last to occur - it begins within seconds after the disturbance and continues until the generators with active governors reach their maximum capacity or until frequency is restored. In addition, properly devised demand response resources can substitute for governor-responsive generators. C. At point B, frequency is stabilized. All of items above occur automatically, without operator intervention. Collectively, these actions are referred to the "primary response" of the Interconnection to loss of generation. Subsequent responses involve operator actions that eventually return system frequency and ACE to a pre-disturbance ACE target. These subsequent responses are not the objective of draft BAL-003-1, but they are the objective of BAL-002-1. 5. Frequency Response Obligation Determination Regarding the Frequency Response Obligation for an Interconnection, Attachment A in draft BAL-003-1 states "Each Interconnection will establish target contingency protection criteria," with the default target "based on the largest category C ( $\mathrm{N}-2$ ) event identified." We have several questions: a. How can two Interconnections (Eastern and Quebec), which are not Registered Entities, comply with the requirement in Attachment A to set a Frequency Response Obligation? In fact, no Interconnection is listed in the Applicability section of BAL-003-1. b. We assume that "category C" in the Attachment A language above references Table 1 in the current TPL standards, but that should be clarified by the SDT. Does the SDT intend to restrict the category C events to those that only result in the loss of two Elements? This question is asked because category C in Table 1 is described as "Event(s) resulting in the loss of two or more (multiple) elements." c. The default target contingency in Attachment A is greater than minimum Contingency Reserve requirement in BAL-002-1 (R3.1), which is based on "the most severe single contingency." Why was the minimum requirement in BAL-002-1 not used? The SDT should explain its rationale for choosing "the largest category C ( $\mathrm{N}-2$ ) event identified" as the basis for setting an Interconnection's Frequency Response Obligation. 6. Frequency Response Obligation Measurement We summarized Frequency Response Obligation measurement below for the SDT to review for any misunderstanding. a. Frequency Response will be measured at point $B$ due to technical limitations in measuring each BA's point C. However, point C can be measured for an Interconnection. Because the C to B ratio is highly consistent within an Interconnection, measuring the response at B also measures the decline at C is achieved. b. For compliance purposes, each BA's performance in meeting its Frequency Response Obligation will be based upon its median Frequency Response of at least 25 events, expressed in megawatts per $0.1 \mathrm{Hertz}(\mathrm{MW} / 0.1 \mathrm{~Hz})$. D. FREQUENCY RESPONSE OPTIONS The discussion below is not inclusive, and the SDT is encouraged to provide guidance on compliance as recommended in Section C. 2 above. 1. Value high inertia generators. Generators that are on line and spinning, even if loaded to their maximum capacity, provide MW by slowing down, and generators with greater mass are preferred. In engineering parlance, this is termed the inertia constant, H , which, for a given generator is: $\mathrm{H}=$ (Stored kinetic energy in megajoules at synchronous speed)/(Generator rating in MVA) Generators with a greater H constant have more value in arresting frequency decline than similarly rated generators with a lower H constant. 2. Value interruptible load on underfrequency relays. Many utilities have interruptible loads, and some of these could be configured to be shed load based upon frequency steps that are above the first UFLS step. As an example, direct load control programs for cycling residential air conditioners and water heaters could be configured to interrupt all appliances on the program for several minutes after a disturbance, with the appliances gradually restored after the frequency decline is arrested. 3. For generators that provide primary Frequency Response through governor action, value rapid response. The rate of increase in generator output due to governor response is both governor and prime-mover specific. The governor's droop determines how much it will increase signal generator power to increase when freauencv declines. Also, aenerators with rapid power increase capabilitv.
such as simple cycle gas turbines, can deliver the governor's signal to increase power more quickly. The more rapid a generator's response capability, the more it should be valued. a. Generators providing primary Frequency Response through governor action or automatically curtailed interruptible load also provide "Operating Reserve - Spinning," which is a component of Operating Reserve. It is defined in the NERC Glossary as follows: Operating Reserve - Spinning The portion of Operating Reserve consisting of: i. Generation synchronized to the system and fully available to serve load within the Disturbance Recovery Period following the contingency event; or ii. Load fully removable from the system within the Disturbance Recovery Period following the contingency event. The term "Disturbance Recovery Period" is used in BAL-002-1, and its default value is 15 minutes. To minimize UFLS activation, which can occur within seconds after a disturbance, primary Frequency Response is the key requirement, and the 15 minute time frame in Operating Reserve - Spinning is not relevant. However, a GO that provides primary Frequency Response via an active governor or a demand response provider that provides automatically curtailed interruptible load is also providing Operating Reserves - Spinning. E. OATT PROVISIONS Unless commercial terms are established which define the relationship between BAs and Frequency Response providers (GOs and demand response resources), BAL-003-1 will not be implementable. Because commercial terms need to be defined in the OATT, we encourage NERC to work with FERC's Office of Energy Market Regulation and/or its Office of Energy Policy and Innovation to initiate proceeding with the goal of developing a new ancillary service - Primary Frequency Response Service. This service would address automatic Frequency Response within a short time frame (up to about 30 seconds) after a disturbance. Overlap between Spinning Reserve Service and Primary Frequency Response Service would need to be addressed. F. COORDINATION WITH PROJ ECT 2010-14.1 After preparing the majority of our comments, a first-time request for comments on a related project, Project 2010-14.1 - Phase 1 of Balancing Authority Reliability-based Controls Reserves - was posted on June 4. This project includes a new draft standard BAL-012-1 that has a proposed definition for Frequency Response Reserve - "An amount of reserve automatically responsive to locally sensed frequency deviation during the primary control time frame." That definition is similar to the ancillary service proposed above. Both SDTs should put themselves in the position of a BA that must comply with R3 and all its subparts in draft standard BAL-012-1 and develop a hypothetical implementation plan for a BA to meet its Frequency Response Obligation. If they did, they would understand why BAs have little understanding of what they must do to comply with draft BAL-003-1. Both SDTs work together to explain the relationship between Regulating Reserve, Contingency Reserve, and Frequency Response Reserve contained in BAL-012-1.

Transmission Reliability Program
Chris Higgins Bonneville Power Administration Transmission Reliability Program cmiggins@bpa.gov 360-418-2132 Submitting on behalf of the BPA's AGC team. BPA continues to fundamentally disagree with the approach that BAL-003-1 is developing into. Please reference BPA's extensive comments submitted on 12/8/11 for Project 2007-12 Frequency Response found here:
http://www.nerc.com/docs/standards/sar/2007-12_comments_received_120911.pdf. BPA also believes that having a special interest group present their perspective on the standard and a consultant provide a sales pitch in relation to load response was inappropriate and ill-served. Individual

## Don Mcl nnis

## Florida Power \& Light

The conference was very informative. Of particular interest was who should be responsible for providing frequency response. The assignment to the BA was well supported and logically presented. The details presented in the conference were different than those in the original version of the standard i.e. the frequency selected to protect for was modified from 59.7 to "prevailing". The prevailing frequency if prevailing is interpreted as dominant is 59.3 Hz yet the standards team choose 59.5 Hz without explanation or justification. There was also a lack of technical justification in increasing the frequency bias minimum from the original $0.8 \%$ to $0.9 \%$. While a minimum should be established there should be no link to frequency response as the two are no longer related.

## Bob Frost

## Portland General Electric

1. BAL-003-1, Attachment A, states that the ERO will provide quarterly posting of candidate frequency events. It then states it will post the final list of frequency excursion events used for standard compliance by December 15 each year. Because the quarterly postings are only candidates and the median frequency response is the measure, Balancing Authorities cannot always be certain they will be compliant with the Standard until December 15. 2. FRS Form 1, sheet "Data Entry", requests entry by the Balancing Authority of next year's FRO (cell O31). However, per Attachment A, this information is provided by the ERO only after Form 1 is submitted by the Balancing Authority. A Balancing Authority is only able to estimate their FRO. 3. FRS Form 2, sheet "Entry Data", has the Balancing Authority modify formulas for cells C8 and C11 in order to identify the beginning and recovery from the event. This is tedious as Form 2 must be completed a minimum of 25 times each year. The spreadsheet should be authored so that the user does not need to modify formulas. The sheet "Data" on Form 2 could have cells adjacent to the data that are marked to identify these points.

MISO Standards Collaborators

## Marie Knox

MISO
We have a strong concern related to the handling of variable bias. The drafting team is fully removing the floor for the minimum amount of bias for these BAs and only asks bias to be equal to natural frequency response when frequency is off normal. There should always be some bias (perhaps 40\% of FRO) provided to the Interconnection and there should be some minimum annual average. This can be managed through the year and still will be well less than the current obligation under BAL-003-0. Since there is no firm technical guidance on how variable bias is to be set, to leave this gap will cause a mass movement of BAs to report as variable bias entities. It will also leave the door open to gaming to artificially improve CPS, DCS and BAAL performance. For example, an algorithm that takes bias to a small positive number once each 15 minutes would assure the BA will never fail DCS or BAAL.

LG\&E and KU Services

## Brent Ingebrigtson

## LG\&E and KU Services

LG\&E and KU Services have two comments/questions related to the material presented at the FR Technical Conference: 1. Data was presented that illustrates a decline in the Frequency Response of the Eastern Interconnect for the period 1994 through 2010. Since FR is partially related to the amount of on-line generation available at the time of the contingency, has the SDT investigated the amount of spinning reserves typically available on the Eastern Interconnect during the same 1994 to 2010 period? If so, was there a correlation between the decline of Frequency Response and available spinning reserve? 2. During the conference, mention was made that there is a cost for obtaining Frequency Response - mainly the cost of unused spinning generator capacity. However, no data, analysis or estimates were presented as to what these costs might be. Cost estimates for attaining the desired amount of Frequency Response would be useful to the industry and FERC in evaluating the proposed Frequency Response standard.

## I ndividual

## Michael Goggin

American Wind Energy Association
AWEA appreciates the opportunity to comment on NERC's ongoing work on frequency response standards. Based on the presentations at NERC's May 2012 technical conferences on frequency response issues, it appears that consensus exists around three important points, which we would like to highlight in our comments. We are pleased that these points appear to be embodied in the ongoing work of the standards drafting team on frequency response (BAL-003-1). 1. The balancing authority
(BA) should be the entity responsible for meeting a frequency response standard. This responsibility would fit in well with a BA's existing responsibilities for maintaining system frequency within acceptable bounds, such as CPS 1\&2 and DCS requirements. Just as a BA currently obtains the reserves and other services required to meet these frequency standards and operates according to these standards, the BA is the logical entity for taking on those responsibilities for frequency
response. The BA is the only entity that has a real-time awareness of overall power system needs and capabilities, and is thus ideally suited for meeting a frequency response standard. 2. A BA's selection of resources to provide frequency response service should be market-based. As was explained at the technical conferences, different resources have widely divergent costs for providing frequency response. Many resources are likely to be able to provide significant frequency response at very low cost, while other resources are likely to face significantly higher costs for providing this service. For example, maintaining the capability to provide sustained frequency response from a wind plant would require holding the wind plant below its operating capability at all times, foregoing significant production of near-zero-marginal cost, zero emissions wind energy. As a result, under normal operating conditions, the wind plant's opportunity cost for providing frequency response capability is likely to be significantly higher than the cost for many other generating resources, which would be able to save on fuel costs by operating below their maximum output. Innovative technologies, including some forms of demand response and energy storage, are also likely to be able to provide frequency response at relatively low cost. The BA is well-positioned to use a market-based mechanism to select the least-cost frequency response resources from the available resources, as conditions change in real-time. This market-based incentive should also provide sufficient incentive for most potential resources to install any equipment necessary to provide frequency response. The market mechanism should be designed to pay for performance, so that frequency response resources are incentivized to provide services with the maximum value for the power system. 3. The decline in frequency response on the Eastern U.S. power system pre-dates the introduction of wind energy and appears to have been caused by changes in how conventional power plants are operated, and not in any way tied to the increased use of wind energy. As NERC noted in comments submitted to FERC on October 14, 2010: "Frequency response of the interconnected North American electric systems has shown a significant decline for several years. The reasons for the decline are numerous, including: - A trend toward larger governor deadband settings, exceeding the historical typical setting of $\pm 36$ millihertz ( mHz ); • Use of steam turbine sliding pressure controls; • Loading units to 100 percent of capacity leaving no "headroom" for response to losses of generation; • Blocked governor response; • Once-through boilers; • Gas Turbine inverse response; • Withdrawal of primary frequency response of generators by MW setpoints, resulting in limited time of response; and • Changes in the frequency response characteristics of the load. These changes have been evolving for some time and are not the direct result of the emergence of renewable resources such as wind and solar." Data presented at the technical conference indicated that only around $30 \%$ of generators are currently providing frequency response. Much of the decline in frequency response provision appears to result from generator owners maximizing efficiency and minimizing costs under current market structures. Implementing a market-based mechanism to select the least-cost frequency response resources from the available resource pool would allow conventional generators to be appropriately compensated for any costs they incur for providing frequency response while simultaneously selecting the least-cost resources for the power system. The technical conference also discussed the fact that only $1 / 3$ of the $30 \%$ of generators that are providing frequency response (so $10 \%$ of the total generation fleet) sustain that frequency response for more than a short period of time. Part of the problem appears to be that some current energy imbalance tariff provisions may penalize generators that increase their output beyond the scheduled amount, and therefore generators are limiting the duration of frequency response following a system disturbance to avoid imbalance penalties. At the technical conference, there appeared to be widespread support for reforming those energy imbalance tariff provisions to remove that perverse incentive, which is commendable.

Introduction The undersigned members of the ISO/RTO Standards Review Committee (SRC) appreciate that NERC provided the opportunity to comment upon NERC's Frequency Response Technical Conference. The Conference addressed an important topic in which the SRC is deeply interested - primary control. The SRC notes that the Conference's presentation of the various and diverse perspectives of this topic highlighted the continued need to resolve and address several issues: - The need for a common language for discussion - The need for an objective analysis of a reliability need • Given the proof of such an objective reliability need, there is a need to define the quantitative parameters involved in measuring the objective • The need to justify the creation of a
mandatory standard that is relevant to the current and future BES. That includes: o Reviewing relevancy of old standards o Clarifying discussions o Objectively assigning responsibilities Discussion Terminology/Common Language The SRC noted that the presenters did not share a common set of terms. The term Frequency Response was used to address issues that are separated by time frames and that deserve separate discussions. Frequency Response was used generically to mean any activity related to controlling frequency. Frequency Response was also used to mean undirected control (such as the change in generator output caused by a governor). Frequency Response was used to mean directed control (aka secondary control). It was also used to mean the Area Control Error equation. Rather than relying on the broad and ill-defined term Frequency Response, the SRC suggests that either newly minted terms be created or that more traditional terms such as Primary Control Response and Secondary Control Response be used. All too often the presenters crossed the traditional boundaries thereby decreasing the clarity (and the value) of the discussion. There was also a tendency to use the term "Service" for both the traditional Ancillary Services (Load Following (aka Economic Dispatch); Spinning reserves; Supplemental reserves; Regulation service (aka AGC); Reactive and voltage control service; Black start) and for conditions that exist (i.e. the reaction from generators to changes in frequency). There is a tendency to equate Frequency Control through tie-line bias (typically this is AGC or secondary control) with Primary control (Dave Lemmons); Bias vs. Beta (is also a secondary control issue but it is linked because the parameters themselves are related to the primary response experienced; but they drive secondary control problems and solutions). In short the Bias is a 1st order approximation of what the magnitude of primary response that goes into the ACE equation to drive secondary control. Unless care is taken with the terms, it is easy to envision differences in discussions. Good resolutions of problems caused on the secondary control system were presented (Terry Bilke) but that need is relatively independent of this SDT. For our comments the SRC will focus on Primary Control response and use the terms primary, primary response, or primary frequency response rather than Frequency Response. Need The SRC notes that the presenters offered a variety of reasons for a "Frequency Response" standard: - Because the governor response in the Eastern Interconnection changed (or appears to be changing) - To avoid Under-Frequency Load Shedding relay operation - To avoid problems for Secondary control (valid need but not a valid justification for Primary Frequency control standard) (Howard IIlian) • FERC Order 693 o Determine the appropriate periodicity of frequency response surveys o Define necessary amount of Frequency Response for reliable operations with methods of obtaining response and measuring that the frequency response is achieved • FERC Technical Conference The SRC observes that the presenters are attempting to address the goal of operating at a reasonable margin away from both UFLS (underfrequency) and OFR (over-frequency) settings, and to avoid any single event (contingency) causing those relays to activate. The SRC fully supports that objective. Several presenters mentioned the above objective and addressed the amount of post-event governor response, i.e. response that was activated after the frequency was arrested. Presenters recognized that not all suppliers are generators, and not all generators have governors, and not all of those generators respond in the same way. They also note that BAs do not all own generators. One presenter documented that the Eastern Interconnection has the worst post event response but also has the highest frequency arrest level (i.e. are farthest from a relay trip point) Most presenters expressed preference to impose Frequency response production requirements on BAs. Most presenters want to focus on the Eastern Interconnection. The SRC believes the requirement addressing primary frequency response must: • Relate to the frequency nadir point not the post event response • Apply to and be assigned to "ALL" Functional Entities registered for that applicable group • Reflect the capabilities of the functional entity to provide the mandated service. - Address both supply capabilities as well as appropriateness of relay settings If the objective is to avoid tripping relays and to minimize the risk of tripping those relays then the requirement must focus on that objective. Some presenters stated that it is traditional and simply easier to focus a Frequency Response requirement on BAs. Others stated that there were too many suppliers to impose a frequency response mandate on the suppliers. The SRC as well as NERC have stated the intention to have performance based standards and to move away from procedural requirements. The majority of the Technical Conference presenters focused on procedural solutions (i.e. governor response) and tried to indicate that both generation and demand response could serve as response providers. Bob Cummings of NERC showed that the typical worst response of the EI was equal to or higher than the best responses in ERCOT or WECC. In effect the concern about lack of post event response does not reflect the margin of reliability experienced even with the "hockey stick" response. Given the fact that none of the presenters proposed increasing the ERCOT and WECC responses to be as effective as the EI response, the observed decrease in the Eastern
interconnection could be seen as a type of "right-sizing" of response - i.e. the east is now coming closer to the rest of North America. Supply The SRC does recognize the change in frequency response in the EI, but is concerned that mandating ill-advised requirements on the wrong applicable entities will foster the loss of the provision of primary response service and not help it. If the "supply" requirement is placed on a coordinator, then the energy producing assets have no incentive to provide a service that takes away from other more lucrative products. If the requirement is placed on a subset of suppliers then those suppliers will likely mimic the suppliers in the other subset and not offer any service at all. The idea of focusing on one given solution - governor response - creates disincentives for new technologies. The Industry is now adopting those innovations without a mandate and should be allowed to continue that expansion without the threat of a standard that would impede such expansion. Suggestions The SRC believes there is a need for more open presentations including people not as focused on governors. The majority of presenters were experts in a given area. Their expertise seemed to preclude exploration of other options than the current option/approach. It should be noted that a Governor-centric requirement violates Order 693's mandate to be resource neutral. It is time to have a discussion of the role of coordinators (like RCs, TOPs and BAs) who can and do use a palette of tools and services to address a given system condition without being obligated to answer for non-production. An alternative could be that such entities are required to provide assessment and analysis but not production; or they are required to arrange for, purchase, or otherwise provide capacity (not energy) capable of providing the primary frequency response. Many of the presenters seemed to be in a vertically integrated industry where the coordinator is the owner and operator. That is no longer universally true. A primary frequency response service for an interconnection may be calculated as discussed by the presenters, but the mandate must be developed so that the default entity will be obligated to provide or purchase the obligation (thus opening the opportunity to all new innovations). Should that be the LSEs who use the service; the suppliers who provide the service; the coordinators who integrate all of the services; or to allow a combination without specifying "how" it must be done? Other SRC Considerations raised by presenters' comments It is invalid to avoid imposing a requirement on the appropriate applicable entity simply because there are many of them; if other standards apply to the same applicable entities then this one can also. Speed should not be a driver contrary to what one presenter stated. As presenters said we are fine today without any mandatory standard for primary control. This prompts the question "why the need for speed?" Because we can correct problems with the requirements later, via SARs, is NOT a justification for creating an inaccurate standard. Why should TOPs be permitted to set relays anywhere, but GOPs be obligated to set governors to avoid those relays? Focusing on improving details of what we have today does not make today's paradigm better!!!! A standard should not serve as a field test for an idea!!!!
Individual
Laura Lee

## Duke Energy

Duke Energy appreciates having the opportunity to participate in the Frequency Response Technical Conference. It was a very helpful for our team to hear the issues that were brought by others to the discussion, along with the opinions of NERC staff, the Frequency Response Standard Drafting Team (FRRSDT), and FERC staff. Duke Energy provides the following comments and proposed resolutions to some of the issues we believe should be addressed. Frequency Response Obligation (FRO) As the FRRSDT reviews all of the issues discussed and subsequent comments provided, we ask that consideration be given to drilling down to the "root cause" of the issues, to see what is driving them. We have found one of the root causes of a few issues to be the allocation of the FRO. In the current proposal, a BA's FRO is the Interconnection Frequency Response Obligation applied to the ratio of the BA's generation and load at peak divided by the Interconnection BA totals of generation and load at peak. Including generation in the allocation helps accommodate treatment of generation-only BAs (representing perhaps one percent of the total generation in the Interconnection), but in the process creates issues for both individual generating resources and all other BAs. Duke Energy believes that the FRO allocation should be based upon load only, based upon the numerous issues and inequities that an FRO allocation based upon load and generation would otherwise create, including but not limited to: a) An FRO allocation based upon generation at peak treats resources on a non-comparable basis within a "traditional" (load and generation) BA, biased against resources dedicated to peaking operation (CTs as an example), and in favor of resources which may not operate at peak capacity during such times (wind resources as an example). b) A third party resource added to a BA footprint
would add to the BA's response requirement, but the third party resource would have no requirement to provide frequency response. If such resources are only providing peaking energy to off-system loads, the generation would add to the response requirement for the BA for the year, though the resources may run a small fraction of that time. Even if the resources were capable of providing frequency response when online, they may do little to compensate the BA for the increased yearround requirement. The allocation methodology creates the issue that the BA must now address compensation for the increased response requirement or some other tariff provision to make it whole. c) The allocation methodology creates a gaming opportunity - a strategy to purchase external energy across the peak would be a small premium to pay to achieve a reduced Frequency Response Obligation for the year - but a large price to pay for the BA with the resources selling off-system outside its control. d) Discussed further below, the inclusion of generation in the FRO allocation creates a significant discrepancy between the methodology used to determine the FRO and the methodology used to determine the minimum Frequency Bias Setting. In our opinion, these are among the issues that neither the BAs nor the resources need to face. An allocation based upon the load within the BA rather than load plus generation would resolve them. An additional modification to enhance equitable treatment and eliminate gaming is the use of total energy for the period rather than peak loads in the FRO allocation. There is uncertainty that the use of 12 monthly peaks accurately represents the load benefiting from the continuous provision of Frequency Response. Similar to the gaming discussed above for generation, BAs capable of "peak shaving" are able to reduce a year-round requirement based upon a few hours of operation. Duke Energy proposes that the determination of a BA's FRO be the Interconnection FRO applied to the ratio of the BA's NEL (for those submitting EIA-714 reports, this would be the annual total in column e of Part II, Schedule 3; for others, this would be the sum of LSE NELs in the BA as reported for determination of NERC and Regional fees) divided by the Interconnection BA totals of these NELs. Basing the FRO allocation upon annual energies rather than peak loads eliminates the potential for a year-round FRO to be pushed to others by peak shaving if a peak value is used. The FRO for generation-only BAs (representing approximately $1 \%$ of the total generation within an Interconnection) can be set to a fixed percentage of total capacity, similar to current requirements for calculating the Frequency Bias Setting. Frequency Bias Setting (FBS) Notwithstanding our concern raised in the past that the secondary control measures are too tightly bound to the FBS and believing that in some cases the FBS is used as a convenient measure of BA size, Duke Energy agrees with the proposal to gradually reduce the magnitude of the FBS to some margin above the natural Frequency Response of the Interconnection. However, as proposed in the "Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard" dated February 21, 2012, the allocation of the FBS reduction would be a margin based upon peak load or peak generation, rather than a margin based upon a methodology similar to that used for the allocation of the Frequency Response Obligation. As an example, based upon the proposed FRO allocation using load plus generation at peak, two BAs with the same peak load, but with differing levels of generation at peak due to off-system transactions, would have a different FRO allocation; however, these two BAs would be given the same minimum Frequency Bias Setting based upon a percentage of peak load only. A generation-only BA with the same amount of generation as a traditional BA serving a similar amount of load, would have an FRO allocation approximately half that of the traditional BA, however these two BAs would be given the same minimum FBS. Under the proposed procedure for reducing the magnitude of the FBS, the generation-only BA would always have a minimum FBS set almost twice what it would need to have compared to the traditional BA. We believe that the incremental reduction in the FBS will not achieve an equitable allocation in its final state. Duke Energy believes that the minimum FBS for each BA should be reduced in magnitude to a fixed percentage above each BA's FRO (but no lower individually than its FRM), while assuring that the Interconnection FBS remains at some margin above the Interconnection FRM. The current procedure posted for the FBS reduction will not achieve that equitable allocation, as the minimum FBS will always be based upon a different methodology than the FRO allocation in its current form. Upon request, Duke Energy can provide a procedure which could be used for determining the minimum FBS which would allow the minimum FBS for each BA to be incrementally reduced in magnitude over time based upon the FRO allocation, and ensure that the Interconnection FBS remains at some margin above the Interconnection FRM. However, given the timeline for moving this standard forward, Duke Energy would propose that consideration be given to basing the FRO allocation on load only as discussed above, setting a value for the generation-only BAs, and returning to the issue of aligning the methodologies used for the FRO allocation and minimum FBS calculation at a later time. Variable Freauencv Bias Settina Duke Enerav disaarees with the FRRSDT's proposal not to reauire a minimum

FBS for BAs using a Variable FBS in multiple BA Interconnections. There are no defined requirements on how a Variable FBS SHALL be calculated, yet its use changes not only the ACE measured against the BAL-001 secondary control requirements, but also the bounds of those secondary control requirements. Overall, Duke Energy questions whether the proposed standard should continue to allow the use of a Variable FBS in calculating ACE or secondary control performance. Duke Energy does not question the value of a BA implementing the logic of a variable FBS in its generation control algorithm, along with other factors to more efficiently control resources, however its operation should be measured in a manner consistent with all other BAs. Nathan Cohn was of the opinion that the secondary control assistance provided by the FBS should be a shared obligation. In the publication "IEEE Transactions on Power Systems, Vol. 3, No. 3, August 1988", Cohn noted the following in the article VARIABLE, NON-LINEAR TIE-LINE FREQUENCY BIAS FOR INTERCONNECTED SYSTEMS CONTROL: "The very conditions that create a variable frequency response to which an area bias is linked as in the subject paper would create a variable level of bias assistance by the area in fulfilling system needs." Nathan Cohn goes on to state, "It is of course recognized that the extent of bias assistance to be scheduled by individual areas is, as are all operating practices, a matter for system operating personnel to determine. This discusser suggests, however, that there are potential advantages in bias assistance based on a common percentage-of-peak for all areas. It would provide an equitable, cooperative, and democratic systems approach." As supported by the statements of Cohn, Duke Energy believes that the assistance provided by the FBS should be a shared obligation equally applied to all BAs by using a fixed FBS in the calculation of ACE and secondary control performance. BAL-003-1 Documents The document, "Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard" dated February 21, 2012, no longer has a reference to being "Attachment B" to the draft BAL-003-1 standard. Duke Energy would appreciate clarification of whether this document is within the scope of what will be eventually be included in the ballot of Project 2007-12 - Frequency Response, and what process would be required to make any subsequent revisions to the procedure.

## Individual <br> Rebecca Moore Darrah

MISO
The Midwest Independent Transmission System Operator, Inc. ("MISO") appreciates the opportunity to comment on the technical conferences that NERC recently held on Frequency Response issues, and, in particular, the proposed changes to BAL-003. MISO adds only two brief comments here. MISO agrees with the proposed change in BAL-003-1 with respect to the calculation of minimum amount of frequency response to be provided by a Balancing Authority (this is the Frequency Response Obligation under Requirement R1 of BAL-003-1). The allocation of Frequency Response Obligation among Balancing Authorities in an Interconnection is to be based on peak load data, which is a reasonable approach to determining what proportion of frequency response should be contributed to each Balancing Authority. MISO also agrees with the manner of calculating each Balancing Authority's Frequency Response Obligation under Requirement R1; the proposal by the Standards Drafting Team will ensure that adequate frequency response is provided by each Balancing Authority. At the same time, the Standards Drafting Team should reconsider its approach to variable bias. Balancing Authorities with variable bias are not subject to some of the requirements. Variable bias methodologies are not identified, and that lack of an identified methodology opens the opportunity for individual Balancing Authorities to engage in gaming (such as having bias go to zero or a small positive number every 15 minutes to ensure DCS and BAAL is never failed).

## Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

## Development Steps Completed:

1. The Standards Committee approved the SAR for posting on January 13, 2005.
2. The SAR was posted for industry comment from January 17, 2005 through February 17, 2005.
3. Reply comments and a revised SAR were posted for a second industry comment period from April 4, 2006 through May 3, 2006.
4. Reply comments and a revised SAR were posted for a third industry comment period from February 8, 2007 through March 9, 2007.
5. Standards Committee approved moving the project into the standards development phase on July 12, 2007.
6. The Standards Committee appointed the Standard Drafting Team on August 13, 2007.
7. The draft standard was posted for a 30 day formal comment period from February 4, 2011 through March 7, 2011.
8. The draft standard was posted for a 45-day formal comment period and a 10 day initial ballot from October 25, 2011 through December 8, 2011.

## Proposed Action Plan and Description of Current Draft:

This is the third posting of the proposed standard and its associated documents for a 30 day formal comment period and a successive 10 day ballot, from October 5, 2012 through November 5, 2012.

## Future Development Plan:

| Anticipated Actions | Anticipated Date |
| :---: | :---: |
| 1. <br> Respond to comments submitted within the comment period <br> and with the successive ballot. <br> 2. Conduct a recirculation ballot for ten days. January, 2013 |  |
| 3. BOT adoption. | February, 2013 |

## Definitions of Terms used in the Standard

## Frequency Response Measure (FRM)

The median of all the Frequency Response observations reported annually by Balancing Authorities or Frequency Response Sharing Groups for frequency events specified by the ERO. This will be calculated as MW/0.1Hz.

## Frequency Response Obligation (FRO)

The Balancing Authority's share of the required Frequency Response needed for the reliable operation of an Interconnection. This will be calculated as MW/0.1Hz.

## Frequency Bias Setting

A number, either fixed or variable, usually expressed in MW/0.1 Hz, included in a Balancing Authority's Area Control Error equation to account for the Balancing Authority's inverse Frequency Response contribution to the Interconnection, and discourage response withdrawal through secondary control systems.

## Frequency Response Sharing Group (FRSG)

A group whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply operating resources required to jointly meet the sum of the Frequency Response Obligations of its members.

## A. Introduction

## Title: Frequency Response and Frequency Bias Setting

Number: BAL-003-1
Purpose: To require sufficient Frequency Response from the Balancing Authority to maintain Interconnection Frequency within predefined bounds by arresting frequency deviations and supporting frequency until the frequency is restored to its scheduled value. To provide consistent methods for measuring Frequency Response and determining the Frequency Bias Setting.

Applicability:
1.1. Balancing Authority
1.1.1 The Balancing Authority is the responsible entity unless the Balancing Authority is a member of a Frequency Response Sharing Group, in which case, the Frequency Response Sharing Group becomes the responsible entity.
1.2. Frequency Response Sharing Group

## Effective Date:

1.3. In those jurisdictions where regulatory approval is required, Requirements R2, R3 and R4 of this standard shall become effective the first calendar day of the first calendar quarter 12 months after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, Requirements R2, R3 and R4 of this standard shall become effective the first calendar day of the first calendar quarter 12 months after Board of Trustees adoption.
1.4. In those jurisdictions where regulatory approval is required, Requirements R 1 of this standard shall become effective the first calendar day of the first calendar quarter 24 months after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, Requirements R1 of this standard shall become effective the first calendar day of the first calendar quarter 24 months after Board of Trustees adoption.

## B. Requirements

R1. Each Frequency Response Sharing Group (FRSG) or Balancing Authority that is not a member of a FRSG shall achieve an annual Frequency Response Measure (FRM) (as calculated and reported in accordance with Attachment A) that is equal to or more negative than its Frequency Response Obligation (FRO) to ensure that sufficient Frequency Response is provided by each FRSG or BA that is not a member of a FRSG to maintain Interconnection Frequency Response equal to or more negative than the Interconnection Frequency Response Obligation. [Risk Factor: Medium ][Time Horizon: Real-time Operations]

R2. Each Balancing Authority that is a member of a multiple Balancing Authority Interconnection and is not receiving Overlap Regulation Service and uses a fixed Frequency Bias Setting shall implement the Frequency Bias Setting determined subject to Attachment A, as validated by the ERO, into its Area Control Error (ACE) calculation during the implementation period specified by the ERO and shall use this Frequency Bias Setting until directed to change by the ERO. [Risk Factor: Medium ][Time Horizon: Operations Planning]

R3. Each Balancing Authority that is a member of a multiple Balancing Authority Interconnection and is not receiving Overlap Regulation Service and is utilizing a variable Frequency Bias Setting shall maintain a Frequency Bias Setting that is: [Risk Factor: Medium ][Time Horizon: Operations Planning]
3.1 Less than zero at all times, and
3.2 Equal to or more negative than its Frequency Response Obligation when Frequency varies from 60 Hz by more than $+/-0.036 \mathrm{~Hz}$.

R4. Each Balancing Authority that is performing Overlap Regulation Service shall modify its Frequency Bias Setting in its ACE calculation, in order to represent the Frequency Bias Setting for the combined Balancing Authority Area, to be equivalent to either: [Risk Factor: Medium ][Time Horizon: Operations Planning]

- The sum of the Frequency Bias Settings as shown on FRS Form 1 and FRS Form 2 for the participating Balancing Authorities as validated by the ERO, or
- $\quad$ The Frequency Bias Setting shown on FRS Form 1 and FRS Form 2 for the entirety of the participating Balancing Authorities’ Areas.

## C. Measures

M1. Each Frequency Response Sharing Group or Balancing Authority that is not a member of a Frequency Response Sharing Group shall have evidence such as dated data plus documented formula in either hardcopy or electronic format that it achieved an annual FRM )in accordance with the methods specified by the ERO in Attachment A with data from FRS Form 1 reported to the ERO as specified in Attachment A) that is equal to or more negative than its FRO to demonstrate compliance with Requirement R1.

M2. The Balancing Authority that is a member of a multiple Balancing Authority Interconnection and is not receiving Overlap Regulation Service shall have evidence such as a dated document in hard copy or electronic format showing the ERO validated Frequency Bias Setting was implemented into its ACE calculation within the implementation period specified or other evidence to demonstrate compliance with Requirement R2.

M3. The Balancing Authority that is a member of a multiple Balancing Authority Interconnection, is not receiving Overlap Regulation Service and is utilizing variable Frequency Bias shall have evidence such as a dated report in hard copy or electronic format showing the average clock-minute average Frequency Bias Setting was less than zero and during periods when the clock-minute average frequency is outside of the
range 59.964 Hz to 60.036 Hz was equal to or more negative than its Frequency Response Obligation to demonstrate compliance with Requirement R3.

M4. The Balancing Authority shall have evidence such as a dated operating log, database or list in hard copy or electronic format showing that when it performed Overlap Regulation Service, it modified its Frequency Bias Setting in its ACE calculation as specified in Requirement R4 to demonstrate compliance with Requirement R4.

## D. Compliance

## 1. Compliance Monitoring Process

### 1.1. Compliance Enforcement Authority

The Regional Entity is the Compliance Enforcement Authority except where the responsible entity works for the Regional Entity. Where the responsible entity works for the Regional Entity, the Regional Entity will establish an agreement with the ERO or another entity approved by the ERO and FERC (i.e. another Regional Entity), to be responsible for compliance enforcement.

### 1.2. Compliance Monitoring and Assessment Processes:

Compliance Audits
Self-Certifications
Spot Checking
Compliance Investigation
Self-Reporting
Complaints

### 1.3. Data Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Balancing Authority shall retain data or evidence to show compliance with Requirements R1, R2, R3 and R4, Measures M1, M2, M3 and M4 for the current year plus the previous three calendar years unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

The Frequency Response Sharing Group shall retain data or evidence to show compliance with Requirement R1 and Measure M1 for the current year plus the previous three calendar years unless directed by its Compliance Enforcement

Authority to retain specific evidence for a longer period of time as part of an investigation.

If a Balancing Authority or Frequency Response Sharing Group is found noncompliant, it shall keep information related to the non-compliance until found compliant or for the time period specified above, whichever is longer.
The Compliance Enforcement Authority shall keep the last audit records and all subsequent requested and submitted records.

### 1.4. Additional Compliance Information

For Interconnections that are also Balancing Authorities, Tie Line Bias control and flat frequency control are equivalent and either is acceptable.

### 2.0 Violation Severity Levels

| R\# | Lower VSL | Medium VSL | High VSL | Severe VSL |
| :---: | :---: | :---: | :---: | :---: |
| R1 | The summation of the Balancing Authorities' FRM within an Interconnection was equal to or more negative than the Interconnection's FRO, and the Balancing Authority's, or Frequency Response Sharing Group's, FRM was less negative than its FRO by more than $1 \%$ but by at most $30 \%$ or 15 MW/0.1 Hz , whichever one is the greater deviation from its FRO | The summation of the Balancing Authorities' FRM within an Interconnection was equal to or more negative than the Interconnection's FRO, and the Balancing Authority's, or Frequency Response Sharing Group's, FRM was less negative than its FRO by more than $30 \%$ or by more than $15 \mathrm{MW} / 0.1 \mathrm{~Hz}$, whichever is the greater deviation from its FRO | The summation of the Balancing Authorities' FRM within an Interconnection did not meet its FRO, and the Balancing Authority's, or Frequency Response Sharing Group's, FRM was less negative than its FRO by more than $1 \%$ but by at most $30 \%$ or 15 MW/0.1 Hz , whichever one is the greater deviation from its FRO | The summation of the Balancing Authorities' FRM within an Interconnection did not meet its FRO, and the Balancing Authority's, or Frequency Response Sharing Group's, FRM was less negative than its FRO by more than $30 \%$ or by more than $15 \mathrm{MW} / 0.1 \mathrm{~Hz}$, whichever is the greater deviation from its FRO |

## Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

## Development Steps Completed:

1. The Standards Committee approved the SAR for posting on January 13, 2005.
2. The SAR was posted for industry comment from January 17, 2005 through February 17, 2005.
3. Reply comments and a revised SAR were posted for a second industry comment period from April 4, 2006 through May 3, 2006.
4. Reply comments and a revised SAR were posted for a third industry comment period from February 8, 2007 through March 9, 2007.
5. Standards Committee approved moving the project into the standards development phase on July 12, 2007.
6. The Standards Committee appointed the Standard Drafting Team on August 13, 2007.
7. The draft standard was posted for a 30 day formal comment period from February 4, 2011 through March 7, 2011.
8. The draft standard was posted for a 45-day formal comment period and a 10 day initial ballot from October 25, 2011 through December 8, 2011.

## Proposed Action Plan and Description of Current Draft:

This is the third posting of the proposed standard and its associated documents for a 30 day formal comment period and a successive 10 day ballot, from October 5, 2012 through November 5, 2012.

## Future Development Plan:

| Anticipated Actions | Anticipated Date |
| :---: | :---: |
| 1. <br> Respond to comments submitted within the comment period <br> and with the successive ballot. <br> 2. Conduct a recirculation ballot for ten days. January, 2013 |  |
| 3. BOT adoption. | February, 2013 |

## Definitions of Terms used in the Standard

## Frequency Response Measure (FRM)

The median of all the Frequency Response observations reported annually by Balancing Authorities or Frequency Response Sharing Groups for frequency events specified by the EROon FRS Form 1. This will be calculated as MW/0.1Hz.

## Frequency Response Obligation (FRO)

The Balancing Authority's share of the required Frequency Response needed for the reliable operation of an Interconnection. This will be calculated as MW/0.1Hz.

## Frequency Bias Setting

A numbervalue, (either a-fixed or variable-Frequency Bias), usually expressed in MW/0.1 Hz , included inset inte a Balancing Authority's Area Control Error equation to account forthat allows the Balancing Authority's inverse Frequency Response contributionto contribute its Frequency Response to the Interconnection, and discourage response withdrawal through secondary control systems.

Frequency Response Sharing Group (FRSG)
A group whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply operating resources required to jointly meet the sum of the Frequency Response Obligations of its members.

## A. Introduction

## Title: Frequency Response and Frequency Bias Setting

## Number: BAL-003-1

Purpose: To require sufficient Frequency Response from the Balancing Authority to maintain Interconnection Frequency within predefined bounds by arresting frequency deviations and supporting frequency until the frequency is restored to its scheduled value. To provide consistent methods for measuring Frequency Response and determining the Frequency Bias Setting.

Applicability:
1.1. Balancing Authority

> 1.1-1.1.1 The Balancing Authority is the responsible entity unless the Balancing Authority is a member of a Frequency Response Sharing Group, in which case, the Frequency Response Sharing Group becomes the responsible entity.

## Effective Date:

1.2-1.3. In those jurisdictions where regulatory approval is required, Requirements R2, R3 and R4 and R5 of this standard shall become effective the first calendar day of the first calendar quarter 12 months after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, Requirements R2, R3 and, R4 and R5 of this standard shall become effective the first calendar day of the first calendar quarter 12 months after Board of Trustees adoption.
1.3.1.4. In those jurisdictions where regulatory approval is required, Requirements R1 of this standard shall become effective the first calendar day of the first calendar quarter 24 months after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, Requirements R1 of this standard shall become effective the first calendar day of the first calendar quarter 24 months after Board of Trustees adoption.

## B. Requirements

R1. Each Frequency Response Sharing Group (FRSG) or Balancing Authority that is not a member of a FRSG(BA) or Reserve Sharing Group (RSG) shall achieve an annual Frequency Response Measure (FRM) (as calculated and reported detailed in accordance with Attachment A and calculated on FRS Form 1) that is equal to or more negative than its Frequency Response Obligation (FRO) to ensure that sufficient Frequency Response is provided by each FRSG or BA that is not a member of a FRSGor RSG to maintain an adequate level of Frequency Response in the Interconnection Frequency Response equal to or more negative than the Interconnection Frequency Response Obligation. [Risk Factor: Medium ][TTime Horizon: Real-time OperationsOperations Assessment]

R2. Each Balancing Authority that is a member of a multiple Balancing Authority Interconnection and is not receivingparticipating in Overlap Regulation Service and uses a fixed Frequency Bias Setting shall implement the Frequency Bias Setting determined subject to Attachment A, as (fixed or variable)-validated by the ERO, into its Area Control Error (ACE) calculation during the implementation periodbeginning on the date specified by the ERO and shall use this Frequency Bias Setting until directed to change by the EROto ensure effectively coordinated Tie Line Bias control. [Risk Factor: Medium ][Time Horizon: Operations Planning]

R3. Each Balancing Authority that is a member of a multiple Balancing Authority Interconnection and is not receiving Overlap Regulation Service and is utilizing a variable Frequency Bias Setting shall maintain a Frequency Bias Setting that is: $\theta$ perate its Automatic Generation Control (AGC) in Tie Line Bias mode to ensure effectively coordinated control, unless such operation would have an Adverse Reliability Impact on the Balancing Authority's Area. [Risk Factor: Medium ][Time Horizon: Operations PlanningReal time Operations]
3.1 Less than zero at all times, and
3.13.2 Equal to or more negative than its Frequency Response Obligation when Frequency varies from 60 Hz by more than $+/-0.036 \mathrm{~Hz}$.

R4. Each Balancing Authority that is performing Overlap Regulation Service shall modify its Frequency Bias Setting in its ACE calculation, in order to represent the Frequency Bias Setting for the combined Balancing Authority Area, to be equivalent to eitherthe sum of the Frequency Bias Settings of the participating Balancing Authorities as validated by the ERO or calculate the Frequency Bias Setting based on the entire area being combined and thereby represent the Frequency Response for the combined area being controlled.: [Risk Factor: Medium ][Time Horizon: Operations Planning]

- $\quad$ The sum of the Frequency Bias Settings as shown on FRS Form 1 and FRS Form 2 for the participating Balancing Authorities as validated by the ERO, or
- The Frequency Bias Setting shown on FRS Form 1 and FRS Form 2 for the entirety of the participating Balancing Authorities' Areas.

R3. In order to ensure adequate control response, each Balancing Authority shall use a monthly average Frequency Bias Setting whose absolute value is at least equal to one of the following: [Risk Factor: Medium ][Time Horizon: Operations Planning

The minimum percentage of the Balancing Authority Area's estimated yearly Peak Demand within its metered boumdary per 0.1 Hz change as specified by the ERO in accordance with Attachment B.

The minimum percentage of the Balancing Authority Area's estimated yearly peak generation for a generation-only Balancing Authority, per 0.1 Hz change as specified by the ERO in accordance with Attachment B.

## C. Measures

M1. Each The-Frequency Response Sharing Group or Balancing Authority that is not a member of a Frequency Response Sharing Group or Reserve Sharing Group-shall have evidence such as dated data plus documented formula in either hardcopy or electronic format that it achieved an annual FRM )in accordance with the methods specified by the ERO in Attachment A with data from FRS Form 1 reported to the ERO as specified in Attachment A) that with data to show that its FRM is equal to or more negative than its FRO to demonstrate compliance with Requirement R1.
M2. The Balancing Authority that is a member of a multiple Balancing Authority Interconnection and is not receiving Overlap Regulation Service shall have evidence such as a dated document in hard copy or electronic format showing the ERO validated Frequency Bias Setting was implementedentered into its ACE calculation within the implementation perioden the date specified or other evidence to demonstrate compliance with Requirement R2.
M3. The Balancing Authority that is a member of a multiple Balancing Authority Interconnection, is not receiving Overlap Regulation Service and is utilizing variable Frequency Bias shall have evidence such as a dated reportoperating log, database or list in hard copy or electronic format showing the average clock-minute average Frequency Bias Setting was less than zero and during periods when the clock-minute average frequency is outside of the range 59.964 Hz to 60.036 Hz was equal to or more negative than its Frequency Response Obligation or operator interviews supported by other evidence showing the AGC operating mode including explanation when operating in other than Tie Line Bias mode-to demonstrate compliance with Requirement R3.

M4.-The Balancing Authority shall have evidence such as a dated operating log, database or list in hard copy or electronic format showing that when it performed Overlap Regulation Service, it modified its Frequency Bias Setting in its ACE calculation as specified in Requirement R4when Overlap Regulation Service is provided including Frequency Bias Setting calculation to to demonstrate compliance with Requirement R4.

M5.M4. _The Balancing Authority shall have evidence such as dated data plus documented formula to suppert the calculation retained in either hardcopy or electronic format showing the monthly average Frequency Bias Setting or other evidence to demonstrate compliance with Requirement R5.

## D. Compliance

## 1. Compliance Monitoring Process

### 1.1. Compliance Enforcement Authority

The Regional Entity is the Compliance Enforcement Authority except where the responsible entity works for the Regional Entity. Where the responsible entity
works for the Regional Entity, the Regional Entity will establish an agreement with the ERO or another entity approved by the ERO and FERC (i.e. another Regional Entity), to be responsible for compliance enforcement.

### 1.2. Compliance Monitoring and Assessment Processes:

Compliance Audits
Self-Certifications
Spot Checking
Compliance Violation-Investigations
Self-Reporting
Complaints
Periodic Data Submittals

### 1.3. Data Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Balancing Authority shall retain data or evidence to show compliance with Requirements R1, R2, R3 and, R4 and R5, Measures M1, M2, M3 and, M4, and M5 for the current year plus the previous three calendar years unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

The Frequency Responseeserve Sharing Group shall retain data or evidence to show compliance with Requirement R1 and Measure M1 for the current year plus the previous three calendar years unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

If a Balancing Authority or Frequency Responseeserve Sharing Group is found non-compliant, it shall keep information related to the non-compliance until found compliant or for the time period specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all subsequent requested and submitted records.

### 1.4. Additional Compliance Information

For Interconnections that are also Balancing Authorities, Tie Line Bias control and $\underline{f} \mp$ lat $\ddagger$ frequency control are equivalent and either is acceptable.

## Attachment A

# BAL-003-1 Frequency Response \& Frequency Bias Setting Standard 

## Supporting Document

## Frequency Response Obligation (FRO) for the Interconnection

The ERO, in consultation with regional representatives, has established a target contingency protection criterion for each Interconnection. The default target listed in Table 1 is based on the largest category C ( $\mathrm{N}-2$ ) event identified except for the Eastern Interconnection, which uses the largest event in the last 10 years. Additionally, this contingency protection criterion includes uncertainty adjustments at a $95 \%$ confidence level to prevent Point C from encroaching on the interconnection's highest Under Frequency Load Shed (UFLS) step for credible contingencies. The Obligation for each Interconnection in Table 1 is calculated by dividing the Target Protection Criteria MWs by 10 times the difference between the starting frequency and the Prevailing UFLS First Step. This number is then multiplied by the C to B Ratio to arrive at a $\mathrm{MW} / 0.1 \mathrm{~Hz}$ number. In the Eastern Interconnection there is an additional adjustment for the event nadir being below the Value B due to primary frequency response withdrawal. This Interconnection Frequency Response Obligation (FRO) includes uncertainty adjustments at a 95 \% confidence level. Detailed descriptions of the calculations used in Table 1 below are defined in the Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard.

Table 1: Interconnection Frequency Response Obligations
*The Eastern Interconnection UFLS set point listed is a compromise value set midway between the stable frequency minimum established in PRC-006-1 (59.3 Hz) and the local protection UFLS setting of 59.7 Hz used in Florida and Manitoba.
**In the Base Obligation measure for ERCOT, 1400 MW (Load Resources triggered by Under Frequency Relays at 59.70 Hz ) was reduced from its Contingency Protection Criteria level of 2750 MW to get 239 MW/0.1 Hz. This was reduced to accurately account for designed response from Load Resources within 30 cycles.

An Interconnection may propose alternate FRO protection criteria to the ERO by submitting a SAR with supporting technical documentation.

## Balancing Authority Frequency Response Obligation (FRO) and Frequency Bias Setting

The ERO will manage the administrative procedure for annually assigning an FRO and implementation of the Frequency Bias Setting for each Balancing Authority. The annual timeline for all activities described in this section are shown below.

For a multiple Balancing Authority interconnection, the Interconnection Frequency Response Obligation shown in Table 1 is allocated based on the Balancing Authority annual load and annual generation. The FRO allocation will be based on the following method:

$$
\mathrm{FRO}_{\mathrm{BA}}=\mathrm{FRO}_{\mathrm{Int}} \times \frac{\text { Annual Gen }_{\mathrm{BA}}+\text { Annual Load }}{\mathrm{BA}} \text { Annual Gen }
$$

Where:

- Annual $\operatorname{Gen}_{B A}$ is the total annual "Output of Generating Plants" within the Balancing Authority Area (BAA), on FERC Form 714, column c of Part II - Schedule 3.
- Annual Load ${ }_{B A}$ is total annual Load within the BAA, on FERC Form 714, column e of Part II Schedule 3.
- Annual Gen $_{\text {Int }}$ is the sum of all Annual $\operatorname{Gen}_{B A}$ values reported in that interconnection.
- Annual Load ${ }_{\text {Int }}$ is the sum of all Annual Load ${ }_{B A}$ values reported in that interconnection.

The data used for this calculation is from the most recently filed Form 714. As an example, a report to NERC in January 2013 would use the Form 714 data filed in 2012, which utilized data from 2011.

Balancing Authorities that are not FERC jurisdictional should use the Form 714 Instructions to assemble and submit equivalent data to the ERO for use in the FRO Allocation process.

Balancing Authorities that elect to form a FRSG will calculate a FRSG FRO by adding together the individual BA FRO's.

Balancing Authorities that elect to form a FRSG as a means to jointly meet the FRO will calculate their FRM performance one of two ways:

- Calculate a group $\mathrm{NI}_{\mathrm{A}}$ and measure the group response to all events in the reporting year on a single FRS Form 1, or
- Jointly submit the individual BAs' Form 1s, with a summary spreadsheet that that contains the sum of each participant's individual event performance.

Balancing Authorities that merge or that transfer load or generation are encouraged to notify the ERO of the change in footprint and corresponding changes in allocation such that the net obligation to the Interconnection remains the same and so that CPS limits can be adjusted.

Each Balancing Authority reports its previous year's Frequency Response Measure (FRM), Frequency Bias Setting and Frequency Bias type (fixed or variable) to the ERO each year to allow the ERO to validate the revised Frequency Bias Settings on FRS Form 1. If the ERO posts the official list of events after the date specified in the timeline below, Balancing Authorities will be given 30 days from the date the ERO posts the official list of events to submit their FRS Form 1.

Once the ERO reviews the data submitted in FRS Form 1 and FRS Form 2 for all Balancing Authorities, the ERO will use FRS Form 1 data to post the following information for each Balancing Authority for the upcoming year:

- Frequency Bias Setting
- Frequency Response Obligation (FRO)

Once the data listed above is fully posted, the ERO will announce the three-day implementation period for changing the Frequency Bias Setting if it differs from that shown in the timeline below.

A BA using a fixed Frequency Bias Setting sets its Frequency Bias Setting to the greater of (in absolute value):

- Any number the BA chooses between $100 \%$ and $125 \%$ of its Frequency Response Measure as calculated on FRS Form 1
- Interconnection Minimum as determined by the ERO

For purposes of calculating the minimum Frequency Bias Setting, a Balancing Authority participating in a Frequency Response Sharing Group will need to calculate its stand-alone Frequency Response Measure using FRS Form 1 and FRS Form 2 to determine its minimum Frequency Bias Setting.

A Balancing Authority providing Overlap Regulation will report the historic peak demand and generation of its combined BAs' areas on FRS Form 1 as described in Requirement R4.

There are occasions when changes are needed to Bias Settings outside of the normal schedule. Examples are footprint changes between Balancing Authorities and major changes in load or generation or the formation of new Balancing Authorities. In such cases the changing Balancing Authorities will

Attachment A
BAL-003-1 Frequency Response and Frequency Bias Setting
Supporting Document
work with their Regions, NERC and the Resources Subcommittee to confirm appropriate changes to Bias Settings, FRO, CPS limits and Inadvertent Interchange balances.

If there is no net change to the Interconnection total Bias, the Balancing Authorities involved will agree on a date to implement their respective change in Bias Settings. The Balancing Authorities and ERO will also agree to the allocation of FRO such that the sum remains the same.

If there is a net change to the Interconnection total Bias, this will cause a change in CPS2 limits and FRO for other Balancing Authorities in the Interconnection. In this case, the ERO will notify the impacted Balancing Authorities of their respective changes and provide an implementation window for making the Bias Setting changes.

## Frequency Response Measure (FRM)

The Balancing Authority will calculate its FRM from Single Event Frequency Response Data (SEFRD), defined as: "the data from an individual event from a Balancing Authority that is used to calculate its Frequency Response, expressed in MW/0.1Hz" as calculated on FRS Form 2 for each event shown on FRS Form 1. The events in FRS Form 1 are selected by the ERO using the Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard. The SEFRD for a typical Balancing Authority in an Interconnection with more than one Balancing Authority is basically the change in its Net Actual Interchange on its tie lines with its adjacent Balancing Authorities divided by the change in Interconnection frequency. (Some Balancing Authorities may choose to apply corrections to their Net Actual Interchange ( $N A_{1}$ ) values to account for factors such as nonconforming loads. FRS Form 1 and 2 shows the types of adjustments that are allowed. Note that with the exception of the Contingent BA column, any adjustments made must be made for all events in an evaluation year. As an example, if an entity has non-conforming loads and makes an adjustment for one event, all events must show the nonconforming load, even if the non-conforming load does not impact the calculation. This ensures that the reports are not utilizing the adjustments only when they are favorable to the BA.) The ERO will use a standardized sampling interval of approximately 16 seconds before the event up to the time of the event for the pre-event $N A_{1}$, and frequency (A values) and approximately 20 to 52 seconds after the event for the post-event $N A_{1}(B$ values) in the computation of SEFRD values, dependent on the data scan rate of the Balancing Authority's Energy Management System (EMS).

All events listed on FRS Form 1 need to be included in the annual submission of FRS Forms 1 and 2. The only time a Balancing Authority should exclude an event is if its tie-line data or its Frequency data is corrupt or its EMS was unavailable. FRS Form 2 has instructions on how to correct the BA's data if the given event is internal to the BA or if other authorized adjustments are used.

Assuming data entry is correct FRS Form 1 will automatically calculate the Balancing Authority's FRM for the past 12 months as the median of the SEFRD values. A Balancing Authority electing to report as an FRSG or a provider of Overlap Regulation Service will provide an FRS Form 1 for the aggregate of its participants.

## Attachment A

BAL-003-1 Frequency Response and Frequency Bias Setting
Supporting Document
To allow Balancing authorities to plan its operations, events with a "Point C" that cause the Interconnection Frequency to be lower than that shown in Table 1 above (for example, an event in the Eastern Interconnection that causes the Interconnection Frequency to go to 59.4 Hz ) or higher than an equal change in frequency going above 60 Hz may be included in the list of events for that interconnection. However, the calculation of the BA response to such an event will be adjusted to show a frequency change only to the Target Minimum Frequency shown in Table 1 above (in the previous example this adjustment would cause Frequency to be shown as 59.5 Hz rather than 59.4 HZ ) or a high frequency amount of an equal quantity. Should such an event happen, the ERO will provide additional guidance.

## Timeline for Balancing Authority Frequency Response and Frequency Bias Setting Activities

Described below is the timeline for the exchange of information between the ERO and Balancing Authorities (BA) to:

- Facilitate the assignment of BA Frequency Response Obligations (FRO)
- Calculate BA Frequency Response Measures (FRM)
- Determine BA Frequency Bias Settings (FBS)

| Target Date | Activity |
| :---: | :---: |
| April 30 | The ERO reviews candidate frequency events and selects frequency events for the first quarter (December to February). |
| May 10 | Form1 is posted with selected events from the first quarter for BA usage by the ERO. |
| May 15 | The BAs receive a request to provide load and generation data as described in Attachment A to support FRO assignments and determining minimum FBS for BAs. |
| July 15 | The BAs provide load and generation data as described in Attachment A to the ERO. |
| July 30 | The ERO reviews candidate frequency events and selects frequency events for the second quarter (March to May). |
| August 10 | Form1 is posted with selected events from the first and second quarters for BA usage by the ERO. |
| October 30 | The ERO reviews candidate frequency events and selects frequency events for the third quarter (June to August) |
| November 10 | Form1 is posted with selected events from the first, second, and third quarters for BA usage by the ERO. |
| November 20 | If necessary, the ERO provides any updates to the necessary Frequency Response. |
| November 20 | The ERO provides the fractional responsibility of each BA for the Interconnection's FRO and Minimum FBS to the BAs. |
| January 30 | The ERO reviews candidate frequency events and selects frequency events for the fourth quarter (September to November). |

BAL-003-1 Frequency Response and Frequency Bias Setting Supporting Document

| $2^{\text {nd }}$ business day in <br> February | Form1 is posted with all selected events for the year for BA usage by the ERO. |
| :--- | :--- |
| February 10 | The ERO assigns FRO values to the BAs for the upcoming year. |
| March 7 | BAs complete their frequency response sampling for all four quarters and their <br> FBS calculation, returning the results to the ERO. |
| March 24 | The ERO validates FBS values, computes the sum of all FBS values for each <br> Interconnection, and determines L10 values for the CPS 2 criterion for each BA as <br> applicable. |
| Any time during <br> first 3 business <br> days of April <br> (unless specified <br> otherwise by the <br> ERO) | The BA implements any changes to their FBS and L10 value. |

NORTH AMERICAN ELECTRIC
RELIABILITY CORPORATION

## I mplementation Plan for BAL-003-1 - Frequency Response \& Frequency Bias Setting Standard

## Prerequisite Approvals

There are no other reliability standards or Standard Authorization Requests (SARs), in progress or approved, that must be implemented before this standard can be implemented.

## Modified Standards

BAL-003-0.1b should be retired at midnight of the day immediately prior to the Effective Date of BAL-003-1 in the Jurisdiction in which the new standard is becoming effective.

## New or Modified Definitions

The following definitions shall become effective when BAL-003-1 Requirements R2, R3, R4 and R5 become effective:

Frequency Response Measure (FRM): The median of all the Frequency Response observations reported annually on FRS Form 1.

Frequency Response Obligation (FRO): The Balancing Authority's share of the required Frequency Response needed for the reliable operation of an Interconnection.

Frequency Bias Setting: A numbervalue, either fixed or variable, usually expressed in MW/0.1 Hz , included inset into a Balancing Authority's Area Control Error equation to account for algorithm that allows the Balancing Authority's Frequency Response contributionto contribute its frequency response to the Interconnection and discourage withdrawal through secondary control systems.

The existing definition of Frequency Bias Setting should be retired at midnight of the day immediately prior to the Effective Date of BAL-003-1 in the Jurisdiction in which the new standard is becoming effective.

The proposed revised definition for "Frequency Bias Setting" is incorporated in the following NERC approved standards:

- BAL-001-0.1a Real Power Balancing Control Performance
- BAL-004-0 Time Error Correction
- BAL-004-1 Time Error Correction
- BAL-005-0.1b Automatic Generation Control

## Compliance with Standards

Once this standard becomes effective, the responsible entities identified in the applicability section of the standard must comply with the requirements. These include:

- Balancing Authorities
- Reserve Sharing Groups

## Proposed Effective Date

Compliance with BAL-003-1 shall be implemented over a two-year period, as follows:

- In those jurisdictions where regulatory approval is required, Requirements R2, R3, R4 and R5 of this standard shall become effective the first calendar day of the first calendar quarter 12 months after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, Requirements R2, R3, R4 and R5 of this standard shall become effective the first calendar day of the first calendar quarter 12 months after Board of Trustees adoption.
- In those jurisdictions where regulatory approval is required, Requirements R1 of this standard shall become effective the first calendar day of the first calendar quarter 24 months after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, Requirements R1 of this standard shall become effective the first calendar day of the first calendar quarter 24 months after Board of Trustees adoption.

# Implementation Plan for BAL-003-1 - Frequency Response \& Frequency Bias Setting Standard 

## Prerequisite Approvals

There are no other reliability standards or Standard Authorization Requests (SARs), in progress or approved, that must be implemented before this standard can be implemented.

## Modified Standards

BAL-003-0.1b-Requirements R1, R2, R3, R4 and R6 should be retired midnight of the day immediately prior to the Effective Date of BAL-003-1 in the Jurisdiction in which the new standard is becoming becomes-effective.

BAL-003-0 Re1quirement R5 should be retired as outlined in the following table.
For those Balancing Authorities that serve native load:

- May 2011 through December $2011 \quad-0.8 \%$ of peak 0.1 Hz
- January 2012 through December $2012 \quad 0.6 \%$ of peak 10.1 Hz
- January 2013 through December $2013 \quad-0.4 \%$ of peak $/ 0.1 \mathrm{~Hz}$
- January 2014 through December $2014 \quad-0.2 \%$ of peak 10.1 Hz
- January 2015 through $0.0 \%$ of peak $/ 0.1 \mathrm{~Hz}$

For those Balancing Authorities that do not serve native load:

- May 2011 through December $2011 \quad-0.8 \%$ of upcoming years maximum generation/ 0.1 Hz
- January 2012 through December 2012 0.6\% of upcoming years maximum generation $/ 0.1 \mathrm{~Hz}$
- January 2013 through December 2013 -0.4\% of upcoming years maximum generation $/ 0.1 \mathrm{~Hz}$
- January 2014 through December $2014 \quad 0.2 \%$ of upcoming years maximum generation $/ 0.1 \mathrm{~Hz}$
- January 2015 through -0.0\% of upcoming years maximum generation/ 0.1 Hz

The FRR drafting team, NERC and the NERC Resources Subcommittee will observe the impact on frequency and will implement a reversion plan should frequency performance decline.

## New or Modified Definitions

The following definitions shall become effective when BAL-003-1 Requirements R2, R3, R4 and R5 become effective:

July 12, 2011
116-390 Village Boulevard, Princeton, New Jersey 08540-5721
Phone: 609.452.8060 • Fax: 609.452.9550 • www.nerc.com

Frequency Response Measure (FRM): The median of all the Frequency Response observations reported annually on FRS Form 1.

Frequency Response Obligation (FRO): The Balancing Authority's share of the required Frequency Response needed for the reliable operation of an Interconnection.

Frequency Bias Setting: A number, either a fixed or variable, usually expressed in MW/0.1 Hz, included in a Balancing Authority's Area Control Error equation to account for the Balancing Authority's Frequency Response contribution to the Interconnection, and discourage response withdrawal through secondary control systems.

The existing definition of Frequency Bias Setting should be retired midnight of the day immediately prior to the Effective Date of BAL-003-1 in the Jurisdiction in which the new standard is becoming effective.

The proposed revised definition for "Frequency Bias Setting" is incorporated in the following NERC approved standards:

- BAL-001-0.1a Real Power Balancing Control Performance
- BAL-004-0 Time Error Correction
- BAL-004-1 Time Error Correction
- BAL-005-0.1b Automatic Generation Control

## Compliance with Standards

Once this standard becomes effective, the responsible entities identified in the applicability section of the standard must comply with the requirements. These include:

- Balancing Authorities
- Reserve Sharing Groups

## Proposed Effective Date

Compliance with BAL-003-1 shall be implemented over a two-year period, as follows:

- In those jurisdictions where regulatory approval is required, Requirements R21, R3, R4 and R 54 of this standard shall become effective the first calendar day of the first calendar quarter 12 months after applicable regulatory approval. In those jurisdictions where no regulatory approval is required,
| Requirements R21, R3, R4 and R54 of this standard shall become effective the first calendar day of the first calendar quarter 12 months after Board of Trustees adoption.
- In those jurisdictions where regulatory approval is required, Requirements R1Z of this standard shall become effective the first calendar day of the first calendar quarter 24 months after applicable regulatory approval. In those jurisdictions where no regulatory approval is
| required, Requirements R $\underline{1 z}$ of this standard shall become effective the first calendar day of the first calendar quarter 24 months after Board of Trustees adoption.

# Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard 

## Event Selection Process

This procedure outlines the ERO process for supporting the Frequency Response Standard (FRS). A Procedure revision request may be submitted to the ERO for consideration. The revision request must provide a technical justification for the suggested modification. The ERO shall post the suggested modification for a 45 -day comment period and discuss the revision request in a public meeting. The ERO will make a recommendation to the NERC BOT, which may adopt the revision request, reject it, or adopt it with modifications. Any approved revision to this Procedure shall be filed with FERC for informational purposes.

## Event Selection Objectives

The goals of this procedure are to outline a transparent, repeatable process to annually identify a list of frequency events to be used by Balancing Authorities (BA) to calculate their Frequency Response to determine:

- Whether the BA met its Frequency Response Obligation, and
- An appropriate fixed Bias Setting.

## Event Selection Criteria

1. The ERO will use the following criteria to select FRS frequency excursion events for analysis. The events that best fit the criteria will be used to support the FRS. The evaluation period for performing the annual Frequency Bias Setting and the Frequency Response Measure (FRM) calculation is December 1 of the prior year through November 30 of the current year.
2. The ERO will identify 20 to 35 frequency excursion events in each Interconnection for calculating the Frequency Bias Setting and the FRM. If the ERO cannot identify 20 frequency excursion events in a 12 month evaluation period satisfying the criteria below, then similar acceptable events from the subsequent year's evaluation period will be included with the data set by the ERO for determining FRS compliance. This is described later.
3. The ERO will use three criteria to determine if an acceptable frequency excursion event for the FRM has occurred:
a. The change in frequency as defined by the difference from the A Value to Point C and the arrested frequency Point $C$ exceeds the excursion threshold values specified for the Interconnection in Table 1 below.
i. The A Value is computed as an average over the period from -16 seconds to 0 seconds before the frequency transient begins to decline.
ii. Point C is the arrested value of frequency observed within 12 seconds following the start of the excursion.

| Interconnection | A Value <br> to Pt C | Point C (Low) | Point C (High) |
| :---: | :---: | :---: | :---: |
| East | 0.04 Hz | $<59.96$ | $>60.04$ |
| West | 0.07 Hz | $<59.95$ | $>60.05$ |
| ERCOT | 0.15 Hz | $<59.90$ | $>60.10$ |
| HQ | 0.30 Hz | $<59.85$ | $>60.15$ |

Table 1: Interconnection Frequency Excursion Threshold Values
b. The time from the start of the rapid change in frequency until the point at which Frequency has stabilized within a narrow range should be less than 18 seconds.
c. If any data point in the $B$ Value average recovers to the $A$ Value, the event will not be included.
4. Pre-disturbance frequency should be relatively steady and near 60.000 Hz for the A Value. The A Value is computed as an average over the period from -16 seconds to 0 seconds before the frequency transient begins to decline. For example, given the choice of the two events below, the one on the right is preferred as the pre-disturbance frequency is stable and also closer to 60 Hz .

5. Excursions that include 2 or more events that do not stabilize within 18 seconds will not be considered.
6. Frequency excursion events occurring during periods when large interchange schedule ramping or load change is happening, and frequency excursion events occurring within 5 minutes of the top of the hour, will be excluded from consideration if other acceptable frequency excursion events from the same quarter are available.
7. The ERO will select the largest (A Value to Point C) 2 or 3 frequency excursion events occurring each month. If there are not 2 frequency excursion events satisfying the selection criteria in a month, then other frequency excursion events should be picked in the following sequence:
a. From the same event quarter of the year.

October 1, 2012

# Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard 

b. From an adjacent month.
c. From a similar load season in the year (shoulder vs. summer/winter)
d. The largest unused event.

As noted earlier, if a total of 20 events are not available in an evaluation year, then similar acceptable events from the next year's evaluation period will be included with the data set by the ERO for determining Frequency Response Obligation (FRO) compliance. The first year's small set of data will be reported and used for Bias Setting purposes, but compliance evaluation on the FRO will be done using a 24 month data set.

To assist Balancing Authority preparation for complying with this standard, the ERO will provide quarterly posting of candidate frequency excursion events for the current year FRM calculation. The ERO will post the final list of frequency excursion events used for standard compliance as specified in Attachment A of BAL-003-1. The following is a general description of the process that the ERO will use to ensure that BAs can evaluate events during the year in order to monitor their performance throughout the year.

## Monthly

Candidate events will be initially screened by the "Frequency Event Detection Methodology" shown on the following link located on the NERC Resources Subcommittee area of the NERC website:
http://www.nerc.com/docs/oc/rs/Frequency Event Detection Methodology and Criteria Oct 2011.p df. Each month's list will be posted by the end of the following month on the NERC website, http://www.nerc.com/filez/rs.html and listed under "Candidate Frequency Events".

## Quarterly

The monthly event lists will be reviewed quarterly with the quarters defined as:

- December through February
- March through May
- June through August
- September through November

Based on criteria established in the "Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard", events will be selected to populate the FRS Form 1 for each Interconnection. The Form 1's will be posted on the NERC website, in the Resources Subcommittee area under the title "Frequency Response Standard Resources". Updated Form 1's will be posted at the end of each quarter listed above after a review by the NERC RS' Frequency Working Group. While the events on this list are expected to be final, as outlined in the selection criteria, additional events may be considered, if the
number of events throughout the year do not create a list of at least 20 events. It is intended that this quarterly posting of updates to the FRS Form 1 would allow BAs to evaluate the events throughout the year, lessening the burden when the yearly posting is made.

## Annually

The final FRS Form 1 for each Interconnection, which would contain the events from all four quarters listed above, will be posted as specified in Attachment A. Each Balancing Authority reports its previous year's Frequency Response Measure (FRM), Frequency Bias Setting and Frequency Bias type (fixed or variable) to the ERO as specified in Attachment A using the final FRS Form 1. The ERO will check for errors and use the FRS Form 1 data to calculate CPS limits and FROs for the upcoming year.

Once the data listed above is fully reviewed, the ERO may adjust the implementation specified in Attachment A for changing the Frequency Bias Settings and CPS limits. This allows flexibility in when each BA implements its settings.

## Process for Adjusting Interconnection Minimum Frequency Bias Setting

This procedure outlines the process the ERO is to use for modifying minimum Frequency Bias Settings to better meet reliability needs. The ERO will adjust the Frequency Bias Setting minimum in accordance with this procedure.

The ERO will post the minimum Frequency Bias Setting values on the ERO website along with other balancing standard limits.

Under BAL-003-1, the minimum Frequency Bias Settings will be moved toward the natural Frequency Response in each interconnection. In the first year, the minimum Frequency Bias Setting for each interconnection is shown in Table 2 below. Each Interconnection Minimum Frequency Bias Setting is based on the sum of the non-coincident peak loads for each BA from the currently available FERC 714 Report or equivalent. This non-coincident peak load sum is multiplied by the percentage shown in Table 1 to get the Interconnection Minimum Frequency Bias Setting. The Interconnection Minimum Frequency Bias Setting is allocated among the BAs on an interconnection using the same allocation method as is used for the allocation of the Frequency Response Obligation (FRO).

| Interconnection | Interconnection Minimum Frequency Bias Setting (in MW/0.1Hz) |
| :--- | :---: |
|  |  |
| Eastern | $0.9 \%$ of non-coincident peak load |
| Western | $0.9 \%$ of non-coincident peak load |
| ERCOT* | N/A |
| HQ* $^{*}$ | N/A |

Table 2. Frequency Bias Setting Minimums
*The minimum Frequency Bias Setting requirement does not apply to a Balancing Authority that is the only Balancing Authority in its Interconnection. These Balancing Authorities are solely responsible for providing reliable frequency control of their Interconnection. These Balancing Authorities are responsible for converting frequency error into a megawatt error to provide reliable frequency control, and the imposition of a minimum bias setting greater than the magnitude the Frequency Response Obligation may have the potential to cause control system hunting, and instability in the extreme.

The ERO, in coordination with the regions of each interconnection, will annually review Frequency Bias Setting data submitted by BAs. If an Interconnection's total minimum Frequency Bias Setting exceeds (in absolute value) the Interconnection's total natural Frequency Response by more (in absolute value) than 0.2 percentage points of peak load (expressed in $M W / 0.1 \mathrm{~Hz}$ ), the minimum Frequency Bias Setting for BAs within that Interconnection may be reduced (in absolute value) based on the technical evaluation and consultation with the regions affected by 0.1 percentage point of peak load (expressed in $\mathrm{MW} / 0.1 \mathrm{~Hz}$ ) to better match that Frequency Bias Setting and natural Frequency Response.

The ERO, in coordination with the regions of each Interconnection, will monitor the impact of the reduction of minimum frequency bias settings, if any, on frequency performance, control performance,

October 1, 2012
and system reliability. If unexpected and undesirable impacts such as, but not limited to, sluggish postcontingency restoration of frequency to schedule or control performance problems occur, then the prior reduction in the minimum frequency bias settings may be reversed, and/or the prospective reduction based on the criterion stated above may not be implemented.

## Interconnection Frequency Response Obligation Methodology

This procedure outlines the process the ERO is to use for determining the Interconnection Frequency Response Obligation (IFRO).

The following are the formulae that comprise the calculation of the IFROs.

$$
\begin{gathered}
D F_{\text {Base }}=F_{\text {Start }}-U F L S \\
D F_{C C}=D F_{B a s e}-C C_{A d j} \\
D F_{C B R}=\frac{D F_{C C}}{C B_{R}} \\
M D F=D F_{C B R}-B C^{\prime}{ }_{A d j} \\
A R L P C=R L P C-C L R \\
I F R O=\frac{A R L P C}{M D F}
\end{gathered}
$$

Where:

- $\mathrm{DF}_{\text {Base }}$ is the base delta frequency.
- $\mathrm{F}_{\text {start }}$ is the starting frequency determined by the statistical analysis.
- UFLS is the highest UFLS trip setpoint for the interconnection.
- $\mathrm{CC}_{\text {Adj }}$ is the adjustment for the differences between 1-second and sub-second Point C observations for frequency events. A positive value indicates that the sub-second C data is lower than the 1 -second data.
- $\quad \mathrm{DF}_{\mathrm{cc}}$ is the delta frequency adjusted for the differences between 1-second and sub-second Point C observations for frequency events.
- $\mathrm{CB}_{\mathrm{R}}$ is the statistically determined ratio of the Point C to Value B .
- $\mathrm{DF}_{C B R}$ is the delta frequency adjusted for the ratio of the Point $C$ to Value $B$.
- $\mathrm{BC}^{\prime}{ }_{A D J}$ is the statistically determined adjustment for the event nadir being below the Value $B$ (Eastern Interconnection only) during primary frequency response withdrawal.
- MDF is the maximum allowable delta frequency.
- RLPC is the resource loss protection criteria.
- CLR is the credit for load resources.
- ARLPC is the adjusted resource loss protection criteria adjusted for the credit for load resources.
- IFRO is the interconnection frequency response obligation.

## Introduction

This document provides background on the development, testing and implementation of BAL-003-1 - Frequency Response Standard (FRS). ${ }^{1}$ The intent is to explain the rationale and considerations for the Requirements of this standard and their associated compliance information. The document also provides good practices and tips for Balancing Authorities ("BAs") with regard to Frequency Response.

In Order No. 693, the Federal Energy Regulatory Commission ("FERC" or the "Commission") directed additional changes to BAL-003. ${ }^{2}$ This document explains how compliance with those directives is met by BAL-003-1.

The original Standards Authorization Request ("SAR"), finalized on June 30, 2007, assumed there was adequate Frequency Response in all the North American Interconnections. The goal of the SAR was to update the Standard to make the measurement process of frequency response more objective and to provide this objective data to Planners and Operators for improved modeling. The updated models will improve understanding of the trends in Frequency Response to determine if reliability limits are being approached. The Standard would also lay the process groundwork for a transition to a performance-based Standard if reliability limits are approached.

This document will be periodically updated by the FRS Drafting Team (FRSDT) until the Standard is approved. Once approved, this document will then be maintained and updated by the ERO and the NERC Resources Subcommittee to be used as a reference and training resource.

## Background

This section discusses the different components of frequency control and the individual components of Primary Frequency Control also known as Frequency Response.

## Frequency Control

Most system operators generally have a good understanding of frequency control and Bias Setting as outlined in the balancing standards and the references to them in the NERC Operating Manual. Frequency control can be divided into four overlapping windows of time as outlined below.

Primary Frequency Control (Frequency Response) - Actions provided by the Interconnection to arrest and stabilize frequency in response to frequency deviations. Primary Control comes from automatic generator governor response (also known as speed

[^66]regulation), load response (typically from motors), and other devices that provide an immediate response based on local (device-level) control systems.

Secondary Frequency Control - Actions provided by an individual BA or its Reserve Sharing Group to correct the resource - load unbalance that created the original frequency deviation, which will restore both Scheduled Frequency and Primary Frequency Response. Secondary Control comes from either manual or automated dispatch from a centralized control system.

Tertiary Frequency Control - Actions provided by Balancing Authorities on a balanced basis that are coordinated so there is a net zero effect on Area Control Error (ACE). Examples of Tertiary Control include dispatching generation to serve native load; economic dispatch; dispatching generation to affect Interchange; and re-dispatching generation. Tertiary Control actions are intended to replace Secondary Control Response by reconfiguring reserves.

Time Control includes small offsets to scheduled frequency to keep long term average frequency at 60 Hz .

## Primary Frequency Control - Frequency Response

Primary Frequency Control, also known generally as Frequency Response, is the first stage of overall frequency control and is the response of resources and load to a locally sensed change in frequency in order to arrest that change in frequency. Frequency Response is automatic, not driven by any centralized system, and begins within seconds rather than minutes. Different resources, loads, and systems provide Frequency Response with different response times, based on current system conditions such as total resource/load and their respective mix.

The proposed NERC Glossary of Terms defines Frequency Response as:

- (Equipment) The immediate and automatic reaction or response of power from a system or power from elements of the system to a change in locally sensed system frequency.
- (System) The sum of the change in demand, and the change in generation, divided by the change in frequency, expressed in megawatts per 0.1 Hertz (MW/0.1 Hz).

As noted above, Frequency Response is the characteristic of load and generation within Balancing Authorities and Interconnections. It reacts or responds with changes in power to attempt changes in load-resource balance that result in changes to system frequency. Because the loss of a large generator is much more likely than a sudden loss of an equivalent amount of load, Frequency Response is typically discussed in the context of a loss of a large generator. Included within Frequency Response are many components of that response. Understanding Frequency Response and the FRS requires an understanding of each of these components and how they relate to each other.

## Frequency Response Illustration

The following simple example is presented to illustrate the components of Frequency Response in graphical form. It includes a series of seven graphs that illustrate the various components of

Frequency Response and a brief discussion of each describing how these components react to attempted changes in the load-resource balance and resulting changes in system frequency. The illustration is based on an assumed Disturbance event of the sudden loss of 1000 MW of generation. Although a large event is used to illustrate the response components, even small frequently occurring events will result in similar reactions or responses. The magnitude of the event only affects the shape of the curves on the graph; it does not obviate the need for Frequency Response.

The first graph, Primary Frequency Control - Frequency Response - Graph 1, presents a sudden loss of generation of 1000 MW . The components are presented relative to time as shown on the horizontal Time axis in seconds. This simplified example assumes a Disturbance event of the sudden loss of generation resulting from a breaker trip that instantaneously removes 1000 MW of generation from the interconnection. This sudden loss is illustrated by the power deficit line shown in black using the MW scale on the left. Interconnection frequency is illustrated by the frequency line shown in red using the Hertz scale on the right. Since the Scheduled Frequency is normally 60 Hz , it is assumed that this is the frequency when the Disturbance event occurs.

Even though the generation has tripped and power injected by the generator has been removed from the interconnection, the loads continue to use the same amount of power. The
"Law of Conservation of Energy" ${ }^{3}$ requires that the 1000 MW must be supplied to the interconnection if energy balance is to be "conserved". This additional 1000 MW of power is produced by extracting kinetic energy that was stored in the rotating mass of all of the synchronized generators and motors on the interconnection when they were increased from zero to synchronous speed - essentially using this equipment as a giant flywheel. The extracted energy supplies the "balancing inertia" ${ }^{4}$ power required to maintain the power and energy balance on the interconnection. This balancing inertia power is produced by the generators' spinning inertial mass' resistance to the slowdown in speed of the rotating equipment on the interconnection that both provides the stored kinetic energy and reduces the frequency of the interconnection. This is illustrated in the second graph, Primary Frequency Control - Frequency Response - Graph 2, by the orange dots representing the balancing inertia power that exactly overlay and offset the power deficit.

As the frequency decreases, synchronized motors slow, as does the work they are providing, resulting in a decrease in load called "load damping." This load damping is the reason that the power deficit initially declines. Synchronously operated motors will contribute to load damping. Variable speed drives that are decoupled from the interconnection frequency do not

[^67]contribute to load damping. In general, any load that does not change with interconnection frequency including resistive load will not contribute to load damping or Frequency Response.

It is important to note that the power deficit equals exactly the balancing inertia, indicating that there is no power or energy imbalance at any time during this process. What is normally considered as "balancing power or energy" is actually power or energy required to correct the frequency error from scheduled frequency. Any apparent power or energy imbalance is corrected instantaneously by the balancing inertia power and energy extracted from the interconnection. Thus the balancing function is really a frequency control function described as a balancing function because ACE is calculated in MWs instead of Hertz, frequency error.

During the initial seconds of the Disturbance event, the governors have yet to respond to the frequency decline. This is illustrated with the Blue line on the third graph, Primary Frequency Control - Frequency Response - Graph 3, showing Governor Response. This time delay results from the time that it takes the controller to adjust the equipment and the time it takes the mass to flow from the source of the energy (main steam control valve for steam turbines, the combustor for gas turbines, or the gate valve for hydro turbines) to the turbine-generator blades where the power is converted to electrical energy.

Note that the frequency continues to decline due to the ongoing extraction by balancing inertia power of energy from the rotating turbine-generators and synchronous motors on the interconnection. The reduction in load also continues as the effect of load damping continues
to reduce the load while frequency declines. During this time delay (before the governor response begins) the balancing inertia limits the rate of change of frequency.

After a short time delay, the governor response begins to increase rapidly in response to the initial rapid decline in frequency, as illustrated on the fourth graph, Primary Frequency Control - Frequency Response - Graph 4. Governor response exactly offsets the power deficit at the point in time that the frequency decline is arrested. At this point in time, the balancing inertia has provided its contribution to reliability and its power contribution is reduced to zero as it is replaced by the governor response. If the time delay associated with the delivery of governor response is reduced, the amount of balancing inertia required to limit the change in frequency by the Disturbance event can also be reduced. This supports the conclusion that balancing inertia is required to manage the time delays associated with the delivery of Frequency Response. Not only is the rapid delivery of Frequency Response important, but the shortening of the time delay associated with its delivery is also important. Therefore, two important components of Frequency Response are 1) how long the time delay is before the initial delivery of response begins; and 2 ) how much of the response is delivered before the frequency change is arrested.

This point, at which the frequency is first arrested, is defined as "Point C" and Frequency Response calculated at this point is called the "arrested frequency response." The arrested frequency is normally the minimum (maximum for load loss events) frequency that will be
experienced during a Disturbance event. From a reliability perspective, this minimum frequency is the frequency that is of concern. Adequate reliability requires that frequency at the time frequency is arrested remain above the under-frequency relay settings so as not to trip these relays and the firm load interrupted by them. Frequency Response delivered after frequency is arrested at this minimum level provides less reliability value than Frequency Response delivered before Point C, but greater value than Secondary Frequency Control power and energy which is delivered minutes later.

Once the frequency decline is arrested, the governors continue to respond because of the time delay associated with their Governor Response. This results in the frequency partially recovering from the minimum arrested value and results in an oscillating transient that follows the minimum frequency (arrested frequency) until power flows and frequency settle during the transient period that ends roughly 20 seconds after the Disturbance event. This postdisturbance transient period is included on the fifth illustrative graph, Primary Frequency Control - Frequency Response - Graph 5.

The total Disturbance event illustration is presented on the sixth graph, Primary Frequency Control - Frequency Response - Graph 6. Frequency and power contributions stabilize at the end of the transient period. Frequency Response calculated from data measured during this settled period is called the "Settled Frequency Response." The Settled Frequency Response is the best measure to use as an estimator for the "Frequency Bias Setting" discussed later.

The final Disturbance event illustration is presented on the seventh graph, Primary Frequency Control - Frequency Response - Graph 7. This graph shows the averaging periods used to estimate the pre-disturbance A-Value averaging period and the post-disturbance B-Value averaging period used to calculate the settled frequency response. A discussion of the measurement of Frequency Response immediately follows these graphs. That discussion includes consideration of the factors that affect the methods chosen to measure Frequency Response for implementation in a reliability standard.

## Frequency Response Measurement (FRM)

The classic Frequency Response points A, C, and B, shown below in Fig. 1 Frequency Response Characteristic, are used for measurement as found in the Frequency Response Characteristic Survey Training Document within the NERC operating manual, found at http://www.nerc.com/files/opman 7-1-11.pdf. This traditional Frequency Response Measure has recently been more specifically termed "settled frequency response." This term has been used because it provides the best Frequency Response Measure to estimate the Frequency Bias Setting in Tie-line Bias Control based Automatic Generation Control Systems. However, the industry has recognized that there is considerable variability in measurement resulting from the selection of Point A and Point B in the traditional measure making the traditional measurement method unsuitable as the basis for an enforceable reliability standard in a real world setting of multiple Balancing Authority interconnections.

Figure 1. Frequency Response Characteristic

By contrast, measuring an Interconnection's settled frequency response is straightforward and fairly accurate. All that's needed to make the calculation is to know the size of a given contingency (MW), divide this value by the change in frequency and multiply the results by 10 since frequency response is expressed in $\mathrm{MW} / 0.1 \mathrm{~Hz}$.

Measuring a BA's frequency response is more challenging. Prior to BAL-003-1, NERC's Frequency Response Characteristic Survey Training Document provided guidance to calculate Frequency Response. In short, it told the reader to identify the BA's interchange values "immediately before" and "immediately after" the Disturbance event and use the difference to calculate the MWs the BA deployed for the event. There are two challenges with this approach:

- Two people looking at the same data would come up with different values when assessing which exact points were immediately before and after the event.
- In practice, the actual response provided by the BA can change significantly in the window of time between point $B$ and when secondary and tertiary control can assist in recovery.

Therefore, the measurement of settled frequency response has been standardized in a number of ways to limit the variability in measurement resulting from the poorly specified selection of Point A and Point B. It should be noted that $\mathrm{t}-0$ has been defined as the first scan value that
shows a deviation in frequency of some significance, usually approaching about 10 mHz . The goal is such that the first scan prior to t-0 was unaffected by the deviation and appropriate for one of the averaging points.

- The A-value averaging period of approximately the previous 16 seconds prior to t-0 was selected to allow for an averaging of at least 2 scans for entities utilizing 6 second scan rates. (All time average period references in this document are for 2 second scan rates unless noted otherwise.)
- The $B$-value averaging period of approximately ( $\mathrm{t}+20 \mathrm{to} \mathrm{t}+52$ seconds) was selected to attempt to obtain the average of the data after primary frequency response was deployed and the transient completed(settled), but before significance influence of secondary control. Multiple periods were considered for averaging the B-value:
- 12 to 24 sec
- 18 to 30 sec
- 20 to 40 sec
- 18 to 52 sec
- 20 to 52 sec

It is necessary for all BAs from an interconnection to use the same averaging periods to provide consistent results. In addition, the SDT decided that until more experience is gained, it is also desirable for all interconnections to use the same averaging periods to allow comparison between interconnections.

The methods presented in this document only address the values required to calculate the frequency response associated with the frequency change between the initial frequency, AValue, and the settling frequency, B-Value. No reasonable or consistent calculations can be made relating to the arresting frequency, C-Value, using Energy Management System (EMS) scan rate data as long as 6 -seconds or tie-line flow values associated with the minimum value of the frequency response characteristic (C-value) as measured at the BA level.

Both the calculation of the frequency at Point $A$ and the frequency at Point $B$ began with the assumption that a 6 -second scan rate was the source of the data. Once the averaging periods for a 6 -second scan rate were selected, the averaging periods for the other scan rates were selected to provide as much consistency as possible between BAs with different scan rates.

The Frequency at Point A was initially defined as the average of the two scans immediately prior to the frequency event. All other averaging periods were selected to be as consistent as possible with this 12 second average scan from the 6 -second scan rate method. In addition, the "actual net interchange immediately before Disturbance" is defined as the average of the same scans as used for the Point A frequency average.

The Frequency at Point B was then selected to be an average as long as the average of 6 -second scan data as possible that would not begin until most of the hydro governor response had been delivered and would end before significant Automatic Generation Control (AGC) recovery response had been initiated as indicated by a consistent frequency restoration slope. The "actual net interchange immediately after Disturbance" is defined as the average of the same scans as used for the Point B frequency average.

## B Averaging Period Selection:

Experience from the Electric Reliability Council of Texas ("ERCOT") and the field trail on other interconnections indicated that the 12 to 24 second and 18 to 30 second averaging periods were not suitable because they did not provide the consistency in results that the other averaging periods provided, and that the remaining measuring periods do not provide significantly different results from each other. The team believed that this was observed because the transients were not complete in all of the samples using these averaging periods.

The 18 to 52 second and 20 to 52 second averaging periods were compared to each other, with the 20 to 52 second period providing more consistent values, believed to result from the incomplete transient in some of the 18 to 52 second samples.

This left a choice between the 20 to 40 second and the 20 to 52 second averaging periods. The team recognized that there would be more AGC response in the 20 to 52 second period, but the team also recognized that the 20 to 52 second period would provide a better measure of squelched response from outer loop control action. The 20 to 52 second period was selected because it would indicate squelched response from outer-loop control and provide incentive to reduce response withdrawal. The final selections for the data averaging periods used in FRS Form 1 are shown in the table below.

| Definitions of Frequency Values for Frequency Response Calculation |  |  |  |
| :---: | :---: | :---: | :---: |
| Scan Rate | T 0 Scan | A Value (average) | B Value (average) |
| 6-Seconds | Identify first significant change in frequency as the T 0 scan | Average of T-1 through T-2 scans | Average of $\mathrm{T}+4$ through $\mathrm{T}+8$ scans |
| 5-Seconds |  | Average of T-1 through T-2 scans | Average of T+5 through T+10 scans |
| 4-Seconds |  | Average of T-1 through T-3 scans | Average of T+6 through T+12 scans |
| 3-Seconds |  | Average of T-1 through T-5 scans | Average of $\mathrm{T}+7$ through $\mathrm{T}+17$ scans |
| 2-Seconds |  | Average of T-1 through T-8 scans | Average of T+10 through T+26 scans |

Consistent measurement of Primary Frequency Response is achievable for a selected number of events and can produce representative frequency response values, provided an appropriate sample size is used in the analysis. Available research investigating the minimum sample size to provide consistent measurements of Frequency Response has shown that a minimum sample size of 20 events should be adequate.

Measurement of Primary Frequency Response on an individual resource or load basis requires analysis of energy amounts that are often small and difficult to measure using current methods. In addition, the number of an interconnection's resources and loads providing their response could be problematic when compiling results for multiple events.

Measurement of Primary Frequency Response on an interconnection (System) basis is straight forward provided that an accurate frequency metering source is available and the magnitude of the resource/load imbalance is known in MWs.

Measurement on a Balancing Authority basis can be a challenge, since the determination of change in MWs is determined by the change in the individual BA's metered tie lines.
Summation of tie lines is accomplished by summing the results of values obtained by the digital scanning of meters at intervals up to six seconds, resulting in a non-coincidental summing of values. Until the technology to GPS time stamp tie line values at the meter and the summing of those values for coincidental times is in use throughout the industry, it is necessary to use averaging of values described above to obtain consistent results.

Figure 2. Frequency Response Measurement

The standardized measure is shown graphically in Fig. 2 Frequency Response Measurement with the averaging periods shown by the solid blue lines on the graph. Since FERC directed a performance obligation for BAL-003-1, it is important to be more objective in the measurement process. The standardized calculation is available on FRS Form 2 for EMS scan rates of 2, 3, 4, 5, and 6 seconds at http://www.nerc.com/filez/standards/Frequency Response.html.

## Arrested Frequency Response

There is another measure of Frequency Response that is of interest when developing a Frequency Response estimate that not only will be used for estimating the Frequency Bias Setting, but will also be used to assure reliability by operating in a manner that will bound interconnection frequency and prevent the operation of Under-frequency Relays. This Frequency Response Measure has recently been named "arrested frequency response." This Frequency Response is significantly affected by the inertial Frequency Response, the governor Frequency Response and the time delays associated with the delivery of governor Frequency Response. It is calculated by using the change in frequency between the initial frequency, A,
and the maximum frequency change during the event, C , instead of using the change between A and B . Arrested Frequency Response is the correct response for determining the minimum Frequency Response related to under-frequency relay operation and the support of interconnection reliability. This is because it can be used to provide a direct estimate of the maximum frequency deviation an interconnection will experience for an initial frequency and a given size event in MW. Unfortunately, arrested frequency response cannot currently be measured using the existing EMS-based measurement infrastructure. This limitation exists because the scan rates currently used in industry EMSs are incapable of measuring the net actual interchange at the same instant that the maximum frequency deviation is reached. Fortunately, the ratio of arrested frequency response and settled frequency response tends to be stable on an interconnection. This allows the settled frequency response value to be used as a surrogate for the arrested frequency response and implement a reasonable measure upon which to base a standard. One consequence of using the settled frequency response as a surrogate for the arrested frequency response is the inclusion of a large reliability margin in Interconnection Frequency Response Obligation to allow for the difference between the settled frequency response as measured and the arrested frequency response that indicates reliability.

As measurement infrastructure improves one might expect the Frequency Response Obligation to transition to a measurement based directly on the arrested frequency response while the Frequency Bias Setting will continue to be based on the settled frequency response. However, at this time, the measurement devices and methods in use do not support the necessary level of accuracy to estimate arrested frequency response contribution for an individual Balancing Authority.

## Frequency Response Definition and Examples

Limitations of the measurement infrastructure determine the measurement methods recommended in this standard. The measurement limitations provide opportunities to improve the Frequency Response as measured in the standard without contributing to an improvement in Frequency Response that contributes to reliability. These definitions and examples provide a basis for determining which contributions to Frequency Response contribute the most to improved reliability. They also provide the basis for determining on a case by case basis whether the individual contributors to the Frequency Response Measure are also contributing to reliability.

## General Frequency Response Characteristics

In the simplest case Frequency Response includes any automatic response to changes in local frequency. If that response works to decrease that change in frequency, it is beneficial to reliability. If that response works to increase that change in frequency, it is detrimental to reliability. However, this definition does not address the relative value of one response as compared to other responses that may be provided in a specific case.

There are numerous characteristics associated with the Frequency Response that affect the reliability value and economic value of the response. These characteristics include:

1. Inertial - the response is inertial or approximates inertial response Inertial response provides power without delay that is proportional to the frequency and the change in frequency. Therefore, power provided by electronic control as
synthetic inertial response must be proportional to the frequency and change in frequency and be provided without a time delay.
2. Immediate - no unnecessary intentional time delays or reduction in the rate of response delivery
a. time delay before the beginning of the response

Turbines that convert heat or kinetic energy have time delays related to the time delay from the time that the control valves are moved to initiate the change in power and the time that the power is delivered to the generator. These times are usually associated with the time it takes a change in mass flow to travel from the control valve to the first blades of the turbine in the turbine generator.
b. reduction in the rate of response delivery

There are natural delays associated with the rate of response delivery that are related to the mass flow travel from the first turbine blades to the last turbine blades. In addition, some turbines have intentional delays designed into the control system to slow the rate of change in the delivery of the kinetic energy or fuel to the turbine to prevent the turbine or other equipment from being damaged, hydro turbines, or to prevent the turbine from tripping due to excessive rate of change, gas turbines.
3. Proportional - the amount of the total response is proportional to the frequency error
a. No Deadband - the response is proportional across the entire frequency range
b. Deadband - the response is only proportional outside of a defined deadband
4. Bi-directional - the response occurs to both increases and decreases in frequency
5. Continuous - there are no discontinuities in the delivery of the response (no step changes)
6. Sustained - the response is sustained until frequency is returned to schedule

## Frequency Response Reliability Value

This section contains a more detailed discussion of the various characteristics of Frequency Response listed in the previous section. It also provides an indication of the relative value of these characteristics with respect to their contribution to reliability. Finally, it includes some examples of the described responses.

Inertial Response is provided from the stored energy in the rotating mass of the turbinegenerators and synchronous motors on the interconnection. It limits the rate of change of frequency until sufficient Frequency Response can be supplied to arrest the change in frequency. Its reliability value increases as the time delay associated with the delivery of other Frequency Response on the interconnection increases. If those time delays are minimal, then the value of inertial response is low. If all time delays associated with the Frequency Response could be eliminated, then inertial response would have little value.

The reliability value of Inertial Response is the greatest on small interconnections because the size of the Disturbance events is larger relative to the inertia of the interconnection. Electronic
controls have been developed to provide synthetic inertial response from the stored energy in asynchronous generators to supplement the natural inertial response. Some Type III \& IV Wind Turbines have this capability. In addition, electronically controlled SCRs have been developed that can store energy in the electrical system and release this stored energy to supply synthetic inertial response when required.

Immediate Response is provided by load damping and because the time delays associated with its delivery are very short (related to the speed of electrical signal in the electrical system); load damping requires very little inertial response to limit arrested frequency effectively. Synthetic immediate response can also be supplied from loads because in many cases, there is no mass flow time delay associated with the load process providing the power and energy reduction. Therefore, loads can provide an immediate response with a higher reliability value than generators with time delays required by the physics of the turbine-generator.

Governor response has time delays associated with its delivery. Governor response provided with shorter time delays has a higher reliability value because those shorter time delays require less inertial response to arrest frequency. Governor response is provided by the turbinegenerators on the interconnection. Time delays associated with governor response vary depending on the type of turbine-generator providing the response.

The longest time delays are usually associated with high head hydro turbine-generators that require long times from the governor action until the additional mass flow through the turbine. These units may also have the longest delivery time associated with the full delivery of response because of the timing designed into the governor response. ${ }^{5}$

Intermediate time delays are usually associated with steam turbine-generators. The response begins when the steam control valves are adjusted and the steam mass flows from the valves to the first high pressure turbine blades. The delivery times associated with the full delivery of response may require the steam to flow through high, intermediate and low pressure turbines including reheat flows before full power is delivered. These times are shorter than those of the hydro turbine-generators in general, but not as fast as the times associated with gas turbines. ${ }^{6}$

Gas turbines typically have the shortest time delays, because control is provided by injecting more or less fuel into the turbine combustor and adjusting the air control dampers. These control changes can be initiated rapidly and the mass flow has the shortest path to the turbine blades. There may be timing limitations related to the rate of change in output of the gas turbine-generator to maintain flame stability in some cases slowing the rate of change. ${ }^{7}$

[^68]Synthetic Governor Response can be supplied by certain loads and storage systems. The immediacy of the response is normally limited only by the electronic controls used to activate the desired response. Synthetic response, when it can be supplied immediately without significant time delay, has a higher reliability value because it requires less inertial response to achieve smaller arrested frequency deviations.

Proportional Response indicates that the response provided is proportional in magnitude to the frequency error. Response deadbands cause a non-proportional response and reduce the value of the response with respect to reliability. Contrary to general consensus, deadbands do not reduce the amount of Frequency Response that must be provided, they only transfer the responsibility for providing that Frequency Response from one source on the interconnection to another. For a given response, the response with the smaller deadband has the greater reliability value. Therefore, deadbands should be set to the smallest value that supports overall reliable operation including the reliable operation of the generator.

Electronic controls have also been developed to provide synthetic governor response. When these controls are applied to certain loads or stored energy systems, they can be programmed to provide synthetic governor response similar to the proportional response of a turbinegenerator governor. Governor response in generators is limited to a small percentage of the output of the generating unit, while synthetic governor response could be applied to much larger percentages of loads or storage devices providing such response.

Load damping provides a proportional response.
Continuous Response is response that has no discontinuous (step) changes in the frequency versus response curve. Step changes (Non-continuous Response) in the Governor Response curve can lead to frequency instabilities at frequencies near the changes. The ERCOT Interconnection observed this and has since prohibited the use of governor response characteristics incorporating step responses.

Step responses also occur with the implementation of load interruption using under-frequency or over-frequency relays.

Bi-directional Response is response that occurs in both directions, when the frequency is increasing and when the frequency is decreasing. A uni-directional response is a response that only occurs once when frequency is decreasing or when frequency is increasing.

Inertial response, governor response and load damping are all bi-directional responses. Certain loads are capable of providing proportional bi-directional response while others are only capable of providing non-proportional bi-directional response.

The ERCOT Load Resource program is a uni-directional response program. Loads are only tripped when frequency declines below a given set-point. When frequency is restored above that set-point, the loads must be manually reconnected. As a consequence, the Frequency Response only occurs once with declining frequency and does not oppose the increase in frequency after the initial decline. If there should be a frequency oscillation, the uni-directional response will not contribute to the opposition of a second frequency decline across the set-
point during an oscillation event. Once a uni-directional response has occurred, it is unavailable for a second decline before reset.

Step or proportional responses implemented bi-directionally can lead to frequency instability when there is less continuous frequency response than the magnitude of the change in continuous response between the trip and reset frequencies in step, or the proportional response rate of change is greater than the underlying continuous response. A step bidirectional response will have the load reconnected as frequency recovers from the event thus opposing the increase in frequency during recovery, and also resetting the load response for the next frequency decline automatically. Bi-directional response obviously has a greater reliability value than uni-directional response.

Sustained Response is provided at its full value until frequency is restored to its scheduled value. On today's interconnections, few frequency responses are fully sustained until frequency has been restored to its scheduled value. On steam based turbine-generators, the steam pressure may drop after a time as the result of the additional steam flow from governor action. However, in general this has not been a problem because most responses are incomplete at the time that frequency has been initially arrested and the additional response has generally been sufficient to make up for more than the these unpreventable reductions in response. However, the intentional withdrawal of response before frequency has been restored to schedule can cause a decline in frequency beyond that which would be otherwise expected. This intentional withdrawal of response is highly detrimental to reliability. Therefore, it can be concluded in general that sustained response has a higher reliability value than un-sustained response.

On an interconnection, the withdrawal of response due to the loss of steam pressure on the steam units may be offset by the slower response of hydro turbine-generators. In these cases, the reliability of the combined response provides greater reliability value than the individual response of each type. The steam turbine-generators provide a fast response that may be reduced, while the hydro turbine-generators provide a slower response, contributing less to the arresting response, offsetting any reduction by the steam turbine-generators to assure a sustained response.

Sustained Response must also be considered for any resource that has a limited duration associated with its response. The amount of stored energy available from a resource may limit its ability to sustain response for a duration of time necessary to support reliability.

## Frequency Response Cost Factors

In every system of exchange there are two sides; the supply side and the demand side. The supply side provides the services used by the demand side. In the case of Frequency Response, the supply side includes all providers of Frequency Response and the demand side includes all participants that create the need for Frequency Response.

## Frequency Response Costs - Supply Side

There are a number of factors that affect the cost of providing Frequency Response from resources. Since there is a cost associated with those factors, some method of appropriate compensation could be made available to those resources providing Frequency Response.

Without compensation, providers of Frequency Response will be put in the position of incurring additional cost that can be avoided only by reducing or eliminating the response they provide. These costs are incurred independently of whether provided for in a formal Regional Transmission Organization/Independent System Operator (RTO/ISO) market or in a traditional BA subject to the FERC pro-forma tariffs.

It is the responsibility of the BA or the RTO/ISO to acquire the necessary amount of Frequency Response to support reliability in the most cost effective manner. This function is performed best when the suppliers are evaluated based on the value of the Frequency Response they provide and compensated appropriately for that Frequency Response. Suppliers provide Frequency Response when they are assured that they will receive fair compensation. Before considering how to perform this evaluation and compensation, the costs associated with providing Frequency Response should be understood and evaluated with respect to the level of reliability they offer.

Some cost factors that have been identified for providing Frequency Response include:

1. Capacity Opportunity Cost - the costs, including opportunity costs, associated with reserving capacity to provide Frequency Response. These costs are usually associated with the alternative use of the same capacity to provide energy or other ancillary services. There may also be capacity opportunity costs associated with the loss in average capacity by a load providing Frequency Response.
2. Fuel Cost - The cost of fuel used to provide the Frequency Response. The costs for fuel to provide Frequency Response can result in energy costs significantly different from the system marginal energy cost, both higher and lower. This is the case when Frequency Response is provided by resources that are not at the system marginal cost.
3. Energy Efficiency Penalty Costs - the costs associated with the loss in efficiency when the resource is operated in a mode that supports the delivery of Frequency Response. This cost is usually in the form of additional fuel use to provide the same amount of energy. An example is the difference between operating a steam turbine in valve control mode with an active governor and sliding pressure mode with valves wide open and no active governor control except for over-speed. This cost is incurred for all of the energy provided by the resource, not just the energy provided for Frequency Response. There may be additional energy costs associated with a load providing Frequency Response from loss in efficiency of their process when load is reduced.
4. Capacity Efficiency Penalty Costs - the costs associated with any reduction in capacity resulting from the loss of capacity associated with the loss in energy efficiency. When efficiency is lost, capacity may be lost at the same time because of limitations in the amount of input energy that can be provided to the resource.
5. Maintenance Costs - the operation of the resource in a manner necessary to provide Frequency Response may result in increases in the maintenance costs associated with the resource.
6. Emissions Costs - the additional costs incurred to manage any additional emissions that result when the resource is providing Frequency Response or stands ready to provide Frequency Response.

A good contract for the acquisition of Frequency Response from a resource will provide appropriate compensation to the resource all of the costs the resource incurs to provide Frequency Response. It will also provide a method to evaluate the least cost mix of resources necessary to provide the minimum required Frequency Response for maintaining reliability. Finally, it will provide the least complex method of evaluation considering the complexity and efficiency of the acquisition process.

## Frequency Response Costs - Demand Side

Not only are there costs associated with acquiring Frequency Response from the supplying resources, there are costs associated with the amount of Frequency Response that must be acquired and influenced by those participants that create the need for Frequency Response. If the costs of acquiring Frequency Response from the supply resources can be assigned to those parties that create the need for Frequency Response, there is the promise that the amount of Frequency Response required to maintain reliability can be minimized. The considerations are the same as those that are driving the development of "real time pricing" and "dynamic pricing". If the costs are passed on to those contributing to the need for Frequency Response, incentives are created to reduce the need for Frequency Response making interconnection operations less expensive and more reliable. The problem is to balance both cost and complexity against reliability on both the supply side and the demand side.

## Rationale by Requirement

## Requirement 1

R1. Each Frequency Response Sharing Group (FRSG) or Balancing Authority that is not a member of a FRSG shall achieve an annual Frequency Response Measure (FRM) (as calculated and reported in accordance with Attachment A) that is equal to or more negative than its Frequency Response Obligation (FRO) to ensure that sufficient Frequency Response is provided by each FRSG or Balancing Authority that is not a member of a FRSG to maintain Interconnection Frequency Response equal to or more negative than the Interconnection Frequency Response Obligation.

## Background and Rationale

R1 is intended to meet the following primary objectives:

- Determine whether a Balancing Authority (BA) has sufficient Frequency Response for reliable operations.
- Provide the feeder information needed to calculate CPS limits and Frequency Bias Settings.

## Primary Objective

With regard to the first objective, FRS Form 1 and the process in Attachment A provide the method for determining the Interconnections' necessary amount of Frequency Response and allocating it to the Balancing Authorities. The field trial for BAL-003-1 is testing an allocation methodology based on the amount of load and generation in the BA. This is to accommodate the wide spectrum of BAs from generation-only all the way to load-only.

## Frequency Response Sharing Groups (FRSGs)

This standard proposes an entity called FRSG, which is defined as:
A group whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply operating resources required to jointly meet the sum of the Frequency Response Obligations of its members.

This standard allows Balancing Authorities to cooperatively form FRSGs as a means to jointly meet the FRS. There is no obligation to form or be a part of FRSGs. The members of the FRSG would determine how to allocate sanctions among its members. This standard does not mandate the formation of FRSGs, but allows them as a means to meet one of FERC's Order No. 693 directives.

FRSG performance may be calculated one of two ways:

- Calculate a group $\mathrm{NI}_{\mathrm{A}}$ and measure the group response to all events in the reporting year on a single FRS Form 1, or
- Jointly submit the individual BAs' Form 1s, with a summary spreadsheet that sums each participant's individual event performance.

## Frequency Response Obligation and Calculation

The basic Frequency Response Obligation is based on non-coincident peak load and generation data reported in FERC Form 714 (where applicable, see below for non-jurisdictional entities) for the previous full calendar year. The basic allocation formula used by NERC is:

Where:

- Annual Gen ${ }_{B A}$ is the annual "Net Generation (MWh)", FERC Form 714, line 13, column c of Part II - Schedule 3.
- Annual Load ${ }_{B A}$ is the annual "Net Energy for Load (MWh)", FERC Form 714, line 13, column e of Part II - Schedule 3.
- Annual Gen $_{\text {Int }}$ is the sum of all Annual Gen $_{B A}$ values reported in that interconnection.
- Annual Load ${ }_{1 n t}$ is the sum of all Annual $\operatorname{Load}_{\mathrm{BA}}$ values reported in that interconnection.

Balancing Authorities that are not FERC jurisdictional should use the Form 714 Instructions to assemble and submit equivalent data. Until the BAL-003-1 process outlined in Attachment 1 is implemented, Balancing Authorities can approximate their FRO by multiplying their Interconnection's FRO by their share of Interconnection Bias. The data used for this calculation should be for the most recently filed Form 714. As an example, a report to NERC in January 2013 would use the Form 714 data filed in 2012, which utilized data from 2011.

Balancing Authorities that merge or that transfer load or generation need to notify the ERO of the change in footprint and corresponding changes in allocation such that the net obligation for the Interconnection remains the same and so that CPS limits can be adjusted.

Attachment A proposes the following Interconnection event criteria as a basis to determine an Interconnection's Frequency Response Obligation:

- Largest category C loss-of-resource (N-2) event.
- Largest total generating plant with common voltage switchyard.
- Largest loss of generation in the interconnection in the last 10 years.

With regard to the second objective above (determining Frequency Bias Settings and CPS limits), Balancing Authorities have been asked to perform annual reviews of their Frequency Bias Settings by measuring their Frequency Response, dating back to Policy 1. This obligation was carried forward into BAL-003-01.b. While the associated training document provided useful information, it left many of the details to the judgment of the person doing the analysis. The FRS Form 1 and FRS Form 2 provide a consistent, objective process for calculating Frequency Response to develop an annual measure, the FRM.

The FRM will be computed from Single Event Frequency Response Data (SEFRD), defined as: "the data from an individual event from a Balancing Authority that is used to calculate its Frequency Response, expressed in MW/0.1Hz". The SEFRD for a typical Balancing Authority in an Interconnection with more than one Balancing Authority is basically the change of its net actual interchange on its tie lines with its adjacent Balancing Authorities divided by the change in interconnection frequency. (Some Balancing Authorities may choose to apply corrections to their net actual interchange values to account for factors such as nonconforming loads. FRS Form 1 shows the types of adjustments that are allowed.)

A standardized sampling interval of approximately 20 to 52 seconds will be used in the computation of SEFRD values. Microsoft Exce ${ }^{\circledR}$ spreadsheet interfaces for EMS scan rates of 2 through 6 seconds are provided to support the computation.

## Single Event Frequency Response Data ${ }^{8}$

The use of a "single event measure" was considered early in the development of the FRS for compliance because a single event measure could be enforced for each event on the interconnection making compliance enforcement a simpler process. The variability of the measurement of Frequency Response for an individual BA for an individual Disturbance event was evaluated to determine its suitability for use as a compliance measure. The individual Disturbance events were normalized and plotted for each BA on the Eastern and Western Interconnections. This data was plotted with a dot representing each event. Events with a measured Frequency Response above the FRO were shown as blue dots and events with a measured Frequency Response below the FRO were shown as red dots. In order to show the full variability of the results the plots have been provide with two scales, a large scale to show all of the events and small scale to show the events closer to the FRO or a value of 1.0. This data is presented on four charts titled Frequency Response Events as Normalized by FRO.

Analysis of this data indicates a single event based compliance measure is unsuitable for compliance evaluation when the data has the large degree of variability shown in these charts. Based on the field trial data provided, only 3 out of 19 BAs on the Western Interconnection would be compliant for all events with a standard based on a single event measure. Only 1 out of 31 BAs on the Eastern Interconnection would be compliant for all events with a standard based on a single event measure. The general consensus of the industry is that there is not a reliability issue with insufficient Frequency Response on any of the North American Interconnections at this time. Therefore, it is unreasonable to even consider a standard that would indicate over $90 \%$ of the BAs in North American to be non-compliant with respect to maintaining sufficient Frequency Response to maintain adequate reliability.

In an attempt to balance the workload of Balancing Authorities with the need for accuracy in the FRM, the standard will require at least 20 samples selected during the course of the year to compute the FRM. Research conducted by the FRSDT indicated that a Balancing Authority's FRM will converge to a reasonably stable value with at least 20 samples.

[^69]

## Sample Size

In order to support field trial evaluations of sample size, sampling intervals, and aggregation techniques, the FRSDT will be retrieving scan rate data from the Balancing Authorities for each SEFRD. Additional frequency events may also be requested for research purposes, though they will not be included in the FRM computation.

FERC Order No. 693 directed the ERO (at P 375) to define the number of Frequency Response surveys that were conducted each year and to define a necessary amount of Frequency Response. R1 addresses both of these directives:

- There is a single annual survey of at least 20 events each year.
- The FRM calculated on FRS Form 1 is compared by the ERO against the FRO determined 12 months earlier (when the last FRS Form 1 was submitted) to verify the Balancing Authority provided its share of Interconnection Frequency Response.

## Median as the Standard's Measure of Balancing Authority Performance

The FRSDT evaluated different approaches for "averaging" individual event observations to compute a technically sound estimate of Frequency Response Measure. The MW contribution for a single BA in a multi-BA Interconnection is small compared to the minute to minute changes in load, interchange and generation. For example, a 3000 MW BA in the east may only be called on to contribute 10MW for the loss of a 1000MW. The 10 MW of governor and load response may easily be masked as a coincident change in load.

In general, statisticians use the median as the best measure of central tendency when a population has outliers. Two independent reviews by the FRSDT has shown the Median to be less influenced by noise in the measurement process and the team has chosen the median as the initial metric for calculating the BAs' Frequency Response Measure.

The FRSDT performed extensive empirical studies and engaged in lively discussions in an attempt to determine the best aggregation technique for a sample set size of at least 20 events. Mean, median, and linear regression techniques were used on a trial basis with the data that was available during the early phases of the effort.

A key characteristic of the "aggregation challenge" is related to the use of actual net interchange data for measuring frequency response. The tie line flow measurements are varying continuously due to other operational phenomena occurring concurrently with the provision of frequency response. (See Appendix 1 for details.) All samples have "noise" in them, as most operational personnel who have computed the frequency response of their BA can attest. What has also become apparent to the FRSDT is that while the majority of the frequency response samples have similar levels of noise in them, a few of the samples may have much larger errors in them than the others that result in unrepresentative results. And with the sample set size of interest, it is common to have unrepresentative errors in these few samples to be very large and asymmetric. For example, one BA's subject matter expert observed recently that 4 out of 31 samples had a much larger error contribution than the other 27 samples, and that 3 out of 4 of the very high error samples grossly underestimated the frequency response. The median value demonstrated greater resiliency to this data quality problem than the mean with this data set. (The median has also demonstrated superiority to
linear regression in the presence of these described data quality problems in other analyses conducted by the FRSDT, but the linear regression showed better performance than the mean.)

The above can be demonstrated with a relatively simple example. Let's assume that a Balancing Authority's true frequency response has an average value of $-200 \mathrm{MW} / .1 \mathrm{~Hz}$. Let's also assume that this Balancing Authority installed "special" perfect metering on key loads and generators, so that we could know the true frequency response of each sample. And then we will compare them with that measured by typical tie line flow metering, with the kind of noise and error that occurs commonly and "not so commonly". Let's start with the following 4 samples having a common level of noise, with MW/ .1 Hz as the unit of measurement.

| Perfect measurement | Noise | Samples from tie lines |
| :--- | :--- | :--- |
| -190 | -30 | -220 |
| -210 | -20 | -230 |
| -220 | 10 | -210 |
| -180 | 20 | -160 |
| -200 | Mean | -205 |
| -200 | Median | -215 |

Now let's add a fifth sample, which is highly contaminated with noise and error that grossly underestimates frequency response.

| Perfect measurement | Noise | Samples from tie lines |
| :--- | :--- | :--- |
| -190 | -30 | -220 |
| -210 | -20 | -230 |
| -220 | 10 | -210 |
| -180 | 20 | -160 |
| -200 | 250 | +50 |
| -200 | Mean | -154 |
| -200 | Median | -210 |

It is clear from the above simplistic example that the mean drops by about $25 \%$ while the median is affected minimally by the single highly contaminated value.

Based on the analyses performed thus far, the FRSDT believes that the median's superior resiliency to this type of data quality problem makes it the best aggregation technique at this time. However, the FRSDT sees merit and promise in future research with sample filtering combined with a technique such as linear regression.

When compared with the mean, linear regression shows superior performance with respect to the elimination of noise because the measured data is weighted by the size of the frequency change associated with the event. Since the noise is independent from frequency change, the greater weighting on larger events provides a superior technique for reducing the effect of noise on the results.

However, linear regression does not provide a better method when dealing with a few samples with large magnitudes of noise and unrepresentative error. There are only two alternatives to improve over the use of median when dealing with these larger unrepresentative errors:

1. Increase the sample size, or
2. Actively eliminate outliers due to unrepresentative error.

Unfortunately, the first alternative, increasing the sample size is not available because significantly more sample events are not available within the measurement time period of one year. Linear regression techniques are being investigated that have an active outlier elimination algorithm that would eliminate data that lie outside ranges of the 96th percentile and 99th percentile, for example.

Still, the use of linear regression has value in the context of this standard. The NERC Resources Subcommittee will use linear regression to evaluate Interconnection frequency response, particularly to evaluate trends, seasonal impacts, time of day influences, etc. The Good Practices and Tools section of this document outlines how a BA can use linear regression to develop a predictive tool for its operators.

Additional discussion on this topic is contained in "Appendix 1 - Data Quality Concerns Related to the Use of Actual Net Interchange Value" of this document.

The NERC Frequency Response Initiative Report addressed the relative merits of using the median versus linear regression for aggregating single event frequency response samples into a frequency response measurement score for compliance evaluation. This report provided 11 evaluation criteria as a basis for recommending the use of linear regression instead of the median for the frequency response measurement aggregation technique. The FRSDT made its own assessment on the basis of these evaluation criteria on September 20, 2012, but concluded that the median would be the best aggregation technique to use initially when the relative importance of each criterion was considered. A brief summary of the FRSDT majority consensus on the basis of each evaluation criterion is provided below.

- Provides two dimensional measurement - The FRSDT agrees that the two dimensional concept is a useful way to perceive frequency response characteristics, and that it may be useful for potential future modeling activities. Better data quality would increase support for such future efforts, and the use of the median for initial compliance evaluations within BAL-003-1 should not hinder any such effort. The FRSDT perceived this as a mild advantage for linear regression.
- Represents nonlinear characteristics - With considerations similar to those applied to the previous criterion, the FRSDT perceived this as a mild advantage for linear regression.
- Provides a single best estimator - The FRSDT put gave minimal importance to the characteristic of the median averaging the middle values when used with an even number of samples.
- Is part of a linear system - With considerations similar to those applied to the first two criteria, the FRSDT perceived this as a mild advantage for linear regression (particularly in the modeling area.)
- Represents bimodal distributions - The FRSDT put minimal weight of this criterion, as a change in Balancing Authority footprint does not seem to be addressed adequately by any aggregation technique.
- Quality statistics available - The FRSDT perceived this as a mild advantage for linear regression in that the statistics would be coupled directly to the compliance evaluation. The FRSDT also included this criterion as part of the modeling advantages cited above.

The FRSDT supports collecting data and performing quality statistical analysis. If it is determined that the use of the median, as opposed to a mean or linear regression aggregation, is yielding undesirable consequences, the FRSDT recommends that other aggregation techniques be re-evaluated at that time.

- Reducing influence of noise - This is the dominant concern of the FRSDT, and it perceives the median to have a major advantage over linear regression in addressing noise in the change in actual net interchange calculation. The FRSDT bases this judgment on: prior FRSDT studies that have shown that the median produces more stable results; the data used in the NERC Frequency Response Initiative document exhibits large quantities of noise; prior efforts of FRSDT members in performing frequency response sampling for their own Balancing Authorities over many years; and similar observations of noise in the CERTS frequency Monitoring Application. The FRSDT has serious concerns that the influence of noise has a greater tendency to yield a "false positive" compliance violation with linear regression than with the median. Also, limited studies performed by the FRSDT indicates the possibility that the resultant frequency response measure would yield more measurement variation across years with linear regression versus the median while the actual Balancing Authority performance remains unchanged.
- Reducing the influence of outliers - This is related to the previous criterion. The FRSDT recognizes four main sources of noise: concurrent operating phenomena (described elsewhere in this document), transient tie line flows for nearby contingencies, data acquisition time skew in tie line data measurements, and time skew and data compression issues in archiving techniques and tools such as PI. Some outliers may be caused in part by true variation in the actual frequency response, and it is desirable to include those in the frequency response measure. The FRSDT supports efforts in the near future to distinguish between outliers caused by noise versus true frequency response, and progress in this area may make it feasible and desirable to replace the median with linear regression, or some other validated technique. The FRSDT does note that this is a substantial undertaking, and it would require substantial input from a sufficient number of experts to help distinguish noise from true frequency response.
- Easy to calculate - The FRSDT perceives this to be a minor to moderate advantage for the median. However, more complex (but reasonably so) techniques would receive more support if clear progress can be made in noise elimination.
- Familiar indicator - The FRSDT perceives this to be a minor to moderate advantage for the median. However, more complex (but reasonably so) techniques would receive more support if clear progress can be made as a result of noise elimination.
- Currently used as a measure in BAL-003 - The present standard refers to an average and does not provide specific guidance on the computation of that average, but the FRSDT puts minimal weight on this evaluation criterion.

In summary, the FRSDT perceives an approximate balance between the modeling advantage for linear regression and the simplicity advantage of the median. However, the clear determinant in endorsing the use of the median is the data quality issue related to concurrent operational phenomena, transient tie line flows, and data acquisition and archiving limitations.

FERC Order No. 693 also directed the Standard (at P 375) to identify methods for Balancing Authorities to obtain Frequency Response. Requirement R1 allows Balancing Authorities to participate in Frequency Response Sharing Groups (FRSGs) to provide or obtain Frequency Response. These may be the same FRSGs that cooperate for BAL-002-0 or may be FRSGs that form for the purposes of BAL-003-1.

If BAs participate as an FRSG for BAL-003-1, compliance is based on the sum of the participants' performance.

Two other ways that BAs could obtain Frequency Response are through Supplemental Service or Overlap Regulation Service:

- No special action is needed if a BA provides or receives supplemental regulation. If the regulation occurs via Pseudo Tie, the transfer occurs automatically as part of Net Actual Interchange (NIA) and in response to information transferred from recipient to provider.
- If a BA provides overlap regulation, its FRS Form 1 will include the Frequency Bias setting as well as peak load and generation of the combined Balancing Authority Areas. The FRM event data will be calculated on the sum of the provider's and recipient's performance.

In the Violation Severity Levels for Requirement R1, the impact of a BA not having enough frequency response depends on two factors:

- Does the Interconnection have sufficient response?
- How short is the BA in providing its FRO?

The VSL takes these factors into account. While the VSLs look different than some other standards, an explanation would be helpful.

VSLs are a starting point for the enforcement process. The combination of the VSL and VRF is intended to measure a violation's impact on reliability and thus levy an appropriate sanction. Frequency Response is an interconnection-wide resource. The proposed VSLs are intended to put multi-BA Interconnections on the same plane as single-BA Interconnections.

Consider a small BA whose performance is $70 \%$ of its FRO. If all other BAs in the Interconnection are compliant, the small BA's performance has negligible impact on reliability, yet would be sanctioned at the same level as a BA who was responsible for its entire Interconnection. It is not rational to sanction this BA the same as a single BA Interconnection that had insufficient Frequency Response, because this would treat multi-BA Interconnections more harshly than single BA Interconnections on a significant scale.

The "Lower" and "Medium" VSLs say that the Interconnection has sufficient Frequency Response but individual BAs are deficient by small or larger amounts respectively. The High and Severe VSLs say the Interconnection does not meet the FRO and assesses sanctions based on whether the BA is deficient by a small or larger amount respectively.

## Requirement 2

R2. Each Balancing Authority that is a member of a multiple Balancing Authority Interconnection and is not receiving Overlap Regulation Service and uses a fixed Frequency Bias Setting shall implement the Frequency Bias Setting determined subject to Attachment A, as validated by the ERO, into its Area Control Error (ACE) calculation during the implementation period specified by the ERO.

## Background and Rationale

Attachment A of the Standard discusses the process the ERO will follow to validate the BA's FRS Form 1 data and publish the official Frequency Bias Settings. Historically, it has taken multiple rounds of validation and outreach to confirm each BA's data due to transcription errors, misunderstanding of instructions, and other issues. While BAs historically submit Bias Setting data by January 1, it often takes one or more months to complete the process.

The target is to have BAs submit their data by January 10. The BAs are given 30 days to assemble their data since the BAs are dependent on the ERO to provide them with FRS Form 1, and there may be process delays in distributing the forms since they rely on identification of frequency events through November 30 of the preceding year.

Frequency Bias Settings generally change little from year to year. Given the fact that BAs can encounter staffing or EMS change issues coincident with the date the ERO sets for new Frequency Bias Setting implementation, the standard provides a 24 hour window on each side of the target date.

To recap the annual process:

1. The ERO posts the official list of frequency events to be used for this Standard in early December. The FRS Form 1 for each Interconnection will be posted shortly thereafter.
2. The Balancing Authority submits its revised annual Frequency Bias Setting value to NERC by January 10.
3. The ERO and the Resources Subcommittee validate Frequency Bias Setting values, perform error checking, and calculate, validate, and update CPS2 L10 values. This data collection and validation process can take as long as two months.
4. Once the L10 and Frequency Bias Setting values are validated, The ERO posts the values for the upcoming year and also informs the Balancing Authorities of the date on which to implement revised Frequency Bias Setting values. Implementation typically would be on or about March $1^{\text {st }}$ of each year.

BAL-003-0.1b standard requires a minimum Frequency Bias Setting equal in absolute value to one percent of the Balancing Authority's estimated yearly peak demand (or maximum generation level if native load is not served). For most Balancing Authorities this calculated amount of Frequency Bias is significantly greater in absolute value than their actual Frequency Response characteristic (which represents an over-bias condition) resulting in over-control
since a larger magnitude response is realized. This is especially true in the Eastern Interconnection where this condition requires excessive secondary frequency control response which degrades overall system performance and increases operating cost as compared to requiring an appropriate balance of primary and secondary frequency control response.

Balancing Authorities were given a minimum Frequency Bias Setting obligation because there had never been a mandatory Frequency Response Obligation. This historic "one percent of peak per 0.1 Hz " obligation, dating back to NERC's predecessor, NAPSIC, was intended to ensure all BAs provide some support to Interconnection frequency.

The ideal system control state exists when the Frequency Bias Setting of the Balancing Authority exactly matches the actual Frequency Response characteristic of the Balancing Authority. If this is not achievable, over-bias is significantly better from a control perspective than under-bias with the caveat that Frequency Bias is set relatively close in magnitude to the Balancing Authority actual Frequency Response characteristic. Setting the Frequency Bias to better approximate the Balancing Authority natural Frequency Response characteristic will improve the quality and accuracy of ACE control, CPS \& DCS and general AGC System control response. This is the technical basis for recommending an adjustment to the long standing " $1 \%$ of peak/0.1Hz" Frequency Bias Setting. The Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard is intended to bring the Balancing Authorities' Frequency Bias Setting closer to their natural Frequency Response. Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard balances the following objectives:

- Bring the Frequency Bias Setting and Frequency Response closer together.
- Allow time to analyze impact on other Standards (CPS, BAAL and to a lesser extent DCS) by adjustments in the minimum Frequency Bias Setting, by accommodating only minor adjustments.
- Do not allow the Frequency Bias Setting minimum to drop below natural Frequency Response, because under-biasing could affect an Interconnection adversely.

Additional flexibility has been added to the Frequency Bias Setting based on the actual Frequency Response (FRM) by allowing the Frequency Bias Setting to have a value in the range from $100 \%$ of FRM to $125 \%$ of FRM. This change has been included for the following reasons:

- When the new standardized measurement method is applied to BAs with a Frequency Response close to the interconnection minimum response, the requirement to use FRM is as likely to result in a Frequency Bias Setting below the actual response as it is to result in a response above the actual response. From a reliability perspective, it is
always better to have a Frequency Bias Setting slightly above the actual Frequency Response.
- As with single BA interconnections, the tuning of the control system may require that the BA implement a Frequency Response Setting slightly greater in absolute terms than its actual Frequency Response to get the best performance.
- The new standardized measurement method for determining FRM in some cases results in a measured Frequency Response significantly lower than the previous methods used by some BAs. It is desirable to not require significant change in the Frequency Bias Setting for these BAs that experience a reduction in their measured Frequency Response.

## Requirement 3

R3. Each Balancing Authority that is a member of a multiple Balancing Authority Interconnection, is not receiving Overlap Regulation Service and utilizing a variable Frequency Bias Setting shall maintain a Frequency Bias Setting that is:

- Less than zero at all times, and
- Equal to or more negative than its Frequency Response Obligation when the Frequency varies from 60 Hz by more that +/- 0.036 Hz .

## Background and Rationale

In multi-Balancing Authority interconnections, the Frequency Bias Setting should be coordinated among all BAs on the interconnection. When there is a minimum Frequency Bias Setting requirement, it should apply for all BAs. However, BAs using a variable Frequency Bias Setting may have non-linearity in their actual response for a number of reasons including the dead-bands implemented on their generator governors. The measurement to ensure that these BAs are conforming to the interconnection minimum is adjusted to remove the deadband range from the calculated average Frequency Bias Setting actually used. For BAs using variable bias, FRS Form 1 has a data entry location for the previous year's average monthly Bias. The Balancing Authority and the ERO can compare this value to the previous year's Frequency Bias Setting minimum to ensure R3 has been met.

On single BA interconnections, there is no need to coordinate the Frequency Bias Setting with other BAs. This eliminates the need to maintain a minimum Frequency Bias Setting for any reason other than meeting the reliability requirement as specified by the Frequency Response Obligation.

## Requirement 4

R4. Each Balancing Authority that is performing Overlap Regulation Service shall modify its Frequency Bias Setting in its ACE calculation, in order to represent the Frequency Bias Setting for the combined Balancing Authority Area, to be equivalent to either:

- The sum of the Frequency Bias Settings as shown on FRS Form 1 and FRS Form 2 for the participating Balancing Authorities as validated by the ERO, or
- The Frequency Bias Setting as shown on FRS Form 1 and FRS Form 2 for the entirety of the participating Balancing Authorities' Areas.

## Background and Rationale

This requirement reflects the operating principles first established by NERC Policy 1 and is similar to Requirement R6 of the approved BAL-003-0.1b standard. Overlap Regulation Service is a method of providing regulation service in which the Balancing Authority providing the regulation service incorporates another Balancing Authority's actual interchange, frequency response, and schedules into the providing Balancing Authority's AGC/ACE equation.

As noted earlier, a BA that is providing Overlap Regulation will report the sum of the Bias Settings in its FRS Form 1. Balancing Authorities receiving Overlap Regulation Service have an ACE and Frequency Bias Setting equal to zero (0).

## How this Standard Meets the FERC Order 693 Directives

## FERC Directive

The following is the relevant paragraph of Order No. 693.
Accordingly, the Commission approves Reliability Standard BAL-003-0 as mandatory and enforceable. In addition, the Commission directs the ERO to develop a modification to BAL-003-0 through the Reliability Standards development process that: (1) includes Levels of Non-Compliance; (2) determines the appropriate periodicity of frequency response surveys necessary to ensure that Requirement R2 and other requirements of the Reliability Standard are being met, and to modify Measure M1 based on that determination and (3) defines the necessary amount of Frequency Response needed for Reliable Operation for each balancing authority with methods of obtaining and measuring that the frequency response is achieved.

## 1. Levels of Non-Compliance

VRFs and VSLs are an equally effective way of assigning compliance elements to the standard.
2. Determine the appropriate periodicity of frequency response surveys necessary to ensure that Requirement R2 and other Requirements of the Reliability Standard are met
BAL-003 V0 R2 (the basis of Order No. 693) deals with the calculation of Frequency Bias Setting such that it reflects natural Frequency Response.

The drafting team has determined that a sample size on the order of at least 20 events is necessary to have a high confidence in the estimate of a BA's Frequency Response. Selection of the frequency excursion events used for analysis will be done via a method outlined in Attachment A to the Standard.

On average, these events will represent the largest 2-3 "clean" frequency excursions occurring each month.

Since Frequency Bias Setting is an annual obligation, the survey of the at least 20 frequency excursion events will occur once each year.

## 3. Define the necessary amount of Frequency Response needed for Reliable Operation for each Balancing Authority with methods of obtaining and measuring that the frequency response is achieved

## Necessary Amount of Frequency Response

The drafting team has proposed the following approach to defining the necessary amount of frequency response. In general, the goal is to avoid triggering the first step of under-frequency load shedding (UFLS) in the given Interconnection for reasonable contingencies expected. The
methodology for determining each Interconnection's and Balancing Authority's obligation is outlined in Attachment A to the Standard.

It should be noted the standard cannot guarantee there will never be a triggering of UFLS as the magnitude of "point C" differs throughout an interconnection during a disturbance and there are local areas that see much wider swings in frequency.

The contingency protection criterion is the largest reasonably expected contingency in the Interconnection. This can be based on the largest observed credible contingency in the previous 10 years or the largest Category C event for the Interconnection.

Attachment A to the standard presents the base obligation by Interconnection and adds a Reliability Margin. The Reliability Margin included addresses the difference between Points B and C and accounts for variables.

For multiple BA interconnections, the Frequency Response Obligation is allocated to BAs based on size. This allocation will be based on the following calculation:

## Methods of Obtaining Frequency Response

The drafting team believes the following are valid methods of obtaining Frequency Response:

- Regulation services.
- Contractual service. The drafting team has developed an approach to obtain a contractual share of Frequency Response from Adjacent Balancing Authorities. See FRS Form 1. While the final rules with regard to contractual services are being defined, the current expectation is that the ERO and the associated Region(s) should be notified beforehand and that the service be at least 6 months in duration.
- Through a tariff (e.g. Frequency Response and regulation service).
- From generators through an interconnection agreement.
- Contract with an internal resource or loads (The drafting team encourages the development of a NAESB business practice for Frequency Response service for linear (droop) and stepped (e.g. LaaR in Texas) response).

Since NERC standards should not prescribe or preclude any particular market related service, BAs and FRSGs may use whatever is most appropriate for their situation.

## Measuring that the Frequency Response is Achieved

FRS Form 1 and the underlying data retained by the BA will be used for measuring whether Frequency Response was provided. FRS Form 1 will provide the guidance on how to account for and measure Frequency Response.

## Going Beyond the Directive

Based on the combined operating experience of the SDT, the drafting team consensus is that each Interconnection has sufficient Frequency Response. If margins decline, there may be a need for additional standards or tools. The drafting team and the Resources Subcommittee are working with the ERO on its Frequency Response Initiative to develop processes and good practices so the Interconnections are prepared. These good practices and tools are described in the following section.

The drafting team is also evaluating a risk-based approach for basing the Interconnection Frequency Response Obligation on an historic probability density of frequency error, and for allocating the obligation on the basis of the Balancing Authority's average annual ACE share of frequency error. This allocation method uses the inverse of the rationale for allocating the CPS1 epsilon requirement by Bias share.

## Good Practices and Tools

## Background

This section outlines tips and tools to help Balancing Authorities meet the Frequency Response Standard or to operate more reliably. If you have suggested additions, please send them to balancing@nerc.com.

## Identifying and Estimating Frequency Responsive Reserves

Knowing the quantity and depth of frequency responsive reserves in real time is a possible next step to being better prepared for the next event. The challenge in achieving this is having the knowledge of the capabilities of all sources of frequency response. Presently the primary source of Frequency Response remains with the generation resources in our fleets.

Understanding how each of these sources performs to changes in system frequency and knowing their limitations would improve the BA's ability to measure frequency responsive reserves. Presently there are only guidelines, criteria and protocols in some regions of the industry that identify specific settings and performance expectations of Primary Frequency Response of resources.

One method of gaining a better understanding of performance is to measure performance during actual events that occur on the system. Measuring performance during actual events would only provide feedback for performance during that specific event and would not provide insight into depth of response or other limitations.

Repeated measurements will increase confidence in expected performance. NERC modeling standards are in process to be revised that will improve the BA's insight into predicting available frequency responsive reserves. However, knowing how resources are operated, what modes of operation provide sustained Primary Frequency Response and knowing the operating range of this response would give the BA the knowledge to accurately predict frequency response and the amount of frequency responsive reserves available in real time.

Some benefits have been realized by communicating to generation resources (GO) the importance of operating in modes that allow Primary Frequency Response to be sustained by the control systems of the resource. Other improvements in implementation of Primary Frequency Response have been achieved through improved settings on turbine governors through the elimination of "step" frequency response with the simultaneous reduction in governor dead-band settings.

Improvements in the full AGC control loop of the generating resource, which accounts for the expected Primary Frequency Response, have improved the delivery of quality Primary Frequency Response while minimizing secondary control actions of generators. Some of these actions can provide quick improvement in delivery of Primary Frequency Response.

Once Primary Frequency Response sources are known, the BA could calculate available reserves that are frequency responsive. Planning for these reserves during normal and emergency operations could be developed and added to the normal planning process.

## Using FRS Form 1 Data

The information collected for this standard can be supplemented by a few data points to provide the Balancing Authority useful tools and information. The BA could do a regression analysis of its frequency response against the following values:

- Load (value A).
- Interchange (Value A).
- Total generation.
- Spinning reserve.

While the last two values above are not part of Form 1, they should be readily available. Small BAs might even include headroom on its larger generators as part of the regression.

The regression would provide a formula the BA could program in its EMS to present the operator a real time estimate of the BA's Frequency Response.

Statistical outliers in the regression would point to cases meriting further inspection to find causes of low Frequency Response or opportunities for improvement.

## Tools

Single generating resource performance evaluation tools for steam turbine, combustion turbine (simple cycle or combined cycle) and for intermittent resources are available at the following link. http://texasre.org/standards rules/standardsdev/rsc/sar003/Pages/Default.aspx.

These tools and the regional standard associated with them are in their final stages of development in the Texas region.

These tools will be posted on the NERC website.

## Appendix 1 - Data Quality Concerns Related To The Use Of The Actual Net Interchange Value

Actual net interchange for a typical Balancing Authority (BA) is the summation of its tie lines to other BAs. In some cases, there are pseudo-ties in it which reflect the effective removal or addition of load and/or generation from another BA, or it could include supplemental regulation as well. But in the typical scenario, actual net interchange values that are extracted from EMS data archiving can be influenced by data latency times in the data acquisition process, and also any timestamp skewing in the archival process.

Of greater concern, however, are the inevitable variations of other operating phenomena occurring concurrently with a frequency event. The impacts of these phenomena are superimposed on actual net interchange values along with the frequency response that we wish to measure through the use of the actual net interchange value.

To explore this issue further, let's begin with the idealized condition:

- frequency is fairly stable at some value near or a little below 60 Hz
- ACE of the non-contingent BA of interest is 0 and has been 0 for an extended period, and AGC control signals have not been issued recently
- Actual net interchange is "on schedule", and there are no schedule changes in the immediate future
- BA load is flat
- All generators not providing AGC are at their targets
- Variable generation such as wind and solar are not varying
- Operators have not directed any manual movements of generation recently

And when the contingency occurs in this idealized state, the change in actual net interchange will be measuring only the decline in load due to lesser frequency and generator governor response, and, none of the contaminating influences. While the ACE may become negative due to the actual frequency response being less than that called for by the frequency bias setting within the BA's AGC system, this contaminating influence on measuring frequency response will not appear in the actual net interchange value if the measurement interval ends before the generation on AGC responds.

Now let's explore the sensitivity of the resultant frequency response sampling to the relaxation of these idealized circumstances.

1. The " 60 Hz load" increases moderately due to time of day concurrent with the frequency event. If the frequency event happens before AGC or operator-directed manual load adjustments occur, then the actual net interchange will be reduced by the moderate increase in load and the frequency response will be underestimated. But if the frequency event happens while AGC response and/or manual adjustments occur, then the actual net interchange will be increased by the AGC response (and/or manual adjustments) and the frequency response will be overestimated.
2. The " 60 Hz load" decreases moderately due to time of day concurrent with the frequency event. If the frequency event happens before AGC or operator-directed manual load adjustments occur, then the actual net interchange will be increased by the moderate reduction in load and the frequency response will be overestimated. But if the frequency event happens while AGC response and/or manual adjustments occur, then the actual net interchange will be decreased by the AGC response (and/or manual adjustments) and the frequency response will be underestimated.
3. In anticipation of increasing load during the next hour, the operator increases manual generation before the load actually appears. If the frequency event happens while the generation "leading" the load is increasing, then the actual net interchange will be increased by the increase in manual generation and the frequency response will be overestimated. But if the frequency event occurs when the result of AGC signals sent to offset the operator's leading actions take effect, then the actual net interchange will be decreased and the frequency response is underestimated.
4. In anticipation of decreasing load during the next hour, the operator decreases manual generation before the load actually declines. If the frequency event happens while the generation "leading" the load downward is decreasing, then the actual net interchange will be decreased by the reduction in manual generation and the frequency response will be underestimated. But if the frequency event occurs when the result of AGC signals sent to offset the operator's leading actions take effect, then the actual net interchange will be increased and the frequency response is overestimated.
5. A schedule change to export more energy is made at 5 minutes before the top of the hour. The BA's " 60 Hz load" is not changing. The schedule change is small enough that the operator is relying on upward movement of generators on AGC to provide the additional energy to be exported. The time at which the AGC generators actually begin to provide the additional energy is dependent on how much time passes before the AGC algorithm gets out of its deadbands, the individual generator control errors get large enough for sending out the control signal, and maybe 20 seconds to 3 minutes for the response to be effected. The key point here is that it is not clear when the effects of a schedule change, as manifested in a change in generation and then ultimately a change in actual net interchange, will occur.
6. With the expected penetration of wind in the near future, unanticipated changes in their output will tend to affect actual net interchange and add noise to the frequency response observation process.

To a greater or lesser extent, 1 through 4 above are happening continuously for the most part with most BAs in the Eastern and Western Interconnections. The frequency response is buried within the typical hour to hour operational cacophony superimposed on actual net interchange values. The choice of metrics will be important to artfully extract frequency response from the noise and other unrepresentative error.

## A. Introduction

1. Title: Frequency Response and Bias
2. Number: BAL-003-0.1b
3. Purpose: This standard provides a consistent method for calculating the Frequency Bias component of ACE.
4. Applicability:
4.1. Balancing Authorities.
5. Effective Date: Immediately after approval of applicable regulatory authorities.

## B. Requirements

R1. Each Balancing Authority shall review its Frequency Bias Settings by January 1 of each year and recalculate its setting to reflect any change in the Frequency Response of the Balancing Authority Area.

R1.1. The Balancing Authority may change its Frequency Bias Setting, and the method used to determine the setting, whenever any of the factors used to determine the current bias value change.

R1.2. Each Balancing Authority shall report its Frequency Bias Setting, and method for determining that setting, to the NERC Operating Committee.

R2. Each Balancing Authority shall establish and maintain a Frequency Bias Setting that is as close as practical to, or greater than, the Balancing Authority's Frequency Response.
Frequency Bias may be calculated several ways:
R2.1. The Balancing Authority may use a fixed Frequency Bias value which is based on a fixed, straight-line function of Tie Line deviation versus Frequency Deviation. The Balancing Authority shall determine the fixed value by observing and averaging the Frequency Response for several Disturbances during on-peak hours.

R2.2. The Balancing Authority may use a variable (linear or non-linear) bias value, which is based on a variable function of Tie Line deviation to Frequency Deviation. The Balancing Authority shall determine the variable frequency bias value by analyzing Frequency Response as it varies with factors such as load, generation, governor characteristics, and frequency.

R3. Each Balancing Authority shall operate its Automatic Generation Control (AGC) on Tie Line Frequency Bias, unless such operation is adverse to system or Interconnection reliability.

R4. Balancing Authorities that use Dynamic Scheduling or Pseudo-ties for jointly owned units shall reflect their respective share of the unit governor droop response in their respective Frequency Bias Setting.

R4.1. Fixed schedules for Jointly Owned Units mandate that Balancing Authority (A) that contains the Jointly Owned Unit must incorporate the respective share of the unit governor droop response for any Balancing Authorities that have fixed schedules (B and C). See the diagram below.

R4.2. The Balancing Authorities that have a fixed schedule (B and C) but do not contain the Jointly Owned Unit shall not include their share of the governor droop response in their Frequency Bias Setting.

R5. Balancing Authorities that serve native load shall have a monthly average Frequency Bias Setting that is at least $1 \%$ of the Balancing Authority's estimated yearly peak demand per 0.1 Hz change.

R5.1. Balancing Authorities that do not serve native load shall have a monthly average Frequency Bias Setting that is at least $1 \%$ of its estimated maximum generation level in the coming year per 0.1 Hz change.

R6. A Balancing Authority that is performing Overlap Regulation Service shall increase its Frequency Bias Setting to match the frequency response of the entire area being controlled. A Balancing Authority shall not change its Frequency Bias Setting when performing Supplemental Regulation Service.

## C. Measures

M1. Each Balancing Authority shall perform Frequency Response surveys when called for by the Operating Committee to determine the Balancing Authority's response to Interconnection Frequency Deviations.
D. Compliance

Not Specified.

## E. Regional Differences

None identified.

## F. Associated Documents

1. Appendix 1 - Interpretation of Requirement R3 (October 23, 2007).
2. Appendix 2 - Interpretation of Requirements R2, R2.2, R5, and R5.1 (February 12, 2008).

## Appendix 1

## Interpretation of Requirement 3

Request: Does the WECC Automatic Time Error Control Procedure (WATEC) violate Requirement 3 of BAL-003-0?

## Interpretation:

Requirement 3 of BAL-003-0 - Frequency Response and Bias deals with Balancing Authorities using Tie-Line Frequency Bias as the normal mode of automatic generation control.

## BAL-003-0

R3. Each Balancing Authority shall operate its Automatic Generation Control (AGC) on Tie Line Frequency Bias, unless such operation is adverse to system or Interconnection reliability.

- Tie-Line Frequency Bias is one of the three foundational control modes available in a Balancing Authority's energy management system. (The other two are flat-tie and flat-frequency.) Many Balancing Authorities layer other control objectives on top of their basic control mode, such as automatic inadvertent payback, CPS optimization, time control (in single BA Interconnections).
- As long as Tie-Line Frequency Bias is the underlying control mode and CPS1 is measured and reported on the associated ACE equation, there is no violation of BAL-003-0 Requirement 3 :

$$
\mathrm{ACE}=\left(\mathrm{NI}_{\mathrm{A}}-\mathrm{NI}_{\mathrm{S}}\right)-10 \mathrm{~B}\left(\mathrm{~F}_{\mathrm{A}}-\mathrm{F}_{\mathrm{S}}\right)-\mathrm{I}_{\mathrm{ME}}
$$

## Appendix 2

## Interpretation of Requirements R2, R2.2, R5, R5.1

Request: ERCOT specifically requests clarification that a Balancing Authority is entitled to use a variable bias value as authorized by Requirement R2.2, even though Requirement 5 seems not to account for the possibility of variable bias settings.

## Interpretation:

The consensus of the Resources Subcommittee is that BAL-003-0 - Frequency Response and Bias Requirement R2 does not conflict with BAL-003-0 Requirement R5.

BAL-003-0 - Frequency Response and Bias Requirement 2 requires a Balancing Authority to analyze its response to frequency excursions as a first step in determining its frequency bias setting. The Balancing Authority may then choose a fixed bias (constant through the year) per Requirement 2.1, or a variable bias (varies with load, specific generators, etc.) per Requirement 2.2.

## BAL-003-0

R2. Each Balancing Authority shall establish and maintain a Frequency Bias Setting that is as close as practical to, or greater than, the Balancing Authority's Frequency Response. Frequency Bias may be calculated several ways:

R2.1. The Balancing Authority may use a fixed Frequency Bias value which is based on a fixed, straight-line function of Tie Line deviation versus Frequency Deviation. The Balancing Authority shall determine the fixed value by observing and averaging the Frequency Response for several Disturbances during on-peak hours.

R2.2. The Balancing Authority may use a variable (linear or non-linear) bias value, which is based on a variable function of Tie Line deviation to Frequency Deviation. The Balancing Authority shall determine the variable frequency bias value by analyzing Frequency Response as it varies with factors such as load, generation, governor characteristics, and frequency.

BAL-003-0 - Frequency Response and Bias Requirement 5 sets a minimum contribution for all Balancing Authorities toward stabilizing interconnection frequency. The $1 \%$ bias setting establishes a minimum level of automatic generation control action to help stabilize frequency following a disturbance. By setting a floor on bias, Requirement 5 also helps ensure a consistent measure of control performance among all Balancing Authorities within a multi-Balancing Authority interconnection. However, ERCOT is a single Balancing Authority interconnection. The bias settings ERCOT uses do produce, on average, the best level of automatic generation control action to meet control performance metrics. The bias value in a single Balancing Authority interconnection does not impact the measure of control performance.

## BAL-003-0

R5. Balancing Authorities that serve native load shall have a monthly average Frequency Bias Setting that is at least $1 \%$ of the Balancing Authority's estimated yearly peak demand per 0.1 Hz change.
R5.1. Balancing Authorities that do not serve native load shall have a monthly average Frequency Bias Setting that is at least $1 \%$ of its estimated maximum generation level in the coming year per 0.1 Hz change.

## Unofficial Comment Form Project 2007-12 Frequency Response

Please DO NOT use this form to submit comments. Please use the electronic form to submit comments on the BAL-003-1 Frequency Response and Bias Setting. The electronic comment form must be completed by 8 p.m. ET November 5, 2012.
http://www.nerc.com/filez/standards/Frequency Response.html
If you have questions please contact Darrel Richardson at darrel.richardson@nerc.net or by telephone at (609) 613-1848.

## Background I nformation

This posting is soliciting formal comment.

Frequency Response, a measure of an Interconnection's ability to stabilize frequency immediately following the sudden loss of generation or load, is a critical component to the reliable operation of the bulk power system, particularly during disturbances and restoration. There is evidence of continuing decline in Frequency Response over the past 10 years, but no confirmed reason for the apparent decline. The proposed standard requires entities to provide data so that Frequency Response in each of the Interconnections can be analyzed, and the reasons for the decline in Frequency Response can be identified. The standard would set a minimum Frequency Response obligation for each Balancing Authority, provide a uniform calculation of Frequency Response and Frequency Bias Settings that transition to values closer to natural Frequency Response, and encourage coordinated AGC operation.

The Drafting Team made significant modifications to the proposed standard BAL-003-1 and associated documents based on industry comments from the second posting and initial ballot. These modifications include:

- Modifying the definition for Frequency Response Measure
- Removing reference to Reserve Sharing Groups and replacing with Frequency Response Sharing Group
- Creation of definition for Frequency Response Sharing Group
- Modifying Requirement R2
- Creating a new Requirement R3 for entities using variable Frequency Bias
- Removing requirement for operating in Tie Line Bias mode
- Removing Requirement R5 and combining into revised Requirement R2 and new Requirement R3
- Modifying Attachment A to provide additional clarity
- Creating a Procedure to provide instructions for the ERO to follow in supporting the standard
- Re-writing the Background Document to incorporate additional language for justification of requirements and provide additional clarity

You do not have to answer all questions. Enter all comments in simple text format.

1. The SDT has made minor modifications to the proposed definition for Frequency Response Measure based on industry comments. Do you agree that these modifications provide sufficient clarity? If not, please explain in the comment area.

Yes
No
Comments:
2. The SDT has created a definition for Frequency Response Sharing Group. The definition is as follows:

A group whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply operating resources required to jointly meet the Frequency Response Obligations of its members.

Do you agree with this definition? If not, please explain in the comment area.

Yes

Comments:
3. The SDT has added Requirement R3 for entities using variable Frequency Bias.

R3. Each Balancing Authority that is a member of a multiple Balancing Authority Interconnection, is not receiving Overlap Regulation Service and utilizing a variable Frequency Bias Setting shall maintain a Frequency Bias Setting that is:

### 3.1 Less than zero at all times, and

3.3 Equal to or more negative than its Frequency Response Obligation when Frequency varies from 60 Hz by more than $+/-0.036 \mathrm{~Hz}$.

Do you agree with the proposed requirement? If not, please explain in the comment area.Yes
No
Comments:
4. Based on Industry comments the SDT has modified "Attachment A- Supporting Document" to provide additional clarity. Do you agree with the modifications? If not, what modifications do you disagree with?
No
Comments:
5. The SDT has moved a portion of the material located in Attachment A and all of the material located in "Attachment B- Process for Adjusting Bias Setting Floor" into a new document "Procedure for ERO Support of Frequency Response and Frequency Bias Setting Standard". The SDT created this document to assign tasks to the ERO and provide instructions for the ERO to follow when carrying them out under the BAL-003-1 standard. Do you agree that the ERO should perform these tasks and that this document provides sufficient detail for the ERO to do it under the BAL-003-1 standard? If not, what needs to be added to the document?".
$\square$
Yes
No
Comments:
6. The SDT is now using the method detailed in the Frequency Response Initiative Report dated September 30, 2012 to calculate the Interconnection Frequency Response Obligation. Do you agree that this method provides for the proper amount of Frequency Response? If not, what specifically needs to be changed?

Comments:
7. Based on Industry comments received the SDT made significant clarifying modifications to the Background Document. Do you agree that this document provides sufficient information to justify the rationale used by the SDT in developing the draft standard and provides the industry with sufficient understanding of the issues being addressed by the standard?Yes
$\square$ No
Comments:
8. If you are not in support of this draft standard, what modifications do you believe need to be made in order for you to support the standard? Please list the issues and your proposed solution to the issue.
$\square$ Yes
$\square$ No
Comments:
9. Please provide any other comments (that you have not already provided in response to the questions above) that you have on the draft standard BAL-003-1.

Comments:

# Violation Risk Factor and Violation Severity Level Assignments 

Project 2007-12 - Frequency Response

This document provides the drafting team's justification for assigning draft standard Requirement violation risk factors (VRFs) and violation severity levels (VSLs) for:

- BAL-003-1 - Frequency Response and Frequency Bias Setting

Each primary Requirement is assigned a VRF and a set of one or more VSLs. These elements support the determination of an initial value range for the Base Penalty Amount regarding violation of requirements in FERC-approved Reliability Standards, as defined in the ERO Sanction Guidelines.

## J ustification for Assignment of Violation Risk Factors

The Frequency Response Standard Drafting Team applied the following NERC criteria when proposing VRFs for the requirements under this project:

## High Risk Requirement

A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

## Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

## Lower Risk Requirement

A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the
ability to effectively monitor and control the bulk electric system; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

The SDT also considered consistency with the FERC Violation Risk Factor Guidelines for setting VRFs ${ }^{1}$ :

## Guideline (1) - Consistency with the Conclusions of the Final Blackout Report

The Commission seeks to ensure that Violation Risk Factors assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System.

In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System: ${ }^{2}$

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief

## Guideline (2) — Consistency within a Reliability Standard

The Commission expects a rational connection between the sub-Requirement Violation Risk Factor assignments and the main Requirement Violation Risk Factor assignment.

Guideline (3) - Consistency among Reliability Standards
The Commission expects the assignment of Violation Risk Factors corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

[^71]Guideline (4) — Consistency with NERC's Definition of the Violation Risk Factor Level Guideline (4) was developed to evaluate whether the assignment of a particular Violation Risk Factor level conforms to NERC's definition of that risk level.

Guideline (5) — Treatment of Requirements that Co-mingle More Than One Obligation Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

## J ustification for Assignment of Violation Severity Levels:

In developing the VSLs for the standards under this project, the SDT anticipated the evidence that would be reviewed during an audit, and developed its VSLs based on the noncompliance an auditor may find during a typical audit. The SDT based its assignment of VSLs on the following NERC criteria:

| Lower | Moderate | High | Severe |
| :--- | :--- | :--- | :--- |
| Missing a minor <br> element (or a small <br> percentage) of the <br> required performance <br> The performance or <br> product measured has <br> significant value as it <br> almost meets the full <br> intent of the <br> requirement. | Missing at least one <br> significant element (or a <br> moderate percentage) <br> of the required <br> performance. <br> The performance or <br> product measured still <br> has significant value in <br> meeting the intent of the <br> requirement. | Missing more than one <br> significant element (or is <br> missing a high <br> percentage) of the <br> required performance or <br> is missing a single vital <br> component. <br> The performance or <br> product has limited <br> value in meeting the <br> intent of the <br> requirement. | Missing most or all of <br> the significant elements <br> (or a significant <br> percentage) of the <br> required performance. <br> The performance <br> measured does not <br> meet the intent of the <br> requirement or the <br> product delivered <br> cannot be used in <br> meeting the intent of the <br> requirement. |

FERC VSL guidelines are presented below, followed by an analysis of whether the VSLs proposed for each requirement in this standard meet the FERC Guidelines for assessing VSLs:

## Guideline 1: Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

Compare the VSLs to any prior levels of non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when levels of non-compliance were used.

## Guideline 2: Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

A violation of a "binary" type requirement must be a "Severe" VSL.
Do not use ambiguous terms such as "minor" and "significant" to describe noncompliant performance.

## Guideline 3: Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

VSLs should not expand on what is required in the requirement.

## Guideline 4: Violation Severity Level Assignment Should Be Based on a Single Violation, Not on a Cumulative Number of Violations

Unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties per violation per day basis is the "default" for penalty calculations.

## VRF and VSL J ustification

BAL-003-1 VRF and VSL Justifications

| Discussion |  |
| :---: | :---: |
| Proposed Lower VSL | The summation of the Balancing Authorities' FRM within an Interconnection was equal to or more negative than the Interconnection's FRO and the Balancing Authority's, or Frequency Response Sharing Group's, FRM was less negative than its FRO by more than $1 \%$ but by at most $30 \%$ or 15 MW/0.1 Hz, whichever one is the greater deviation from its FRO |
| Proposed Moderate VSL | The summation of the Balancing Authorities' FRM within an Interconnection was equal to or more negative than the Interconnection's FRO and the Balancing Authority's, or Frequency Response Sharing Group's, FRM was less negative than its FRO by more than $30 \%$ or by more than 15 MW/0.1 Hz , whichever is the greater deviation from its FRO |
| Proposed High VSL | The summation of the Balancing Authorities' FRM within an Interconnection did not meet its FRO and the Balancing Authority's, or Frequency Response Sharing Group's, FRM was less negative than its FRO by more than $1 \%$ but by at most $30 \%$ or $15 \mathrm{MW} / 0.1 \mathrm{~Hz}$, whichever one is the greater deviation from its FRO |
| Proposed Severe VSL | The summation of the Balancing Authorities' FRM within an Interconnection did not meet its FRO and the Balancing Authority's, or Frequency Response Sharing Group's, FRM was less negative than its FRO by more than $30 \%$ or by more than $15 \mathrm{MW} / 0.1 \mathrm{~Hz}$, whichever is the greater deviation from its FRO |
| Compliance with NERC Revised VSL Guidelines | The NERC VSL guidelines are satisfied by incorporating percentage of noncompliance performance for the calculated FRM being less negative than FRO. |
| FERC VSL G1 Discussion | This is not applicable since there was not a Requirement mandating a certain level of Frequency Response prior to this standard. |
| FERC VSL G2 Discussion | Proposed VSL's is not binary. Proposed VSL language does not include ambiguous terms and ensures uniformity and consistency in the determination of penalties based only on the amount the calculated FRM is less negative than FRO. |
| FERC VSL G3 Discussion | Proposed VSL's do not expand on what is required. The VSL's assigned only consider results of the calculation required. Proposed VSL's are consistent with the requirement. |
| FERC VSL G4 Discussion | Proposed VSL's are based on a single violation and not a cumulative violation methodology. |

|  | Proposed VRF | Medium |
| :---: | :---: | :---: |
|  | NERC VRF Discussion | This Requirement, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but would unlikely result in the bulk electric system instability, separation, or cascading failures since a Balancing Authority would have the previous year's Frequency Bias Setting already in its ACE equation and would provide support $f$ the contingency. This is consistent with the NERC definition. |
|  | FERC VRF G1 Discussion | This Requirement is more administrative in nature requiring entities to implement the Frequency Bias Setting validated by the ERO. The requirement does not directly correlate to the list of critical areas identified in the FERC VRF Guideline 1. <br> Guideline 1 appears to conflict with guideline 4. Guideline 1 identifies a list of topics that encompass nearly all topics within the NERC Reliability Standards and implies that these requirements should be assigned a High VRF. Guideline 4 directs assignment of VRFs based on the impact of a specific requirement on the reliability of the system. The SDT believes that Guideline 4 better reflects the intent for assigning VRFs for this standard since this approach is focused on the reliability impact of the requirement. |
| R2 | FERC VRF G2 <br> Discussion | Consistency within a Reliability Standard exists. This Requirement does not contain Parts. Requirement action is unique with respect to other standard requirements. All standard requirements have a common reliability focus relevant to Frequency Response and Frequency Bias Setting. |
|  | FERC VRF G3 Discussion | The Requirement VRF is consistent with other BES standards addressing responsiveness. This Requirement is similar in concept to the current enforceable BAL-003-0.1b Requirement R1 which specifies a Lower VRF however BAL-003-1 Requirements R1, R3, and R4 specify a Medium VRF and the SDT believes it is appropriate for this Requirement to also possess a Medium VRF given the nature of the revision to BAL-003-0.1b. |
|  | FERC VRF G4 Discussion | This Requirement, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but would unlikely result in the bulk electric system instability, separation, or cascading failures since a Balancing Authority would have the previous year's Frequency Bias Setting already in its ACE equation and would provide support $f$ the contingency. This is consistent with the NERC definition. |
|  | FERC VRF G5 Discussion | This requirement does not co-mingle reliability objectives. |

|  | Proposed Lower VSL | The Balancing Authority in a multiple Balancing Authority Interconnection and not receiving Overlap Regulation Service and uses a fixed Frequency Bias Setting failed to implement the validated Frequency Bias Setting value into its ACE calculation within the implementation period specified but did so within 5 calendar days from the implementation period specified by the ERO. |
| :---: | :---: | :---: |
|  | Proposed Moderate VSL | The Balancing Authority in a multiple Balancing Authority Interconnection and not receiving Overlap Regulation Service and uses a fixed Frequency Bias Setting implemented the validated Frequency Bias Setting value into its ACE calculation in more than 5 calendar days but less than or equal to 15 calendar days from the implementation period specified by the ERO. |
|  | Proposed High VSL | The Balancing Authority in a multiple Balancing Authority Interconnection and not receiving Overlap Regulation Service and uses a fixed Frequency Bias Setting implemented the validated Frequency Bias Setting value into its ACE calculation in more than 15 calendar days but less than or equal to 25 calendar days from the implementation period specified by the ERO. |
|  | Proposed Severe VSL | The Balancing Authority in a multiple Balancing Authority Interconnection and not receiving Overlap Regulation Service and uses a fixed Frequency Bias Setting did not implement the validated Frequency Bias Setting value into its ACE calculation in more than 25 calendar days from the implementation period specified by the ERO. |
|  | Compliance with NERC Revised VSL Guidelines | The NERC VSL guidelines are satisfied by incorporating increments for tardiness implementing the validated Frequency Bias Setting into the ACE calculation. |
|  | FERC VSL G1 <br> Discussion | This Requirement is similar in concept to the current enforceable BAL-003-0.1b Requirement R1 which specifies a Lower VRF. Proposed VSL's meet or exceed the current threshold of compliance. |
|  | FERC VSL G2 <br> Discussion | Proposed VSL's is not binary. Proposed VSL language does not include ambiguous terms and ensures uniformity and consistency in the determination of penalties based only on how late the validated Frequency Bias Setting is implemented. |
|  | FERC VSL G3 <br> Discussion | Proposed VSL's do not expand on what is required. The VSL's assigned only consider performance of required action. Proposed VSL's are consistent with the requirement. |
|  | FERC VSL G4 | Proposed VSL's are based on a single violation and not a cumulative |

|  | Discussion | violation methodology. |
| :---: | :---: | :---: |
| R3 | Proposed VRF | Medium |
|  | NERC VRF Discussion | This Requirement, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but would unlikely result in the bulk electric system instability, separation, or cascading failures since a Balancing Authority would have the previous year's Frequency Bias Setting in its ACE equation and would provide support for a contingency. This is consistent with the NERC definition. |
|  | FERC VRF G1 Discussion | This Requirement is more administrative in nature requiring entities to implement a Frequency Bias Setting validated by the ERO. The requirement does not directly correlate to the list of critical areas identified in the FERC VRF Guideline 1. <br> Guideline 1 appears to conflict with guideline 4. Guideline 1 identifies a list of topics that encompass nearly all topics within the NERC Reliability Standards and implies that these requirements should be assigned a High VRF. Guideline 4 directs assignment of VRFs based on the impact of a specific requirement on the reliability of the system. The SDT believes that Guideline 4 better reflects the intent for assigning VRFs for this standard since this approach is focused on the reliability impact of the requirement. |
|  | FERC VRF G2 Discussion | Consistency within a Reliability Standard exists. This Requirement does not contain Parts. Requirement action is unique with respect to other standard requirements. All standard requirements have a common reliability focus relevant to Frequency Response and Frequency Bias Setting. |
|  | FERC VRF G3 Discussion | The Requirement VRF is consistent with other BES standards addressing responsiveness. This Requirement is similar in concept to the current enforceable BAL-003-0.1b Requirement R1 which specifies a Lower VRF however BAL-003-1 Requirements R1, R2, and R4 specify a Medium VRF and the SDT believes it is appropriate for this Requirement to also possess a Medium VRF given the nature of the revision to BAL-003-0.1b. |
|  | FERC VRF G4 Discussion | This Requirement, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but would unlikely result in the bulk electric system instability, separation, or cascading failures since a Balancing Authority would have the previous year's Frequency Bias Setting already in its ACE equation and would provide support for a contingency. This is consistent with the NERC definition. |
|  | FERC VRF G5 | This requirement does not co-mingle reliability objectives. |

| Discussion |  |
| :--- | :--- |
| Proposed Lower VSL | The Balancing Authority that is a member of a multiple <br> Balancing Authority Interconnection and not receiving Overlap <br> Regulation Service and uses a variable Frequency Bias Setting <br> average Frequency Bias Setting during periods when the clock- <br> minute average frequency was outside of the range 59.964 Hz <br> to 60.036 Hz was less negative than its Frequency Response <br> Obligation by more than 1\% but by at most 10\%. |
| Proposed Moderate VSL | The Balancing Authority that is a member of a multiple <br> Balancing Authority Interconnection and not receiving Overlap <br> Regulation Service and uses a variable Frequency Bias Setting <br> average Frequency Bias Setting during periods when the clock- <br> minute average frequency was outside of the range 59.964 Hz <br> to 60.036 Hz was less negative than its Frequency Response <br> Obligation by more than 10\% but by at most 20\%. |
| Proposed High VSL | The Balancing Authority that is a member of a multiple <br> Balancing Authority Interconnection and not receiving Overlap <br> Regulation Service and uses a variable Frequency Bias Setting <br> average Frequency Bias Setting during periods when the clock- <br> minute average frequency was outside of the range 59.964 Hz <br> to 60.036 Hz was less negative than its Frequency Response <br> Obligation by more than 20\% but by at most 30\%. |
| Proposed Severe VSL | The Balancing Authority that is a member of a multiple <br> Balancing Authority Interconnection and not receiving Overlap <br> Regulation Service and uses a variable Frequency Bias Setting <br> average Frequency Bias Setting during periods when the clock- <br> minute average frequency was outside of the range 59.964 Hz <br> to 60.036 Hz was less negative than its Frequency Response <br> obligation by more than 30\%.. |
| oERC VSL G1 <br> Discussion | The NERC VSL guidelines are satisfied by incorporating percentage <br> of noncompliance performance for the calculated average <br> Frequency Bias Setting being less negative than its minimum as <br> defined in Attachment B. |
| FERC VSL G2 | This Requirement is similar in concept to the current enforceable <br> BAL-003-0.1b Requirement R1 which specifies a Medium VRF. <br> Proposed VSL’s meet or exceed the current threshold of compliance. |

## Violation Risk Factor and Violation Severity Level Assignments

## Project 2007-12 - Frequency Response

This document provides the drafting team's justification for assigning draft standard Requirement violation risk factors (VRFs) and violation severity levels (VSLs) for:

- BAL-003-1 — Frequency Response and Frequency Bias Setting

Each primary Requirement is assigned a VRF and a set of one or more VSLs. These elements support the determination of an initial value range for the Base Penalty Amount regarding violation of requirements in FERC-approved Reliability Standards, as defined in the ERO Sanction Guidelines.

## Justification for Assignment of Violation Risk Factors

The Frequency Response Standard Drafting Team applied the following NERC criteria when proposing VRFs for the requirements under this project:

## High Risk Requirement

A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

## Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

## Lower Risk Requirement

A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system; or, a requirement that is administrative in nature and a requirement in a planning time frame
that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

The SDT also considered consistency with the FERC Violation Risk Factor Guidelines for setting VRFs ${ }^{1}$ :

Guideline (1) — Consistency with the Conclusions of the Final Blackout Report The Commission seeks to ensure that Violation Risk Factors assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System.

In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System: ${ }^{2}$

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief

## Guideline (2) — Consistency within a Reliability Standard

The Commission expects a rational connection between the sub-Requirement Violation
Risk Factor assignments and the main Requirement Violation Risk Factor assignment.

## Guideline (3) — Consistency among Reliability Standards

The Commission expects the assignment of Violation Risk Factors corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

## Guideline (4) - Consistency with NERC's Definition of the Violation Risk Factor Level <br> Guideline (4) was developed to evaluate whether the assignment of a particular Violation Risk Factor level conforms to NERC's definition of that risk level.

[^72]
## Guideline (5) - Treatment of Requirements that Co-mingle More Than One Obligation

Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

## Justification for Assignment of Violation Severity Levels:

In developing the VSLs for the standards under this project, the SDT anticipated the evidence that would be reviewed during an audit, and developed its VSLs based on the noncompliance an auditor may find during a typical audit. The SDT based its assignment of VSLs on the following NERC criteria:

| Lower | Moderate | High | Severe |
| :---: | :---: | :---: | :---: |
| Missing a minor element (or a small percentage) of the required performance The performance or product measured has significant value as it almost meets the full intent of the requirement. | Missing at least one significant element (or a moderate percentage) of the required performance. <br> The performance or product measured still has significant value in meeting the intent of the requirement. | Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital component. <br> The performance or product has limited value in meeting the intent of the requirement. | Missing most or all of the significant elements (or a significant percentage) of the required performance. <br> The performance measured does not meet the intent of the requirement or the product delivered cannot be used in meeting the intent of the requirement. |

FERC VSL guidelines are presented below, followed by an analysis of whether the VSLs proposed for each requirement in this standard meet the FERC Guidelines for assessing VSLs:

## Guideline 1: Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

Compare the VSLs to any prior levels of non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when levels of noncompliance were used.

## Guideline 2: Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

A violation of a "binary" type requirement must be a "Severe" VSL.
Do not use ambiguous terms such as "minor" and "significant" to describe noncompliant performance.

## Guideline 3: Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

VSLs should not expand on what is required in the requirement.
Guideline 4: Violation Severity Level Assignment Should Be Based on a Single Violation, Not on a Cumulative Number of Violations

Unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties per violation per day basis is the "default" for penalty calculations.

## VRF and VSL Justification

## BAL-003-1 VRF and VSL Justifications

| Proposed VRF | Medium |
| :--- | :--- |
| NERC VRF Discussion | This Requirement, if violated, could directly affect the electrical state <br> or the capability of the bulk electric system, or the ability to <br> effectively monitor and control the bulk electric system but would <br> unlikely result in the bulk electric system instability, separation, or <br> cascading failures since a Balancing Authority would have the <br> previous year's Frequency Bias Setting already in its ACE equation <br> and would provide support for the contingency. This is consistent <br> with the NERC definition. |
| FERC VRF G1 <br> Discussion | This Requirement is more administrative in nature requiring <br> calculated FRM to be equal to or more negative than FRO. The <br> requirement does not directly correlate to the list of critical areas <br> identified in the FERC VRF Guideline 1. <br> Guideline 1 appears to conflict with guideline 4. Guideline 1 <br> identifies a list of topics that encompass nearly all topics within the <br> NERC Reliability Standards and implies that these requirements <br> should be assigned a High VRF. Guideline 4 directs assignment of <br> VRFs based on the impact of a specific requirement on the reliability <br> of the system. The SDT believes that Guideline 4 better reflects the <br> intent for assigning VRFs for this standard since this approach is <br> focused on the reliability impact of the requirement. |
| R1 | Consistency within a Reliability Standard exists. This Requirement <br> does not contain Parts. Requirement action is unique with respect to <br> other standard requirements. All standard requirements have a <br> common reliability focus relevant to Frequency Response and <br> Frequency Bias Setting. |
| Discussion |  |

|  FERC VSL G3 <br> Discussion Proposed VSL's do not expand on what is required. The VSL's <br> assigned only consider results of the calculation required. Proposed <br> VSL's are consistent with the requirement. <br> FERC VSL G4 <br> Discussion Proposed VSL's are based on a single violation and not a cumulative <br> violation methodology.  <br>  Proposed VRF Medium <br> NERC VRF Discussion This Requirement, if violated, could directly affect the electrical state <br> or the capability of the bulk electric system, or the ability to <br> effectively monitor and control the bulk electric system but would <br> unlikely result in the bulk electric system instability, separation, or <br> cascading failures since a Balancing Authority would have the <br> previous year's Frequency Bias Setting already in its ACE equation <br> and would provide support f the contingency. This is consistent with <br> the NERC definition.  <br> FERC VRF G1 <br> Discussion This Requirement is more administrative in nature requiring entities <br> to implement the Frequency Bias Setting validated by the ERO. The <br> requirement does not directly correlate to the list of critical areas <br> identified in the FERC VRF Guideline 1.  <br> Guideline 1 appears to conflict with guideline 4. Guideline 1   <br> identifies a list of topics that encompass nearly all topics within the   <br> NERC Reliability Standards and implies that these requirements   <br> should be assigned a High VRF. Guideline 4 directs assignment of   <br> VRFs based on the impact of a specific requirement on the reliability   <br> of the system. The SDT believes that Guideline 4 better reflects the   <br> intent for assigning VRFs for this standard since this approach is   <br> focused on the reliability impact of the requirement.   |
| :--- |
| R2 |

|  | FERC VRF G5 Discussion | This requirement does not co-mingle reliability objectives. |
| :---: | :---: | :---: |
|  | Proposed Lower VSL | The Balancing Authority in a multiple Balancing Authority Interconnection and not receiving Overlap Regulation Service and uses a fixed Frequency Bias Setting failed to implement the validated Frequency Bias Setting value into its ACE calculation within the implementation period specified but did so within 5 calendar days from the implementation period specified by the ERO. The Balancing Authority failed to implement the validated Frequency Bias Setting value in to its ACE calculation on the date specified but did so within 5 calendar days following the date specified by the ERO. |
|  | Proposed Moderate VSL | The Balancing Authority in a multiple Balancing Authority Interconnection and not receiving Overlap Regulation Service and uses a fixed Frequency Bias Setting implemented the validated Frequency Bias Setting value into its ACE calculation in more than 5 calendar days but less than or equal to 15 calendar days from the implementation period specified by the ERO. The Balaneing Authority implemented the validated Frequeney Bias Setting value in to its ACE calculation in more than 5 calendar days but less than or equal to 15 calendar days following the date specified by the ERO. |
|  | Proposed High VSL | The Balancing Authority in a multiple Balancing Authority Interconnection and not receiving Overlap Regulation Service and uses a fixed Frequency Bias Setting implemented the validated Frequency Bias Setting value into its ACE calculation in more than 15 calendar days but less than or equal to 25 calendar days from the implementation period specified by the ERO. The Balancing Authority implemented the validated Frequency Bias Setting value in to its ACE calculation in more than 15 calendar days following the date specified by the ERO, but the new Bias Setting was within $10 \%$ of the previous year's Bias Setting |
|  | Proposed Severe VSL | The Balancing Authority in a multiple Balancing Authority Interconnection and not receiving Overlap Regulation Service and uses a fixed Frequency Bias Setting did not implement the validated Frequency Bias Setting value into its ACE calculation in more than 25 calendar days from the implementation period specified by the ERO. The Balancing Authority implemented the validated Frequency Bias Setting value in to its ACE calculation in more than 15 calendar days following the date specified by the ERO and the Bias Setting was more than $10 \%$ different from the previous year. |
|  | Compliance with NERC Revised VSL Guidelines | The NERC VSL guidelines are satisfied by incorporating increments for tardiness implementing the validated Frequency Bias Setting into the ACE calculation.. |

|  | FERC VSL G1 Discussion | This Requirement is similar in concept to the current enforceable BAL-003-0.1b Requirement R1 which specifies a Lower VRF. Proposed VSL's meet or exceed the current threshold of compliance. |
| :---: | :---: | :---: |
|  | FERC VSL G2 Discussion | Proposed VSL's is not binary. Proposed VSL language does not include ambiguous terms and ensures uniformity and consistency in the determination of penalties based only on how late the validated Frequency Bias Setting is implemented. |
|  | FERC VSL G3 Discussion | Proposed VSL's do not expand on what is required. The VSL's assigned only consider performance of required action. Proposed VSL's are consistent with the requirement. |
|  | FERC VSL G4 Discussion | Proposed VSL's are based on a single violation and not a cumulative violation methodology. |
| R3 | Proposed VRF | Medium |
|  | NERC VRF Discussion | This Requirement, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but would unlikely result in the bulk electric system instability, separation, or cascading failures since a Balancing Authority would have the previous year's Frequency Bias Setting in its ACE equation and would provide support for a contingency who was not operating its AGC in Tie Line Bias would typically be the only Balancing Authority that is operating in this manner and the rest of the Balancing Authorities would pick up the slack. In addition, this Requirement VRF is the same as the BAL 003-0 standard VRF and was approved by FERC. This is consistent with the NERC definition. |
|  | FERC VRF G1 Discussion | This Requirement is more administrative in nature requiring entities to implement a Frequency Bias Setting validated by the EROeperate AGC in Tie Line Bias mode. The requirement does not directly correlate to the list of critical areas identified in the FERC VRF Guideline 1. <br> Guideline 1 appears to conflict with guideline 4. Guideline 1 identifies a list of topics that encompass nearly all topics within the NERC Reliability Standards and implies that these requirements should be assigned a High VRF. Guideline 4 directs assignment of VRFs based on the impact of a specific requirement on the reliability of the system. The SDT believes that Guideline 4 better reflects the intent for assigning VRFs for this standard since this approach is focused on the reliability impact of the requirement. |
|  | FERC VRF G2 Discussion | Consistency within a Reliability Standard exists. This Requirement does not contain Parts. Requirement action is unique with respect to other standard requirements. All standard requirements have a common reliability focus relevant to Frequency Response and Frequency Bias Setting. |
|  | FERC VRF G3 Discussion | The Requirement VRF is consistent with other BES standards addressing responsiveness. This Requirement is similar in concept to the current enforceable BAL-003-0.1b Requirement R1 which |

|  |  | specifies a Lower VRF however BAL-003-1 Requirements R1, R2, and R4 specify a Medium VRF and the SDT believes it is appropriate for this Requirement to also possess a Medium VRF given the nature of the revision to BAL-003-0.1b.R3 which specifies a Medium VRF |
| :---: | :---: | :---: |
|  | FERC VRF G4 Discussion | This Requirement, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but would unlikely result in the bulk electric system instability, separation, or cascading failures since a Balancing Authority would have the previous year's Frequency Bias Setting already in its ACE equation and would provide support for a contingency who was not operating its AGC in Tie Line Bias would typically be the only Balaneing Authority that is operating in this manner and the rest of the Balancing Authorities would pick up the slack. In addition, this Requirement VRF is the same as the BAL-003-0 standard VRF and was approved by FERG. This is consistent with the NERC definition. |
|  | FERC VRF G5 Discussion | This requirement does not co-mingle reliability objectives. |
|  | Proposed Lower VSL | The Balancing Authority that is a member of a multiple Balancing Authority Interconnection and not receiving Overlap Regulation Service and uses a variable Frequency Bias Setting average Frequency Bias Setting during periods when the clockminute average frequency was outside of the range 59.964 Hz to 60.036 Hz was less negative than its Frequency Response Obligation by more than $1 \%$ but by at most $10 \%$. The Balaneing Authority could not provide the type of evidence as outlined in Measure M3 that Tie Line Bias is the normal mode of AGC. |
|  | Proposed Moderate VSL | The Balancing Authority that is a member of a multiple Balancing Authority Interconnection and not receiving Overlap Regulation Service and uses a variable Frequency Bias Setting average Frequency Bias Setting during periods when the clockminute average frequency was outside of the range 59.964 Hz to 60.036 Hz was less negative than its Frequency Response Obligation by more than $10 \%$ but by at most 20\%.N/A |
|  | Proposed High VSL | The Balancing Authority that is a member of a multiple Balancing Authority Interconnection and not receiving Overlap Regulation Service and uses a variable Frequency Bias Setting average Frequency Bias Setting during periods when the clockminute average frequency was outside of the range 59.964 Hz to 60.036 Hz was less negative than its Frequency Response Obligtation by more than $20 \%$ but by at most $30 \%$. A spot check during an audit found the Balaneing Authority's AGC out of Tie Line Bias mode without documentation supporting the need to operate in a different AGC mode. |

| Proposed Severe VSL |  | The Balancing Authority that is a member of a multiple Balancing Authority Interconnection and not receiving Overlap Regulation Service and uses a variable Frequency Bias Setting average Frequency Bias Setting during periods when the clockminute average frequency was outside of the range 59.964 Hz to 60.036 Hz was less negative than its Frequency Response obligation by more than $30 \%$.. A system event occurred and it was found that a contributing factor was that the Balaneing Authority failed to operate AGC in Tie Line Bias mode. |
| :---: | :---: | :---: |
|  | Compliance with NERC Revised VSL Guidelines | The NERC VSL guidelines are satisfied by incorporating percentage of noncompliance performance for the calculated average Frequency Bias Setting being less negative than its minimum as defined in Attachment B. The NERC VSL guidelines are satisfied by incorporating a binary requirement for failing to operating AGC in Tie Line Bias mode when an Adverse Reliability Impact did not exist. |
|  | FERC VSL G1 Discussion | This Requirement is similar in concept to the current enforceable BAL-003-0.1b Requirement R13 which specifies a Medium VRF. Proposed VSL's meet or exceed the current threshold of compliance. |
|  | FERC VSL G2 Discussion | Proposed VSL is not binary. Proposed VSL language does not include ambiguous terms and ensures uniformity and consistency in the determination of penalties based enly on the calculated average Frequency Bias Setting being less negative than its minimum as defined in Attachment B.if AGC is not operating in Tie Line Bias mode umless there is an Adverse Reliability Impact. |
|  | FERC VSL G3 Discussion | Proposed VSL does not expand on what is required. The VSLs assigned only consider compliance with the Frequency Bias Setting calculation and implementationAGC control mode status required. Proposed VSL's are consistent with the requirement. |
|  | FERC VSL G4 Discussion | Proposed VSL's are based on a single violation and not a cumulative violation methodology. |
|  | Proposed VRF | Medium |
| R4 | NERC VRF Discussion | This Requirement, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but would unlikely result in the bulk electric system instability, separation, or cascading failures since a Balancing Authority would have the previous year's Frequency Bias Setting already in its ACE equation and would provide support $f$ the contingency. This is consistent with the NERC definition. In addition, this Requirement VRF is consistent with the BAL-003-0 Requirement which has been approved by FERC. |
|  | FERC VRF G1 Discussion | This Requirement is more administrative in nature requiring entities providing Overlap Regulation Services to correctly increase its Frequency Bias Setting. The requirement does not directly correlate to the list of critical areas identified in the FERC VRF Guideline 1. |

|  | Guideline 1 appears to conflict with guideline 4. Guideline 1 <br> identifies a list of topics that encompass nearly all topics within the <br> NERC Reliability Standards and implies that these requirements <br> should be assigned a High VRF. Guideline 4 directs assignment of <br> VRFs based on the impact of a specific requirement on the reliability <br> of the system. The SDT believes that Guideline 4 better reflects the <br> intent for assigning VRFs for this standard since this approach is <br> focused on the reliability impact of the requirement. |
| :--- | :--- |
| FERC VRF G2 <br> Discussion | Consistency within a Reliability Standard exists. This Requirement <br> does not contain Parts. Requirement action is unique with respect to <br> other standard requirements. All standard requirements have a <br> common reliability focus relevant to Frequency Response and <br> Frequency Bias Setting. |
| FERC VRF G3 <br> Discussion | The Requirement VRF is consistent with other BES standards <br> addressing responsiveness. This Requirement is similar in concept to <br> the current enforceable BAL-003-0.1b Requirement R6 which <br> specifies a Medium VRF |
| FERC VRF G4 <br> Discussion | This Requirement, if violated, could directly affect the electrical state <br> or the capability of the bulk electric system, or the ability to <br> effectively monitor and control the bulk electric system but would <br> unlikely result in the bulk electric system instability, separation, or <br> cascading failures since a Balancing Authority would have the <br> previous year's Frequency Bias Setting already in its ACE equation <br> and would provide support f the contingency. This is consistent with <br> the NERC definition. In addition, this Requirement VRF is consistent <br> with the BAL-003-0 Requirement which has been approved by <br> FERC. |
| FERC VRF G5 | This requirement does not co-mingle reliability objectives. |
| Discussion |  |$|$| Proposed Lower VSL | The Balancing Authority incorrectly changed the Frequency Bias <br> Setting value used in its ACE calculation when providing Overlap <br> Regulation Services with combined footprint setting error less than <br> 105\% of the validated or calculatedeorrect value. |
| :--- | :--- |
| Proposed High VSL Moderate VSL | The Balancing Authority incorrectly changed the Frequency Bias <br> Setting value used in its ACE calculation when providing Overlap <br> Regulation Services with combined footprint setting error more than <br> 105\% but less than or equal to 2015\% of the validated or <br> calculatedeorreet value |
| The Balancing Authority incorrectly changed the Frequency Bias <br> Setting value used in its ACE calculation when providing Overlap <br> Regulation Services with combined footprint setting error more than <br> 2015\% but less than or equal to 3025\% of the validated or <br> calculatedeorreet value. |  |

| Proposed Severe VSL | The Balancing Authority incorrectly changed the Frequency Bias <br> Setting value used in its ACE calculation when providing Overlap <br> Regulation Services with setting error more than 3025\% of the <br> validated or calculatedeorrect value. <br> OR |
| :--- | :--- | :--- |
|  | The Balancing Authority failed to change the Frequency Bias Setting <br> value used in its ACE calculation when providing Overlap Regulation <br> Services |
| Compliance with NERC <br> Revised VSL Guidelines | The NERC VSL guidelines are satisfied by incorporating percentage <br> of noncompliance performance for the absolute value of the <br> Balancing Authorities' calculated monthly average Frequency Bias <br> Setting being below the minimum percentage specified by the ERO. <br> The VSL also includes a binary requirement for failing to change the <br> Frequency Bias Setting value when providing Overlap Regulation <br> Services. |
| FERC VSL G1 <br> Discussion | This Requirement is similar in concept to the current enforceable <br> BAL-003-0.1b Requirement R6 which specifies a Medium VRF. <br> Proposed VSL's meet or exceed the current threshold of compliance. |
| FERC VSL G2 <br> Discussion | Proposed VSL's has both a percentage of noncompliance <br> performance and binary element. The binary element is designated <br> severe. Proposed VSL language does not include ambiguous terms <br> and ensures uniformity and consistency in the determination of <br> penalties based only on the amount the calculated monthly average <br> Frequency Bias Setting is below the minimum percentage specified <br> by the ERO or if the entity fails to change the Frequency Bias Setting <br> value when providing Overlap Regulation Services. |
|  | Proposed VSL's do not expand on what is required. The VSL's <br> assigned only consider results of the calculation required and if the <br> Frequency Bias Setting is correctly set when providing Overlap <br> Regulation Services. Proposed VSL's are consistent with the <br> requirement. |
| FERC VRF G1 |  |
| Diseussion |  |

|  | meets specified criteria. The requirement does not directly correlate to the list of critical areas identified in the FERC VRF Guideline - 1. <br> Guideline 1 appears to conflict with guideline 4. Guideline 1 identifies a list of topies that encompass nearly all topics within the NERC Reliability Standards and implies that these requirements should be assigned a High VRF. Guideline 4 directs assignment of VRFs based on the impact of a specific requirement on the reliability of the system. The SDT believes that Guideline 4 better reflects the intent for assigning VRFs for this standard since this approach is focused on the reliability impact of the requirement. |
| :---: | :---: |
| FERC VRF GZ <br> Discussion | Gonsistency within a Reliability Standard exists. This Requirement does not contain Parts. Requirement action is unique with respect to ether standard requirements. All stamdard requirements have a common reliability focus relevant to Frequency Response and Frequency Bias Setting. |
| FERC VRF G3 Discussion | The Requirement VRF is consistent with other BES standards addressing responsiveness. This Requirement is similar in concept to the current enforceable BAL-003-0.1b Requirement R5 which specifies a Medium VRF |
| FERC VRF G4 <br> Discussion | This Requirement, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but would unlikely result in the bulk electric system instability, separation, or eascading failures since a Balancing Authority would have the previous year's Frequency Bias Setting already in its ACE equation and would provide support $f$ the contingency. This is consistent with the NERC definition. In addition, this Requirement VRF is consistent with the BAL-003-0 Requirement which has been approved by FERC. |
| FERC VRF G5 Discussion | This requirement does not co-mingle reliability objectives. |
| Proposed Lower VSL | The absolute value of the Balaneing Authorities' calculated monthly average Frequency Bias Setting is $5 \%$ or less below the minimum specified by the ERO. |
| Proposed Moderate VSL | The absolute value of the Balancing Authorities' calculated monthly average Frequency Bias Setting is more than $5 \%$ but less than or equal to $15 \%$ below the minimum specified by the ERO. |
| Proposed High VSL | The absolute value of the Balancing Authorities' calculated monthly average Frequency Bias Setting is more than $15 \%$ but less than or equal to $25 \%$ below the minimum specified by the ERO. |
| Proposed Severe VSL | The absolute value of the Balaneing Authorities' calculated monthly average Frequency Bias Setting is more than $25 \%$ below the minimum specified by the ERO. |
| Gompliance with NERC Revised VSL Guidelines | The NERC VSL guidelines are satisfied by incorporating percentage of noncompliance performance for the calculated monthly average |

|  | Frequency Bias Setting absolute value being below the minimumm specified by the ERO. |
| :---: | :---: |
| FERC VSL G1 <br> Discussion | This Requirement is similar in concept to the current enforceable BAL-003-0.1b Requirement R5 which specifies a Medium VRF. Proposed VSL's meet or exceed the current threshold of compliance. |
| FERC VSL GZ <br> Discussion | Propesed VSL's is not binary. Propesed VSL language does not inelude ambiguous terms and ensures uniformity and consistency in the determination of penalties based only on the amount the ealculated monthly average Frequency Bias Setting absolute value is below the minimum specified by the ERO. |
| FERC VSL G3 <br> Discussion | Propesed VSL's do not expand on what is required. The VSL's assigned only consider results of the calculation required. Proposed VSL's are consistent with the requirement. |
| FERC VSL G4 <br> Discussion | Proposed VSL's are based on a single violation and not a cummulative violation methodology. |

Step 2 For identified events in column C of the "Data Entry" worksheet, collect data and complete one FRS Form 2 workbook for each event in the list.
Detailed Instructions for utilizing the "Adjustments" are located on the "Adjustments" worksheet below the table,
Step 3 PasteSpecial/Values data from FRS Form 2 "Form 1 Summary Data" worksheet into "BA Form 2 Event Data" worksheet of this workbook. Do this for each event in the list.
Step 4 Enter FERC Form 714 data from the most recent completed Form 714 in the worksheet "Form 714 Data" in cells C7 through D18. Use Copy/PasteSpecial/Values to enter data Your current year's Frequency Response Obligation will be calculated in cell R20 of the "Data Entry" worksheet.
a) If a Fixed Bias was selected, cell R27 will calculate the minimum Bias (least negative) allowed based on your Peak Demand or Peak Generation for Generation only BAs b) If a Fixed Bias was selected, cell R28 will calculate the minimum (in absolute terms) Bias allowed based on $100 \%$ of your FRN d) If R29 was more negative than the value in R27, you may choose a Bias setting that is between R29 and the lesser of R27 or R28 and enter it here. Based on your choice, your Bias Setting wil appear in cell R 33 .

Step 6 -a) If a Variable Bias was selected, cell R27 will indicate "not applicable" where there is no maximum or minimum Bias Setting. a Variable Bias was selected, enter "Variable" in cell R31.
c) If a Variable Bias was selected, cell R30 will calculate the minimum Bias (in absolute terms) allowed based on your FRM and Peak Demand/Peak Generation. Calculate your monthly one minute average Variable Bias setting when frequency is lower than 59.964 Hz or higher than 60.036 Hz and enter these monthly values on the "Variable Bias Supplemental Info" worksheet in cells B2 through D13.
an俍 e) Depending on when the Implementation date is each year for the annual Bias Setting, the ERO may be required to edit the selection of each months' minimum average FBS value. This should be completed by the ERO before each year's FRS Form 1 is published.
analysis prior to the current year and the dates in the table starting at J 3 will indicate the appropriate year's data to use. For example, if it is Feb 1, 2013 and you are calculating your 2012 FBS time weigted average, the minimum FBS value will be determined from your FRM that you calculated in Feb of 2012 and based on the Peak Demand/Peak Gen reported in June of 2011 for 2010 data. Enter each field in green using the appropriate year's data.
Two FRMs are calculated. One for the BA Bias Setting and one for meeting R1 of the standard
The FRM for the BA Bias Setting will use all selected events and all SEFRD values will use the delta frequency as measured
The FRM for the BA compliance to R1 will limit the delta frequency to no greater than those listed in Table 2 of Attachment A for each Interconnection. (Eastern $+/-0.500 \mathrm{~Hz}$, Western $+/-0.500 \mathrm{~Hz}$, ERCOT $+/-0.700 \mathrm{~Hz}$ and HQ $+/-1.500 \mathrm{~Hz}$.)

Step 7 Save this workbook using the following file name format:NYISO_yyyy_FRS_Form_1.9.xlsx. (where NYISO is replaced with your Balancing Authority abbreviation). See cell "G74" on the Data Entry worksheet for your exact file name.
Step 8

$T+166$ Performance Adjusted P.U. Based on Bias Sete netting

FPl. NERC Freavencor Resonsens mianave

Step 2 For identified events in column C of the "Data Entry" worksheet, collect data and complete one FRS Form 2 workbook for each event in the list.
Detailed Instructions for utilizing the "Adjustments" are located on the "Adjustments" worksheet below the table,
Step 3 PasteSpecial/Values data from FRS Form 2 "Form 1 Summary Data" worksheet into "BA Form 2 Event Data" worksheet of this workbook. Do this for each event in the list.
Step 4 Enter FERC Form 714 data from the most recent completed Form 714 in the worksheet "Form 714 Data" in cells C7 through D18. Use Copy/PasteSpecial/Values to enter data Your current year's Frequency Response Obligation will be calculated in cell R20 of the "Data Entry" worksheet.
a) If a Fixed Bias was selected, cell R27 will calculate the minimum Bias (least negative) allowed based on your Peak Demand or Peak Generation for Generation only BAs b) If a Fixed Bias was selected, cell R28 will calculate the minimum (in absolute terms) Bias allowed based on $100 \%$ of your FRN d) If R29 was more negative than the value in R27, you may choose a Bias setting that is between R29 and the lesser of R27 or R28 and enter it here. Based on your choice, your Bias Setting wil appear in cell R 33 .

Step 6 -a) If a Variable Bias was selected, cell R27 will indicate "not applicable" where there is no maximum or minimum Bias Setting. a Variable Bias was selected, enter "Variable" in cell R31.
c) If a Variable Bias was selected, cell R30 will calculate the minimum Bias (in absolute terms) allowed based on your FRM and Peak Demand/Peak Generation. Calculate your monthly one minute average Variable Bias setting when frequency is lower than 59.964 Hz or higher than 60.036 Hz and enter these monthly values on the "Variable Bias Supplemental Info" worksheet in cells B2 through D13.
an俍 e) Depending on when the Implementation date is each year for the annual Bias Setting, the ERO may be required to edit the selection of each months' minimum average FBS value. This should be completed by the ERO before each year's FRS Form 1 is published.
analysis prior to the current year and the dates in the table starting at J 3 will indicate the appropriate year's data to use. For example, if it is Feb 1, 2013 and you are calculating your 2012 FBS time weigted average, the minimum FBS value will be determined from your FRM that you calculated in Feb of 2012 and based on the Peak Demand/Peak Gen reported in June of 2011 for 2010 data. Enter each field in green using the appropriate year's data.
Two FRMs are calculated. One for the BA Bias Setting and one for meeting R1 of the standard
The FRM for the BA Bias Setting will use all selected events and all SEFRD values will use the delta frequency as measured
The FRM for the BA compliance to R1 will limit the delta frequency to no greater than those listed in Table 2 of Attachment A for each Interconnection. (Eastern $+/-0.500 \mathrm{~Hz}$, Western $+/-0.500 \mathrm{~Hz}$, ERCOT $+/-0.700 \mathrm{~Hz}$ and HQ $+/-1.500 \mathrm{~Hz}$.)

Step 7 Save this workbook using the following file name format:NYISO_yyyy_FRS_Form_1.9.xlsx. (where NYISO is replaced with your Balancing Authority abbreviation). See cell "G74" on the Data Entry worksheet for your exact file name.
Step 8

The

T+166 Performance Adjusted P.U. Based on Bias Setting

Step 4 Enter FERC Form 714 data from the most recent completed Form 714 in the worksheet "Form 714 Data" in cells C7 through D18. Use Copy/PasteSpecial/Values to enter data. Enter FERC Form 714 data from the most recent completed Form 714 in the worksheet "Form 714 Data" in cells

Step 5 a) If a Fixed Bias was selected, cell R27 will calculate the minimum Bias (least negative) allowed based on your Peak Demand or Peak Generation for Generation only BAs b) If a Fixed Bias was selected, cell R28 will calculate the minimum (in absolute terms) Bias allowed based on $100 \%$ of your FRM c) If a Fixed Bias was selected, cell R29 will calculate the maximum Bias (in absolute terms) allowed based on $125 \%$ of your FRM
d) If R29 was more negative than the value in R27, you may choose a Bias setting that is between R29 and the lesser of R27 or R28 and enter it here. Based on your choice, your Bias Setting will appear in cell R33.
Step 6 a) If a Variable Bias was selected, cell R27 will indicate "not applicable" where there is no maximum or minimum Bias Setting,
) If a Variable Bias was selected, enter "Variable" in cell R31.
c) If a Variable Bias was selected, cell R30 will calculate the minimum Bias (in absolute terms) allowed based on your FRM and Peak Demand/Peak Generation. Calculate your monthly one minute average Variable Bias setting when frequency is lower than 59.964 Hz or higher than 60.036 Hz and enter these monthly values on the "Variable Bias Supplemental Info" worksheet in cells B2 through d) If the "average annual Variable Bias Setting" in cell D14 on the "Variable Bias Supplemental Info" worksheet is less negative than cell E14 of this worksheet, R3 of the standard has not been met and cell D14 on the "Variable Bias Supplementa Info" worksheet will turn red. The average minimum Bias Setting will cover two different reporting periods and Cells J3 through K10 require past year's data from those year's Form 1 s for this evaluation.
e) Depending on when the Implementation date is each year for the annual Bias Setting, the ERO may be required to edit the selection of each months' minimum average FBS value. This should be ompleted by the ERO before each year's FRS Form 1 is published.
example, if it is Feb 1, 2013 and you are calculating your 2 previous year's analysis prior to the current year and the dates in the table starting at J 3 will indicate the appropriate year's data to use. For he Peak Demand/Peak Gen reported in June of 2011 for 2010 FBS time weigted average, the minimum FBS value will be determined from your FRM that you calculated in Feb of 2012 and based on - 2010 data. Enter each field in green using the appropriate year's data.

Two FRMs are calculated. One for the BA Bias Setting and one for meeting R1 of the standard
The FRM for the BA Bias Setting will use all selected events and all SEFRD values will use the delta frequency as measured.
he FRM for the BA compliance to R1 will limit the delta frequency to no greater than those listed in Table 2 of Attachment A for each Interconnection. (Eastern $+/-0.500 \mathrm{~Hz}$, Western $+/-0.500 \mathrm{~Hz}$, ERCOT $+/-0.700 \mathrm{~Hz}$ and $\mathrm{HQ}+/-1.500 \mathrm{~Hz}$.)

Step 7 Save this workbook using the following file name format:NYISO_yyy__FRS_Form_1.9.xlsx. (where NYISO is replaced with your Balancing Authority abbreviation). See cell "G74" on the Data Entry worksheet for your exact file name. Step 8 Send completed Form 1 and each Form 2 to NERC.

Sign Convention for scan data collected in Form 2

## Instructions for utilizing Adjustments:

1) Balancing Authorities making adjustments must retain evidence to verify

Adjustment values are determined from scan-cycle data using Value A and Value B averaging periods. Scan-cycle data must be available if adjustments are made. Adjustments are necessary to improve accuracy of calculations compared to using Net Actual Interchange solely.
Said differently, unless an adjustment compensates for significant known error, it should not be made. However, as noted in the next item, once a decision to include an adjustment for one or more of the five types is made for one event, the entity must calculate adjustments for that (those) type(s) for all events except for the Contengent BA Adjustment which is only utilized for the events that you are contengent during that event.

Adjustments are included consistently for all events (e.g. if adjustments for nonconforming load are made for one event, the load must be included for all events, etc.).
2) Dynamic Schedules:

Adjustments should include only dynamic schedules accounting for joint-owned units. Other dynamic schedules should be ignored
3) Nonconforming Loads:

- Values must be negative numbers.

4) Pumped Hydro:

Values for pumping must be negative values

- Values for generating must be positive values.

5) Rampling Units

Values are positive values.
6) Transferred Frequency Response:

This value is the amount agreed upon between the entities expressed in MW/0.1 Hz . Form 2 will adjust this amount for the frequency deviation experienced
(e.g. if an entity agrees to provide $20 \mathrm{MW} / 0.1 \mathrm{~Hz}$ to another entity and a frequency event with a deviation of 50 mHz occurs, the delivering entity should enter +20 in the data column of Form 2 and the receiving entity should enter - 20. The spreadsheet will adjust the SEFRD for each entity by the 10 for this event.)
Values for the entity receiving the response must be entered as a negative number.
Values for the entity delivering the response must be entered as a positive number.
Values between entities must sum to zero
7) Contingent Balancing Authority Adjustment

Data for Value A is the pre-contingency scan rate generation (+MW values) from the contingent unit(s).
Data for Value $B$ is usually 0 MW , but may be the demand (-MW values) that remains on the system that was "netted" out by the now offline generation.

Time
Time weighted ** weighted ${ }^{* *}$ minimum average FBS* for month month

## alancing Authority: HOT

1899 Reporting period FRS Form 1 data
0.001899 Reporting period: Balancinig Authority FRM MW/0.1 Hz, enter from FRS Form 1 for that year's FRM. If not know enter zero.
1.00\% 1899 Reporting period: Interconnection Minimum Fixed Frequency Bias Setting \% of Peak Demand or Peak Generation (Set by ERO) 1899 Reporting period: Your BA's Annual Peak Demand or Peak Gen for Gen only BAs from your BA Form 714.
0.00 Your BA's lowest absolute Fixed Frequency Bias Setting based on BA Peak Demand (Peak Generation for Generation only BA) MW/0.1 Hz
0.00 Your BA's lowest absolute Fixed Frequency Bias Setting based on $100 \%$ of FRM.
0.001900 Minimum, lowest absolute, conditional average Frequency Bias Setting MW/ 0.1 Hz

* Frequency Bias Setting (FBS)
${ }^{* *}$ Based on the one minute values used in BAL 001 when frequency is greater than 60.036 Hz or less than 59.964 Hz .

II- NERC F Fequency Response iniaidive

 Sone basic obsenvaions toon tilis staxa

Step 2 For identified events in column C of the "Data Entry" worksheet, collect data and complete one FRS Form 2 workbook for each event in the list. Detailed Instructions for utilizing the "Adjustments" are located on the "Adjustments" worksheet below the table.
Step 3 PasteSpecial/Values data from FRS Form 2 "Form 1 Summary Data" worksheet into "BA Form 2 Event Data" worksheet of this workbook. Do this for each event in the list.
Step 4 Enter FERC Form 714 data from the most recent completed Form 714 in the worksheet "Form 714 Data" in cells C7 through D18. Use Copy/PasteSpecial/Values to enter data Your current year's Frequency Response Obligation will be calculated in cell R20 of the "Data Entry" Worksheet.
a) If a Fixed Bias was selected, cell R27 will calculate the minimum Bias (least negative) allowed based on your Peak Demand or Peak Generation for Generation only BAs. b) If a Fixed Bias was selected, cell R28 wil calculate the minimum (in absolute terms) Bias allowed based on $100 \%$ of your FRN.
d) If R29 was more negative than the value in R27, you may choose a Bias setting that is between R29 and the lesser of R27 or R28 and enter it here. Based on your choice, your Bias Setting wil appear in cell R33.

Step 6 a) If a Variable Bias was selected, cell R27 will indicate "not applicable" where there is no maximum or minimum Bias Setting. If a Variable Bias was selected, enter "Variable" in cell R31.
c) If a Variable Bias was selected, cell R30 will calculate the minimum Bias (in absolute terms) allowed based on your FRM and Peak Demand/Peak Generation. Calculate your monthly one minute average Variable Bias setting when frequency is lower than 59.964 Hz or higher than 60.036 Hz and enter these monthly values on the "Variable Bias Supplemental Info" worksheet in cells B2 through D13
dell D14 average annual Variable Bias Setting" in cell D14 on the "Variable Bias Supplemental Info" worksheet is less negative than cell E14 of this worksheet, R3 of the standard has not been met and
 e) those year's Form 1 is for this evaluation.
completed by the whe the Implementation date is each year for the an completed by the ERO before each year's FRS Form 1 is published
 the Peak Demand/Peak Gen reported in June of 2011 for 2010 data. data. Enter each field in green using the appropriate year's data.
Two FRMs are calculated. One for the BA Bias Setting and one for meeting R1 of the standard
The FRM for the BA Bias Setting will use all selected events and all SEFRD values will use the delta frequency as measured
 ERCOT $+/-0.700 \mathrm{~Hz}$ and $\mathrm{HQ}+/-1.500 \mathrm{~Hz}$.)
Step 7 Save this workbook using the following file name format:NYISO_yyyy_FRS_Form_1.9.x|sx. (where NYISO is replaced with your Balancing Authority abbreviation). See cell "G74" on the Data Entry worksheet for your exact file name.
Step 8 Send completed Form 1 and each Form 2 to NERC.

Saturday, April 14, 2012

Monday, April 30, 2012

FR1- NeRC F Fequency Response nitaidive

Sone basic obsenaions toom his satax

Step 4 Enter FERC Form 714 data from the most recent completed Form 714 in the worksheet "Form 714 Data" in cells C7 through D18. Use Copy/PasteSpecial/Values to enter data. Enter FERC Form 714 data from the most recent completed Form 714 in the worksheet "Form 714 Data" in cells

Step 5 a) If a Fixed Bias was selected, cell R27 will calculate the minimum Bias (least negative) allowed based on your Peak Demand or Peak Generation for Generation only BAs b) If a Fixed Bias was selected, cell R28 will calculate the minimum (in absolute terms) Bias allowed based on $100 \%$ of your FRM c) If a Fixed Bias was selected, cell R29 will calculate the maximum Bias (in absolute terms) allowed based on $125 \%$ of your FRM
d) If R29 was more negative than the value in R27, you may choose a Bias setting that is between R29 and the lesser of R27 or R28 and enter it here. Based on your choice, your Bias Setting will appear in cell R33.
Step 6 a) If a Variable Bias was selected, cell R27 will indicate "not applicable" where there is no maximum or minimum Bias Setting,
) If a Variable Bias was selected, enter "Variable" in cell R31.
c) If a Variable Bias was selected, cell R30 will calculate the minimum Bias (in absolute terms) allowed based on your FRM and Peak Demand/Peak Generation. Calculate your monthly one minute average Variable Bias setting when frequency is lower than 59.964 Hz or higher than 60.036 Hz and enter these monthly values on the "Variable Bias Supplemental Info" worksheet in cells B2 through d) If the "average annual Variable Bias Setting" in cell D14 on the "Variable Bias Supplemental Info" worksheet is less negative than cell E14 of this worksheet, R3 of the standard has not been met and cell D14 on the "Variable Bias Supplementa Info" worksheet will turn red. The average minimum Bias Setting will cover two different reporting periods and Cells J3 through K10 require past year's data from those year's Form 1 s for this evaluation.
e) Depending on when the Implementation date is each year for the annual Bias Setting, the ERO may be required to edit the selection of each months' minimum average FBS value. This should be ompleted by the ERO before each year's FRS Form 1 is published.
example, if it is Feb 1, 2013 and you are calculating your 2 previous year's analysis prior to the current year and the dates in the table starting at J 3 will indicate the appropriate year's data to use. For he Peak Demand/Peak Gen reported in June of 2011 for 2010 FBS time weigted average, the minimum FBS value will be determined from your FRM that you calculated in Feb of 2012 and based on - 2010 data. Enter each field in green using the appropriate year's data.

Two FRMs are calculated. One for the BA Bias Setting and one for meeting R1 of the standard
The FRM for the BA Bias Setting will use all selected events and all SEFRD values will use the delta frequency as measured.
he FRM for the BA compliance to R1 will limit the delta frequency to no greater than those listed in Table 2 of Attachment A for each Interconnection. (Eastern $+/-0.500 \mathrm{~Hz}$, Western $+/-0.500 \mathrm{~Hz}$, ERCOT $+/-0.700 \mathrm{~Hz}$ and $\mathrm{HQ}+/-1.500 \mathrm{~Hz}$.)

Step 7 Save this workbook using the following file name format:NYISO_yyy__FRS_Form_1.9.xlsx. (where NYISO is replaced with your Balancing Authority abbreviation). See cell "G74" on the Data Entry worksheet for your exact file name. Step 8 Send completed Form 1 and each Form 2 to NERC.

Instructions for utilizing Adjustments:

1) Balancing Authorities making adjustments mustretain evidence to verify:

Said dififerenty, unless an adjustment compensates for sigifificant known error, it should not be made. However. as noted in the next item, once a decision to incluce an
adiustment tor one or more of the five types is made for one event, the entity must calculuate adjustments for that (those) type(s) for all events except for the Contengent BA Adiustment

2) Dynamic Schedules:

Adjustments should include only dynamic schedules
3) Nonconforming Loads:
4) Pumped Hydro:
-Values for pumping must be negative values.
-Values for generating must be positive values.
5) Rampling Units
,
6) Transferred Frequency Response-
-This value is the amount agreed upon between the entities expressed in $\mathrm{MW} / 0.1 \mathrm{~Hz}$. Form 2 will adjust this amount for the frequency deviaion experienced.
(e.g. if a en entity agrees to provide $20 \mathrm{MW} / 0.1 \mathrm{~Hz}$ to another entity and a frequency event with a deviation of 50 mHz occurs, the delivering entity should enter +20 in the
data column of Form 2 and the receiving entity should enter - 20 . The spreadsheet will adjust the SEFRD for each entity by the 10 for this event.)

- Values for the entity receiving the response must be entered as a negative number.
- Values for the entity delivering the response must be entered as a positive number.

Contingent Balancing Authority Adiustment.

- Data or Value A is the pre-contingency scan rate generation (+MW values) from the contingent unit(s)
- Data for Value B is usually 0 MW , but may be the demand (-MW values) that remains on the system

Sone easic obsenaions stom this datax

Step 2 For identified events in column C of the "Data Entry" worksheet, collect data and complete one FRS Form 2 workbook for each event in the list. Detailed Instructions for utilizing the "Adjustments" are located on the "Adjustments" worksheet below the table.
Step 3 PasteSpecial/Values data from FRS Form 2 "Form 1 Summary Data" worksheet into "BA Form 2 Event Data" worksheet of this workbook. Do this for each event in the list.
Step 4 Enter FERC Form 714 data from the most recent completed Form 714 in the worksheet "Form 714 Data" in cells C7 through D18. Use Copy/PasteSpecial/Values to enter data Your current year's Frequency Response Obligation will be calculated in cell R20 of the "Data Entry" Worksheet.
a) If a Fixed Bias was selected, cell R27 will calculate the minimum Bias (least negative) allowed based on your Peak Demand or Peak Generation for Generation only BAs. b) If a Fixed Bias was selected, cell R28 wil calculate the minimum (in absolute terms) Bias allowed based on $100 \%$ of your FRN.
d) If R29 was more negative than the value in R27, you may choose a Bias setting that is between R29 and the lesser of R27 or R28 and enter it here. Based on your choice, your Bias Setting wil appear in cell R33.

Step 6 a) If a Variable Bias was selected, cell R27 will indicate "not applicable" where there is no maximum or minimum Bias Setting. If a Variable Bias was selected, enter "Variable" in cell R31.
c) If a Variable Bias was selected, cell R30 will calculate the minimum Bias (in absolute terms) allowed based on your FRM and Peak Demand/Peak Generation. Calculate your monthly one minute average Variable Bias setting when frequency is lower than 59.964 Hz or higher than 60.036 Hz and enter these monthly values on the "Variable Bias Supplemental Info" worksheet in cells B2 through D13
dell D14 average annual Variable Bias Setting" in cell D14 on the "Variable Bias Supplemental Info" worksheet is less negative than cell E14 of this worksheet, R3 of the standard has not been met and
 e) those year's Form 1 is for this evaluation.
completed by the whe the Implementation date is each year for the an completed by the ERO before each year's FRS Form 1 is published
 the Peak Demand/Peak Gen reported in June of 2011 for 2010 data. data. Enter each field in green using the appropriate year's data.
Two FRMs are calculated. One for the BA Bias Setting and one for meeting R1 of the standard
The FRM for the BA Bias Setting will use all selected events and all SEFRD values will use the delta frequency as measured
 ERCOT $+/-0.700 \mathrm{~Hz}$ and $\mathrm{HQ}+/-1.500 \mathrm{~Hz}$.)
Step 7 Save this workbook using the following file name format:NYISO_yyyy_FRS_Form_1.9.x|sx. (where NYISO is replaced with your Balancing Authority abbreviation). See cell "G74" on the Data Entry worksheet for your exact file name.
Step 8 Send completed Form 1 and each Form 2 to NERC.

## \# of rows to shift T(0)

Azeroval 1
A zero value aligns the data to the hightest Frequency change value. Usually the event begins one or two data scans earlier than this scan.

Increasing this value shifts graph data to the right.
Decreasing this value shifts graph data to the left.

Note: The P.U. Performance values indicate performance as a P.U. value of BA Bias setting. For BAs that utilize a variable Bias, the Bias average during $T(+20)$ to $T(+52)$ is used.
P.U. values above 1.0 indicate that the Bias setting was below measured Frequency Response P.U. values below 1.0 indicate that the Bias setting was above measured Frequency Response.

First change in frequency of the event should occur here on the vertical grid line. It is important that the pre-event frequency average to NOT contain frequency data of the event, "Average Frequency" trend to the left of center of the graph. To shift the data on the graph left or right, adjust the value in cell Q 3 highlighted in yellow above.

Steps To be completed for each event evaluated.
1 Set-up Data collection in exact same order as the "Data" sheet of this work book. Data should be in this order Column A: Date and Time in this format, mm/dd/yy HH:MM:S
Column B: Frequency Hz
Column C: Net Actual Interchange
Column D: Joint Owned Unit dynamic schedule
Column E: Non Conforming Load
Column F: Pumped Hydro
Column G: Not Used
Column H: Transferred Frequency Response
Column I: Contingent BA Lost load or generatio
Column J: BA Bias Setting
Column K: BA Load
2 Note: Columns D, E, F and H are optional data. If you choose not to use these, leave the columns blank. Do not delete the columns. Use the sign (+/-) convention defined in FRS Form 1.
3 Data compression must be turned off for each data point. Quality data will give you quality results in the evaluation.
4 Data must start a minimum of two (2) minutes before the event begins and includes a minimum of 15 minutes after the beginning of the event with up to 60 minutes of data. Be sure the "Data" worksheet is clear of any old data. Collect the same total minutes of data for each event evaluated to minimize your effort and time.
If using PI historian as your data source, use "PasteSpecial/Values" to enter data into the spreadsheet. Do not include historian data collection formulas in the data.
5 Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on the graph on the "Copy Results" worksheet.
If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should you have to use the "Manual" process

6 Once data is in place in the "Data" worksheet, confirm the Auto selection of the beginning of the event by observing the "Graph 20 to 52 s " worksheet. Adjust the selection if necessary To make an adjustment, change the value in cell "Q3" on the "Graph 20 to 52 s " worksheet. Usually a 0,1 or 2 will achive the correct alignment of $\mathrm{T}(0)$.

7 If the correct row is selected, the "Graph 20 to 52 s " worksheet will indicate the first change in frequency (red trend) of the event on the center vertical grid line of the graph.
8 The end of the event will be Auto selected based on the frequency value in cell " N 2 " on the Data worksheet. This will be the frequency at the beginning of the event or 60 Hz , whichever is lower. (for low Hz events) This value controls the end of the "Sustained Frequency Response" evaluation period.
Primary Frequency Response should be sustained during the event recovery period. This evaluation determines how well you achieved this goal.
9 Use the "Copy Form 2 data for Pasting into Form 1" button provided on the "Copy Results" worksheet (Cells B21 through B28) to copy the evaluation and event specific data for the "FRS Form 1" of this field trial. This data is summarized in the correct order on worksheet "Form 1 Summary Data".
10 Use PasteSpecial/Values and paste the copied data into FRS Form 1 on the appropriate event row. Be sure to use the latest version of Form 1, currently Form 1.9
11 Save this Form 2 using the file name convention on the "Copy Results" worksheet. The complete file name is in bold in cell B38. Return all completed Form 2 s with your form 1 to NERC.

## Steps To be completed the first time you use Form 2 for your BA.

A Enter the Balancing Authority name as you want it to appear on the graphs in cell "B1" of the "Copy Results" worksheet. For example: "NYISO".
B For informational and educational purposes, a "Sustained" performance evaluation is provided in the "Evaluation" worksheet and in the "Sustained" Graph. This evaluation uses a Time Constant (TC) to model the frequency response of your BA. The time constant is located in cell "L13" of the "Evaluation" spreadsheet and should be edited for the types of generators in your BA. Presently this time constant is set at 0.35 .
The higher the value of the time constant, the faster the delivery of frequency response is expected. Setting the TC to 1.0 effectively turns off the delay and instantaneous frequency response will be modeled. Do not set higher than 1.0 . This time constant is only used in the "Sustained" evaluation and is not used for the Field Trial evaluation of performance to the FRO.
A typical setting for this time constant is 0.08 to 0.15 for hydro units, 0.10 to 0.20 for large steam turbines and 0.20 to 0.40 for combustion turbines,
By observing the slope of your "Interchange Actual" on the "Sustained" Graph, adjust the time constant until the initial slope of the "Target" is similar to the slope of the NAI data.
When set appropriately, the "Target" trend on the "Sustained" graph will model what the Net Actua Interchange should have done during the event recovery period based on your Bias setting during the event.

## $T(0)$

First change in frequency of the event should occur here on the vertical grid line. It is important that the pre-event frequency average to NOT contain frequency data of the event, "Average Frequency" trend to the left of center of the graph. To shift the data on the graph left or right, adjust the value in cell Q3 highlighted in yellow above.

Auto" Event Detection adjustment of $\mathrm{T}(0)$.
\# of rows to shift T(0)
A zero value aligns the data to the hightest Frequency change value. Usually the event begins one or two data scans earlier than this scan.

Increasing this value shifts graph data to the right
Decreasing this value shifts graph data to the left.

Note: The P.U. Performance values indicate performance as a P.U. value of BA Bias setting For BAs that utilize a variable Bias, the Bias average during $T(+20)$ to $T(+52)$ is used.
P.U. values above 1.0 indicate that the Bias setting was below measured Frequency Response. P.U. values below 1.0 indicate that the Bias setting was above measured Frequency Response

## To be completed for each event evaluated.

Set-up Data collection in exact same order as the "Data" sheet of this work book. Data should be in this order:
Column A: Date and Time in this format, mm/dd/yy HH:MM:SS
Column B: Frequency Hz
Column C: Contingent Resouce Lost MW or Lost Load
Column D: Load Resources tripped during the event.
Column E: Non Conforming Load
Column F: Spare
Column G: Not Used
Column H: Spare
Column I: Spare
Column J: BA Bias Setting
Column K: BA Load
2 Note: Columns D \& E are optional data. If you choose not to use these, leave the columns blank. Do not delete the columns. Use the sign ( $+/-$ ) convention defined in FRS Form 1
3 Data compression must be turned off for each data point. Quality data will give you quality results in the evaluation.
4 Data must start a minimum of two (2) minutes before the event begins and includes a minimum of 15 minutes after the beginning of the event with up to 60 minutes of data.
Be sure the "Data" worksheet is clear of any old data. Collect the same total minutes of data for each event evaluated to minimize your effort and time.
If using PI historian as your data source, use "PasteSpecial/Values" to enter data into the spreadsheet. Do not include historian data collection formulas in the data.
5 Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on the graph on the "Copy Results" worksheet
If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should you have to use the "Manual" process.
6 Once data is in place in the "Data" worksheet, confirm the Auto selection of the beginning of the event by observing the "Graph 20 to 52 s " worksheet. Adjust the selection if necessary. To make an adjustment, change the value in cell "Q3" on the "Graph 20 to 52 s " worksheet. Usually a 0,1 or 2 will achive the correct alignment of $\mathrm{T}(0)$.

If the correct row is selected, the "Graph 20 to 52s" worksheet will indicate the first change in frequency (red trend) of the event on the center vertical grid line of the graph.
The end of the event will be Auto selected based on the frequency value in cell " N 2 " on the Data worksheet. This will be the frequency at the beginning of the event or 60 Hz , whichever is lower. (for low Hz events) This value controls the end of the "Sustained Frequency Response" evaluation period.
Primary Frequency Response should be sustained during the event recovery period. This evaluation determines how well you achieved this goal
 in the correct order on worksheet "Form 1 Summary Data"
10 Use PasteSpecial/Values and paste the copied data into FRS Form 1 on the appropriate event row. Be sure to use the latest version of Form 1, currently Form 1.9.
11 Save this Form 2 using the file name convention on the "Copy Results" worksheet. The complete file name is in bold in cell B38. Return all completed Form $2 s$ with your Form 1 to NERC

## Steps To be completed the first time you use form 2 for your BA.

A Enter the Balancing Authority name as you want it to appear on the graphs in cell "B1" of the "Copy Results" worksheet. For example: "ERCOT".

Balancing Authority Name: MyBA $\quad$ Interconnection Prevailing UFLS First Step Relay trip poin

## Interconnection Prevaliing ULL

Note: See "Instruction" tab for more detailed instructions.

MyBA_110516_0806_FRS_Form2.9.xlsm
58.500 Hz
61.500 Hz

## 8:06.38 Auto Event Detection

8:06:30

Event Frequency Data

11/05/16 Date yymmdd
8:06 Time hh:ss of T(0)
Where "МуВA" = your BA mnemonic

$$
=
$$

Time of Frequency Recovery to 60 Hz or Pre-Perturbation Hz Value A Pre-Perturbation Average Frequency [ $\mathrm{T}(-2)$ to $\mathrm{T}(-16)]$ Value B Post-Perturbation Average Frequency [ $T(+20$ to $T(+52)]$
Pre to Post Perturbation Delta Frequency Actual

Value A Pre-Perturbation Average Contingent MW [T(-2) to $\mathrm{T}(-16)]$ Value B Post-Perturbation Average Contingent $\mathrm{MW}[\mathrm{T}(+20$ to $\mathrm{T}(+52)]$ Pre to Post Perturbation Contingent Delta MW Actual Initial Performance Ramp Magnitude Adjustment

EPFR Pre-Perturbation Average
EPFR Post-Perturbation Average
EPFR Delta

EPFR = Expected Primary Frequency Response

Monday, May 16, 2011
8:06:38
0.00 Actual Interchange MW Average during frequency recovery period
617.52 Target Interchange MW Average during frequency recovery period 226.52 Interchange Average Ramp MW during frequency recovery period 470.90 Actual MW @ T(-4)
-494.59 Starting and Ending Difference in Interchange MW during frequency recovery per 0:03:52 Event Duration (h:mm:ss)

No Target MW Average minus MW @ T(-4) less than zero
641.21 Interchange Target Relative Average Change - MW (Low Frequency Event)
23.69 Interchange Actual Relative Average Change - MW (Low Frequency Event)

Yes Interchange Actual Average minus MW @ T(-4) less than zero
No Interchange Average MW minus MW @ $\mathrm{T}(-4)$ greater than zero
Yes Interchange Target MW Average minus MW @ $\mathrm{T}(-4)$ greater than zero
146.62 Interchange Target Relative Average Change - MW (High Frequency Event) -470.90 Interchange Actual Relative Average Change - MW (High Frequency Event) Down Ramp Direction during frequency recovery period

"Auto" Event Detection adjustment of $\mathrm{T}(0)$.
\# of rows to shift $T(0)$
1
A zero value aligns the data to the hightest Frequency change value. Usually the event begins one or two data scans earlier than this scan

Increasing this value shifts graph data to the right.
Decreasing this value shifts graph data to the left.

Note: The P.U. Performance values indicate performance as a P.U. value of BA Bias setting. For BAs that utilize a variable Bias, the Bias average during $T(+20)$ to $T(+52)$ is used.
P.U. values above 1.0 indicate that the Bias setting was below measured Frequency Response. P.U. values below 1.0 indicate that the Bias setting was above measured Frequency Response.

First change in frequency of the event should occur here on the vertical grid line.
It is important that the pre-event frequency average to NOT contain frequency data of the event, "Average Frequency" trend to the left of center of the graph
To shift the data on the graph left or right, adjust the value in cell Q3 highlighted in yellow above.

## teps To be completed for each event evaluated.

1 Set-up Data collection in exact same order as the "Data" sheet of this work book. Data should be in this order
Set-up Data collection in exact same order as the "Data" sheet
Column B: Frequency Hz
Column C: Contingent Resouce Lost MW or Lost Load
Column D : Load Resources tripped during the event.
Column E: Non Conforming Load
lumn F: Spare
olumn G: Not Used
Column H: Spare
Column l: Spare
Column J: BA Bias Setting
Column K: BA Load
2 Note: Columns D \& E are optional data. If you choose not to use these, leave the columns blank. Do not delete the columns. Use the sign (+/-) convention defined in FRS Form 1. Data compression must be turned off for each data point. Quality data will give you quality results in the evaluation.
and Be sure the "Data" worksheet is clear of any old data. Collect the same total minutes of data for each event evaluated to minimize your effort and time.
fusing PI historian as your data source, use "PasteSpecial/Values" to enter data into the spreadsheet. Do not include historian data collection formulas in the data
5 Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on the graph on the "Copy Results" worksheet. If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should you have to use the "Manual" process.
6 Once data is in place in the "Data" worksheet, confirm the Auto selection of the beginning of the event by observing the "Graph 20 to 52 s " worksheet. Adjust the selection if necessary To make an adjustment, change the value in cell "Q3" on the "Graph 20 to 52 s " worksheet. Usually a 0,1 or 2 will achive the correct alignment of $\mathrm{T}(0)$.

7 If the correct row is selected, the "Graph 20 to 52 s " worksheet will indicate the first change in frequency (red trend) of the event on the center vertical grid line of the graph.
8 The end of the event will be Auto selected based on the frequency value in cell " N 2 " on the Data worksheet. This will be the frequency at the beginning of the event or 60 Hz , whichever is lower. (for low Hz events) This value controls the end of the "Sustained Frequency Response" evaluation period.
Primary Frequency Response should be sustained during the event recovery period. This evaluation determines how well you achieved this goal.
9 Use the "Copy Form 2 data for Pasting into Form 1" button provided on the "Copy Results" worksheet (Cells B21 through B28) to copy the evaluation and event specific data for the "FRS Form 1" of this field trial. This data is summarized in the correct order on worksheet "Form 1 Summary Data",
10 Use PasteSpecial/Values and paste the copied data into FRS Form 1 on the appropriate event row. Be sure to use the latest version of Form 1, currently Form 1.9 .
11 Save this Form 2 using the file name convention on the "Copy Results" worksheet. The complete file name is in bold in cell B38. Return all completed Form 2 s with your Form 1 to NERC.

Steps To be completed the first time you use Form 2 for your BA.
A Enter the Balancing Authority name as you want it to appear on the graphs in cell "B1" of the "Copy Results" worksheet. For example: "ERCOT".

Balancing Authority Name: MyBA
Interconnection Prevailing UFLS First Step Relay trip poin
terconnection High Relay trip point
Note: See "Instruction" tab for more detailed instructions.

| Step 1. | Copy and Paste Event Data into the appropriate cells of the "Data" worksheet. Maintain date and time format of mm/dd/yy hh:mm:ss. |
| :---: | :---: |
| Step 2. | Data must start at least $\mathbf{2}$ full minutes before the beginning of the event. <br> Collect the same amount of data for each event. Suggest 2 to 3 minutes before to 15 minutes after (up to 60 minutes total). Delete unused rows of data in the Data worksheet below your data, columns A through R. You must also delete any un-used event detection formulas in columns N through R as well. |
| Step 3. Step 4. | Enter your BA name in cell B1 of this worksheet. <br> Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on graph to the right to that on Form 1 for this event. If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should you have to use the "Manual" process. |
| Step 5. | Verify that the "Auto" selection of $\mathrm{T}(0)$ is correct by observing "Graph 20 to 52 s ". The very first frequency data point of the event on the graph must not be included in the "A Value" average. This is accomplished when the first frequency data point of the event is dead center of the graph on the center vertical grid line. The Auto event detection will select the single largest event in the data provided. An adjustment for $\mathrm{T}(0)$ alignment is provided in Cell Q 3 on the Graph 20 to 52 s . |
| Step 6. | When $\mathrm{T}(0)$ is properly aligned. Hit the big blue button to copy your data for pasting into FRS Form 1 "BA Event Data" worksheet. <br> Copy Form 2 data for Pasting into Form 1 |
| Step 7. | Paste data into "FRS Form 1" in the appropriate row on the "BA Event Data" worksheet. Be sure to use the latest version of Form 1. This is Form 2.9 so use Form 1.9. |
| Step 8. | Save this workbook using the following file name in bold below: |

[^73]Event Frequency Data

09/10/12 Date yymmdd
2:27 Time hh:ss of T(0)
Where "MyBA" = your BA mnemonic

|  |  |  |

A zero value aligns the data to the hightest Frequency change value. Usually the event begins one or two data scans earlier than this scan.

Increasing this value shifts graph data to the right.
Decreasing this value shifts graph data to the left.

Note: The P.U. Performance values indicate performance as a P.U. value of BA Bias setting. For BAs that utilize a variable Bias, the Bias average during $T(+20)$ to $T(+52)$ is used.
P.U. values above 1.0 indicate that the Bias setting was below measured Frequency Response, P.U. values below 1.0 indicate that the Bias setting was above measured Frequency Response.

First change in frequency of the event should occur here on the vertical grid line.
It is important that the pre-event frequency average to NOT contain frequency data of the event, "Average Frequency" trend to the left of center of the graph
To shift the data on the graph left or right, adjust the value in cell Q3 highlighted in yellow above.

## Teps To be completed for each event evaluated

1 Set-up Data collection in exact same order as the "Data" sheet of this work book. Data should be in this order:
Set-up Data collection in exact same order as the "Data" sheet
Column A: Date and Time in this format, $\mathrm{mm} / \mathrm{dd} / \mathrm{yy} \mathrm{HH}: \mathrm{MM}$ : SS
Column B: Frequency H
Column C. Net Actual Interchang
Column D: Joint Owned Unit dynamic schedule
Column E: Non Conforming Load
Column f. Pumped Hy
olumn G: Not Used
Column H: Transferred Frequency Response
Column I: Contingent BA Lost load or generation
Column J: BA Bias Setting
Column K: BA Load
2 Note: Columns D, E, F and H are optional data. If you choose not to use these, leave the columns blank. Do not delete the columns. Use the sign ( $+/$-) convention defined in FRS Form 1.
3 Data compression must be turned off for each data point. Quality data will give you quality results in the evaluation.
4 Data must start a minimum of two (2) minutes before the event begins and includes a minimum of 15 minutes after the beginning of the event with up to 60 minutes of data Be sure the "Data" worksheet is clear of any old data. Collect the same total minutes of data for each event evaluated to minimize your effort and time.
using PI historian as your data source, use "PasteSpecial/Values" to enter data into the spreadsheet. Do not include historian data collection formulas in the data.
5 Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on the graph on the "Copy Results" worksheet If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should you have to use the "Manual" process.

6 Once data is in place in the "Data" worksheet, confirm the Auto selection of the beginning of the event by observing the "Graph 20 to 52 s " worksheet. Adjust the selection if necessary. To make an adjustment, change the value in cell "Q3" on the "Graph 20 to 52 s " worksheet. Usually a 0,1 or 2 will achive the correct alignment of $\mathrm{T}(0)$.

7 If the correct row is selected, the "Graph 20 to 52 s " worksheet will indicate the first change in frequency (red trend) of the event on the center vertical grid line of the graph.
8 The end of the event will be Auto selected based on the frequency value in cell " N 2 " on the Data worksheet. This will be the frequency at the beginning of the event or 60 Hz , whichever is lower. (for low Hz events his value controls the end of the "Sustained Frequency Response" evaluation period.
Primary Frequency Response should be sustained during the event recovery period. This evaluation determines how well you achieved this goal
9 Use the "Copy Form 2 data for Pasting into Form 1" button provided on the "Copy Results" worksheet (Cells B21 through B28) to copy the evaluation and event specific data for the "FRS Form 1" of this field trial. This data is summarized in the correct order on worksheet "Form 1 Summary Data"
10 Use PasteSpecial/Values and paste the copied data into FRS Form 1 on the appropriate event row. Be sure to use the latest version of Form 1, currently Form 1.9.
11 Save this Form 2 using the file name convention on the "Copy Results" worksheet. The complete file name is in bold in cell B38. Return all completed Form $2 s$ with your Form 1 to NERC.

## Steps To be completed the first time you use Form 2 for your BA.

A Enter the Balancing Authority name as you want it to appear on the graphs in cell "B1" of the "Copy Results" worksheet. For example: "NYISO"
B For informational and educational purposes, a "Sustained" performance evaluation is provided in the "Evaluation" worksheet and in the "Sustained" Graph. This evaluation uses a Time Constant (TC) to model the frequency response of your BA. The time constant is located in cell "L13" of the "Evaluation" spreadsheet and should be edited for the types of generators in your BA. Presently this time constant is set at 0.35 ,
he higher the value of the time constant, the faster the delivery of frequency response is expected. Setting the TC to 1.0 effectively turns off the delay and instantaneous frequency response will be modeled. Do not set higher than 1.0 his time constant is only used in the "Sustained" evaluation and is not used for the Field Trial evaluation of performance to the FRO.
A typical setting for this time constant is 0.08 to 0.15 for hydro units, 0.10 to 0.20 for large steam turbines and 0.20 to 0.40 for combustion turbines.
By observing the slope of your "Interchange Actual" on the "Sustained" Graph, adjust the time constant until the initial slope of the "Target" is similar to the slope of the NAl data.
When set appropriately, the "Target" trend on the "Sustained" graph will model what the Net Actua Interchange should have done during the event recovery period based on your Bias setting during the event

Balancing Authority Name: MyBA
Interconnection Prevailing UFLS First Step Relay trip point
terconnection High Relay trip point
Note: See "Instruction" tab for more detailed instructions.

| Step 1. | Copy and Paste Event Data into the appropriate cells of the "Data" worksheet. <br> Maintain date and time format of mm/dd/yy hh:mm:ss. |
| ---: | :--- | :--- |
| Step 2. | Data must start at least 2 full minutes before the beginning of the event. <br> Collect the same amount of data for each event. Suggest 2 to 3 minutes before to 15 minutes after (up <br> to 60 minutes total). Delete unused rows of data in the Data worksheet below your data, columns A <br> through R. You must also delete any un-used event detection formulas in columns N through R as well. |
| Step 3. | Enter your BA name in cell B1 of this worksheet. |

11/05/16 Date yymmdd
8:06 Time hh:ss of T(0)
Where "MyBA" = your BA mnemonic

"Auto" Event Detection adjustment of $\mathrm{T}(0)$.
\# of rows to shift $\mathrm{T}(0)$
A zero value aligns the data to the hightest Frequency change value. Usually the event begins one or two data scans earlier than this scan

Increasing this value shifts graph data to the right.
Decreasing this value shifts graph data to the left.

Note: The P.U. Performance values indicate performance as a P.U. value of BA Bias setting. For BAs that utilize a variable Bias, the Bias average during $T(+20)$ to $T(+52)$ is used
P.U. values above 1.0 indicate that the Bias setting was below measured Frequency Response. P.U. values below 1.0 indicate that the Bias setting was above measured Frequency Response.

## $\mathrm{T}(0)$ <br> First change in frequency of the event should occur here on the vertical grid line.

It is important that the pre-event frequency average to NOT contain frequency data of the event, "Average Frequency" trend to the left of center of the graph
To shift the data on the graph left or right, adjust the value in cell Q 3 highlighted in yellow above.

$\left.\begin{array}{ccccc|cc|}\hline \text { mary Frequency Response Evaluation Points } & & & \\ \hline \text { Adjusted } & \text { Adjusted } & \text { Adjusted } & \text { Adjusted } & \text { Adjusted } & & \\ \begin{array}{c}\text { PFR }\end{array} & \begin{array}{c}\text { PFR }\end{array} & \text { PFR } & \text { PFR } & \text { PFR }\end{array}\right)$

## To be completed for each event evaluated.

1 Set-up Data collection in exact same order as the "Data" sheet of this work book. Data should be in this order
Column A: Date and Time in this format, mm/dd/yy HH:MM:SS
Column B: Frequency Hz
Column C: Contingent Resouce Lost MW or Lost Load
Column D: Load Resources tripped during the event.
Column E: Non Conforming Load
Column F: Spare
Column G: Not Used
Column H: Spare
Column I: Spare
Column J: BA Bias Setting
Column K: BA Load
2 Note: Columns D \& E are optional data. If you choose not to use these, leave the columns blank. Do not delete the columns. Use the sign (+/-) convention defined in FRS Form 1.
3 Data compression must be turned off for each data point. Quality data will give you quality results in the evaluation.
4 Data must start a minimum of two (2) minutes before the event begins and includes a minimum of 15 minutes after the beginning of the event with up to 60 minutes of data
Be sure the "Data" worksheet is clear of any old data. Collect the same total minutes of data for each event evaluated to minimize your effort and time.
If using PI historian as your data source, use "PasteSpecial/Values" to enter data into the spreadsheet. Do not include historian data collection formulas in the data.
5 Verify that the "Auto" Event Detection selected the correct event. Verify time and delta Hz by comparing time of event and delta Hz on the graph on the "Copy Results" worksheet.
If the wrong event was selected, in cell "E4" of this worksheet select "Manual" and manually select the beginning and ending row numbers of the desired event and enter these in cells "E5" and "E6". Only rarely should you have to use the "Manual" process.
6 Once data is in place in the "Data" worksheet, confirm the Auto selection of the beginning of the event by observing the "Graph 20 to 52 s " worksheet. Adjust the selection if necessary. To make an adjustment, change the value in cell "Q3" on the "Graph 20 to 52 s " worksheet. Usually a 0,1 or 2 will achive the correct alignment of $\mathrm{T}(0)$.

7 If the correct row is selected, the "Graph 20 to 52 s " worksheet will indicate the first change in frequency (red trend) of the event on the center vertical grid line of the graph.
8 The end of the event will be Auto selected based on the frequency value in cell "N2" on the Data worksheet. This will be the frequency at the beginning of the event or 60 Hz , whichever is lower. (for low Hz events) This value controls the end of the "Sustained Frequency Response" evaluation period.
Primary Frequency Response should be sustained during the event recovery period. This evaluation determines how well you achieved this goal
 in the correct order on worksheet "Form 1 Summary Data"
10 Use PasteSpecial/Values and paste the copied data into FRS Form 1 on the appropriate event row. Be sure to use the latest version of Form 1, currently Form 1.9
11 Save this Form 2 using the file name convention on the "Copy Results" worksheet. The complete file name is in bold in cell B38. Return all completed Form 2 s with your Form 1 to NERC.

## Steps To be completed the first time you use form 2 for your BA.

A Enter the Balancing Authority name as you want it to appear on the graphs in cell "B1" of the "Copy Results" worksheet. For example: "ERCOT"
