# Project 2007-12 Frequency Response 

Related Files

## Status:

A recirculation ballot for BAL-003-1 closed on December 21, 2012 with a quorum of $86.19 \%$ and $76.53 \%$ approval. The standard will be presented to the NERC Board of Trustees for adoption at its February meeting.

## Purpose/Industry Need:

Frequency Response, a measure of an Interconnection's ability to stabilize frequency immediately following the sudden loss of generation or load, is a critical component to the reliable operation of the bulk power system, particularly during disturbances and restoration. Failure to maintain frequency can disrupt the operation of equipment and initiate disconnection of power plant equipment to prevent them from being damaged, which could lead to wide-spread blackouts. There is evidence of continuing decline in Frequency Response in the three Interconnections over the past 10 years, but no confirmed reason for the apparent decline. The proposed standard would set a minimum Frequency Response obligation for each Balancing Authority, provide a uniform calculation of Frequency Response and Frequency Bias Settings that transition to values closer to natural Frequency Response, and encourage coordinated AGC operation.

## Purpose/Industry Need (Provide one or two sentences)

In regard to frequency response, one shortcoming of the recommendations in policy today is that there is no guidance regarding how much governor response (in MW) is required at the $5 \%$ droop rate. This has led to confusion among plant operators and turbine-generator manufacturers alike, and has led to confusion among CA and Generation Operators as to their responsibilities and obligations.

This SAR is suggested to ensure frequency of Interconnection remains above underfrequency load shedding setpoints during transient period following the sudden loss of generation on the Interconnection.

Reliability Functions
The Standard will Apply to the Following Functions (Check box for each one that applies by
double clicking the grey boxes.)

| X | Reliability Authority | Ensures the reliability of the bulk transmission system within its Reliability Authority area. This is the highest reliability authority. |
| :---: | :---: | :---: |
| ® | Balancing Authority | Integrates resource plans ahead of time, and maintains load-interchangeresource balance within its metered boundary and supports system frequency in real time |
| $\square$ | Interchange Authority | Authorizes valid and balanced Interchange Schedules |
| $\square$ | Planning Authority | Plans the bulk electric system |
| $\square$ | Resource <br> Planner | Develops a long-term (>1year) plan for the resource adequacy of specific loads within a Planning Authority area. |
| $\square$ | Transmission Planner | Develops a long-term (>1 year) plan for the reliability of transmission systems within its portion of the Planning Authority area. |
| $\square$ | Transmission Service Provider | Provides transmission services to qualified market participants under applicable transmission service agreements |
| $\square$ | Transmission Owner | Owns transmission facilities |
| $\square$ | Transmission Operator | Operates and maintains the transmission facilities, and executes switching orders |
| $\square$ | Distribution Provider | Provides and operates the "wires" between the transmission system and the customer |
| $\square$ | Generator Owner | Owns and maintains generation unit(s) |
| $\boxtimes$ | Generator Operator | Operates generation unit(s) and performs the functions of supplying energy and Interconnected Operations Services |
| $\square$ | PurchasingSelling Entity | The function of purchasing or selling energy, capacity and all necessary Interconnected Operations Services as required |
| $\square$ | Market Operator | Integrates energy, capacity, balancing, and transmission resources to achieve an economic, reliability-constrained dispatch. |
| $\square$ | Load-Serving Entity | Secures energy and transmission (and related generation services) to serve the end user |

Reliability and Market Interface Principles

|  | s.) |
| :---: | :---: |
| 区 | 1. Interconnected bulk electric systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards. |
| $\square$ | 2. The frequency and voltage of interconnected bulk electric systems shall be control within defined limits through the balancing of real and reactive power supply and d |
| $\square$ | 3. Information necessary for the planning and operation of interconnected bulk electric systems shall be made available to those entities responsible for planning and operating the systems reliably. |
| $\square$ | 4. Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed, coordinated, maintained and implemented. |
| $\square$ | 5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk electric systems. |
|  | 6. Personnel responsible for planning and operating interconnected bulk electric systems shall be trained, qualified and have the responsibility and authority to implement actions. |
| 区 | 7. The security of the interconnected bulk electric systems shall be assessed maintained on a wide area basis. |
| Does the proposed Standard comply with all of the following Market Interface Principles? (Select 'yes' or 'no' from the drop-down box by double clicking the grey area.) |  |
| 1. The planning and operation of bulk electric systems shall recognize that reliability is an essential requirement of a robust North American economy. Yes |  |
| An Organization Standard shall not give any market participant an unfair competitive advantage.Yes |  |
| 3. An Organization Standard shall neither mandate nor prohibit any specific market structure. Yes |  |
| 4. An Organization Standard shall not preclude market solutions to achieving compliance with that Standard. Yes |  |
|  | An Organization Standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially nonsensitive information that is required for compliance with reliability standards. Yes |

Detailed Description (Provide enough detail so that an independent entity familiar with the industry could draft, modify, or withdraw a Standard based on this description.)
This proposed standard would coordinate with and complement the Load and Balancing SAR, which addresses Interconnection frequency control from 10 minutes and longer, by addressing the requirements for control during the seconds timeframe. Ideally, an integrated set of performance-based "balancing standards" should be in place that monitors the entire spectrum of the adequacy component of reliability. Figure 1 depicts the interrelationships of the set of "Balancing" standards, which ultimately checks that Control Areas have and deploy adequate resources to maintain reliability.
Seconds Minutes Hours Days

Figure 1 Interrelationships of "Balancing" Standards

The Control Performance Standards (CPS1 and CPS2) are well-defined and generally accepted by the Industry. The Disturbance Control Standard (DCS) measures deployment of reserves for specific events. This SAR is proposed to develop a standard to measure sub-minute responses to changes in frequency and to set minimum acceptable responses to system these events.

A Frequency Response Standard should address the following issues:

- There must be a minimum response for each event (rate, amount, and duration). Reliance on average response could result in all areas being short at the same time (similar to the short-term excursions seen with CPS1). The amount (depth of response) should not be under-emphasized.
- The measurement selected must be accurate and, to the extent practical, easy to implement.
- The requirements must integrate with and be consistent with the assumptions used in setting the BAAL limits within the Load and Balancing Standard (if and as ultimately adopted)
- A method of allocation must be developed
- The standard should not preclude market solutions (e.g. allow purchasing of response as long as deliverability and restoration criteria can be met). There must be a means for sale/purchase of frequency response as for any other quantity.

## PREFACE

Frequency response as used in this paper is defined as an automatic and sustained change in the power consumption or output of a device that occurs within $5-30$ seconds of and is in a direction to oppose a change in the Interconnection frequency. Frequency response as so defined is declining within the Eastern and Western Interconnections when it should be increasing because of increasing load and the associated increase in generation. Frequency Response within the Texas Interconnection has been statistically constant.

The NERC Resources subcommittee posted a Frequency Response Standard for comment in 2001. The comments received against the standard centered on 1) those not understanding the metric and 2 ) those questioning the need for a standard.

The intent of this paper is to create an understanding of the need for a standard and the technical and economic drivers motivating its development

## INTRODUCTION

The NERC Resources subcommittee drafted this paper to document the need for a frequency response standard. Provided in this paper are statistical background data showing how the frequency response of the Interconnections has declined along with an analysis of the technical and economic drivers that have contributed to the decline. Further, the paper attempts to refute through examples and simulation the arguments that this decline in the response is not a reliability issue. Instead, the paper will demonstrate that both the Western and Eastern Interconnections run a strong risk of under-frequency action if a standard is not adopted that establishes minimum levels of frequency response. The Union for the Coordination for the Transmission of Electricity (a European Standards Group) has already adopted a standard addressing the same technical issues raised within this paper. While the primary focus of the paper is the impact to each Interconnection as a whole, the need for primary frequency response also is a major consideration in islanding situations.

## Background

Each Control Area's contribution to frequency support is provided by the natural response of its generators and load to frequency variations. Figure 1 depicts a typical frequency excursion caused by a loss of a large generator on an Interconnection. Frequency Response is typically comprised of two components:
"Load rejection" or the reduction in the power consumption by motors that slow down in response to a decline in frequency. This is reflected in the general slope of the line from Points A-C. Load response to a change in frequency can vary anywhere from no response from equipment like computers to 1.5 times for some motor loads. Load response occurs directly or with minimal lag as the frequency changes. In addition,

Control Areas may use "high set" interruptible loads that disconnect on a pre-determined trigger frequency.
"Generator response" or a change in the output of a generating unit due to inertia and the movement of its governor valves. Governor response from properly tuned units occurs in the $3-10$ second timeframe and is responsible for the bottoming of frequency at Point C and the partial recovery of frequency to Point $B$.

Figure 1 Typical Frequency Excursion
All else being constant, frequency will not recover to its scheduled value (typically 60 Hz ) unless the Control Area that lost the resource replaces it.

The turn around in frequency from points C to B attributable to unit governor response has markedly declined and at times is non-existent in the Eastern Interconnection. The line from points C to D is shifting down and becoming horizontal. This means that on many occasions the only frequency response in the East is coming solely from load response. This critical fact is important since as will be discussed later in the paper. The changing nature of loads means that there will be markedly less load response available in the future. Therefore, reliance on load as the sole support to arrest the frequency can lead to a decline in the reliability of the grid.

One of the fundamental obligations of a Control Area as stated the Control Area Criteria of the NERC Operating Manual is the provision of frequency support. Once this support is produced it is the purpose and the intent of the frequency bias component of the ACE

## 1/17/2005

equation to ensure that this response is not withdrawn after the initial transient period or through AGC action.

Ideally, an integrated set of performance-based "balancing standards" should be in place that monitors the entire spectrum of the Adequacy component of Reliability. Figure 2 shows the interrelationships of the set of "Balancing" standards, which ultimately checks that Control Areas have and deploy adequate resources to maintain reliability.

Seconds Minutes Hours Days
Proposed FRS

DCS

Figure 2 Interrelationships of "Balancing" Standards

The Control Performance Standards (CPS1 and CPS2) are well-defined and generally accepted by the Industry. The Disturbance Control Standard (DCS) measures deployment of reserves for specific events. This paper focuses on a proposed standard to measure sub-minute responses to changes in frequency. This sub-minute response is commonly called Governor Response (if viewed at the generator level) and Primary Frequency Control or Frequency Response (from a Control Area perspective).). The resource pyramid diagram below shows the same concept in a different fashion.

Response Time

Seconds

Seconds to Minutes

10 to 15 minutes

30 minutes

Hourly

Note: Frequency Response is actually a negative value i.e. as frequency drops a generator's output should increase. When discussing Frequency Response, people generally talk about the raw numbers (i.e. $50 \mathrm{MW} / 0.1 \mathrm{~Hz}$ ); the (-) sign is assumed. This should be kept in mind when reading this paper.

## CURRENT SITUATION

## Eastern Interconnection

Technical papers (Ingleson and Nagle) and analysis (Bourque) point to a continued decline in Eastern Interconnection Frequency Response. Figure 3 is a summary of this work.

Figure 3 Trend in Eastern Interconnection Frequency Response

The plot shows an annual decline of slightly over $70 \mathrm{MW} / 0.1 \mathrm{~Hz}$. This nine-year trend reflects an $18 \%$ decline in frequency response while load and generation grew nearly 20\% over the same period. Frequency response should have increased proportionally with generation and load.

## Western Interconnection

Figure 4 Trend in Western Interconnection Frequency Response
Figure 4 shows a proportionally similar decline in the Western Interconnection's Frequency Response. The graph represents response to events 25 milliHz or larger. There were a few data points available for prior years that put the West's response in the order of $1650 \mathrm{MW} / 0.1 \mathrm{~Hz}$ in 1994. This would be consistent with a decline of 20MW/year. Again, response should be increasing with increasing load and generation.

## Texas Interconnection

The trend in the Texas Interconnection frequency response has been statistically flat. Figure 5 is a different representation of response over an 8-year period (1995-2002). The plot is a "box and whisker" graph. The rectangle or bar for each year represents the range of the "middle $50 \%$ " of observed events. The average value is the horizontal line within the year's rectangle. The "whiskers" attached to each box represent the upper and lower "quartiles". The asterisk in 1999 is an "outlier" or rare events. The plots represent 65 "medium sized" events over this period.

Comparing the Texas Interconnection Frequency Response to the other Interconnections is a challenge. This is because ERCOT has two groups of "high set" interruptible load. The first group trips at 59.8 Hz , the second at 59.7 Hz . Customers in the Texas Interconnection choose to participate in this and ERCOT uses it as a supplement to governor response. Once disconnected, the load provides no other assistance to frequency control such as inertial response. Additionally, this interruptible load provides no response to high frequency events.

Figure 5 ERCOT Frequency Response 1995-2002

## IS THERE A PROBLEM?

Those arguing against the need for a standard contend that the decline in the frequency response illustrated above is not a significant reliability problem. The argument put forward against a standard is that even if frequency response is declining there is so much margin in the system that reliability i.e. loss of load from under- frequency is not impacted. The calculation to demonstrate this argument is straightforward. The first significant amount of under-frequency load shedding in the Eastern Interconnection is set at $59.70 \mathrm{~Hz}^{1}$. The current level of frequency response of the Eastern Interconnection is taken as $3100 \mathrm{MW} / 0.1 \mathrm{~Hz}$. Therefore an under-frequency decline to 59.7 Hz would require a generation loss of 9300 MW . This is well beyond any generation loss that has ever occurred except in an islanded situation. Furthermore, at the current rate of decline of $70 \mathrm{MW} / \mathrm{yr}$, as shown in figure 3 it will be thirty-four years before the response level declines to a level where a loss of even 2400 MW becomes a problem with respect to potential under-frequency load shedding.

As a starting point, this paper will show that the above logic is based on at least three incorrect assumptions.

The first assumption is that the Interconnection frequency starts at 60 Hz . An examination of Eastern Interconnection frequency statistics shows significant periods when the

[^0]Interconnection frequency is operating at or below 59.98 Hz . If 59.98 Hz is used to determine how long before the loss of 2400 MW causes an under-frequency the result reduces to 25 years. This is still beyond the range of concern.

The second and most critical assumption is that the frequency response will be $3100 \mathrm{MW} / 0.1 \mathrm{~Hz}$. This is representative of the average frequency response within the Eastern Interconnection. However, the standard (or average) deviation of responses is $\pm$ $1870 \mathrm{MW} / 0.1 \mathrm{~Hz}$; giving a range of responses from 4970 to $1230 \mathrm{MW} / 0.1 \mathrm{~Hz}$. If the lower response of $1230 \mathrm{MW} / 0.1 \mathrm{~Hz}$ is used in the calculation then, even today, a loss of 2400Mw has significant potential to cause under-frequency load shedding to occur. The fact that an under-frequency event has not happened yet is only coincidence. The multiple unit trips that have approached 2400MW have, fortunately, occurred when there was good response available.

A third assumption that is believed to be unfounded but is harder to disprove explicitly is, namely that the decline in frequency response will continue at a rate of only
$70 \mathrm{MW} / 0.1 \mathrm{~Hz}$. Many drivers are contributing to the response decline. Among these are:

- Steam turbine generators operating on "sliding pressure" or "boiler-follower" control and/or with "valves wide-open" (VWO) operation.
- Blocked governors on nuclear units for licensing reasons.
- Less heavy manufacturing in North America (proportionally fewer large motor loads and a reduction in "load rejection").
- Variable-speed drives on motors that do not provide the traditional "load rejection".
- A larger proportion of combine cycle units being installed on the system. Combined-cycle units when operating at full output operate in temperature control mode. When the frequency declines, there is a drop in combustion air volume that results from the slowing of compressor speed. This drop in combustion air volume can cause a reduction in the unit output. Figure 6 is a graph of the output of a combine cycle unit responding to a frequency decline.

Figure 6 Combustion Turbine Response to Frequency Change

The blue line in Figure 6 is frequency and the red is MW output of the generators. The oval envelops the Frequency Response time window. For a change in frequency of $-0.83 \%$, the station lost $2.5 \%$ of machine output. If the plant provided 5\% droop, its output should have increased 6.6 MW with the frequency event. The drop in output implies a POSITIVE Frequency Response characteristic.

While this is one specific model of combined-cycle unit, the graph is illustrative of this class of unit. As more of this class of unit comes on line, not only may there be no response but the response may actually decline as the frequency declines. This is of particular concern during Interconnection valley periods when these units may potentially make up a large proportion of the on-line generation. It is noteworthy that this phenomenon in the form of deloading or outright tripping after no more than one or two seconds of good response was a contributing factor in the Malaysia blackout in 1996 (Mansour 2003). Combinedcycle units can be tuned to provide correct frequency response; however, the operators need to be educated to the problem or have contractual or financial obligations and incentives to ensure that their units meet the requirements.

- Deregulation has resulted in a large increase in reserve-sharing groups. In the past, many Control Areas carried full reserves for their individual largest contingency and some for multiple contingencies. De-regulation and competitive
pressures have ended both of these practices. The majority of Control Areas have formed into Reserve Sharing Groups and each now carries its proportional share of the largest contingency.

While some of the above trends have slowed, the rate of decline has not been linear. In four out of the eight years examined, the frequency response decline has been over 100MW/0.1Hz.

## Analysis of a Load Only Response

Currently, the wide variation of frequency response tends to be a self-correcting problem. During high load periods when units are operating at full output, the frequency response is available from the load. In light load periods when there is less load response, the online units are at less than full output and produce governor response. Without a standard in place, however, there is no guarantee that unit response will continue. What happens if it does not? A simple calculation provides the answer.

The Eastern Interconnection peaks at 600,000 MW and remains at loads of $200,000 \mathrm{MW}$ and below for roughly $20 \%$ of the time. At best, motor and other similar types of loads respond on a linear basis as the frequency declines. In other words a $1 \%$ change in frequency, equivalent to 0.6 Hz , produces a $1 \%$ change in load. A drop in the Interconnection frequency that reaches the first step of underfrequency load shedding, 59.7 Hz , represents a $0.5 \%$ change in frequency and therefore would produce only a $0.5 \%$ change in load or 1000 MW . There are roughly 16-22 single generators of this size or larger within the Eastern Interconnection. Without unit or other equivalent frequency support, a single unit trip could potentially cause the Eastern Interconnection to drop firm load.

## 1/17/2005

The following simulation results show the response of the Eastern Interconnection under two scenarios. The load level analyzed is 280,000MW or about the load on 4/23/03 when there was a loss of 2500 MW on the system. Figure 7 shows the response of the system assuming there had only been load response available. The model assumes a linear decline of load with frequency as stated above. At 59.5 Hz , the simulation drops $7 \%$ of the load by under-frequency load shedding.

Figure 7 Simulation Assuming no Governor Response

Figure 8 shows the same system conditions and assumptions except that there is 1000MW of generator governor reserves.

Figure 8 Simulation with 1000 MW of Governor Reserves

The impact of the governor response even though only half of the unit loss is sufficient to maintain the frequency above the under frequency tripping point.

Without a frequency response standard there is no assurance that unit response will be available in any of the Interconnections. Current economics will continue to drive most units to operate at maximum output. Presently, system operating conditions are counterbalancing and the problem is self-correcting. As pointed out above, combinedcycle units are an increasing proportion of the generation. What incentive is there for other, newer technologies to incorporate frequency response if no requirement (i.e. a standard) exists to define adequacy?

## Secondary Impacts

There are many secondary effects from having an unknown and uncontrolled frequency response. Among these are:

- System oscillations may not be damped and may actually be aggravated. Recent testing of governor response in the Western Interconnection (Pereira) shows that existing models using an expected $5 \%$ governor droop are overly optimistic.
Calculations indicate only $40 \%$ of expected response was obtained. As a result,
oscillations persist for roughly twice as long as models predict, and they are substantially stronger.
- Some areas may be incapable of "self restoration" during islanding and black-start conditions.
- Without a measure or requirement, market forces will likely continue to drive a decline in performance.
- Stability transfer limits will be incorrect if assumptions about frequency response are wrong.
- There is no way to tell whether the decline in response is spread among all Control Areas or whether there are regions with little or no response (and therefore not able to provide support to the Interconnection during disturbances or "self start" during restoration).

## CURRENT REQUIREMENTS

This section highlights the current requirements and good practices regarding Frequency Response.

The NERC Control Area Criteria document outlines the fundamental obligations of the operation of the grid. In particular, it states:

The CONTROL AREA shall operate generation or have the necessary contracts to operate generation to... Provide its frequency bias obligations.

Policy 1 has several guides (suggested good practices) regarding governors:

- Generating units with nameplate ratings of 10 MW or greater should be equipped with governors operational for Frequency Response unless restricted by regulatory mandates.
- Turbine governors and HVDC controls, where applicable, should respond to system frequency deviation, unless there is a temporary operating problem.
- All turbine generators equipped with governors should be capable of providing immediate and sustained response to abnormal frequency excursions. Governors should provide a 5\% droop characteristic. Governors should, as a minimum, be fully responsive to frequency deviations exceeding $\pm 0.036 \mathrm{~Hz}$.
- Turbine control systems that provide adjustable limits to governor valve movement (valve position limit or equivalent) should not restrict travel more than necessary to coordinate boiler and turbine response characteristics.

## ISN'T EXISTING POLICY SUFFICIENT?

Current NERC policy, as seen above, has no "requirements" for primary frequency response. Policy 1C deals primarily with Bias, which relates more to determining regulation and Secondary Frequency Control, rather than Frequency Response. The
portions of Policy 1C regarding governors are "guides" and carry no force. This may partially explain why Frequency Response is declining. Mandatory requirements for governors, even if adopted, do not guarantee that the unit would not be operated at wideopen valves and, therefore, have no response for an under-frequency condition. In other words, both responsiveness and depth of response must be assured.

## COMMENTS TO THE FIRST PROPOSED FREQUENCY RESPONSE STANDARD

A Frequency Response Standard was proposed in mid 2001 in conjunction with approval of the current version of Policy 1. Table 1 summarizes the comments received.

| Summary Comment | Respondents |
| :--- | :---: |
| "Wordsmithing" or clarification or minor modification <br> comments | 62 |
| Governor requirement needs more definition (what is a <br> "governor" on a combined cycle unit) and should be <br> consistent with Planning Standards. | 1 |
| In favor of a standard | 3 |
| Measure should be tested before implementation | 2 |
| Add a requirement for common set points for under-frequency <br> load shedding so that one CONTROL AREA won't drag <br> another one down, | 1 |
| "Loss of load" risk should not be the basis for establishing the <br> standard. | 1 |
| There does not appear to be sufficient evidence on hand at this <br> time to warrant rigorous Standards and possible non- <br> compliance penalties. | 1 |
| Not sure using one-minute data will measure what's needed. | 1 |

Table 1 Summary of Comments to Policy 1C
The Balancing SAR task force posed questions to the Industry on the need for a Frequency Response Measure (FRM) that would likely mirror the FRS suggested by the Resources Subcommittee. The NERC Director of Standards returned the proposal because of concerns raised by the Industry. A closer look at the responses reveals that the Industry was not so much opposed to the standard as they were looking for information and clarification of the requirements. Table 2 summarizes the responses.

| Summary Comment | Respondents |
| :--- | :---: |
| Difficulty measuring | 6 |
| Didn't understand measure | 1 |
| Only if Generation governors required in "interconnection <br> standard" | 1 |
| More work needed in definition | 1 |
| In favor | 6 |
| Should hold sub-entities (generators, LSEs) accountable | 6 |

| Current guides requiring generators to respond are adequate | 2 |
| :--- | :--- |
| Eliminate the Frequency Response Measure | 1 |

Table 2 Summary of Comments Received on a Frequency Response Measure

## FREQUENCY RESPONSE STANDARD CONSIDERATIONS

## Introduction

A frequency response standard must explain clearly what is to be measured and why. This will help with the design of the process and provide direction on how it should evolve. Logical goals and considerations for a FRS include:

- Benchmark and track performance (both Control Area and Interconnection).
- Maintain historic levels of reliability (or some other level justified by an in-depth analysis).
- Be performance-based rather than commodity-based.
o This is similar to CPS where impact on interconnection frequency is measured rather than requiring a target set-aside of regulating resources.
o Specifically measuring Frequency Response allows more flexibility in meeting the needs of the Interconnection and Region (a target spinning reserve amount does not ensure Frequency Response)
o Rather than telling entities how to meet the standard, let the Industry and markets find innovative solutions.
- Be "tunable", thereby providing a means to adjust the standards as information allows.
- Be empirically valid (results statistically provable).
- Be objectively calculated.
- Be consistent and verifiable in application by all parties.
- Enable simple compliance monitoring.
- Be consistent with direction of the Industry (i.e. FERC RTO rule, IOSITF, etc.).

## Issues

A Frequency Response Standard should address the following issues:

- There must be a minimum response for each event (rate, amount, and duration) such that the problems described above do not occur. Reliance on average response could result in all areas being short at the same time (similar to the short-term excursions seen with CPS1). The amount (depth of response) should not be under-emphasized. One shortcoming of the recommendations in policy today is that there is no guidance regarding how much governor response (in MW) is required at the 5\% droop rate. This has led to confusion among plant operators and turbine-generator manufacturers alike, and has resulted in an objectionable lack of response from some units when the

## 1/17/2005

boiler controls are suppressed out of legitimate fear of tripping the unit on a frequency change.

- The measurement selected must be accurate and, to the extent practical, easy to implement.
- The requirements must integrate with and be consistent with the assumptions used in setting the BAAL limits within the Load and Balancing Standard (if and as ultimately adopted)
- A method of allocation must be developed
- The standard should not preclude market solutions (e.g. allow purchasing of response as long as deliverability and restoration criteria can be met).There must be a means for sale/purchase of frequency response as for any other quantity.

## ACRONYMS, TERMS AND DEFINITIONS

ACE - Area Control Error: ACE is the algebraic sum of the net scheduled and net actual interchange and a bias term based on the difference between scheduled and actual system frequency. This parameter is used to determine a Control Area's control performance with respects to its impact on system frequency.

CPS - Control Performance Standard: CPS defines a standard of minimum control performance. Each Control Area is to have the best operation above this minimum that can be achieved within the bounds of reasonable economic and physical limitations. Each Control Area shall monitor its performance on a continuous basis against two standards: CPS1 and CPS2.

CPS1 - Control Performance Standard 1: Over a (running) year, the average of the clock-minute averages of a Control Area's ACE times the clock minute average frequency error shall be less than a specific limit. This limit is a constant derived from a target frequency bound reviewed and set as necessary by the NERC Resources Subcommittee.
CPS2 - Control Performance Standard 2: The average ACE for each of six ten-minute periods during the hour (i.e., 10, 20, 30, 40, 50 and 60 minutes after the hour) must be within $\mathrm{L}_{10}$ at least $90 \%$ of the time during each calendar month.

DCS - Disturbance Control Standard: The standard used to monitor a Control Area's ability to recover from a disturbance.

ERCOT - Electric Reliability Council of Texas: One of the ten NERC regional coordinating councils.

FRC - Frequency Response Characteristic: For any change in generation/load balance in an interconnection, a frequency change occurs. FRC defines how any system (Control Area) responds to this change during any imbalance resulting from a sudden loss of load or generation. System frequency does not usually return to its pre-disturbance level until the Control Area experiencing the imbalance corrects its imbalance.

## FRS - Frequency Response Standard.

IOS - Interconnected Operating Services: IOS are the elemental 'reliability building blocks’ from generation (and sometimes load) necessary to maintain bulk electric system reliability, (sometimes referred to as ancillary services, such as regulation, load following, contingency reserves, Frequency Response, reactive power supply, and black-start capability).

LSE- Load Serving Entity.
NAESB - North American Energy Standards Board.

Frequency Response Standard Whitepaper 1/17/2005

SAR - Standards Authorization Request.

## Comment Form <br> Proposed Frequency Response Standard

This form is to be used to submit comments on the proposed Frequency Response Standard Authorization Request. Comments must be submitted by February 17, 2005. You may submit the completed form by emailing it to: sarcomm@nerc.com with the words "Frequency Response SAR Comments" in the subject line. If you have questions please contact Mark Ladrow at mark.ladrow@nerc.net or by telephone at 609-452-8060.

## ALL DATA ON THIS FORM WILL BE TRANSFERRED AUTOMATICALLY TO A DATABASE AND IT IS THEREFORE IMPORTANT TO ADHERE TO THE FOLLOWING REQUIREMENTS:

DO: Do enter text only, with no formatting or styles added.
Do use punctuation and capitalization as needed (except quotations).
Do use more than one form if responses do not fit in the spaces provided.
Do submit any formatted text or markups in a separate WORD file.

DO NOT: Do not insert tabs or paragraph returns in any data field.
Do not use numbering or bullets in any data field.
Do not use quotation marks in any data field.
Do not submit a response in an unprotected copy of this form.

## Background Information:

Posted for comments is the first posting of the Frequency Response SAR. The Frequency Task Force of the NERC Resources Subcommittee has identified the transient frequency response characteristics as degrading over time and potentially threatening the reliability of the bulk electric system. This Standard Authorization Request was initiated to address this concern by developing a standard to specify a measuring convention for frequency response and by specifying a minimum required response to system disturbances based on the convention.

The requestor would like to receive industry comments on this SAR and to obtain the input of the industry prior to determining the final scope and requirements of the SAR. Accordingly, we request your comments included on this form, emailed with the subject "Frequency Response SAR Comments" by February 17, 2005.

Question 1: Do you agree there is a reliability need for a specifying the quality and quantity of frequency response?
$\boxtimes$ YesNo

If no, please explain in the space provided below.

## Comments

# Question 2: Do you agree with the scope and applicability of the proposed standard? 

$\boxtimes$ YesNo

If no, please explain in the space provided below.

## Comments

Scope:
The scope of the proposed standard is appropriate. However, the reliability requirements would be better addressed by a comprehensive review that considers the adequacy of existing reliability standards.

Applicability:
The applicability of the proposed standard is understood to be Reliability Authorities, Balancing Authorities, and Generator Operators. However, substantial questions remain as to how the responsibilities implied in the proposed standard will be equitably distributed.

Question 3: Do you believe these standards are more appropriately additions to existing standards as opposed to creating new standards?
$\boxtimes$ Yes
No

If yes, please identify the location you believe would be the most appropriate for the proposed standard.

The reliability requirements provided in the proposed standard would be better addressed by a comprehensive review that considers the adequacy of the existing reliability standards (i.e., 300 Balance Resources and Demand)

## Comments

Question 4: Do you have any additional comments regarding the SAR that you believe should be addressed?
® No

If yes, please share those comments in the space provided below.

## Background Information:

Posted for comments is the first posting of the Frequency Response SAR. The Frequency Task Force of the NERC Resources Subcommittee has identified the transient frequency response characteristics as degrading over time and potentially threatening the reliability of the bulk electric system. This Standard Authorization Request was initiated to address this concern by developing a standard to specify a measuring convention for frequency response and by specifying a minimum required response to system disturbances based on the convention.

The requestor would like to receive industry comments on this SAR and to obtain the input of the industry prior to determining the final scope and requirements of the SAR. Accordingly, we request your comments included on this form, emailed with the subject "Frequency Response SAR Comments" by February 17, 2005.

Question 1: Do you agree there is a reliability need for a specifying the quality and quantity of frequency response?Yes
No

If no, please explain in the space provided below.

## Comments

Question 2: Do you agree with the scope and applicability of the proposed standard?
$\mathrm{x} \square$

If no, please explain in the space provided below.
The scope needs to be expanded - see detailed comments in a following section - based on extensive modeling and validation work in WECC.

## Comments

Question 3: Do you believe these standards are more appropriately additions to existing standards as opposed to creating new standards?Yes
$\qquad$ No

If yes, please identify the location you believe would be the most appropriate for the proposed standard.

## Comments

A new SAR will be more prescriptive, however there is also need for other related sections in NERC Operating Policy and Planning that need to be modified - see other comments below.

## Question 4: Do you have any additional comments regarding the SAR that you believe should be addressed?

If yes, please share those comments in the space provided below.
Two statements are made in the SAR:

1. The purpose of the proposed SAR is to ensure that frequency of the Interconnection remains above underfrequency load shedding setpoints during the transient period following the sudden loss of generation on the Interconnection.
2. Furthermore, it is stated that " In regard to frequency response, one shortcoming of the recommendations in policy today is that there is no guidance regarding how much governor response (in MW) is required at the 5\% droop rate."

The first is a calculated number and depends not only on the amount of generation tripped, but also the total generation in the Whole Interconnection at the time of trip. Obviously two very different answers will be obtained : one with the Interconnection intact (normal operation) and the second when islanded. Both affect reliability.

The second issue has been thoroughly investigated in the WECC and a new Thermal Governor modeling approach has been implemented in the WECC after system tests, an exhaustive modeling validation effort and obtaining data from the generator owners. This has been documented in two IEEE Transaction papers described below. These papers present the development of a new turbinegovernor modeling approach in WECC that correctly represents thermal units that have demonstrated unresponsive characteristics such as "base loaded" units operated with limiters, or partially responsive units with MW-load-controllers. The May $18^{\text {th }} 2001$ system trip test for 1250 MW performed with all AGCs off indicated that only about $40 \%$ of the governors effectively responded in the real system. If all the governors were responsive the calculated generation pickup for governors with a $5 \%$ droop for a 0.1 Hz frequency deviation would be 3185 MW instead of 1250 MW. The new modeling approach has been extensively validated against recordings from three WECC system tests and several large disturbances, and has been approved for use in all operation and planning studies in the WECC. The second paper describes the steps being taken to obtain validated data for the new governor models.

The work done by WECC indicate clearly that we do not get the required 5\% droop from all units as required by NERC. The modeling approach taken was to model the governors in planning and operating studies exactly as they are being actually operated. Enforcement/compliance of the 5\% droop is a separate issue and must be addressed by operating policies.

Obviously, the SAR touches upon only part of the problem, but it is a good start and should be expanded. It also needs to be cross-referenced with other areas such as the $5 \%$ droop requirement, an effective spinning reserves policy that actually works (see the
papers), and the effect on 'governor' powerflow and voltage stability analysis as a result of "unresponsive" governors.

The white paper referred by the SAR only touches upon the WECC effort and seems to miss the whole point of the modeling and validation work by the Governor Modeling Task Force in WECC - and what we have achieved in WECC to address realistic modeling of unresponsive governors in the real system.

## Background Information:

Posted for comments is the first posting of the Frequency Response SAR. The Frequency Task Force of the NERC Resources Subcommittee has identified the transient frequency response characteristics as degrading over time and potentially threatening the reliability of the bulk electric system. This Standard Authorization Request was initiated to address this concern by developing a standard to specify a measuring convention for frequency response and by specifying a minimum required response to system disturbances based on the convention.

The requestor would like to receive industry comments on this SAR and to obtain the input of the industry prior to determining the final scope and requirements of the SAR. Accordingly, we request your comments included on this form, emailed with the subject "Frequency Response SAR Comments" by February 17, 2005.

## Question 1: Do you agree there is a reliability need for a specifying the quality and quantity of frequency response?

No
## If no, please explain in the space provided below.

## Comments

We agree in general that there is a reliability need to have frequency response, particularly during disturbances, islanding and restoration. The standard should provide the process for a technically sound calculation of frequency response and bias (both fixed and variable).

Any new standards on frequency response need not and should not be onerous by finding BAs noncompliant with response less than average or below some un-validated norms. There may be valid reasons why a BA is below observed norms in response. For example, the BA may meet most of its obligations with schedules or its native load may be non-responsive.

If performance is significantly less than an Interconnection norm, the standard should not trigger an automatic non-compliance. In these situations the BA should perform an internal review/assessment that ensures governors are working as designed, that the BA knows which resources are frequency responsive (so the information can be included in restoration plans), whether governors can be put in more responsive modes during disturbances, etc.

When required, the validation of governor performance could be achieved either through online monitoring in an EMS or periodic testing (both methods should be explained in a reference document to support the standard).

The standard should acknowledge that some units might not provide response under normal operations (e.g. nuclear units operating at full load) and that response is highly variable event-toevent based on simultaneous load changes. The standard should acknowledge the differing Interconnection requirements (smaller Interconnections need greater response).

The standard should also track Interconnection response over time (years) and be reevaluated as performance changes.

## Question 2: Do you agree with the scope and applicability of the proposed standard?

Yes® No

## If no, please explain in the space provided below.

There is a general need for a standard, but the outcomes and expectations should address the comments raised in question 1 .

While we agree that the standard should not preclude market solutions (e.g. allow purchasing of response as long as deliverability and restoration criteria can be met), we have concerns with the statement: There must be a means for sale/purchase of frequency response as for any other quantity.

It is not clear what is meant by A method of allocation must be developed". Is this an allocation of Interconnection response to BAs, BA allocation to generators or something different?

## Comments

Question 3: Do you believe these standards are more appropriately additions to existing standards as opposed to creating new standards?
【 No

If yes, please identify the location you believe would be the most appropriate for the proposed standard.

## Comments

## Question 4: Do you have any additional comments regarding the SAR that you believe should be addressed?

## If yes, please share those comments in the space provided below.

We appreciate the opportunity to comment and believe there is a need for such a standard. Published studies show frequency response is declining when it should be increasing with load. The main concerns with this decreasing performance are:

There may be areas unable to withstand severe disturbances.
Following a grid separation or collapse, control areas may be unable to fulfill their blackstart and restoration responsibilities, thereby becoming a burden to neighbors.

Because engineering models use theoretical frequency response, they are likely overoptimistic and may misstate grid stability limits.

This standard would allow the industry to determine whether the decline is local or global.
Rather than implementing a complicated infrastructure or process, we would suggest that NERC automate the calculation of frequency response by either:

Asking BAs to save their CPS-source data in a common format so a common tool can be used (MAPP BAs and some others use a common tool that can calculate frequency response with CPS-source data).

Embed the calculation in the NERC ACE-monitoring application.
Refer to our earlier comments the structure of the standard (where lower amounts of BA response trigger an internal assessment rather than automatic assignment of non-compliance). BAs (and ultimately generators) would only be initially non-compliant if their response was low AND the BA failed to perform a reliability assessment in conjunction with its TOP. This default assessment would be at the BA level, but could be on an area basis (likely islanding area or where a TSP has responsibility for frequency responsive and black start ancillary services).

The standard should employ a methodology that not only captures initial response (first few seconds after the event) but also the sustained response until AGC action takes over

Each Interconnection should have the ability to add and further define the standard to meet its needs.

Providing visibility on where and when performance is substandard will likely initiate sufficient action to arrest the decline in performance. Minimum performance standards could be
implemented after the industry has identified what is reasonably achievable and technically justified.

CHANGE
This SAR is proposed to develop a standard to measure sub-minute responses to changes in frequency and to set minimum acceptable responses to system these events.
TO
This SAR is proposed to develop a standard to measure sub-minute responses to changes in frequency and to set minimum acceptable responses to these system events.

## Comment Form <br> Proposed Frequency Response Standard

This form is to be used to submit comments on the proposed Frequency Response Standard Authorization Request. Comments must be submitted by February 17, 2005. You may submit the completed form by emailing it to: sarcomm@nerc.com with the words "Frequency Response SAR Comments" in the subject line. If you have questions please contact Mark Ladrow at mark.ladrow@nerc.net or by telephone at 609-452-8060.

## Background Information:

Posted for comments is the first posting of the Frequency Response SAR. The Frequency Task Force of the NERC Resources Subcommittee has identified the transient frequency response characteristics as degrading over time and potentially threatening the reliability of the bulk electric system. This Standard Authorization Request was initiated to address this concern by developing a standard to specify a measuring convention for frequency response and by specifying a minimum required response to system disturbances based on the convention.

The requestor would like to receive industry comments on this SAR and to obtain the input of the industry prior to determining the final scope and requirements of the SAR. Accordingly, we request your comments included on this form, emailed with the subject "Frequency Response SAR Comments" by February 17, 2005.

Question 1: Do you agree there is a reliability need for a specifying the quality and quantity of frequency response?
$\boxtimes$ YesNo

If no, please explain in the space provided below.

## Comments

Question 2: Do you agree with the scope and applicability of the proposed standard? $\boxtimes$ Yes

If no, please explain in the space provided below.

## Comments

Question 3: Do you believe these standards are more appropriately additions to existing standards as opposed to creating new standards?
【 No

If yes, please identify the location you believe would be the most appropriate for the proposed standard.

## Comments

Question 4: Do you have any additional comments regarding the SAR that you believe should be addressed?
$\boxtimes$ Yes
No

## If yes, please share those comments in the space provided below.

Given the language in the accompanying White Paper: The standard should not preclude market solutions (e.g. allow purchasing of response as long as deliverability and restoration criteria can be met).There must be a means for sale/purchase of frequency response as for any other quantity. - I believe this Standard should be developed in conjunction with NAESB. The definition, attributes and procurement metrics of the frequency response product will be a critical component of this Standard. Some guidance in defining and developing this service to the bulk interconnected system can be found in the NERC IOS Reference Document. The Standard should build on this previous IOS work.

## Comment Form <br> Proposed Frequency Response Standard

This form is to be used to submit comments on the proposed Frequency Response Standard Authorization Request. Comments must be submitted by February 17, 2005. You may submit the completed form by emailing it to: sarcomm@nerc.com with the words "Frequency Response SAR Comments" in the subject line. If you have questions please contact Mark Ladrow at mark.ladrow@nerc.net or by telephone at 609-452-8060.

## Background Information:

Posted for comments is the first posting of the Frequency Response SAR. The Frequency Task Force of the NERC Resources Subcommittee has identified the transient frequency response characteristics as degrading over time and potentially threatening the reliability of the bulk electric system. This Standard Authorization Request was initiated to address this concern by developing a standard to specify a measuring convention for frequency response and by specifying a minimum required response to system disturbances based on the convention.

The requestor would like to receive industry comments on this SAR and to obtain the input of the industry prior to determining the final scope and requirements of the SAR. Accordingly, we request your comments included on this form, emailed with the subject "Frequency Response SAR Comments" by February 17, 2005.

Question 1: Do you agree there is a reliability need for a specifying the quality and quantity of frequency response?
$\boxtimes$ YesNo

If no, please explain in the space provided below.

## Comments

A frequency response standard is needed but only within the scope and range of the previously provided guides in Policy 1 such as a design criteria of $5 \%$ droop, a 36 mHz deadband with exclusions for nuclear, combined cycle and small generating units.

Question 2: Do you agree with the scope and applicability of the proposed standard? $\boxtimes$ Yes

If no, please explain in the space provided below.

## Comments

Question 3: Do you believe these standards are more appropriately additions to existing standards as opposed to creating new standards?
$\boxtimes$ Yes
No

If yes, please identify the location you believe would be the most appropriate for the proposed standard.

We would recommend that this standard be incorporated into the Balance Resource and Demand Standard (Standard 300) or the Version 0 BAL Standard.

## Comments

Question 4: Do you have any additional comments regarding the SAR that you believe should be addressed?
® No

If yes, please share those comments in the space provided below.

## Background Information:

Posted for comments is the first posting of the Frequency Response SAR. The Frequency Task Force of the NERC Resources Subcommittee has identified the transient frequency response characteristics as degrading over time and potentially threatening the reliability of the bulk electric system. This Standard Authorization Request was initiated to address this concern by developing a standard to specify a measuring convention for frequency response and by specifying a minimum required response to system disturbances based on the convention.

The requestor would like to receive industry comments on this SAR and to obtain the input of the industry prior to determining the final scope and requirements of the SAR. Accordingly, we request your comments included on this form, emailed with the subject "Frequency Response SAR Comments" by February 17, 2005.

## Question 1: Do you agree there is a reliability need for a specifying the quality and quantity of frequency response?

X Yes
No

If no, please explain in the space provided below.

## Comments

Frequency response provided by speed governors and loads helps to prevent load shedding and generator trips at significant frequency excursions caused by sudden active power mismatches in the systems. Without a sufficient frequency response emerging during the first seconds after a frequency disturbance, there is a danger of further cascading development or frequency instability and system collapse cased by underfrequency generator trips. It has been already noted that insufficient frequency response in some parts of an Interconnection may cause certain temporary redistribution of power flows and reduce stability margins after frequency disturbances that may limit the OTC on critical paths within the Interconnection. It has been also observed that insufficient frequency response may cause a weaker frequency recovery that bears a greater risk of system collapse at subsequent frequency disturbances. Therefore, frequency response is definitely a reliability issue that needs to be addressed by a NERC standard.

## Question 2: Do you agree with the scope and applicability of the proposed standard?

X Yes
No

## If no, please explain in the space provided below.

## Comments

Generally, our answer is yes, but the matter of applicability needs a very careful consideration. The question is whether the proposed standard should be applied to only the reliability and balancing authorities and plant operators, or also to the resource and system planning authorities and generator owners. For example, wind generators do not provide a frequency response, whereas the response from the Combined Cycle units is limited. This is a matter of design as well as the matter of controllability of the primary energy source. If the generation portfolio contains a lot of wind and CC generators, the balancing authority cannot do much to improve its summary frequency response in general terms. Also, if frequency responsive generators in a CA are heavily loaded, would the new standard force the balancing authorities to re-dispatch generation in favor of nonresponsive generation and commit more responsive generation ahead of the non-responsive generation? Another issue is whether the standard should specify the required response in the area or individual responses from generators. Perhaps, NERC should work with NASB to find the right answers before establishing the standard. One possible solution is to establish penalties for noncompliance that would stimulate generator owners to invest in frequency responsive generation. Another possible recommendation could be establishing a market for frequency response. Without resolving these difficult issues, this standard cannot be accepted.

Question 3: Do you believe these standards are more appropriately additions to existing standards as opposed to creating new standards?Yes
X No

If yes, please identify the location you believe would be the most appropriate for the proposed standard.

## Comments

The new standard should a stand-alone standard because of its potential implications for control areas and the necessity to stage the implementation of the standard in coordination with resolution of the issues discussed above.

Question 4: Do you have any additional comments regarding the SAR that you believe should be addressed?Yes
X No

If yes, please share those comments in the space provided below.

# Question 1: Do you agree there is a reliability need for a specifying the quality and quantity of frequency response? 

## If no, please explain in the space provided below.

## Comments

We agree in general that there is a reliability need to have frequency response, particularly during disturbances, islanding and restoration. The standard should provide the process for a technically sound calculation of frequency response and bias (both fixed and variable).

Any new standards on frequency response need not and should not be onerous by finding BAs noncompliant with response less than average or below some un-validated norms.

If performance is significantly less than an Interconnection norm, the standard should not trigger an automatic non-compliance. In these situations the BA should perform an internal review/assessment that ensures governors are working as designed, that the BA knows which resources are frequency responsive (so the information can be included in restoration plans), whether governors can be triggered to be more responsive during disturbances, etc and satisfy the Interconnection requirement. If the Interconnection requirement is not met within a reasonable timeframe then the BA should be deemed as non-compliant.

When required, the validation of governor performance could be achieved either through online monitoring in an EMS or periodic testing (both methods should be explained in a reference document to support the standard).

The standard should acknowledge that some units might not provide response under normal operations (e.g. nuclear units operating at full load) and that response is highly variable event-toevent based on simultaneous load changes.

The standard should acknowledge the differing Interconnection requirements (smaller Interconnections need greater response).

The standard should also track Interconnection and BA areas response over time (years) and be reevaluated as performance changes.

## Question 2: Do you agree with the scope and applicability of the proposed standard?

Yes® No

## If no, please explain in the space provided below.

There is a general need for a standard, but the outcomes and expectations should address the comments raised in question 1 .

While we agree that the standard should not preclude market solutions (e.g. allow purchasing of response as long as deliverability and restoration criteria can be met), we have concerns with the statement There must be a means for sale/purchase of frequency response as for any other quantity.

It is not clear what is meant by A method of allocation must be developed" Is this an allocation of Interconnection response to BAs, BA allocation to generators or something different?

## Comments

Question 3: Do you believe these standards are more appropriately additions to existing standards as opposed to creating new standards?
【 No

If yes, please identify the location you believe would be the most appropriate for the proposed standard.

## Comments

Unless the Version 0 (BAL-003-0 - Frequency Response and Bias) can be clarified and brought in line with this proposed standard, it should be stand-alone.

## Question 4: Do you have any additional comments regarding the SAR that you believe should be addressed?

## If yes, please share those comments in the space provided below.

We appreciate the opportunity to comment and believe there is a need for such a standard.
It needs to be recognized that there are two objectives for governor response, namely, to provide response on an interconnection wide basis to maintain an acceptable frequency and secondly to control frequency in island situations. The former may allow for averaging over an area of the response requirement but the latter may limit the extent of averaging.

Published studies show frequency response is declining when it should be increasing with load. The main concerns with this decreasing performance are:

There may be areas unable to withstand severe disturbances.
Following a grid separation or collapse, control areas may be unable to fulfill their blackstart and restoration responsibilities, thereby becoming a burden to neighbors.

Because engineering models use theoretical frequency response, they are likely over optimistic and may misstate grid stability limits.

This standard would allow the industry to determine whether the decline is local or global.
Rather than implementing a complicated infrastructure or process, we would suggest that NERC automate the calculation of frequency response by either:

Asking BAs to save their CPS-source data in a common format so a common tool can be used (MAPP BAs and some others use a common tool that can calculate frequency response with CPS-source data).

Embed the calculation in the NERC ACE-monitoring application.
Refer to our earlier comments the structure of the standard (where lower amounts of BA response trigger an internal assessment rather than automatic assignment of non-compliance). BAs (and ultimately generators) would only be initially non-compliant if their response was low AND the BA failed to perform a reliability assessment in conjunction with its TOP. Non compliance should be assessed if the BA does not alleviate the deficiency within a reasonable timeframe. This default assessment would be at the BA level, but could be on an area basis (likely islanding area or where a TSP has responsibility for frequency responsive and black start ancillary services).

The standard should employ a methodology that not only captures initial response (first few seconds after the event) but also the sustained response until AGC action takes over

Each Interconnection should have the ability to add and further define the standard to meet its needs.

Providing visibility on where and when performance is substandard will likely initiate sufficient action to arrest the decline in performance. Minimum performance standards could be implemented after the industry has identified what is reasonably achievable and technically justified.

## Background Information:

Posted for comments is the first posting of the Frequency Response SAR. The Frequency Task Force of the NERC Resources Subcommittee has identified the transient frequency response characteristics as degrading over time and potentially threatening the reliability of the bulk electric system. This Standard Authorization Request was initiated to address this concern by developing a standard to specify a measuring convention for frequency response and by specifying a minimum required response to system disturbances based on the convention.

The requestor would like to receive industry comments on this SAR and to obtain the input of the industry prior to determining the final scope and requirements of the SAR. Accordingly, we request your comments included on this form, emailed with the subject "Frequency Response SAR Comments" by February 17, 2005.

## Question 1: Do you agree there is a reliability need for a specifying the quality and quantity of frequency response?

邓 No

## If no, please explain in the space provided below.

NERC should not involve itself in the development of these standards and should allow individual interconnections to address frequency response issues independently. For example, the WECC is currently working on standards that will address this concern. They will be tailored to the specific requirements of this interconnection and will provide the best possible solution to the problem.
There may be a need to specify frequency response requirements within some interconnections; however, it is not necessary, or most effective for them to be defined at the NERC level.

## Comments

## Question 2: Do you agree with the scope and applicability of the proposed standard?

Yes邓 No

## If no, please explain in the space provided below.

The main theme that there needs to be a relationship between response and frequency decline is the right approach but requirements would be different from region to region. Standards to manage frequency response should be developed by individual interconnections; not NERC. The scope and applicability should be defined by the needs of the interconnection to provide the most benefit to system wide reliability.

## Comments

## Question 3: Do you believe these standards are more appropriately additions to existing

 standards as opposed to creating new standards?\No

If yes, please identify the location you believe would be the most appropriate for the proposed standard.
WECC has been working on frequency response standards for a few years and is close to finalizing standards specifically for the WECC interconnection. We do think there is a need for standardization of frequency response (clearly we do since WECC is doing it) BUT this standard should be developed at the Regional Council or Interconnection level and then adopted by NERC as a "Standard" with regional differences. Any new standards concerning frequency response should be developed by the individual interconnections.

## Comments

Question 4: Do you have any additional comments regarding the SAR that you believe should be addressed?

If yes, please share those comments in the space provided below.
Frequency response requirements are likely different for each of the three interconnected regions and a generalized approach will likely not meet WECC needs. The danger here is that a NERCwide approach may not be compatible with the needs of a regional approach. Standards are currently being developed within WECC to address the frequency response concerns of this interconnection. We feel that if the Eastern Interconnection needs a Frequency Response Standard, they should utilize the NERC Frequency Response Standard Whitepaper to draft an Eastern Interconnection-specific Frequency Response Standard.

## Comment Form <br> Proposed Frequency Response Standard

This form is to be used to submit comments on the proposed Frequency Response Standard Authorization Request. Comments must be submitted by February 17, 2005. You may submit the completed form by emailing it to: sarcomm@nerc.com with the words "Frequency Response SAR Comments" in the subject line. If you have questions please contact Mark Ladrow at mark.ladrow@nerc.net or by telephone at 609-452-8060.

## Background Information:

Posted for comments is the first posting of the Frequency Response SAR. The Frequency Task Force of the NERC Resources Subcommittee has identified the transient frequency response characteristics as degrading over time and potentially threatening the reliability of the bulk electric system. This Standard Authorization Request was initiated to address this concern by developing a standard to specify a measuring convention for frequency response and by specifying a minimum required response to system disturbances based on the convention.

The requestor would like to receive industry comments on this SAR and to obtain the input of the industry prior to determining the final scope and requirements of the SAR. Accordingly, we request your comments included on this form, emailed with the subject "Frequency Response SAR Comments" by February 17, 2005.

Question 1: Do you agree there is a reliability need for a specifying the quality and quantity of frequency response?
No

If no, please explain in the space provided below.

## Comments

Question 2: Do you agree with the scope and applicability of the proposed standard?

Yes

If no, please explain in the space provided below.

## Comments

The proposed scope and applicability, to the extent that they are in the given in the SAR, are good.

Question 3: Do you believe these standards are more appropriately additions to existing standards as opposed to creating new standards?YesNo

If yes, please identify the location you believe would be the most appropriate for the proposed standard.

## Comments

Question 4: Do you have any additional comments regarding the SAR that you believe should be addressed?

```
Yes
```

If yes, please share those comments in the space provided below. Please see the attachment <SAR_Comments_RPSchulz.doc>

## Comments on SAR Frequency Response

First, I make these comments based on work that I've done principally at American Electric Power Service Corp, before my retirement from there in November 2000, and as founding Chair of the IEEE Task Force on Large Interconnected Power System Response to Generation Governing. These comments are entirely mine, and reflect no views of either body.

Second. It appears that the final standard will differ from any single person's opinions. Thus the specific comments below may not prevail.

## Specific Comment 1:

The comment on page 4 of the SAR, "The standard should not preclude market solutions (e.g. allow purchasing of response as long as deliverability and restoration criteria can be met).There must be a means for sale/purchase of frequency response as for any other quantity." is workable only in near-normal operating conditions. But it will fail miserably when there is any islanding condition. An analogy:

Several skydivers agree that reserve parachutes are a very good idea, but don't want to invest in 1 reserve each. So they agree that they'll buy one to share among them, so each will be saved by that spare. This means that they will hold hands until they pull their ripcords.

Sounded good, until they tried it, and the first guy to pull his cord came unhitched, had a failed main 'chute, and the spare was on someone else. Specific Comment 2:

The comment on page 4 of the SAR, "The measurement selected must be accurate and, to the extent practical, easy to implement.' may be met in the Eastern Interconnection by the underway DOE "Eastern Interconnection Phasor Project ' and by the similar WECC measurement systems, commonly called "WAMS". Les Peieira's paper, cited in the White Paper, used the WAMS measurements.

## Question 1: Do you agree there is a reliability need for a specifying the quality and quantity of frequency response?

xYesNo

## If no, please explain in the space provided below.

## Comments

Yes, I agree there is a reliability need for specifying the quality and quantity of frequency response. There is ample evidence that specifying a droop value or that specifying governors must be in operation will not necessarily result in any useful governor response to a sudden large drop in system frequency. So yes, I think a SAR team should look into this matter. I would suggest the part load can play in arresting frequency decline be included in the scope. I would also suggest that the frequency response needs of the regions will likely vary, so final specific requirements should probably be made at the region level.

Question 2: Do you agree with the scope and applicability of the proposed standard?
$\square$ x Yes

If no, please explain in the space provided below.

## Comments

Yes, I agree.

Question 3: Do you believe these standards are more appropriately additions to existing standards as opposed to creating new standards?YesNo

If yes, please identify the location you believe would be the most appropriate for the proposed standard.

## Comments

No opinion.

Question 4: Do you have any additional comments regarding the SAR that you believe should be addressed?xNo

If yes, please share those comments in the space provided below.

## Question 1: Do you agree there is a reliability need for a specifying the quality and quantity of frequency response?

Yes
\ No

## If no, please explain in the space provided below.

## Comments

The FRCC does not support the development of a Frequency Response Standard at this time. A standard for each Interconnection, although informative would be unenforceable as far as identifying short term, frequency response deficient, entities or areas. As such measurability and compliance by the relevant entities would be all but impossible. As far as an Interconnection allocation program for frequency response, we feel that the "apparent" decline in response is not significant enough to warrant a standard at this time and we would require additional details of how such a plan would be implemented and the potential economic impacts on the Regions that would be associated with that plan.

Question 2: Do you agree with the scope and applicability of the proposed standard?Yes
邓 No

If no, please explain in the space provided below.

## Comments

The SAR indicates a measure of frequency response for the Interconnection, as a measure of performance. This would be very difficult to translate to individual entity compliance and thus render the standard applicable to no entities.

Question 3: Do you believe these standards are more appropriately additions to existing standards as opposed to creating new standards?
【 No

If yes, please identify the location you believe would be the most appropriate for the proposed standard.

## Comments

Question 4: Do you have any additional comments regarding the SAR that you believe should be addressed?
$\boxtimes$ Yes
No

## If yes, please share those comments in the space provided below.

At this time the FRCC has the highest frequency settings for load shedding in the Eastern Interconnection (southern part of the Region). Being a peninsula and out of necessity, the Region has developed a well coordinated, under-frequency program for extreme frequency excursions. Ambiguity of the requirements, uncertainty of measurement and the lack of benefit to the Region require that the FRCC to oppose this Standard Authorization Request at this time.

## Question 1: Do you agree there is a reliability need for a specifying the quality and quantity of frequency response?

Yes
$\square$ No

## If no, please explain in the space provided below.

## Comments

Manitoba Hydro , from a reliability perspective, supports the idea of specifying the quantity and quality of frequency response and incorporating these elements in a Standard. However, the development of this standard should not be rushed since the evidence provided in the Standard Authorization Request form and in the Frequency Response Standard White paper shows that current frequency response and projected frequency response trends do not pose a significant potential for compromising system reliability and for major under-frequency load shedding to occur in the near term.

Also in the section of the white paper which examines "frequency response standard considerations", a broad scope and outline is given, more detail is required especially regarding methods of ensuring compliance.

In paragraph 2, page 9 of the white paper where the current frequency response of the Eastern Interconnection is stated as $3100 \mathrm{MW} / 0.1 \mathrm{~Hz}$ with a standard deviation of $1870 \mathrm{MW} / 0.1 \mathrm{~Hz}$ and the statement is made that "the fact that an under-frequency event has not happened yet is only coincidence" requires much more detailed information regarding the origin and calculations of these numbers before these assumptions can be made. Could it be that instead of a frequency response closer to $1230 \mathrm{MW} / 0.1 \mathrm{~Hz}$ it is actually practically closer to $3100 \mathrm{MW} / 0.1 \mathrm{~Hz}$ or even 4970 MW/ 0.1 Hz most of the time?

One understandable major concern addressed in the white paper is the response of combined-cycle units to frequency decline and the fact that due to a drop in combustion air volume their output may actually decrease with a drop in frequency or even result in unit tripping. Also there was concern with the possibility that larger amounts of these types of units will be installed on the system thereby potentially increasing the decline in frequency response rate from $70 \mathrm{MW} / 0.1 \mathrm{~Hz} / \mathrm{Year}$ (Eastern Interconnection).

It is also mentioned (on page 10) that with proper tuning combined cycle units can provide correct frequency response. Maybe part of the focus should be on finding ways of enforcing the Current Requirements (Page 14) and including specific frequency response requirements for combinedcycle units.

Question 2: Do you agree with the scope and applicability of the proposed standard?

Yes
$\square$ No

If no, please explain in the space provided below.

## Comments

Question 3: Do you believe these standards are more appropriately additions to existing standards as opposed to creating new standards?

No

If yes, please identify the location you believe would be the most appropriate for the proposed standard.

## Comments

# Question 4: Do you have any additional comments regarding the SAR that you believe should be addressed? 

Yes

## If yes, please share those comments in the space provided below.

Below are a few general comments on the SAR:
There is general agreement with the statement "reliance on load as the sole support to arrest the frequency can lead to a decline in the reliability of the grid" in paragraph 3, page 4 of the white paper. However enough information is not provided to substantiate statements earlier in the paragraph such as, "the turn around in frequency from points C to B attributable to unit governor response has markedly declined and at times is non-existent in the eastern interconnection" and "the line from points C to D is shifting down and becoming horizontal".

In areas where governor response is limited it may be necessary to explore the necessity of earmarking "high-set" blocks of load, as is practiced in ERCOT, to act as a supplementary to governor response. Although it is anticipated that this approach would probably be much more difficult and challenging to co-ordinate in larger areas.
There should be careful thought put into the system/interconnection performance targets for frequency response. Perhaps the bar should be higher than preventing UFLS for credible generation loss events, i.e., provide a margin above this level. At the same time the standard should not impose unreasonable costs on entities to demonstrate compliance. The performance target should address both total interconnection response and also area or system response (potential islanding) and be very clear how generator operators (or load) obligations are allocated to achieve the performance targets.

NERC should investigate a process to monitor interconnection frequency response to be able to measure performance.

Posted for comments is the first posting of the Frequency Response SAR. The Frequency Task Force of the NERC Resources Subcommittee has identified the transient frequency response characteristics as degrading over time and potentially threatening the reliability of the bulk electric system. This Standard Authorization Request was initiated to address this concern by developing a standard to specify a measuring convention for frequency response and by specifying a minimum required response to system disturbances based on the convention.

The requestor would like to receive industry comments on this SAR and to obtain the input of the industry prior to determining the final scope and requirements of the SAR. Accordingly, we request your comments included on this form, emailed with the subject "Frequency Response SAR Comments" by February 17, 2005.

## Question 1: Do you agree there is a reliability need for a specifying the quality and quantity of frequency response?

No
## If no, please explain in the space provided below.

## Comments

We agree in general that there is a reliability need to have frequency response, in order to maintain interconnection frequency and particularly during disturbances, islanding and restoration. The standard need to address both the system needs as well as island requirements for frequency response.

The standard should provide the process for a technically sound calculation of frequency response and bias.

The standard should acknowledge that some units might not provide response under normal operations (e.g. nuclear units operating at full load) and that load response is highly variable event based on time of day or year.

The standard should acknowledge smaller areas need greater response.
Where BA areas are deficient in meeting the interconnection requirement , they should be allowed a reasonable period of time to take appropriate steps to make corrections before being assessed as non compliant.

The standard should also track area response over time (years) and be reevaluated as performance changes.

Quality should be defined. For generators it should include dead-band, droop characteristics, etc.

## Question 2: Do you agree with the scope and applicability of the proposed standard?

Yes
® No

## If no, please explain in the space provided below.

While we agree that the standard should not preclude market solutions (e.g. allow purchasing of response as long as deliverability and restoration criteria can be met), we have concerns with the statement There must be a means for sale/purchase of frequency response as for any other quantity. The scope should exclude any reference to a means for sale/purchase of frequency response as it should only address reliability requirements.

It is not clear what is meant by A method of allocation must be developed. Is this an allocation of Interconnection response to BAs, BA allocation to generators or something different?

The requirements should recognize the capabilities and limitations of generators (e.g. nuclear units operating at full load).

## Comments

Question 3: Do you believe these standards are more appropriately additions to existing standards as opposed to creating new standards?Yes
$\boxtimes$ No

If yes, please identify the location you believe would be the most appropriate for the proposed standard.

## Comments

If the existing Frequency Response and Bias Standard Version 0 (Bal-003-0) can not be clarified and brought in line with this proposed standard, it should be standalone .

## Question 4: Do you have any additional comments regarding the SAR that you believe should be addressed?

No
## If yes, please share those comments in the space provided below.

We appreciate the opportunity to comment and believe there is a need for such a standard.
It needs to be recognized that there are two objectives for governor response, namely, to provide response on an interconnection wide basis to maintain an acceptable frequency and secondly to control frequency in island situations. The former may allow for averaging over an area of the response requirement but the latter may limit the extent of averaging.

Published studies show frequency response is declining when it should be increasing with load. The main concerns with this decreasing performance are:

There may be areas unable to withstand severe disturbances.
Following a grid separation or collapse, control areas may be unable to fulfill their blackstart and restoration responsibilities, thereby becoming a burden to neighbors.

Because engineering models use theoretical frequency response, they are likely over optimistic and may misstate grid stability limits.

This standard would allow the industry to determine whether the decline is local or global.
Rather than implementing a complicated infrastructure or process, we would suggest that NERC automate the calculation of frequency response by either:

Asking BAs to save their CPS-source data in a common format so a common tool can be used (MAPP BAs and some others use a common tool that can calculate frequency response with CPS-source data).

Embed the calculation in the NERC ACE-monitoring application.

The standard should employ a methodology that not only captures initial response (first few seconds after the event) but also the sustained response until AGC action takes over

Providing visibility on where and when performance is substandard will likely initiate sufficient action to arrest the decline in performance. Minimum performance standards could be implemented after the industry has identified what is reasonably achievable and technically justified.

## Comment Form <br> Proposed Frequency Response Standard

This form is to be used to submit comments on the proposed Frequency Response Standard Authorization Request. Comments must be submitted by February 17, 2005. You may submit the completed form by emailing it to: sarcomm@nerc.com with the words "Frequency Response SAR Comments" in the subject line. If you have questions please contact Mark Ladrow at mark.ladrow@nerc.net or by telephone at 609-452-8060.

## ALL DATA ON THIS FORM WILL BE TRANSFERRED AUTOMATICALLY TO A DATABASE AND IT IS THEREFORE IMPORTANT TO ADHERE TO THE FOLLOWING REQUIREMENTS:

DO: Do enter text only, with no formatting or styles added. Do use punctuation and capitalization as needed (except quotations). Do use more than one form if responses do not fit in the spaces provided. Do submit any formatted text or markups in a separate WORD file.

DO NOT: Do not insert tabs or paragraph returns in any data field.
Do not use numbering or bullets in any data field.
Do not use quotation marks in any data field.
Do not submit a response in an unprotected copy of this form.

# Question 1: Do you agree there is a reliability need for a specifying the quality and quantity of frequency response? 

## If no, please explain in the space provided below.

There is a need for governors but not for frequency response.
Governors are needed to resynchronize during restoration. But the need for a short-term frequency response characteristic has been obviated by the pending Version1 Balancing Standard. That standard is designed to ensure that interconnection frequency is never at such a level that the loss of the largest contingency will cause instability or cascading outages. If the system is always in such a state why would the instantaneous response to the loss of a single contingency add to the system reliability?

The SAR has not provided any definitive need.
The SAR has not provided sufficient focus vis-à-vis who is responsible to meet the standard (the generator, the BA, the Load, the RA)

This proposal has not provided any additional information concerning the need for this proposed Standard since the last time (during the Balancing Resources and Demand consensus) that a similar Frequency Response Requirement was overwhelming rejected by those who commented to that proposal.
Transient frequency response has not been the target of any major public concern. The current Version 1 Control Standard proposal provides limits on the frequency excursions that can be controlled by system-operators and their control systems. Relays and other Protection Devices serve to protect those time frames too short for an operator to respond to. What does this standard add?

## Comments

This SAR is not clear as to what it really is intended to mandate. Does the requestor want to create a standard for Generator Owners to install governors? Or a standard on Generator Operators for individuals unit governor response? Or a standard for Balancing Authorities for Area response? Or for Reliability Authorities for Regional response? All of these are different requirements and have different effects.

The requestor must be clear as to what is intended. To ensure that frequency doesn't hit a relay limit (as in the Balancing standard?) or is it to address the need for governors when synchronizing?

When does the standard apply? All times (which means that NERC can go to a unit, BA or RA to check that some finite response is available?) Just at times when large events occur (the problem is of course whether or not the outage is near or far from the entity being checked)? Only during test conditions (since a unit under stress - 'valves wide open' has not governor response at that time even though it may have the greatest of responses at other times).

The requestor's intent may be laudable but the description is no where near ready to be considered as 'standard material'.

Question 2: Do you agree with the scope and applicability of the proposed standard?Yes
$\boxtimes$ No

If no, please explain in the space provided below.
Frequency Response characteristics should be dictated by the Reliability entities as part of their respective control services to meet the regional synchronizing requirements as well as the longer duration control standards and of the needs of the interconnection in which they operate.

## Comments

Question 3: Do you believe these standards are more appropriately additions to existing standards as opposed to creating new standards?
【 No

If yes, please identify the location you believe would be the most appropriate for the proposed standard.

## Comments

Question 4: Do you have any additional comments regarding the SAR that you believe should be addressed?
$\boxtimes$ Yes

If yes, please share those comments in the space provided below.
The SAR requestor has not provided any indication of a reliability problem. Decreasing frequency response is in and of itself not a reliability problem - more evidence is required as to the magnitude of the threat.

Any standard that is proposed, regarding frequency response, should consider both generator and load response. If Load response does provide a significant portion of the frequency response (as some people contend) then that resource must be considered in the proposal. In short the standard must make clear whether it is for interconnection response or for balancing area response or for individual generator response and individual load response.

Question 4: Do you have any additional comments regarding the SAR that you believe should be addressed?

X Yes
No

If yes, please share those comments in the space provided below.
The Standard should define the term "event" in terms of time and frequency deviation. The frequency deviation the event must fall outside the droop deadband.

## Question 1: Do you agree there is a reliability need for a specifying the quality and quantity of frequency response?

NoIf no, please explain in the space provided below.

## Comments

Trends in Eastern and Western Interconnection Turbine Governor Response and primary frequency response over the past two decades (as documented by EPRI Project RP2473-53 and Decline of Eastern Interconnection Frequency Response by Ingleson and Nagle) as well as trends in frequency error magnitude and variance over the past five years (as documented by the NERC Resources Subcommittee at URL http://www.nerc.com/~filez/rs.html) indicate that significant frequency response degradation is occurring, particularly in the Eastern Interconnection. While not yet a crisis, these trends are indicative of significant changes in design and operational practices on the interconnected electrical systems of North America which, if not managed intelligently, can cause significant degradation in reliability. I strongly urge the industry to support this SAR and begin the process of controlled management before the processes behind these trends reach crisis proportion.

Question 2: Do you agree with the scope and applicability of the proposed standard? $\boxtimes$ Yes

If no, please explain in the space provided below.

## Comments

## Question 3: Do you believe these standards are more appropriately additions to existing

 standards as opposed to creating new standards?NoIf yes, please identify the location you believe would be the most appropriate for the proposed standard.

The Frequency Response Standard could be included as part of the Balance Resources and Demand Standard.

## Comments

Since both the Frequency Response Standard and the Balance Resources and Demand Standard address frequency, they obviously must work together closely. If they are crafted, as originally intended by the Frequency Taskforce, to utilize the same CPS database, there may be savings in administrative overhead in putting them both in the same standard.

## Question 4: Do you have any additional comments regarding the SAR that you believe should be addressed?

No

## If yes, please share those comments in the space provided below.

I personally believe that the industry will be exposing the interconnected electrical systems of North America to a significant degree of reliability risk if a Frequency Response Standard similar to the one proposed by this SAR is not adopted. This risk can be mitigated somewhat by the turbine governor requirements of Standard MOD-014-1 from the Phase III/IV Standards SAR, if passed. However, the risk can be managed properly (and in the most economical manner) only on an interconnection/balancing authority basis, not on an individual generator basis as required by Standard MOD-014-1.

What is important is that the interconnections maintain sufficient frequency responsive resources to ensure the stability of interconnection frequency under first contingency conditions. The Frequency Response Standard, as proposed, sets requirements for the management and deployment of frequency responsive resources that achieve this goal without unduly interfering with the on going operation of the interconnection. I strongly urge the industry to support this SAR.

RLV

Question 2: Do you agree with the scope and applicability of the proposed standard? $\boxtimes$ Yes

If no, please explain in the space provided below.

## Comments

## Question 3: Do you believe these standards are more appropriately additions to existing

 standards as opposed to creating new standards?NoIf yes, please identify the location you believe would be the most appropriate for the proposed standard.

The Frequency Response Standard could be included as part of the Balance Resources and Demand Standard.

## Comments

Since both the Frequency Response Standard and the Balance Resources and Demand Standard address frequency, they obviously must work together closely. If they are crafted, as originally intended by the Frequency Taskforce, to utilize the same CPS database, there may be savings in administrative overhead in putting them both in the same standard.

## Question 4: Do you have any additional comments regarding the SAR that you believe should be addressed?

No

## If yes, please share those comments in the space provided below.

We believe that the industry will be exposing the interconnected electrical systems of North America to a significant degree of reliability risk if a Frequency Response Standard similar to the one proposed by this SAR is not adopted. This risk can be mitigated somewhat by the turbine governor requirements of Standard MOD-014-1 from the Phase III/IV Standards SAR, if passed. However, the risk can be managed properly (and in the most economical manner) only on an interconnection/balancing authority basis, not on an individual generator basis as required by Standard MOD-014-1.

What is important is that the interconnections maintain sufficient frequency responsive resources to ensure the stability of interconnection frequency under first contingency conditions. The Frequency Response Standard, as proposed, sets requirements for the management and deployment of frequency responsive resources that achieve this goal without unduly interfering with the on going operation of the interconnection. We strongly urge the industry to support this SAR.

## Comment Form <br> Proposed Frequency Response Standard

This form is to be used to submit comments on the proposed Frequency Response Standard Authorization Request. Comments must be submitted by February 17, 2005. You may submit the completed form by emailing it to: sarcomm@nerc.com with the words "Frequency Response SAR Comments" in the subject line. If you have questions please contact Mark Ladrow at mark.ladrow@nerc.net or by telephone at 609-452-8060.

## ALL DATA ON THIS FORM WILL BE TRANSFERRED AUTOMATICALLY TO A DATABASE AND IT IS THEREFORE IMPORTANT TO ADHERE TO THE FOLLOWING REQUIREMENTS:

DO: Do enter text only, with no formatting or styles added. Do use punctuation and capitalization as needed (except quotations). Do use more than one form if responses do not fit in the spaces provided. Do submit any formatted text or markups in a separate WORD file.

DO NOT: Do not insert tabs or paragraph returns in any data field.
Do not use numbering or bullets in any data field.
Do not use quotation marks in any data field.
Do not submit a response in an unprotected copy of this form.

## Background Information:

Posted for comments is the first posting of the Frequency Response SAR. The Frequency Task Force of the NERC Resources Subcommittee has identified the transient frequency response characteristics as degrading over time and potentially threatening the reliability of the bulk electric system. This Standard Authorization Request was initiated to address this concern by developing a standard to specify a measuring convention for frequency response and by specifying a minimum required response to system disturbances based on the convention.

The requestor would like to receive industry comments on this SAR and to obtain the input of the industry prior to determining the final scope and requirements of the SAR. Accordingly, we request your comments included on this form, emailed with the subject "Frequency Response SAR Comments" by February 17, 2005.

## Question 1: Do you agree there is a reliability need for a specifying the quality and quantity of frequency response?

No
## If no, please explain in the space provided below.

## Comments

We agree (with qualifications). Any new standards on frequency response need not and should not be onerous (identifying BAs noncompliant with less than average response or some un-validated norms).

The standard should provide the process for a sound calculation of frequency response and bias (both fixed and variable).

There may be valid reasons why a BA is below observed norms in response. It may meet most of its obligations with schedules.

Rather than generate an automatic non-compliance when response is below some benchmark, the standard should require an internal review that ensures governors are working as designed, that the BA knows which resources are frequency responsive (so the information can be included in restoration plans), whether governors can be put in more responsive modes during disturbances, etc.

The standard should have some requirements on generators if the BA is not providing the response outlined in the standard (governors should be working as designed).

The standard should also track Interconnection response over time and identify a target response (different for each Interconnection). NERC or NAESB will want to look at how this is allocated to BAs and generators.

Question 2: Do you agree with the scope and applicability of the proposed standard? $\boxtimes$ Yes

If no, please explain in the space provided below.

## Comments

Question 3: Do you believe these standards are more appropriately additions to existing standards as opposed to creating new standards?
$\boxtimes$ Yes

If yes, please identify the location you believe would be the most appropriate for the proposed standard.

Version 0 (BAL-003-0 - Frequency Response and Bias) or its successor is a logical place.
Depending on the outcome of the V1 Balance Resource and Demand standard, it could reside there.

## Comments

## Question 4: Do you have any additional comments regarding the SAR that you believe should be addressed?

No

## If yes, please share those comments in the space provided below.

We appreciate the opportunity to comment and believe there is a need for such a standard. Published studies show frequency response is declining when it should be increasing with load.

Because there is no process in place to track BA or Interconnection response, we don’t know whether the decline is local or global. Primary concerns with this decreasing performance in primary control:

1. There may be areas unable to withstand severe disturbances.
2. Following a grid separation or collapse, control areas may be unable to fulfill their blackstart and restoration responsibilities, thereby becoming a burden to neighbors.
3. Because engineering models use theoretical frequency response, they are likely overoptimistic and may misstate grid stability limits.

Rather than putting in a complicated infrastructure or process, we would suggest that NERC automate the calculation of frequency response by either:

- Asking BAs to save their CPS-source data in a common format so a common tool can be used (MAPP BAs and some others use a common tool that can calculate frequency response with CPS-source data).
- Embed the calculation in the NERC ACE-monitoring application.

The standard will need to acknowledge the large variability in individual responses at each BA due to coincident load changes and amount and mix of generation. In addition, smaller Interconnections likely need greater response.

Refer to our earlier comments the structure of the standard (where lower amounts of response trigger an internal assessment rather than assessment non-compliance). BAs (and ultimately generators) would only be initially non-compliant if their response was low AND they failed to perform the reliability assessment.

Providing visibility on where and when performance is substandard will likely initiate sufficient action to arrest the decline in performance. Minimum performance standards could be implemented after the industry has identified what is reasonably achievable and technically justified.

The standard should not preclude market solutions to providing frequency response, but such arrangements would need to be looked at closely to be sure they fulfill reliability needs.

## Background Information:

Posted for comments is the first posting of the Frequency Response SAR. The Frequency Task Force of the NERC Resources Subcommittee has identified the transient frequency response characteristics as degrading over time and potentially threatening the reliability of the bulk electric system. This Standard Authorization Request was initiated to address this concern by developing a standard to specify a measuring convention for frequency response and by specifying a minimum required response to system disturbances based on the convention.

The requestor would like to receive industry comments on this SAR and to obtain the input of the industry prior to determining the final scope and requirements of the SAR. Accordingly, we request your comments included on this form, emailed with the subject "Frequency Response SAR Comments" by February 17, 2005.

## Question 1: Do you agree there is a reliability need for a specifying the quality and quantity of frequency response?

No
## If no, please explain in the space provided below.

## Comments

Based on the NERC white paper Frequency Response Standard Whitepaper dated April 6, 2004 that was prepared by the Frequency task Force of the NERC Resources Subcommittee, it would appear that the decline in frequency response of both the Eastern and Western Interconnections is a reliability concern. As a transmission provider, however, there is probably little that can be done other than make sure that governor response and load modeling can be made as accurate as reasonably possible in conducting dynamic simulations and be aware of this issue in studying existing as well as new generating facilities. The control area, generation operators and turbinegenerator manufacturers need guidance provided as to their responsibilities and obligations regarding frequency response. Changes in the load characteristics (e.g. fewer large motors, variable speed drives, etc ) over time, plus changes in reserve sharing practices brought on by deregulation and competition are and will affect load response to frequency excursions. The type of generation (e.g. combustion turbine units, combined-cycle units) being interconnected to the system as well as the operation of the governors (e.g. blocked or improper settings) and turbines (e.g. sliding pressure, boiler-follower, etc.) of existing generators have a significant effect on the system frequency response.

Question 2: Do you agree with the scope and applicability of the proposed standard?
$\boxtimes$ Yes
No

If no, please explain in the space provided below.

## Comments

The Frequency control standard needs to address levels required for reliability, be consistent and verifiable, and be simple to monitor for compliance purposes.

Question 3: Do you believe these standards are more appropriately additions to existing standards as opposed to creating new standards?No

If yes, please identify the location you believe would be the most appropriate for the proposed standard.
II.B.S1M5, Test results of speed/load governor controls.

## Comments

It may be appropriate to include this standard in the Phase III/IV standards that address speed/load governor controls (II.B.S1M5, Test results of speed/load governor controls). The three following customer demand related standards would be helpful in defining load response to frequency excursions:
II.E.S1.M1, Plans for the evaluation and reporting of voltage \& Frequency characteristics of customer demands.

IIE.S1.M2 Documentation or requirements for determining dynamic characteristics of customer demands.
II.E.S1.M3, Customer (dynamic) demand data.

Question 4: Do you have any additional comments regarding the SAR that you believe should be addressed?
® No

If yes, please share those comments in the space provided below.

## Background Information:

Posted for comments is the first posting of the Frequency Response SAR. The Frequency Task Force of the NERC Resources Subcommittee has identified the transient frequency response characteristics as degrading over time and potentially threatening the reliability of the bulk electric system. This Standard Authorization Request was initiated to address this concern by developing a standard to specify a measuring convention for frequency response and by specifying a minimum required response to system disturbances based on the convention.

The requestor would like to receive industry comments on this SAR and to obtain the input of the industry prior to determining the final scope and requirements of the SAR. Accordingly, we request your comments included on this form, emailed with the subject "Frequency Response SAR Comments" by February 17, 2005.

## Question 1: Do you agree there is a reliability need for a specifying the quality and quantity of frequency response?

NoIf no, please explain in the space provided below.

## Comments

Trends in Eastern and Western Interconnection Turbine Governor Response and primary frequency response over the past two decades (as documented by EPRI Project RP2473-53 and Decline of Eastern Interconnection Frequency Response by Ingleson and Nagle) as well as trends in frequency error magnitude and variance over the past five years (as documented by the NERC Resources Subcommittee at URL http://www.nerc.com/~filez/rs.html) indicate that frequency response degradation is occurring, particularly in the Eastern Interconnection. While not yet a crisis, these trends are indicative of significant changes in design and operational practices on the interconnected electrical systems of North America which, if not managed intelligently, can cause degradation in reliability. We support this SAR in an effort to begin the process of controlled management before the processes behind these trends reach crisis proportion.

Question 2: Do you agree with the scope and applicability of the proposed standard? $\boxtimes$ Yes

If no, please explain in the space provided below.

## Comments

## Question 3: Do you believe these standards are more appropriately additions to existing

 standards as opposed to creating new standards?NoIf yes, please identify the location you believe would be the most appropriate for the proposed standard.

The Frequency Response Standard could be included as part of the Balance Resources and Demand Standard.

## Comments

Since both the Frequency Response Standard and the Balance Resources and Demand Standard address frequency, they obviously must work together closely. If they are crafted, as originally intended by the Frequency Taskforce, to utilize the same CPS database, there may be savings in administrative overhead in putting them both in the same standard.

## Question 4: Do you have any additional comments regarding the SAR that you believe should be addressed?

No
## If yes, please share those comments in the space provided below.

It is believed that the industry will be exposing the interconnected electrical systems of North America to a significant degree of reliability risk if a Frequency Response Standard similar to the one proposed by this SAR is not adopted. This risk can be mitigated somewhat by the turbine governor requirements of Standard MOD-014-1 from the Phase III/IV Standards SAR, if passed. However, the risk can be managed properly (and in the most economical manner) on an interconnection/Balancing Authority basis, not on an individual generator basis as required by Standard MOD-014-1.

The governor response in MW for generators is not just dependent on the governor droop and dead-band settings, but on the design of the plant control system (sliding pressure boiler, nuclear pressurized water reactor, etc.). For example, nuclear plant operators must control reactivity changes in the core and generally cannot allow external controls to increase or decrease power levels on demand. This standard should take such factors into account and address frequency \& MW response at the Balancing Authority level, not at the individual generator level.

What is important is that the interconnections maintain sufficient frequency responsive resources to ensure the stability of interconnection frequency under first contingency conditions. The Frequency Response Standard, as proposed, sets requirements for the management and deployment of frequency responsive resources that achieve this goal without unduly interfering with the on going operation of the interconnection. We support this SAR.

## Background Information:

Posted for comments is the first posting of the Frequency Response SAR. The Frequency Task Force of the NERC Resources Subcommittee has identified the transient frequency response characteristics as degrading over time and potentially threatening the reliability of the bulk electric system. This Standard Authorization Request was initiated to address this concern by developing a standard to specify a measuring convention for frequency response and by specifying a minimum required response to system disturbances based on the convention.

The requestor would like to receive industry comments on this SAR and to obtain the input of the industry prior to determining the final scope and requirements of the SAR. Accordingly, we request your comments included on this form, emailed with the subject "Frequency Response SAR Comments" by February 17, 2005.

## Question 1: Do you agree there is a reliability need for a specifying the quality and quantity of frequency response?

No
## If no, please explain in the space provided below.

## Comments

There is a reliability need but it is not an immediate reliability need for all of the interconnections. The amount of Frequency Response on the Texas Interconnection is close to the minimum acceptable amount, and therefore, there is an immediate need for a FRS on the Texas Interconnection. On the Western Interconnection, the WECC keeps close tabs on Frequency Response and takes immediate action when a problem arises with frequency response on that interconnection. Although there is no immediate need for a Frequency Response Standard on the Western Interconnection at this time, the observed reductions in Frequency Response on that interconnection make this issue an ongoing concern. Finally, there is no current need for a Frequency Response Standard on the Eastern Interconnection because current Frequency Response is adequate. However, it takes significant time to develop an effective standard and put it in place. The Balancing Resources and Demand Standard is entering its fourth year of development with expectations of at least another year before implementation. A Frequency Response Standard would be expected to take a similar period to develop. That means that it will be at least 2010 before a new FRS would be put in place. There is no question that adequate Frequency Response is required for reliability. There is no question that Frequency Response on the Eastern Interconnection is declining. There are two paths of action available; 1) Wait until adequate Frequency Response causes reliability problems and then begin the five year process to develop a standard; 2) Begin development of a FRS and determine the final need for implementation during the five year development process. I would rather have a standard that requires measurement that does not result in enforcement action, and therefore, has no effect on operations, than not have a standard when there are definite reliability problems. It will be much easier to implement a standard for Frequency Response before reliability problems occur than to implement a standard after reliability problems occur. NERC should develop a Frequency Response Standard and continue to investigate the need for the standard during its development.

# Question 2: Do you agree with the scope and applicability of the proposed standard? 

Y Yes

If no, please explain in the space provided below.

## Comments

Planning standards are not enough by themselves. Without continuous measurement, there can be no assurance that those responsible for meeting the reliability need for Frequency Response are fulfilling those responsibilities. Only a Frequency Response Standard that continuously measures response can insure that the response is available when required.

## Question 3: Do you believe these standards are more appropriately additions to existing

 standards as opposed to creating new standards?NoIf yes, please identify the location you believe would be the most appropriate for the proposed standard.

Frequency Response is closely related to the Frequency Bias used in the Balancing Resources and Demand Standard and therefore this standard should be included as an addition to that standard. If it is not included in the BRD Standard, a separate standard would require coordination between the two standards. This would make the process of updating the standards more complex.

## Comments

Question 4: Do you have any additional comments regarding the SAR that you believe should be addressed?

If yes, please share those comments in the space provided below.
NERC has the responsibility of maintaining reliability on the North American Interconnections.
NERC cannot perform that function effectively if it waits for reliability problems to become apparent in system operations before it takes actions to address those problems. NERC must be a forward looking organization that anticipates future reliability problems and takes actions to resolve those problems before they affect interconnection reliability.

## Comment Form <br> Proposed Frequency Response Standard

This form is to be used to submit comments on the proposed Frequency Response Standard Authorization Request. Comments must be submitted by February 17, 2005. You may submit the completed form by emailing it to: sarcomm@nerc.com with the words "Frequency Response SAR Comments" in the subject line. If you have questions please contact Mark Ladrow at mark.ladrow@nerc.net or by telephone at 609-452-8060.

## ALL DATA ON THIS FORM WILL BE TRANSFERRED AUTOMATICALLY TO A DATABASE AND IT IS THEREFORE IMPORTANT TO ADHERE TO THE FOLLOWING REQUIREMENTS:

DO: Do enter text only, with no formatting or styles added. Do use punctuation and capitalization as needed (except quotations). Do use more than one form if responses do not fit in the spaces provided. Do submit any formatted text or markups in a separate WORD file.

DO NOT: Do not insert tabs or paragraph returns in any data field.
Do not use numbering or bullets in any data field.
Do not use quotation marks in any data field.
Do not submit a response in an unprotected copy of this form.

## Background Information:

Posted for comments is the first posting of the Frequency Response SAR. The Frequency Task Force of the NERC Resources Subcommittee has identified the transient frequency response characteristics as degrading over time and potentially threatening the reliability of the bulk electric system. This Standard Authorization Request was initiated to address this concern by developing a standard to specify a measuring convention for frequency response and by specifying a minimum required response to system disturbances based on the convention.

The requestor would like to receive industry comments on this SAR and to obtain the input of the industry prior to determining the final scope and requirements of the SAR. Accordingly, we request your comments included on this form, emailed with the subject "Frequency Response SAR Comments" by February 17, 2005.

## Question 1: Do you agree there is a reliability need for a specifying the quality and quantity of frequency response?

No
## If no, please explain in the space provided below.

## Comments

These are my individual comments as a member of the NERC Resources subcommittee and not those of representing any organization.

There is a reliability need for a light-handed standard that allows us to do a better job of ensuring response is available when required. As some entities might comment, there is adequate response in all interconnections during "system normal" conditions. The problem is what occurs during major disturbances and restoration.

A primary reason the industry needs to do a better job of tracking frequency response is the fact that response is declining when it should actually be increasing with load and generation growth.

The standard should not be structured such that it finds BAs noncompliant if response is below average or if response is low for a given event. Frequency response at the BA level is extremely variable as the measure is mingled with load fluctuation.

The standard should guide a technically sound calculation of response at the BA level and track interconnection performance over time to enable informed decisions.

If a BA performs significantly below an Interconnection norm, the standard should require the BA do an internal assessment of its key generation to verify governors are working as designed and that there will be frequency responsive resources for disturbances and restoration.

If Interconnection response significantly changes over time, the standard should be reevaluated.

Question 2: Do you agree with the scope and applicability of the proposed standard?
$\boxtimes$ YesNo

If no, please explain in the space provided below.
I agree, with some qualification. While the standard shouldn't preclude market solutions, I don't think it must enable a market as the scope implies. A little more clarity on the goals of the standard is needed.

## Comments

Question 3: Do you believe these standards are more appropriately additions to existing standards as opposed to creating new standards?
$\boxtimes$ Yes

If yes, please identify the location you believe would be the most appropriate for the proposed standard.

## Comments

It's not a major issue. It appears it should be include in the Version 0 (BAL-003-0 - Frequency Response and Bias).

## Question 4: Do you have any additional comments regarding the SAR that you believe should be addressed?

No
## If yes, please share those comments in the space provided below.

Thanks for the opportunity to comment. I hope the SAC puts all comments in perspective. We are in a period where the industry is reluctant to adopt new standards that generate extra work and compliance exposure. The reliability of the Interconnections can benefit with minimal impact to most BAs with a light-handed standard.

Rather than implementing a complicated process, why not embed most of the effort in the NERC ACE-monitoring application? Only those BAs with unusually low response would need to drill down and do an internal assessment to determine their ability to withstand disturbances and whether they have responsive resources for blackstart.

Knowing where and when performance is substandard will likely arrest the decline in performance. Minimum performance standards could be implemented once the industry has identified what is reasonably achievable and technically justified.

## Comment Form <br> Proposed Frequency Response Standard

## Background Information:

Posted for comments is the first posting of the Frequency Response SAR. The Frequency Task Force of the NERC Resources Subcommittee has identified the transient frequency response characteristics as degrading over time and potentially threatening the reliability of the bulk electric system. This Standard Authorization Request was initiated to address this concern by developing a standard to specify a measuring convention for frequency response and by specifying a minimum required response to system disturbances based on the convention.

The requestor would like to receive industry comments on this SAR and to obtain the input of the industry prior to determining the final scope and requirements of the SAR. Accordingly, we request your comments included on this form, emailed with the subject "Frequency Response SAR Comments" by February 17, 2005.

## Question 1: Do you agree there is a reliability need for a specifying the quality and quantity

 of frequency response?$\mathrm{X} \square$ Yes

If no, please explain in the space provided below.

## Comments

There may be a reliability need in the near future. The Whitepaper does an excellent job of making that case. For the purpose of commenting on a SAR that has not yet produced a proposed Standard, I can give it the benefit of the doubt and say yes, there is reliability need.

## Question 2: Do you agree with the scope and applicability of the proposed standard?

Yes$\mathrm{X} \square$ No

## If no, please explain in the space provided below.

Quoted from the SAR (with corrections): This SAR is proposed to develop a standard to measure sub-minute responses to changes in frequency and to set minimum acceptable responses of the system to these events. Also quoted: The measurement selected must be accurate and, to the extent practical, easy to implement. This seems more like a research project than a request for a standard. There is no mention of any possible measurements that might be in the standard. I'm afraid that proceeding with such a vague idea of a measurement will lead the SAR or later Standard to become bogged down with research and field testing even more so than the Balance Load and Demand Standard. And Balance Load and Demand did have definite measurements in mind, thereby not requiring much research, mainly field testing. Come back with a SAR after the research is done, or at least started.

## Comments

Question 3: Do you believe these standards are more appropriately additions to existing standards as opposed to creating new standards?Yes
$\mathrm{X} \square$ No

If yes, please identify the location you believe would be the most appropriate for the proposed standard.

## Comments

Adding this requirement to another standard would only slow down the progress of both.

Question 4: Do you have any additional comments regarding the SAR that you believe should be addressed?
$\mathrm{X} \square$ Yes

If yes, please share those comments in the space provided below.
It appears Frequency Response is an accepted term used for this requirement, and therefore might be difficult to change. However, Frequency Response is not a very good description of the requirement. A term such as Transient Generator and Load Response would be more descriptive.

## Comment Form <br> Proposed Frequency Response Standard

## Background Information:

Posted for comments is the first posting of the Frequency Response SAR. The Frequency Task Force of the NERC Resources Subcommittee has identified the transient frequency response characteristics as degrading over time and potentially threatening the reliability of the bulk electric system. This Standard Authorization Request was initiated to address this concern by developing a standard to specify a measuring convention for frequency response and by specifying a minimum required response to system disturbances based on the convention.

The requestor would like to receive industry comments on this SAR and to obtain the input of the industry prior to determining the final scope and requirements of the SAR. Accordingly, we request your comments included on this form, emailed with the subject "Frequency Response SAR Comments" by February 17, 2005.

## Question 1: Do you agree there is a reliability need for a specifying the quality and quantity of frequency response?

No
## If no, please explain in the space provided below.

## Comments

The CPS1 equation is a single equation in two variables, primary (governor) response and secondary response. Two variables require two equations in order to have a unique solution. That second equation does not currently exist and must be the proposed Frequency Response standard that pins down the value of primary (governor) response. Currently, the single CPS1 equation allows any Balancing Authority an infinity of solutions for any given CPS1 value. Accordingly, Balancing Authorities have been tending to reduce expensive primary response and increase cheaper secondary response (AGC, regulation, load following) to achieve a given CPS1 score, which is an average over time. The result has been a halving of system bias in the Eastern Interconnection and the rest of the case made for the standard in the supporting White Paper.

Question 2: Do you agree with the scope and applicability of the proposed standard?

```
Yes
```

If no, please explain in the space provided below.

## Comments

## Question 3: Do you believe these standards are more appropriately additions to existing

 standards as opposed to creating new standards?】 No

If yes, please identify the location you believe would be the most appropriate for the proposed standard.

## Comments

The SAR acknowledges that the proposed Standard not only is complementary to the Balancing Resources and Demand Standard, but also must be coordinated with that Standard. The two standards could be combined. But that is insufficient reason to oppose development of a separate Frequency Response Standard. Moreover, combining the standards would reverse the great progress made in consensus on the Balancing Resources and Demand Standard.

Question 4: Do you have any additional comments regarding the SAR that you believe should be addressed?
® No

If yes, please share those comments in the space provided below.

## Background:

The Frequency Response SAR drafting team thanks all commenters who submitted comments on the first draft of the Frequency Response SAR. The SAR was posted for comment from January 17 - February 17, 2005. The SAR drafting team asked stakeholders to provide feedback on the SAR through a special SAR Comment Form. There were 30 sets of comments.

Based on the comments received, the drafting team has revised the SAR and is reposting it for an additional 30-day comment period

In this 'Consideration of Comments' document, stakeholder comments have been organized so that it is easier to see the summary of changes being requested of the SAR. All comments received on the first draft of the Frequency Response SAR can be viewed in their original format at:
ftp://www.nerc.com/pub/sys/all_updl/standards/sar/Frequency_Response_SAR_Comments_02_17_05.pdf
If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Gerry Cauley at 609-452-8060 or at gerry.cauley@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process. ${ }^{1}$

4. Do you have any additional comments regarding the SAR that you believe should be addressed? 28

## 1. Do you agree there is a reliability need for specifying the quality and quantity of frequency response?

Summary Consideration: Most commenters agreed that there is a reliability need to specify the quality and quantity of frequency response.

| Commenter | Yes | No | Comment |
| :---: | :---: | :---: | :---: |
| MAAC Staff (2) <br> Al DiCaprio - MAAC (2) <br> Joe Willson - MAAC (2) <br> Mark Kuras - MAAC (2) |  | $\checkmark$ | There is a need for governors but not for frequency response. Governors are needed to resynchronize during restoration. But the need for a short-term frequency response characteristic has been obviated by the pending Version1 Balancing Standard. That standard is designed to ensure that interconnection frequency is never at such a level that the loss of the largest contingency will cause instability or cascading outages. If the system is always in such a state why would the instantaneous response to the loss of a single contingency add to the system reliability? <br> The SAR has not provided any definitive need. <br> The SAR has not provided sufficient focus vis-à-vis who is responsible to meet the standard (the generator, the BA, the Load, the RA) <br> This proposal has not provided any additional information concerning the need for this proposed Standard since the last time (during the Balancing Resources and Demand consensus) that a similar Frequency Response Requirement was overwhelming rejected by those who commented to that proposal. Transient frequency response has not been the target of any major public concern. The current Version 1 Control Standard proposal provides limits on the frequency excursions that can be controlled by system-operators and their control systems. Relays and other Protection Devices serve to protect those time frames too short for an operator to respond to. What does this standard add? <br> Comments <br> This SAR is not clear as to what it really is intended to mandate. Does the requestor want to create a standard for Generator Owners to install governors? Or a standard on Generator Operators for individuals unit governor response? Or a standard for Balancing Authorities for Area response? Or for Reliability Authorities for Regional response? All of these are different requirements and have different effects. <br> The requestor must be clear as to what is intended. To ensure that frequency doesn't hit a relay limit (as in the Balancing standard?) or is it to address the need for governors when synchronizing? <br> When does the standard apply? All times (which means that NERC can go to a unit, BA or RA to check that some finite response is available?) Just at times when large events occur (the problem is of course whether or not the outage is near or far from the entity being checked)? Only during test conditions (since a unit under stress - 'valves wide open' has not governor response at that time - even though it may have the greatest of |

| Commenter | Yes | No | Comment |
| :---: | :---: | :---: | :---: |
|  |  |  | responses at other times). <br> The requestor's intent may be laudable but the description is no where near ready to be considered as 'standard material'. |
| Response: The dra many of the questio agree that the stand revised SAR. While we don't know how purpose of this stan problem. <br> We disagree that th states. The standard rror the metrics within its boundaries (evaluate generators and <br> sh a large set of arbitrary requirements, but will establish the make informed engineering decisions. <br> cted. |
| BPA <br> Bart McManus Brian Tuck James Randall Francis Halpin Bill Mittlestat James Murphy |  | $\checkmark$ | NERC should not involve itself in the development of these standards and should allow individual interconnections to address frequency response issues independently. For example, the WECC is currently working on standards that will address this concern. They will be tailored to the specific requirements of this interconnection and will provide the best possible solution to the problem. There may be a need to specify frequency response requirements within some interconnections; however, it is not necessary, or most effective for them to be defined at the NERC level. |

Response: The Resources Subcommittee Frequency Task Force agrees that frequency response is primarily an Interconnection issue and, as envisioned, the proposed standard would accommodate Interconnection differences both in amounts of response and methodology in calculating response. The standard would identify technical and engineering principles that should be met to calculate and evaluate the amount and distribution of frequency response within each Interconnection. The drafting team believes that stakeholders would prefer the assurance of knowing that NERC is providing oversight to ensure that all Interconnections have a technically sound basis for the development of respective frequency response requirements.

| FRCC (2) <br> Linda Campbell <br> Ron Donahey - TEC (1) <br> Mark Bennett - GRU (3) <br> Steve Wallace - SEC (5) <br> S. McElhaney - FMPA (5) <br> Ted Hobson - JEA (1) | $\checkmark$ | The FRCC does not support the development of a Frequency Response Standard at this time. A standard for each Interconnection, although informative would be unenforceable as far as identifying short term, frequency response deficient, entities or areas. As such measurability and compliance by the relevant entities would be all but impossible. As far as an Interconnection allocation program for frequency response, we feel that the "apparent" decline in response is not significant enough to warrant a standard at this time and we would require additional details of how such a plan would be implemented and the potential economic impacts on the Regions that would be |
| :---: | :---: | :---: |

| Commenter | Yes | No | Comment |
| :---: | :---: | :---: | :---: |
|  |  |  | associated with that plan. |
| Response: The standard as envisioned does not mandate a specific amount of frequency response. With regard to the "apparent" decline in frequency response, the most widely published report (Ingleson and Nagle, 1999) documented a change in Eastern Interconnection response from $3750 \mathrm{MW} / 0.1 \mathrm{~Hz}$ in 1994 to $3390 \mathrm{MW} / 0.1 \mathrm{~Hz}$ in 1998. The Resources Subcommittee evaluation of 44 events in 2005 showed an average frequency response well below $3000 \mathrm{MW} / 0.1 \mathrm{~Hz}$. Theoretically, response should be increasing over time with increasing load and generation in an Interconnection. One of the primary reasons for the standard is to enable a better analysis of response and also enable informed decisions. As envisioned, the standard will provide a fairly simple methodology to verify compliance. |  |  |  |

Yeung - SPP (2) | $\checkmark$ | $\checkmark$ | We agree in general that there is a reliability need to have frequency response, particularly during disturbances, islanding and restoration. The standard should provide the process for a technically sound calculation of frequency response and bias (both fixed and variable). <br> Any new standards on frequency response need not and should not be onerous by finding BAs noncompliant with response less than average or below some un-validated norms. <br> If performance is significantly less than an Interconnection norm, the standard should not trigger an automatic non-compliance. In these situations the BA should perform an internal review/assessment that ensures governors are working as designed, that the BA knows which resources are frequency responsive (so the information can be included in restoration plans), whether governors can be triggered to be more responsive during disturbances, etc and satisfy the Interconnection requirement. If the Interconnection requirement is not met within a reasonable timeframe then the BA should be deemed as non-compliant. <br> When required, the validation of governor performance could be achieved either through online monitoring in an EMS or periodic testing (both methods should be explained in a reference document to support the standard). <br> The standard should acknowledge that some units might not provide response under normal operations (e.g. nuclear units operating at full load) and that response is highly variable event-to-event based on simultaneous load changes. <br> The standard should acknowledge the differing Interconnection requirements (smaller Interconnections need greater response). <br> The standard should also track Interconnection and BA areas response over time (years) and be reevaluated as performance changes. |

Response: The Resources Subcommittee Frequency Task Force agrees with these comments as a whole. As envisioned, the standard would not mandate a given amount of response, but would require

| Commenter | Yes | No | Comment |
| :---: | :---: | :---: | :---: |
| an analysis if response were measurably below the norm (this detail has been added to the detailed description in the SAR). <br> There is another standard under development, (Phase III \& IV MOD-027 - Verification and Status of Generator Frequency Response) that requires Generator Owners to verify that their governors are working as designed. <br> The standard would accommodate the simplification ideas you propose, and in fact, if data is saved in a common format, the Resources Subcommittee Frequency Task Force has a tool that could calculate the BA's performance to the standard. <br> The SAR was also changed to reflect the suggestions to accommodate: <br> - Both fixed and variable bias. <br> - Cases where a specific unit (e.g. nuclear) is prohibited from providing frequency response. <br> - Differing Interconnection needs. |  |  |  |
| CAISO (2) <br> Ed Riley <br> Yuri Makarov <br> Steve McCoy | $\checkmark$ |  | Frequency response provided by speed governors and loads helps to prevent load shedding and generator trips at significant frequency excursions caused by sudden active power mismatches in the systems. Without a sufficient frequency response emerging during the first seconds after a frequency disturbance, there is a danger of further cascading development or frequency instability and system collapse cased by underfrequency generator trips. It has been already noted that insufficient frequency response in some parts of an Interconnection may cause certain temporary redistribution of power flows and reduce stability margins after frequency disturbances that may limit the OTC on critical paths within the Interconnection. It has been also observed that insufficient frequency response may cause a weaker frequency recovery that bears a greater risk of system collapse at subsequent frequency disturbances. Therefore, frequency response is definitely a reliability issue that needs to be addressed by a NERC standard. |

Response: The Resources Subcommittee Frequency Task Force agrees that there are several issues that must be addressed in the standard or in supporting business practices. As envisioned, the proposed standard would not be prescriptive with regard to "how much" and "where" the response is carried.

| Manitoba Hydro (1, 3, 5, 6) <br> Gerald Rheault | $\checkmark$ |  | Manitoba Hydro, from a reliability perspective, supports the idea of specifying the quantity and quality of frequency response and incorporating these elements in a Standard. However, the development of this standard should not be rushed since the evidence provided in the Standard Authorization Request form and in the Frequency Response Standard White paper shows that current frequency response and projected frequency response trends do not pose a significant potential for compromising system reliability and for major under-frequency load shedding to occur in the near term. <br> Also in the section of the white paper which examines "frequency response standard considerations", a broad scope and outline is given, more detail is required especially regarding methods of ensuring compliance. <br> In paragraph 2, page 9 of the white paper where the current frequency response of the Eastern Interconnection is stated as $3100 \mathrm{MW} / 0.1 \mathrm{~Hz}$ with a standard deviation of $1870 \mathrm{MW} / 0.1 \mathrm{~Hz}$ and the statement is made that "the fact that an under-frequency |
| :---: | :---: | :---: | :---: |

| Commenter | Yes | No | Comm |
| :---: | :---: | :---: | :---: |
|  |  |  | event has not happened yet is only coincidence" requires much more detailed information regarding the origin and calculations of these numbers before these assumptions can be made. Could it be that instead of a frequency response closer to 1230MW/ 0.1 Hz it is actually practically closer to $3100 \mathrm{MW} / 0.1 \mathrm{~Hz}$ or even $4970 \mathrm{MW} / 0.1 \mathrm{~Hz}$ most of the time? <br> One understandable major concern addressed in the white paper is the response of combined-cycle units to frequency decline and the fact that due to a drop in combustion air volume their output may actually decrease with a drop in frequency or even result in unit tripping. Also there was concern with the possibility that larger amounts of these types of units will be installed on the system thereby potentially increasing the decline in frequency response rate from $70 \mathrm{MW} / 0.1 \mathrm{~Hz} / \mathrm{Year}$ (Eastern Interconnection). <br> It is also mentioned (on page 10) that with proper tuning combined cycle units can provide correct frequency response. Maybe part of the focus should be on finding ways of enforcing the Current Requirements (Page 14) and including specific frequency response requirements for combined-cycle units. |
| Response: The Resources Subcommittee Frequency Task Force agrees that the standard should not rush to a decision on the amount and location of frequency response, but should set the framework for making informed decisions. Frequency response is needed for more than protection against UFLS. <br> Response is also needed during disturbances and restoration. With regard to "current requirements", the Whitepaper listed what existed in NERC Policy, mostly as guides. There is very little in the V0 Standards regarding governors or frequency response. We agree that the standard should not impose unreasonable costs to demonstrate compliance. We agree that frequency response should be monitored both at the BA and Interconnection level. <br> Characterizing how frequency response changes under varying interconnection load and unit commitment conditions will be addressed by a sampling methodology. <br> The drafting team is pursuing the addition of functionality in the "NERC -ACE monitoring application" that will identify generator trips and automate the calculation of Interconnection frequency response. Evidence to date indicates that frequency response declines significantly during light load periods, even though the exact mechanism for this is not well defined. Most of the major frequency excursions experienced in the Eastern Interconnection have occurred during the shoulder period of the year during either the early morning or late evening periods. <br> Regarding the last comment, there currently are no governor or frequency response requirements for generators. |  |  |  |

| The standard should have some requirements on generators if |  |  |  |
| the BA is not providing the response outlined in the standard |  |  |  |
| (governors should be working as designed). |  |  |  |$\}$| The standard should also track Interconnection response over |
| :--- |
| time and identify a target response (different for each |
| Interconnection). NERC or NAESB will want to look at how this is |
| allocated to BAs and generators. |

Response: The Resources Subcommittee Frequency Task Force agrees with these comments as a whole. As envisioned the proposed standard would not mandate a given amount of response, but would require an analysis if response is measurably below the norm. As envisioned the proposed standard is would acknowledge the variability inherent in measuring frequency response and would provide two methods of capturing sufficient samples to make an objective measurement. The standard would not preclude market solutions. The SAR detailed description has been expanded to state that the standard will include a sound calculation for measuring frequency response with consideration of interconnection specifics. Another detail added to the SAR requires generator units with nameplate ratings of 10 MW or greater to be equipped with governors. There is another standard under development, (Phase III \& IV MOD-027 - Verification and Status of Generator Frequency Response) that requires Generator Owners to verify that their governors are working as designed. Finally, the SAR was modified to accommodate both fixed and variable bias.

| Southern Company Transmission, Operations, Planning and EMS Divisions (1) <br> Marc Butts <br> Steve Corbin <br> Jim Viikinsalo <br> Jim Griffith <br> Doug McLaughlin <br> Monroe Landrum | $\checkmark$ | Trends in Eastern and Western Interconnection Turbine Governor Response and primary frequency response over the past two decades (as documented by EPRI Project RP2473-53 and Decline of Eastern Interconnection Frequency Response by Ingleson and Nagle) as well as trends in frequency error magnitude and variance over the past five years (as documented by the NERC Resources Subcommittee at URL http://www.nerc.com/~filez/rs.html) indicate that significant frequency response degradation is occurring, particularly in the Eastern Interconnection. While not yet a crisis, these trends are indicative of significant changes in design and operational practices on the interconnected electrical systems of North America which, if not managed intelligently, can cause significant degradation in reliability. We strongly urge the industry to support this SAR and begin the process of controlled management before the processes behind these trends reach crisis proportion. |

|  |  |  | governors (e.g. blocked or improper settings) and turbines (e.g. sliding pressure, boiler-follower, etc.) of existing generators have a significant effect on the system frequency response. |
| Response: The Resources Subcommittee Frequency Task Force agrees with your technical comments in support of this standard. The team also supports the development of the planning "MOD" standards that address frequency response at the generator level. |  |  |  |
| NERC Frequency Task Force Raymond L. Vice, Chairman | $\checkmark$ |  | Trends in Eastern and Western Interconnection Turbine Governor Response and primary frequency response over the past two decades (as documented by EPRI Project RP2473-53 and Decline of Eastern Interconnection Frequency Response by Ingleson and Nagle) as well as trends in frequency error magnitude and variance over the past five years (as documented by the NERC Resources Subcommittee at URL http://www.nerc.com/~filez/rs.html) indicate that significant frequency response degradation is occurring, particularly in the Eastern Interconnection. While not yet a crisis, these trends are indicative of significant changes in design and operational practices on the interconnected electrical systems of North America which, if not managed intelligently, can cause significant degradation in reliability. I strongly urge the industry to support this SAR and begin the process of controlled management before the processes behind these trends reach crisis proportion. |
| Response: The Resources Subcommittee Frequency Task Force agrees with these comments. |  |  |  |
| Robert Blohm | $\checkmark$ |  | The CPS1 equation is a single equation in two variables, primary (governor) response and secondary response. Two variables require two equations in order to have a unique solution. That second equation does not currently exist and must be the proposed Frequency Response standard that pins down the value of primary (governor) response. Currently, the single CPS1 equation allows any Balancing Authority an infinity of solutions for any given CPS1 value. Accordingly, Balancing Authorities have been tending to reduce expensive primary response and increase cheaper secondary response (AGC, regulation, load following) to achieve a given CPS1 score, which is an average over time. The result has been a halving of system bias in the Eastern |

| Commenter | Yes | No | Comment |
| :--- | :--- | :--- | :--- |
| G. Campoli - NYISO (2) |  |  |  |
| Response: The Resources Subcommittee Frequency Task Force will add LSE to the standard's <br> applicability list. |  | $\checkmark$ | Quoted from the SAR (with corrections): This SAR is proposed <br> to develop a standard to measure sub-minute responses to <br> changes in frequency and to set minimum acceptable responses <br> of the system to these events. Also quoted: The measurement <br> selected must be accurate and, to the extent practical, easy to <br> implement. This seems more like a research project than a <br> request for a standard. There is no mention of any possible <br> John Horakh <br> measurements that might be in the standard. I'm afraid that <br> proceeding with such a vague idea of a measurement will lead <br> the SAR or later Standard to become bogged down with <br> research and field testing even more so than the Balance Load <br> and Demand Standard. And Balance Load and Demand did <br> have definite measurements in mind, thereby not requiring much <br> research, mainly field testing. Come back with a SAR after the <br> research is done, or at least started. |

Response: The Resources Subcommittee Frequency Task Force agrees that the whitepaper bears some resemblance to the description for a research project. Many in the industry are concerned with the decline in Frequency Response, while at the same time some are asking how much of a problem is the decline in response. The drafting team's goal is to put the infrastructure and process in place to make informed decisions in the future and to allow the Regions to evaluate the distribution and adequacy of response and take mitigating action if there are areas found to be deficient. The Resources Subcommittee Frequency Task Force disagrees with delaying the standard development. The SAR will define the scope of the standard. The specific detailed requirements and measures will be developed by the standard drafting team.

| TVA (1) <br> Kathie Davis <br> Larry Akens Mitch Needham Chuck Feagans Ed Forsythe |  | If the purpose is to purchase frequency response, then the Market Operator needs to be includes. Will this be considered an Ancillary Service? <br> Others that may need to be involved are Transmission Service Provider, Generator Owner, Planning Authority and Resource Planner. <br> Applicability should include \#2 |
| :---: | :---: | :---: |
| Response: The Resources Subcommittee Frequency Task Force agrees that others have roles in providing Frequency Response, but have focused on the higher level calculation of response at the balancing authority and Interconnection level. The primary reason for this is that there are about 150 balancing authorities. Only those balancing authorities with sub-normal response need to investigate to the generator level. The NERC 2002 Generating Unit Statistical Brochure identifies 3694 generators of 1 MW or greater. It would be difficult (and unnecessary if the BA has good response) to monitor thousands of generators with this standard. The standard doesn't preclude market solutions, which NAESB may adopt. The Resources Subcommittee Frequency Task Force agrees with the comment to include \#2 in the SAR. |  |  |
| ISO/RTO Standards <br> Review Committee (2) <br> K. Tammar - NYISO (2) <br> D. McMaster - AESO (2) <br> Ed Riley - CAISO (2) <br> Sam Jones - ERCOT (2) |  | There is a general need for a standard, but the outcomes and expectations should address the comments raised in question 1 While we agree that the standard should not preclude market solutions (e.g. allow purchasing of response as long as deliverability and restoration criteria can be met), we have concerns with the statement There must be a means for sale/purchase of frequency response as for any other quantity. |

| Reliability Authorities, Balancing Authorities, and Generator |  |  |  |$\}$

| Commenter | Yes | No | Comment |
| :---: | :---: | :---: | :--- |
|  |  |  | Operators. However, substantial questions remain as to how <br> the responsibilities implied in the proposed standard will be <br> equitably distributed. |

Response: The Resources Subcommittee Frequency Task Force appreciates your comment. The new standard for verifying generator governor controls will be under field test through part of 2007 and then will be finalized, balloted and then implemented. The implementation plan for MOD-027 includes additional time for entities to become compliant with the requirements. This would mean that any work on this standard could be delayed for several years. With the decline in Eastern Interconnection frequency response, the drafting team thinks it would be unwise to wait for the new standards to be developed and reviewed before developing this standard.
Your questions regarding the applicability of the responsibilities will be better defined during the standard drafting phase of this standard.

| :---: | :---: | :---: | :---: |
| MAAC Staff (2) <br> AI DiCaprio - MAAC (2) <br> Joe Willson - MAAC (2) <br> Mark Kuras - MAAC (2) | $\checkmark$ |  | The SAR requestor has not provided any indication of a reliability problem. Decreasing frequency response is in and of itself not a reliability problem - more evidence is required as to the magnitude of the threat. <br> Any standard that is proposed, regarding frequency response, should consider both generator and load response. If Load response does provide a significant portion of the frequency response (as some people contend) then that resource must be considered in the proposal. In short the standard must make clear whether it is for interconnection response or for balancing area response or for individual generator response and individual load response. |
| Response: Most commenters indicated that they feel that there is a reliability-related need for a standard to address Frequency Response. <br> The standard is not intended to establish a large set of arbitrary requirements, but will establish the framework to collect the information to make informed engineering decisions. Additional detail has been added to the SAR's Purpose/Industry Need and the Detailed Description. The revised SAR does not specifically consider load response but does state that the proposed standard will include requirements for the Interconnection response, for the installation of governors and for BAs to operate their automatic generation control function on tie-line frequency bias and for BAs to respond to requests for information on frequency response. The revised SAR does not include requirements for generators to provide response and does not address load response. |  |  |  |
| BPA <br> Bart McManus Brian Tuck James Randall Francis Halpin Bill Mittlestat James Murphy | $\checkmark$ |  | Frequency response requirements are likely different for each of the three interconnected regions and a generalized approach will likely not meet WECC needs. The danger here is that a NERCwide approach may not be compatible with the needs of a regional approach. Standards are currently being developed within WECC to address the frequency response concerns of this interconnection. We feel that if the Eastern Interconnection needs a Frequency Response Standard, they should utilize the NERC Frequency Response Standard Whitepaper to draft an Eastern Interconnection-specific Frequency Response Standard. |

Response: The Resources Subcommittee Frequency Task Force agrees that frequency response is primarily an Interconnection issue and the proposed standard accommodates Interconnection differences both in amounts of response and methodology in calculating response. As noted in and earlier response, we would expect some general technical and engineering principles that should be met in order to calculate and evaluate the amount and distribution of frequency response. Additional SAR Detailed Description details have been added.
The drafting team believes that stakeholders would prefer the assurance of knowing that NERC is providing oversight to ensure that all Interconnections have a technically sound basis for the development of respective frequency response requirements.

| Manitoba Hydro (1, 3, 5, <br> $6)$ <br> Gerald Rheault | $\checkmark$ |  | Below are a few general comments on the SAR: <br> There is general agreement with the statement "reliance on load <br> as the sole support to arrest the frequency can lead to a decline <br> in the reliability of the grid" in paragraph 3, page 4 of the white <br> paper. However enough information is not provided to |

| Providing visibility on where and when performance is |  |  |  |
| substandard will likely initiate sufficient action to arrest the |  |  |  |
| decline in performance. Minimum performance standards could |  |  |  |
| be implemented after the industry has identified what is |  |  |  |
| reasonably achievable and technically justified. |  |  |  |$\}$| The standard should not preclude market solutions to providing |
| :--- |
| frequency response, but such arrangements would need to be |
| looked at closely to be sure they fulfill reliability needs. |

Response: The Resources Subcommittee Frequency Task Force agrees with these comments as a whole. As envisioned, the proposed standard would not mandate a given amount of response, but would require an analysis if response were measurably below the norm. The proposed standard would accommodate the simplification ideas you propose, and in fact, if data is saved in a common format, the Resources Subcommittee has a tool that could calculate the BA's performance to the standard.
The Resources Subcommittee Frequency Task Force acknowledges the variability inherent in measuring frequency response. The standard will require capturing sufficient samples to make an objective measurement. The proposed standard does not preclude market solutions.
The new requirements may need to be field tested for a long duration before compliance with the requirements is mandatory. As envisioned, the standard does not mandate a specific amount of response, but requires analysis if response is markedly below the norm. Analysis may identify the need for corrective measures and the standard will accommodate the necessary time to make corrections.
The references to market solutions that were contained in the original SAR have been removed. NAESB may choose to develop associated business practices.

| NCPA (4) <br> Les Pereira | $\checkmark$ |  | Two statements are made in the SAR: <br> 1. The purpose of the proposed SAR is to ensure that frequency of the Interconnection remains above underfrequency load shedding setpoints during the transient period following the sudden loss of generation on the Interconnection. <br> 2. Furthermore, it is stated that " In regard to frequency response, one shortcoming of the recommendations in policy today is that there is no guidance regarding how much governor response (in MW) is required at the 5\% droop rate." <br> The first is a calculated number and depends not only on the amount of generation tripped, but also the total generation in the Whole Interconnection at the time of trip. Obviously two very different answers will be obtained : one with the Interconnection intact (normal operation) and the second when islanded. Both affect reliability. <br> The second issue has been thoroughly investigated in the WECC and a new Thermal Governor modeling approach has |
| :---: | :---: | :---: | :---: |

| Commenter | Yes | No | Comment |
| :---: | :---: | :---: | :---: |
|  |  |  | been implemented in the WECC after system tests, an exhaustive modeling validation effort and obtaining data from the generator owners. This has been documented in two IEEE Transaction papers described below. These papers present the development of a new turbine-governor modeling approach in WECC that correctly represents thermal units that have demonstrated unresponsive characteristics such as "base loaded" units operated with limiters, or partially responsive units with MW-load-controllers. The May $18^{\text {th }} 2001$ system trip test for 1250 MW performed with all AGCs off indicated that only about $40 \%$ of the governors effectively responded in the real system. If all the governors were responsive the calculated generation pickup for governors with a $5 \%$ droop for a 0.1 Hz frequency deviation would be 3185 MW instead of 1250 MW. The new modeling approach has been extensively validated against recordings from three WECC system tests and several large disturbances, and has been approved for use in all operation and planning studies in the WECC. The second paper describes the steps being taken to obtain validated data for the new governor models. <br> The work done by WECC indicate clearly that we do not get the required 5\% droop from all units as required by NERC. The modeling approach taken was to model the governors in planning and operating studies exactly as they are being actually operated. Enforcement/compliance of the 5\% droop is a separate issue and must be addressed by operating policies. <br> Obviously, the SAR touches upon only part of the problem, but it is a good start and should be expanded. It also needs to be cross-referenced with other areas such as the 5\% droop requirement, an effective spinning reserves policy that actually works (see the papers), and the effect on 'governor' powerflow and voltage stability analysis as a result of "unresponsive" governors. <br> The white paper referred by the SAR only touches upon the WECC effort and seems to miss the whole point of the modeling and validation work by the Governor Modeling Task Force in WECC - and what we have achieved in WECC to address realistic modeling of unresponsive governors in the real system. <br> 1. "A New Thermal Governor Modeling Approach in the WECC" <br> by L. Pereira, J. Undrill, D. Kosterev, D. Davies, S. Patterson, IEEE Trans. Power Systems, vol. 18, Issue.2, pp. 819-829, May 2003. (IEEE 2004 prize paper). Presented at Toronto IEEE PES, July 2003. <br> 2. "New Thermal Governor Model Selection and Validation in the WECC" by Les Pereira, Dmitry |

|  |  |  | Kosterev, Donald Davies, and Shawn Patterson - IEEE <br> TPWRS - Vol.19, No.1, pp 517-523, February 2004. |
|  |  |  | Presented at Denver IEEE PES, July 2004. |

Response: The Resources Subcommittee Frequency Task Force appreciates the significant work that has been done in this area by the WECC and has referenced some of this research in the Whitepaper. We believe the Planning Standards under development (MOD-13 and MOD-27) deal with the detailed governor issues that you have outlined.

The Resources Subcommittee Frequency Task Force appreciates the importance of the modeling effort you mention. This standard is not intended to address the modeling issues, but provides the framework and data needed to support the modeling.

The SAR was modified to include basic governor requirements.

| FRCC (2) <br> Linda Campbell <br> Ron Donahey - TEC (1) <br> Mark Bennett - GRU (3) <br> Steve Wallace - SEC (5) <br> S. McElhaney - FMPA <br> (5) <br> Ted Hobson - JEA (1) | $\checkmark$ | At this time the FRCC has the highest frequency settings for load shedding in the Eastern Interconnection (southern part of the Region). Being a peninsula and out of necessity, the Region has developed a well coordinated, under-frequency program for extreme frequency excursions. Ambiguity of the requirements, uncertainty of measurement and the lack of benefit to the Region require that the FRCC to oppose this Standard Authorization Request at this time. |
| :---: | :---: | :---: |
| Response: The interconnection measure of response is intended as a benchmark and as a validation of BAs' reported performance. |  |  |
| Southern Company Transmission, Operations, Planning and EMS Divisions (1) Marc Butts Steve Corbin Jim Viikinsalo Jim Griffith Doug McLaughlin Monroe Landrum | $\checkmark$ | We believe that the industry will be exposing the interconnected electrical systems of North America to a significant degree of reliability risk if a Frequency Response Standard similar to the one proposed by this SAR is not adopted. This risk can be mitigated somewhat by the turbine governor requirements of Standard MOD-014-1 from the Phase III/IV Standards SAR, if passed. However, the risk can be managed properly (and in the most economical manner) only on an interconnection/balancing authority basis, not on an individual generator basis as required by Standard MOD-014-1. <br> What is important is that the interconnections maintain sufficient frequency responsive resources to ensure the stability of interconnection frequency under first contingency conditions. The Frequency Response Standard, as proposed, sets requirements for the management and deployment of frequency responsive resources that achieve this goal without unduly interfering with the on going operation of the interconnection. We strongly urge the industry to support this SAR. |
| Response: The Resources Subcommittee Frequency Task Force agrees with these comments. |  |  |
| New York ISO (2) Mike Calimano | $\checkmark$ | We appreciate the opportunity to comment and believe there is a need for such a standard. Published studies show frequency response is declining when it should be increasing with load. The main concerns with this decreasing performance are: |

| Commenter | Yes | No | Comment |
| :---: | :---: | :---: | :---: |
|  |  |  | CHANGE <br> This SAR is proposed to develop a standard to measure subminute responses to changes in frequency and to set minimum acceptable responses to system these events. <br> TO <br> This SAR is proposed to develop a standard to measure subminute responses to changes in frequency and to set minimum acceptable responses to these system events. |
| Response: The Resources Subcommittee Frequency Task Force agrees with these comments as a whole. The proposed standard does not mandate a given amount of response, but requires an analysis if response is measurably below the norm. The proposed standard accommodates the simplification ideas you propose, and in fact, if data is saved in a common format, the Resources Subcommittee has a tool that will calculate the BA's performance to the standard. The Resources Subcommittee Frequency Task Force has added to the Detailed Description requirements that all balancing authorities shall operate their AGC function on tie-line frequency bias and that all balancing authorities shall perform frequency response characteristics surveys when called for by NERC. The Resources Subcommittee Frequency Task Force agrees with the sub-minute responses comment and has made the change. |  |  |  |
| IESO (2) <br> Pete Henderson | $\checkmark$ |  | We appreciate the opportunity to comment and believe there is a need for such a standard. <br> It needs to be recognized that there are two objectives for governor response, namely, to provide response on an interconnection wide basis to maintain an acceptable frequency and secondly to control frequency in island situations. The former may allow for averaging over an area of the response requirement but the latter may limit the extent of averaging. <br> Published studies show frequency response is declining when it should be increasing with load. The main concerns with this decreasing performance are: <br> There may be areas unable to withstand severe disturbances. Following a grid separation or collapse, control areas may be unable to fulfill their blackstart and restoration responsibilities, thereby becoming a burden to neighbors. <br> Because engineering models use theoretical frequency response, they are likely over optimistic and may misstate grid stability limits. |

| Commenter | Yes | No | Comment |
| :---: | :---: | :---: | :---: |
|  |  |  | This standard would allow the industry to determine whether the decline is local or global. <br> Rather than implementing a complicated infrastructure or process, we would suggest that NERC automate the calculation of frequency response by either: <br> Asking BAs to save their CPS-source data in a common format so a common tool can be used (MAPP BAs and some others use a common tool that can calculate frequency response with CPS-source data). <br> Embed the calculation in the NERC ACE-monitoring application. <br> The standard should employ a methodology that not only captures initial response (first few seconds after the event) but also the sustained response until AGC action takes over <br> Providing visibility on where and when performance is substandard will likely initiate sufficient action to arrest the decline in performance. Minimum performance standards could be implemented after the industry has identified what is reasonably achievable and technically justified. |

Response: The Resources Subcommittee Frequency Task Force agrees with these comments. We agree that smaller areas need greater response, and this concept will be applied in establishing the initial target responses for the interconnections (the historic response will bear this out). Under the ERO, interconnections can also establish stricter targets.
The new requirements may need to be field tested for a long duration before compliance with the requirements is mandatory. A long field test with extensive data collection may be needed before justifiable minimum performance standards can be identified.
As envisioned, the standard will measure the response for up to 60 seconds to ensure initial response is not withdrawn.

The references to market solutions that were contained in the original SAR have been removed. NAESB may choose to develop associated business practices.

| NERC Frequency Task <br> Force <br> Raymond L. Vice, <br> Chairman | $\checkmark$ |  | I personally believe that the industry will be exposing the <br> interconnected electrical systems of North America to a <br> significant degree of reliability risk if a Frequency Response <br> Standard similar to the one proposed by this SAR is not adopted. <br> This risk can be mitigated somewhat by the turbine governor <br> requirements of Standard MOD-014-1 from the Phase III/IV <br> Standards SAR, if passed. |  |  |  | interconnection frequency under first contingency conditions. The Frequency Response Standard, as proposed, sets requirements for the management and deployment of frequency responsive resources that achieve this goal without unduly interfering with the on going operation of the interconnection. I strongly urge the industry to support this SAR. |
| Response: The Resources Subcommittee Frequency Task Force agrees with these comments. |  |  |  |
| Dick Schulz <br> Chair, IEEE Task Force on Large Interconnected Power System Response to Generation Governing |  |  | First, I make these comments based on work that I've done principally at American Electric Power Service Corp, before my retirement from there in November 2000, and as founding Chair of the IEEE Task Force on Large Interconnected Power System Response to Generation Governing. These comments are entirely mine, and reflect no views of either body. <br> Second. It appears that the final standard will differ from any single person's opinions. Thus the specific comments below may not prevail. <br> Specific Comment 1: <br> The comment on page 4 of the SAR, "The standard should not preclude market solutions (e.g. allow purchasing of response as long as deliverability and restoration criteria can be met).There must be a means for sale/purchase of frequency response as for any other quantity." is workable only in near-normal operating conditions. But it will fail miserably when there is any islanding condition. An analogy: <br> Several skydivers agree that reserve parachutes are a very good idea, but don't want to invest in 1 reserve each. So they agree that they'll buy one to share among them, so each will be saved by that <br> spare. This means that they will hold hands until they pull their ripcords. <br> Sounded good, until they tried it, and the first guy to pull his cord came <br> unhitched, had a failed main 'chute, and the spare was on someone else. <br> Specific Comment 2: <br> The comment on page 4 of the SAR, "The measurement selected must be accurate and, to the extent practical, easy to implement.' may be met in the Eastern Interconnection by the underway DOE "Eastern Interconnection Phasor Project ' and by the similar WECC measurement systems, commonly called "WAMS". Les Peieira's paper, cited in the White Paper, used the WAMS measurements. |
| Response: The Resources Subcommittee Frequency Task Force appreciates the comments. The proposed standard does not preclude market solutions. The SAR's intent is to define the proposed standard's scope, the actual detail that you recommend will be developed during the standard drafting phase. The phasor projects in both the Eastern and Western Interconnections may indeed be a source of accurate and time stamped frequency data for this standard's application. |  |  |  |

| Commenter | Yes | No | Comment |
| :---: | :---: | :---: | :---: |
| Southern Co. Generation <br> (6) <br> Roman Carter <br> Tony Reed <br> Joel Dison <br> Lucius Burris <br> Lloyd Barnes <br> Clifford Shepard <br> Terry Crawley <br> Roger Green <br> Tom Higgins | $\checkmark$ |  | It is believed that the industry will be exposing the interconnected electrical systems of North America to a significant degree of reliability risk if a Frequency Response Standard similar to the one proposed by this SAR is not adopted. This risk can be mitigated somewhat by the turbine governor requirements of Standard MOD-014-1 from the Phase III/IV Standards SAR, if passed. However, the risk can be managed properly (and in the most economical manner) on an interconnection/Balancing Authority basis, not on an individual generator basis as required by Standard MOD-014-1. <br> The governor response in MW for generators is not just dependent on the governor droop and dead-band settings, but on the design of the plant control system (sliding pressure boiler, nuclear pressurized water reactor, etc.). For example, nuclear plant operators must control reactivity changes in the core and generally cannot allow external controls to increase or decrease power levels on demand. This standard should take such factors into account and address frequency \& MW response at the Balancing Authority level, not at the individual generator level. <br> What is important is that the interconnections maintain sufficient frequency responsive resources to ensure the stability of interconnection frequency under first contingency conditions. The Frequency Response Standard, as proposed, sets requirements for the management and deployment of frequency responsive resources that achieve this goal without unduly interfering with the on going operation of the interconnection. We support this SAR. |
| Response: The Resources Subcommittee Frequency Task Force appreciates and supports your comments. As envisioned, the standard will measure response at the Interconnection and Balancing Authority level. Only when a Balancing Authority's response measurably below the norm is additional analysis involved. |  |  |  |
| MISO <br> Terry Bilke | $\checkmark$ |  | Thanks for the opportunity to comment. I hope the SAC puts all comments in perspective. We are in a period where the industry is reluctant to adopt new standards that generate extra work and compliance exposure. The reliability of the Interconnections can benefit with minimal impact to most BAs with a light-handed standard. <br> Rather than implementing a complicated process, why not embed most of the effort in the NERC ACE-monitoring application? Only those BAs with unusually low response would need to drill down and do an internal assessment to determine their ability to withstand disturbances and whether they have responsive resources for blackstart. <br> Knowing where and when performance is substandard will likely arrest the decline in performance. Minimum performance standards could be implemented once the industry has identified |

| :---: | :---: | :---: | :---: |
|  |  |  | what is reasonably achievable and technically justified. |
| Response: The Resources Subcommittee Frequency Task Force agrees with these comments. |  |  |  |
| New York State Reliability Council (2) Theodore Pappas | $\checkmark$ |  | The Standard should define the term "event" in terms of time and frequency deviation. The frequency deviation the event must fall outside the droop deadband. |
| Response: Response: The Resources Subcommittee Frequency Task Force agrees that there should be clear criteria set for identifying events that will be used in calculating frequency response. The SAR was revised to indicate that the standard will require governors to provide droop characteristics within a specified range (to be determined during standard drafting). At this point, the Resources Subcommittee Frequency Task Force recommends each interconnection set a target excursion size that is used for selection of samples and recommends that the target be at least equal to the traditional 36 mHz deadband. |  |  |  |

| Fax $\quad$ (317) $249-5994$ |  |  |

## Purpose/Industry Need (Provide one or two sentences)

There is evidence of continuing decline in frequency response in the three Interconnections over the past 10 years, while it should be increasing with increasing load and generation. The Interconnections may have sufficient frequency response for normal operations, however, it is not known how this response is dispersed or at what point it will pose a reliability risk. The proposed standard's intent is to ensure frequency of the Interconnections remains above under-frequency load shedding setpoints during transient period following the sudden loss of generation on the Interconnections. By addressing the requirements for control during the "seconds" timeframe, this proposed standard coordinates with and complements the Balance Resources and Demand standards, which addresses Interconnection frequency control generally 5 minutes and longer. (The whitepaper submitted with the original Frequency Response SAR provides the rationale and justification for this standard.)

Reliability Functions
The Standard will Apply to the Following Functions（Check box for each one that applies by
double clicking the grey boxes．）

| 区 | Reliability Authority | Ensures the reliability of the bulk transmission system within its Reliability Authority area．This is the highest reliability authority． |
| :---: | :---: | :---: |
| 【 | Balancing Authority | Integrates resource plans ahead of time，and maintains load－interchange－ resource balance within its metered boundary and supports system frequency in real time |
| $\square$ | Interchange Authority | Authorizes valid and balanced Interchange Schedules |
| $\square$ | Planning Authority | Plans the bulk electric system |
| $\square$ | Resource Planner | Develops a long－term（＞1year）plan for the resource adequacy of specific loads within a Planning Authority area． |
| $\square$ | Transmission Planner | Develops a long－term（＞1 year）plan for the reliability of transmission systems within its portion of the Planning Authority area． |
| $\square$ | Transmission Service Provider | Provides transmission services to qualified market participants under applicable transmission service agreements |
| $\square$ | Transmission Owner | Owns transmission facilities |
| $\square$ | Transmission Operator | Operates and maintains the transmission facilities，and executes switching orders |
| $\square$ | Distribution Provider | Provides and operates the＂wires＂between the transmission system and the customer |
| マ | Generator Owner | Owns and maintains generation unit（s） |
| $\square$ | Generator Operator | Operates generation unit（s）and performs the functions of supplying energy and Interconnected Operations Services |
| $\square$ | Purchasing－ Selling Entity | The function of purchasing or selling energy，capacity and all necessary Interconnected Operations Services as required |
| $\square$ | Market Operator | Integrates energy，capacity，balancing，and transmission resources to achieve an economic，reliability－constrained dispatch． |
| 区 | Load－Serving Entity | Secures energy and transmission（and related generation services）to serve the end user |

Reliability and Market Interface Principles

| Applicable Reliability Principles（Check boxes for all that apply by double clicking the grey boxes．） |  |
| :---: | :---: |
| 区 | 1．Interconnected bulk electric systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the N Standards． |
| 区 | 2．The frequency and volta within defined limits throug |
| $\square$ | 3．Information necessary for the planning and operation of interconnected bulk electric systems shall be made available to those entities responsible for planning and operating the systems reliably． |
|  | 4．Plans for emergency operation and system restoratio systems shall be developed，coordinated，maintaine |
|  | 5．Facilities for communication，monitoring and control shall be provided，used and maintained for the reliability of interconnected bulk electric systems． |
| $\square$ | 6．Personnel responsible for planning and operating interconnected bulk electric systems shall be trained，qualified and have the responsibility and authority to implement actions． |
| 区 | 7．The security of the interconnected bulk electric s maintained on a wide area basis． |
| Does the proposed Standard comply with all of the following Market Interface Principles？（Select＇yes＇or＇no＇from the drop－down box by double clicking the grey area．） |  |
| 1．The planning and operation of bulk electric systems shall recognize that reliability is an essential requirement of a robust North American economy．Yes |  |
| An Organization Standard shall not give any market participant an unfair competitive advantage．Yes |  |
| 3．An Organization Standard shall neither mandate nor prohibit any specific market structure．Yes |  |
| 4．An Organization Standard shall not preclude market solutions to achieving compliance with that Standard．Yes |  |
|  | An Organization Standard shall not require the public disclosure of commercially sensitive information．All market participants shall have equal opportunity to access commercially non－ sensitive information that is required for compliance with reliability standards．Yes |

## Detailed Description (Provide enough detail so that an independent entity familiar with the industry could draft, modify, or withdraw a Standard based on this description.)

The proposed standard will require or provide the following:
o A technically-sound calculation and report of Balancing Authority and Interconnection frequency response.
o Flexibility to meet specific needs of each Interconnection.
o Will require Balancing Authority and Regional analysis if response is measurably below the Interconnection norm.

0 An objective measure of the Balancing Authority's and Interconnection's sub-minute response to changes in frequency.
o The standard will accommodate both fixed and variable bias.

O Will not mandate a given amount of frequency response, but will provide long-term Interconnection target levels for average response to frequency excursions, performance below which triggers Balancing Authority and Regional Reliability Organizations evaluation and analysis.

- Reasonable time to make corrections, if analysis show a Balancing Authority needs additional frequency response.
o Balancing Authorities to operate their automatic generation control function on tie-line frequency bias.
o Balancing Authorities to perform frequency response characteristic surveys when called for by NERC.
o Generator owners to equip generating units with nameplate ratings of 10 MW or greater, with a governor capable of providing immediate and sustained response to frequency deviations.
- Governors shall provide droop characteristics within a specified range (to be determined during standard drafting.
- Governors shall, as a minimum, respond to frequency deviations with a deadband not to exceed a specific limit (to be determined during standard drafting).

0 Generator owners seeking exception to the governor requirements to provide specific information (to be determined during standard drafting) to their Balancing Authority and Regional Reliability Organization.

## North American Electric Reliability Council

TO: REGISTERED BALLOT BODY
Ladies and Gentlemen:

## Announcement <br> Comment Periods, Ballot Pool, and Drafting Team Self-nominations Open April 4

The Standards Authorization Committee (SAC) announces the following standards actions:
Reliability Standards Process Manual Posted for 45-day Comment Period (April 4-May 18, 2006)
The Reliability Standards Process Manual was revised to align with NERC's electric reliability organization application and to make modifications based on 'lessons learned'. Several of the changes are to 'basic tenets' and, in accordance with the latest version of the Reliability Standards Process Manual, must go through a full review and approval process. Please use the comment form to provide comments on the changes to the manual.

One of the proposed changes to the reliability standards process is to move the responsibility for development of compliance information from standard drafting teams to the compliance program. The proposed Compliance Elements Development Process and an associated comment form are posted for review and comment.

## Nominations for Reliability Standards Process Manual Drafting Team Open (April 4-18, 2006)

The SAC is soliciting drafting team members to respond to stakeholder comments on the proposed changes to the Reliability Standards Process Manual. If you are interested in volunteering for this drafting team, please submit the nomination form by April 18, 2006.

Ballot Pool for Reliability Standards Process Manual Open (April 4)
A ballot pool has been created in anticipation of voting on the proposed changes to the Reliability Standards Procedure Manual. The ballot pool is available for any ballot body member to join until the respective ballot is opened.

Two Phase III \& IV Standards Posted for 30-day Comment Period (April 4-May 3, 2006) Two of the Phase III \& IV standards were revised based on stakeholder comments and are being re-posted for a fourth comment period. Please use the comment form to provide comments on these two standards:

PRC-002-1 Define Regional Disturbance Monitoring and Reporting Requirements requires regions to establish requirements for installation of disturbance monitoring equipment and reporting of disturbance data to facilitate analyses of events.

PRC-018-1 Disturbance Monitoring Equipment Installation and Data Reporting requires entities to install Disturbance Monitoring Equipment and report disturbance data to facilitate analyses of events.

A New Jersey Nonprofit Corporation

## REGISTERED BALLOT BODY

April 4, 2006
Page Two

## One SAR Posted for 30-day Comment Period (April 4-May 3, 2006)

A revised SAR for Frequency Response is posted for a 30 -day comment period. The SAR proposes adding requirements to ensure frequency of the Interconnections remains above underfrequency load shedding set points during transient periods following the sudden loss of generation. Please use the comment form to provide comments on this SAR.

## Standards Development Process

The NERC posting and balloting procedures are described in the Reliability Standards Process Manual, which contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

Please send questions to Maureen Long at maureen.long@nerc.net, or call 813-468-5998.
Sincerely,
Maareen E. Long
Maureen E. Long
Standards Process Manager

## Background Information

Please review the drafting team's consideration of the comments submitted with the first draft of the Frequency Response SAR and then review the drafting team's conforming changes made to SAR. Because the changes to the SAR were so extensive, there is no 'red line' version to show the changes from the first draft.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that comments from the first posting of the SAR were adequately addressed?
$\square$ Yes

Comments:
2. Do you agree with the list of proposed requirements included in the detailed description of the revised SAR?Yes
$\boxtimes$ No
The requirements on individual generator are unnecessary. The requirements should be on a group of generators in a control area to achieve a desired response. Thus, one could have some generators which are being operated as non responsive and the others which are responding well to offset for those which are not responsive.

Additionally, the 10 MW size requirements are too restrictive and unnecessary. It should be plant based and should apply to plants of 100 MW or more aggregate capacity. In any realistic scenario, the smaller plants are not expected to contribute much to frequency response and hence subjecting them to frequency response requirements is uneconomic.

Comments:
3. Do you agree that the proposed standard(s) would be applicable to the Reliability Coordinator, Balancing Authority, Generator Owner, and Load-serving Entity?YesNo
Comments:
4. The current standard on Bias requires a Balancing Authority to carry a minimum bias equal to $1 \%$ of peak load. As an example, in the Eastern Interconnection, this value is double current natural frequency response. Should the standard provide an incentive, such that a Balancing Authority can use a bias equal to their natural response, but less than $1 \%$ of peak, if the response is above an acceptable target?YesNo
Comments:
5. Several commenters suggested response should be measured for an extended period after a frequency excursion, up to the point where automatic generation control (AGC) would take over. This was to ensure initial response wasn't withdrawn prematurely. Should the standard measure out to 60 seconds following an excursion?

Yes
$\boxtimes$ No
Most of the frequency recovery happens in first 30 seconds. Thus anything more than 30 seconds is unnecessary. It is also seen that the response of a unit varies greatly within that 30 seconds period. Thus, it is very important that the measured response be the average response over the 30 seconds period and not be the response at 30 seconds.

Comments:
6. Do you have other comments on the SAR?

Because the changes to the SAR were so extensive, there is no 'red line' version to show the changes from the first draft.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that comments from the first posting of the SAR were adequately addressed?
$\boxtimes$ Yes
Comments:
2. Do you agree with the list of proposed requirements included in the detailed description of the revised SAR?Yes
$\boxtimes$ No
The purpose is definitely suggested for under frequency conditions. However, when specifying that the generators shall have governors with droop etc... the role of the governor is for both high and low frequency conditions and not just underfrequency FRR. In a market environment it is very possible that not every generator will provide FRR services. Thus, the governor and governor deadband should be a requirement to interconnect to a power system. Generators that provide FRR shall have responsive governor and prime mover.

The standard is based on balancing area response which will include generators and in some jurisdications will include load. So is the intent that whatever load is considered, additional FRR resources such as generators are used to provide the required FRR?

What about load as FRR providers? Some industrial facilities are capable to dynamically vary the load of the facility to frequency (ie virtual governor). The standard should apply to FRR providers which can be generators and loads.

We agree that generator owners have an obligation to have working governors or provide explanations why not. The "10 MW" requirement should be evaluated for consistency with other standards. This should not hold up the progress of the SAR, but should be evaluated by the ultimate standard drafting team. Comments:
3. Do you agree that the proposed standard(s) would be applicable to the Reliability Coordinator, Balancing Authority, Generator Owner, and Load-serving Entity?
$\boxtimes$ Yes
$\boxtimes$ No
The Generator Operator may also have some responsibilities, such as the selection of control modes.

We're not sure what the LSE can do regarding the standard. They cannot control response from load. The exception may be coordination of frequency response with UFLS.

Planners may have some responsibilities with regard to new interconnections and also using observed frequency response in models as opposed to theoretical response. Comments:
4. The current standard on Bias requires a Balancing Authority to carry a minimum bias equal to $1 \%$ of peak load. As an example, in the Eastern Interconnection, this value is double current natural frequency response. Should the standard provide an incentive, such that a Balancing Authority can use a bias equal to their natural response, but less than $1 \%$ of peak, if the response is above an acceptable target?
$\boxtimes$ YesNo
There should be a safeguard in place, such that if frequency performance declines, the industry reverts to the $1 \%$ minimum. Comments:
5. Several commenters suggested response should be measured for an extended period after a frequency excursion, up to the point where automatic generation control (AGC) would take over. This was to ensure initial response wasn't withdrawn prematurely. Should the standard measure out to 60 seconds following an excursion?
$\boxtimes$ Yes
No
Sixty seconds is a reasonable balance to capture the period prior to AGC response. Comments:
6. Do you have other comments on the SAR?

1. Do you agree that comments from the first posting of the SAR were adequately addressed?
$\square$ Yes
No
No - The intent of this SAR is unclear which highlights that this issue requires additional studies and investigation. In the future, it may be beneficial to develop a standard after a reliabliity issue is identified, and a specific standard can be developed and implemented to address the issue.
Comments:
2. Do you agree with the list of proposed requirements included in the detailed description of the revised SAR?
$\square$ Yes
$\boxtimes$ No
The proposed requirements nor the White Paper adequately make the case that there is a need for a frequency response standard at this time. However, it is recommended that the subject be further investigated. The analysis should evaulate if a frequency response standard that addresses the three major short term frequency control components (inertial response, governor response, and automatic generation control) are required. The report writers should include a broad range of participants including (at least) 3 OEM's (original equipment manufacturers) representing steam, gas and hydro generation control. Some specific issues that should be addressed are:
3. Inertial Response: Evaluate historical changes in the inertial response of the electric grid as a result of changing power equipment designs and types of load. For example, the addition of new industrial and aero-derivative turbinegenerators have lower inertia-power ratios than tranditonal nuclear/fossil units and, in addition, they are not base loaded (as a result of more efficient dispatching and improved power plant controls).
4. Governor Response: Evaulate generation governor performance as a result of newer, more configurable prime mover controls. Digital controls provide increased plant reliability, however, this may be at the expense of decreased governor response. For example, the use of main steam pressure controls on steam units and low NOx controls on gas turbines may produce unexpected droop output responses.
5. Automatic Generation Control (AGC): Perform a control area survey to determine if there is sufficient regulation capacity within control areas to maintain generation and load balance. Include a review of incentives and
penalties for generators to respond accurately and reliably to AGC signals. Comments:
6. Do you agree that the proposed standard(s) would be applicable to the Reliability Coordinator, Balancing Authority, Generator Owner, and Load-serving Entity?

Q YesNo
If required. Comments:
4. The current standard on Bias requires a Balancing Authority to carry a minimum bias equal to $1 \%$ of peak load. As an example, in the Eastern Interconnection, this value is double current natural frequency response. Should the standard provide an incentive, such that a Balancing Authority can use a bias equal to their natural response, but less than $1 \%$ of peak, if the response is above an acceptable target?YesNo
Comments:
5. Several commenters suggested response should be measured for an extended period after a frequency excursion, up to the point where automatic generation control (AGC) would take over. This was to ensure initial response wasn't withdrawn prematurely. Should the standard measure out to 60 seconds following an excursion?

Yes
$\boxtimes$ No
This question is not clear. AGC control pulses generation every 5 seconds, therefore, the measurement should be based on the amount of time it takes to restore the generation load balance. Comments:
6. Do you have other comments on the SAR?

Comments:

Please use this form to submit comments on the second draft of the Frequency Response SAR. Comments must be submitted by May 3, 2006. You must submit the completed form by emailing it to sarcomm@nerc.com with the words "Frequency Response" in the subject line. If you have questions please contact Maureen Long at maureen.long@nerc.net or 813-468-5998.

## Background Information

Please review the drafting team's consideration of the comments submitted with the first draft of the Frequency Response SAR and then review the drafting team's conforming changes made to SAR. Because the changes to the SAR were so extensive, there is no 'red line' version to show the changes from the first draft.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that comments from the first posting of the SAR were adequately addressed?
$\square$ Yes
$\boxtimes$ No
The Resources Subcommittee in a response to the first draft states "A primary purpose of this standard is to collect information so informed decisions can be made before there is a problem. " It is clear from that reply that the Resources Subcommittee wishes to undertake an analysis of the system and needs to collect additional information. This data collection effort may be laudable but it does not rise to the level of being a federally enforced mandatory standard. What if later on the 'data' were to show there is no problem, then there will be a need to rescind the standard and repay those who were non-compliant to a data collection effort.

In their response to the first draft, the Resources Subcommittee cite a WECC study. But they have no similar study for the East. The Resources Subcommittee still has not shown that the decrease in sub-minute response is either (1) a problem or (2) nothing more than an indication that a larger system has more inertia and therefore less response that the smaller system in the past.

This SAR, with its present theoretical focus, posits the BA as the responsible entity for governor response. Even those who agreed with the first posting that Frequency Response is an important issue - stated that a standard cannot define fixed norms (MRO, NYISO, IESO(2) ). The BA is not responsible to instantaneous response -at best it can establish a capacity obligation but it can't guarantee continuous response.

Comments:
2. Do you agree with the list of proposed requirements included in the detailed description of the revised SAR?
$\boxtimes$ No
The SAR is still not clear about what is to be developed in the standard. Of the ten bulleted items several seem to show a misunderstanding between a sub-minute frequency response obligation and Automatic Generation control. The RS must make clear what it wants to do. Sub-minute frequency response occurs with or without frequency bias; sub-minute frequency response is not helped or hurt by having AGC. This is a major problem with the proposal. It is not clear and it is not definitive.

Item 1 indicates the standard will be a Report
Item 2 states the standard will be flexible (that is mandated in the Process Manual)

Item 3 seems to indicate that non-compliance will be met with a requirement to analyze the incident (if this is standard is so important why isn't every event critical?)

Item 5 is the most unusual - the standard will not mandate a response but will provide "LONG-TERM" targets (how is it that a sub-minute response gets translated into a long-term target?)

Item 6 is to mandate AGC. This is not related to sub-minute frequency response.

Item 7 is to mandate a post-incident survey. Again this is a good idea but it a data collection mandate - it is not a frequency response standard. The RS has the tools to collect that information today, without the need to resort to mandatory penalties.

Item 10 will allow generators to seek exceptions (which means that the RS will allow a generator to opt out and still require the BA to comply. In the absurd case that all generators opt out (let's say the BA has only nuclear units) then according to the RS, the BA is held non-compliant. This is just not a good idea.

In summary: \#1 is a calculation and report on response but no measure of performance; \#3 requires a BA and the RRO to perform an analysis if response is measurable (by what amount) below the norm (which is a constantly moving value); \#4 is the only possibility for true standard; \#9 generators must have governors is more a certification issue than a BA standard. Three of the bullets are not requirements (\#2, \#5, and \#10). Two of the bullets are already in other standards while two of the bullets duplicate each other. The SAR team needs to better describe exactly what is being proposed to be in the standard so that the industry can evaluate the proposal. The industry does not need to get involved in a research project. Comments:
3. Do you agree that the proposed standard(s) would be applicable to the Reliability Coordinator, Balancing Authority, Generator Owner, and Load-serving Entity?
$\boxtimes$ No
This question would require an assumption of what the standard would be. If the standard is to provide sub-minute frequency response, then the only entity should be the generator owner.

## Comments:

4. The current standard on Bias requires a Balancing Authority to carry a minimum bias equal to $1 \%$ of peak load. As an example, in the Eastern Interconnection, this value is double current natural frequency response. Should the standard provide an incentive, such that a Balancing Authority can use a bias equal to their
natural response, but less than $1 \%$ of peak, if the response is above an acceptable target?Yes
$\boxtimes$ No
The RS again is avoiding the issue of what sub-minute frequency response it MUST mandate. The $1 \%$ is related to the frequency bias setting (basically a long term average response). The BRD deals with the longer term issue of frequency response - this standard was designed for the shorter-term response.

If the RS is willing to accept under-biased systems then it would seem to be going against conventional wisdom, and should explain why it would even consider such an idea. If the real intent of this frequency SAR is to establish a minimum frequency response value then the SAR needs to state that.

Perhaps the SAR should establish a minimum 1 minute response for every generator (if they can't provide it they are obligated to contract for it from another unit) and maybe a 1 minute average over a week, month, or year if a longer term value is needed. However, since the SAR authors state the problem is sub-minute response, it is suggested that the long term response is better be addressed by the BRD standard.
In addition the SAR does not adequately address the load portion of the frequency response. The standard seems to presuppose the solution is having governors.
Comments:
5. Several commenters suggested response should be measured for an extended period after a frequency excursion, up to the point where automatic generation control (AGC) would take over. This was to ensure initial response wasn't withdrawn prematurely. Should the standard measure out to 60 seconds following an excursion?

Yes
$\boxtimes$ No
Unsure as to what is being suggested here. The SAR drafters need to be specific about what requirements are needed and how they will be measured. The details contained in the white paper are supporting information but they do not define the standard that is being proposed. Comments:
6. Do you have other comments on the SAR?

Please be clear about the terminology. Frequency response comes in many flavors - sub-minute; several minutes; and hours. The RS seems to touch on all of them in this proposal.

Comments:

Please use this form to submit comments on the second draft of the Frequency Response SAR. Comments must be submitted by May 3, 2006. ## Background Information

Please review the drafting team's consideration of the comments submitted with the first draft of the Frequency Response SAR and then review the drafting team's conforming changes made to SAR. Because the changes to the SAR were so extensive, there is no 'red line' version to show the changes from the first draft.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that comments from the first posting of the SAR were adequately addressed?
$\boxtimes$ Yes
Comments:
2. Do you agree with the list of proposed requirements included in the detailed description of the revised SAR?
$\boxtimes$ YesNo
In particular we agree that generator owners have an obligation to have working governors or provide explanations why not. The 10 MW requirement should be evaluated for consistency with other standards. This should not hold up the progress of the SAR, but should be evaluated by the ultimate standard drafting team. Comments:
3. Do you agree that the proposed standard(s) would be applicable to the Reliability Coordinator, Balancing Authority, Generator Owner, and Load-serving Entity?

Q YesNo
The Generator Operator may also have some responsibilities, such as the selection of control modes.

We're not sure what the LSE can do regarding the standard. They cannot control response from load. The exception may be coordination of frequency response with UFLS.

Planners may have some responsibilities with regard to new interconnections and also using observed frequency response in models as opposed to theoretical response. Comments:
4. The current standard on Bias requires a Balancing Authority to carry a minimum bias equal to $1 \%$ of peak load. As an example, in the Eastern Interconnection, this value is double current natural frequency response. Should the standard provide an incentive, such that a Balancing Authority can use a bias equal to their
natural response, but less than $1 \%$ of peak, if the response is above an acceptable target?
$\boxtimes$ YesNo
There should be a safeguard in place, such that if frequency performance declines, the industry reverts to the $1 \%$ minimum. Comments:
5. Several commenters suggested response should be measured for an extended period after a frequency excursion, up to the point where automatic generation control (AGC) would take over. This was to ensure initial response wasn't withdrawn prematurely. Should the standard measure out to 60 seconds following an excursion?

Q Yes
No
This is a significant issue, because if the governor system withdraws the unit's support prior to the recovery of frequency, this does have a problematic impact. A period of at least 60 seconds should be considered, and 60 seconds may not be adequate as often frequency recovery of the interconnection extends beyond the initial 60 seconds. Comments:
6. Do you have other comments on the SAR?

## Background Information

Please review the drafting team's consideration of the comments submitted with the first draft of the Frequency Response SAR and then review the drafting team's conforming changes made to SAR. Because the changes to the SAR were so extensive, there is no 'red line' version to show the changes from the first draft.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that comments from the first posting of the SAR were adequately addressed?
$\boxtimes$ Yes
$\boxtimes$ No
Yes, with respect to the responses to the IESO's comments. However, the revised SAR appears to get somewhat mixed up between sub-minute frequency response performance with a longer term (> 1 minute) performance, and lacks clarity on what the proposed standard is intended to stipulate.

Is the proposed standard intended to stipulate:
(a) a minimum frequency response performance level with which to determine if follow-up analysis is to be conducted, or,
(b) requirements for calculating, measuring, reporting and analyzing frequency response, or,
(c) both, in addition to,
(d) requirements for generators to be equipped with governors and if so, the target to be responding to?

If (a) is not specified in the standard, we see a difficulty in stipulating the threshold for (b) and the target for (d).

From the SDT's response to our previous comments ("The new requirements may need to be field tested for an extended duration before compliance with the requirements becomes mandatory. A long field test with extensive data collection may be needed before justifiable minimum performance standards can be identified"). It is our belief the standard is intended to stipulate (b) only. We see this as a necessary first step. However, it may then beg the question of the need of having a standard to develop the basis for a future standard. Might there not be other alternatives to achieve (b) such as by means of a request from the standing committees or NERC to the BAs and the regions to compile this information? Comments:
2. Do you agree with the list of proposed requirements included in the detailed description of the revised SAR?
$\boxtimes$ No
The intent of some of the requirements is again unclear to the IESO, for example.
(i) Does Bullet \#2 mean the flexibility in the calculation and reporting process or in the target/minimum frequency response level?
(ii) Assuming Bullet \#4 a requirement, and one which relates to the minimum level of frequency response, how is this requirement stipulated at this time while data collection and follow-up analysis are to be proposed as standard requirements and field testing has yet to commence? Same comment applies to Bullet \#9.
(iii) Bullet \#6 appears to go beyond the sub-minute time frame. Further, we are unable to understand the leading sentence "Will not mandate a given amount of frequency response". We feel it is important that if poor frequency response performance in the sub-minute time frame is to be assessed and improved, specific target which may well be the minimum amount of frequency recovery would need to be stipulated.
(iv) Bullet \#7 also appears to be beyond the sub-minute time frame, which is to mandate AGC but which should be covered by other BAL standards.
(v) Bullets \#8 and \#1 appear to be the main requirements for the proposed standard that are achievable at this time.
(vi) As mentioned in (ii) above, we are unable to visualize how the range and target of response be stipulated in the standard before Bullets \#1 and \#8 are implemented.
(v) If generators are allowed to seek exception, the standard should provide some basic premise that bounds the exception cases rather than leaving the door wide open and the decision solely to the judgment of the BAs and RROs. Comments:
3. Do you agree that the proposed standard(s) would be applicable to the Reliability Coordinator, Balancing Authority, Generator Owner, and Load-serving Entity?
$\square$ Yes
$\boxtimes$ No
Not having a good handle on what the standard is intended to achieve and stipulate, we are unable to comment on whom the standard should apply to. Among the ones included in the question, we are unclear on the role of the RC in requiring anyone to install devices or take actions to improve frequency response in day to day operation.

Comments:
4. The current standard on Bias requires a Balancing Authority to carry a minimum bias equal to $1 \%$ of peak load. As an example, in the Eastern Interconnection, this value is double current natural frequency response. Should the standard provide an incentive, such that a Balancing Authority can use a bias equal to their natural response, but less than $1 \%$ of peak, if the response is above an acceptable target?

இ No
(i) The question seems to get the sub-minute and longer-term targets intertwined. We are unclear on which "standard be provided an incentive". Is it the proposed sub-minute standard which has yet to be determined or the current standard on Bias? If it is the former, then this question seems a bit premature as we don't even know what the performance target for subminute response should be. If it's the latter, then the issue belongs to other BAL standards.

Comments:
5. Several commenters suggested response should be measured for an extended period after a frequency excursion, up to the point where automatic generation control (AGC) would take over. This was to ensure initial response wasn't withdrawn prematurely. Should the standard measure out to 60 seconds following an excursion?

No
This should cover the entire spectrum of immediate response before AGC kicks in. Comments:
6. Do you have other comments on the SAR?
(i) The SAR does not address the load portion of the frequency response but it indicates that the standard would apply to the LSEs as well. Please clarify or eliminate LSE from the Reliability Function check list.
(ii) We feel that the SAR needs to be very clear on what the proposed standard is intended and what will be included. Conducting calculation, measuring and report on frequency excursion events followed by analysis would help to ascertain whether or not poor performance exists. However, the determination of poor performance also relies on having a minimally acceptable level to gauge. If the standard is to provide requirements for calculation, reporting and conducting analysis only, then there needs to be some general guideline on the threshold for reporting and analyzing, which in turn begs the question of should this "guideline" be included as the initial standard, whose compliance would not be enforced until sufficient experience has been gained and field test conducted, with possible revision as experience and field test so suggest. Absent a minimum performance level, the requirements for governor setting would be difficult to determine. Comments:

Please use this form to submit comments on the second draft of the Frequency Response SAR. Comments must be submitted by May 3, 2006. You must submit the completed form by emailing it to sarcomm@nerc.com with the words "Frequency Response" in the subject line. If you have questions please contact Maureen Long at maureen.long@nerc.net or 813-468-5998.

## Background Information

Please review the drafting team's consideration of the comments submitted with the first draft of the Frequency Response SAR and then review the drafting team's conforming changes made to SAR. Because the changes to the SAR were so extensive, there is no 'red line' version to show the changes from the first draft.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that comments from the first posting of the SAR were adequately addressed?
$\square$ Yes
No
There is an expectation apparent in the first set of responses that indicates that the drafting team believes they have more knowledge of the solutions that will be required than the final standard will contain. The two greatest areas of insufficient understanding lie in the measurement of Frequency Response at less than the full interconnection level and the effect of the standard as envisioned on markets. These two problems are addressed in the comments to later questions in this comment form. Comments:
2. Do you agree with the list of proposed requirements included in the detailed description of the revised SAR?
$\boxtimes$ No
Requirements that apply to individual generators cannot be implemented as indicated in the standard without failing to comply with Market Interface Principle 2. Frequency Response (Governor Response) have economic costs associated with standing ready to supply. These costs have been documented in EPRI Reports on Ancillary Services. If any generator is given an exception to not provide a response, that generator will also be given a market advantage resulting from the savings they will receive by not providing a response. The SAR as currently written will create a market advantage for all generators below 10 MW and all generators that are given an exception to the governor response requirement. The alternatives to these generator requirements are either not have a competitive market and decide the provision of frequency response administratively (the old VIU method), or determine who provides frequency response through a competitive market process. Comments:
3. Do you agree that the proposed standard(s) would be applicable to the Reliability Coordinator, Balancing Authority, Generator Owner, and Load-serving Entity?
$\boxtimes$ Yes
No

The requirements applicable to the Generator Owner and Load-serving Entity may only include requirements for measurement processes, not necessairly requirements to provide any frequency response. Comments:
4. The current standard on Bias requires a Balancing Authority to carry a minimum bias equal to $1 \%$ of peak load. As an example, in the Eastern Interconnection, this value is double current natural frequency response. Should the standard provide an incentive, such that a Balancing Authority can use a bias equal to their natural response, but less than $1 \%$ of peak, if the response is above an acceptable target?
$\boxtimes$ Yes
There is a minimum frequency response below which the interconnection will be less reliable than acceptable. We currently do not know what this value is but we do know that a value exists. We also know that this value is less than the $1 \%$ of peak load specificed in the current standards. A standard that arbitrairly requires a $1 \%$ of peak load response without a technical justification based on reliability cannot be called a reliabiltiy standard. However, even though we do not know the minimum frequency response below which the interconnection will be less reliable than acceptable, we can perform the work necessary to estimate a reasonable value for a minimum frequency response and assign responsibility for that response among the Balancing Authorities on an interconnection. A Frequency Response Standard without this characteristic cannot maintain reliability of the interconnection. Comments:
5. Several commenters suggested response should be measured for an extended period after a frequency excursion, up to the point where automatic generation control (AGC) would take over. This was to ensure initial response wasn't withdrawn prematurely. Should the standard measure out to 60 seconds following an excursion?

```
Z Yes
No
```

There are two issues associated with this question. The first is that the change in instantaneous frequency be limited to within a range that limits the risk of a cascading outage on the interconnection. The second is that each generation technology provides a different response characteristic within the first minute after a sudden frequency excursion. Work performed at NIPSCo and published by IEEE indicated that a measurement interval of one to two minutes worked well for the measurement of frequency response. Without specific knowledge of the nature of the individual responses that make up the sustained frequency response to an excursion, it may be difficult to justify the selection of a measurement interval shorter than one-minute that might put some generation technologies at a disadvantage with respect to the measurement method. This is a subject that the drafting team should technically evaluate before including a specific measurement period in the standard. Comments:
6. Do you have other comments on the SAR?

The current measurement methods for determining individual Balancing Authority Frequency Response may not be reliable. This is because the current measurement methods only capture a small sample of the frequency responses provided limited to only several minutes per year. The metering methods we currently use on the interconnection can shed some light on this problem. Since the each BA measures its Tie Line Error with common metering with adjancent BAs, the sum of the Tie Line Errors over the total interconnection must equal zero at all times. Each tie line has a positive error for one BA and a negative error of equal value to the other BA that the tie line connects. If the errors must sum to zero, then the change in errors must also sum to zero between any two points in time. Since the Frequency on an interconnection is the same throughtout the interconnection at any point in time for the purpose of the frequency response measurement, the change in frequency between two points in time must also be the same throughout the interconnection. Therefore, the change in tie-line error divided by the change in frequency must indicate a total frequency response for the interconnection as measured by the sum of the individual BA frequency responses must be equal to zero. In other words, there is a BA or a set of BAs that cause each frequency response on the interconnection. Only knowledge of the distribution of individual frequency responses among BAs will provide the necessary information to determine whether or not the frequency response indicated by current measurement methods will maintain adequate reliablity. It may not be the average frequency response to large events that indicates interconnection reliability, but the distribution of frequency responses among BAs including both the positive and negative responses. Therefore, the measurement methods included in the standard should have the goal of
capturing the distribution of both positive and negative frequency responses over the entire range of frequency operation should be a goal of standard.
The measurement methods suggested will not accomplish this goal.
Comments:

Please use this form to submit comments on the second draft of the Frequency Response SAR. Comments must be submitted by May 3, 2006. You must submit the completed form by emailing it to sarcomm@nerc.com with the words "Frequency Response" in the subject line. If you have questions please contact Maureen Long at maureen.long@nerc.net or 813-468-5998.

Because the changes to the SAR were so extensive, there is no 'red line' version to show the changes from the first draft.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that comments from the first posting of the SAR were adequately addressed?
$\boxtimes$ YesNo
Comments:
2. Do you agree with the list of proposed requirements included in the detailed description of the revised SAR?

Q YesNo
Comments:
3. Do you agree that the proposed standard(s) would be applicable to the Reliability Coordinator, Balancing Authority, Generator Owner, and Load-serving Entity?
$\boxtimes$ YesNo
Comments:
4. The current standard on Bias requires a Balancing Authority to carry a minimum bias equal to $1 \%$ of peak load. As an example, in the Eastern Interconnection, this value is double current natural frequency response. Should the standard provide an incentive, such that a Balancing Authority can use a bias equal to their natural response, but less than $1 \%$ of peak, if the response is above an acceptable target?
$\boxtimes$ Yes
$\square$ No
The 1\% minimum frequency bias is obsolete and does not take into account the changes in interconnection frequency response over recent years. If not modified, it will lead to increased frequency oscillations within the interconnections and needless maneuvering of generating assets with associated wear and tear on these assets.

Comments:
5. Several commenters suggested response should be measured for an extended period after a frequency excursion, up to the point where automatic generation control (AGC) would take over. This was to ensure initial response wasn't withdrawn prematurely. Should the standard measure out to 60 seconds following an excursion?

Yes
$\boxtimes$ No
AGC response begins within only a few seconds after the disturbance with a maximum ramp rate achieved within three to five minutes. Governor response and load frequency response typically peak within 30 seconds. There is some logic to monitoring governor respone for sustainability past its initial peak, but we have not seen anything about that in this SAR.

Comments:
6. Do you have other comments on the SAR?

In our opinion, this SAR, or one like it, is required to ensure that the primary frequency response of the interconnections and the BAs do not deteriorate to a point where 1) the interconnection can not adequately respond to major generator trips (including potential multiple contingencies which, though rare, do happen) and 2) primary frequency response of the BAs is inadequate to support islanding during severe local disturbances, thus allowing local disturbances to cascade into regional or interconnection wide disturbances. Primary frequency response is declining in at least the Eastern and Western Interconnections. WECC has taken a proactive approach to addressing this problem, but there is no similar work being done in the Eastern Interconnection. This SAR, or one like it, is needed to take the best practices in the industry, wherever they may be found, and utilize them to protect the interconnections from disturbances that could be avoided if we take action now rather than waiting until the problems actually occur.

1. Do you agree that comments from the first posting of the SAR were adequately addressed?
$\square$ Yes
Comments:
2. Do you agree with the list of proposed requirements included in the detailed description of the revised SAR?Yes
$\boxtimes$ No
Not totally, I need to understand more of what would be reuired to meet the obligation of Generator owners to equip generating units with nameplate ratings of 10 MW or greater, with a governor capable of providing immediate and sustained response to frequency deviations. Comments:
3. Do you agree that the proposed standard(s) would be applicable to the Reliability Coordinator, Balancing Authority, Generator Owner, and Load-serving Entity?

Q YesNo
Comments:
4. The current standard on Bias requires a Balancing Authority to carry a minimum bias equal to $1 \%$ of peak load. As an example, in the Eastern Interconnection, this value is double current natural frequency response. Should the standard provide an incentive, such that a Balancing Authority can use a bias equal to their natural response, but less than $1 \%$ of peak, if the response is above an acceptable target?
$\boxtimes$ Yes
$\square$ No
I believe that an incentive should be included in the standard Comments:
5. Several commenters suggested response should be measured for an extended period after a frequency excursion, up to the point where automatic generation control (AGC) would take over. This was to ensure initial response wasn't withdrawn prematurely. Should the standard measure out to 60 seconds following an excursion?

YesNo
I did not provide an answer but believe that this is a decision that could be made over time and not necessarily with the inception of the standard.. Comments:
6. Do you have other comments on the SAR?

I believe we have to address the frequency issue, but feel that it can be developed over time proactivly. Comments:

Please use this form to submit comments on the second draft of the Frequency Response SAR. Comments must be submitted by May 3, 2006. ## Background Information

Please review the drafting team's consideration of the comments submitted with the first draft of the Frequency Response SAR and then review the drafting team's conforming changes made to SAR. Because the changes to the SAR were so extensive, there is no 'red line' version to show the changes from the first draft.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that comments from the first posting of the SAR were adequately addressed?
$\boxtimes$ Yes
We are still concerned with a NERC standard countering some aspects of the standard we are in the process of drafting in WECC, so will continue to be active on the drafting team to insure it does not adversely impact the WECC standard. Comments:
2. Do you agree with the list of proposed requirements included in the detailed description of the revised SAR?
$\boxtimes$ No
RE: bullet 2: Instead of flexibility to meet interconnection needs, each interconnection should have its own requirements on frequency response, this is due to the unique frequency response of each interconnection.
re bullet 4: This Standard will need to measure frequency response for the duration of the frequency deviation. Measuring it until frequency recovers will overlap with the Balance Resources and Demand standard slightly, but will give much better results than simply going out a few minutes.
re bullet 6: Target levels should be BA specific to insure there is not an incentive to lean on other BA's. How will the target levels be calculated?
Re bullet 7: BAs must be free to operate their automatic generation control in any method they desire. The tie-line frequency bias is used for compliance monitoring, but must not be a requirement for the actual automatic generation control algorithm. Recommend this be modified to state: Balancing Authorities will calculate an Area Control Error for monitoring purposes using tie-line frequency bias.
re bullet 8: WECC should call FRC surveys for WECC instead of NERC.
re bullet 9: Recommend generating unit nameplate of 10 MW plus multi-unit installations of 10 MW or greater be required to have a governor(s) capable of providing immediate and sustained response to frequency deviations.
Re bullets 9 and 10: Currently wind generation does not have governor response capability. Due to the amount of wind integration planned in the next decade, new installations should have a requirement for frequency responsive units. Historically, requirements have provided incentive for
manufacturers to modify machine design (low-voltage ride-through capability, voltage control capability) to meet the requirements.
Comments:
3. Do you agree that the proposed standard(s) would be applicable to the Reliability Coordinator, Balancing Authority, Generator Owner, and Load-serving Entity?
$\boxtimes$ YesNo
The only portion we can think of that would applicable to the Load-serving entity is for the load-serving entity to report their underfrequency load shedding settings. We believe LSEs should be removed as applicable entities. Comments:
4. The current standard on Bias requires a Balancing Authority to carry a minimum bias equal to $1 \%$ of peak load. As an example, in the Eastern Interconnection, this value is double current natural frequency response. Should the standard provide an incentive, such that a Balancing Authority can use a bias equal to their natural response, but less than $1 \%$ of peak, if the response is above an acceptable target?
$\boxtimes$ Yes
$\boxtimes$ No
The standard should not provide an incentive, but the standard should provide a methodology that would allow a Balancing Authority to calculate a bias based on their natural response, provided that response is above an acceptable target. Comments:
5. Several commenters suggested response should be measured for an extended period after a frequency excursion, up to the point where automatic generation control (AGC) would take over. This was to ensure initial response wasn't withdrawn prematurely. Should the standard measure out to 60 seconds following an excursion?
```
Yes
```

$\boxtimes$ No
The standard should measure out to when the frequency recovers. This could be up to the 15 minute DCS limit. AGC control may or may not kick in within 60 seconds depending on deadbands, etc. However, generators on setpoint control may hold for between 10 and 60 seconds then drop back off prior to AGC pulses reaching the generator. In order to see the full response of a BA it is necessary to see data for the full event rather than just the first minute. Rather than overlapping the BRD standard, this will work hand-in-hand with this standard. Comments:
6. Do you have other comments on the SAR?

Comments:

Please use this form to submit comments on the second draft of the Frequency Response SAR．Comments must be submitted by May 3，2006．You must submit the completed form by emailing it to sarcomm＠nerc．com with the words＂Frequency Response＂in the subject line．If you have questions please contact Maureen Long at maureen．long＠nerc．net or 813－468－5998．

## Background Information

Please review the drafting team's consideration of the comments submitted with the first draft of the Frequency Response SAR and then review the drafting team's conforming changes made to SAR. Because the changes to the SAR were so extensive, there is no 'red line' version to show the changes from the first draft.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that comments from the first posting of the SAR were adequately addressed?
$\square$ Yes
Comments:
2. Do you agree with the list of proposed requirements included in the detailed description of the revised SAR?
$\boxtimes$ Yes
$\boxtimes$ No
Generally, yes, but more clarity is desired on a number of points, e.g., who decides which generators will be granted exemptions - the BA or the RRO; who sets the criteria - BA or RRO. In addition, I think some of the proposed requirements may conflict with each other as details are driven out; if a number of a BA's generators applied for and were granted exemptions from governor response, the (anticipated) 5\% droop range may need to be adjusted for the generators which do provide governor response for the BA.

Governor response is not the only equipment consideration at the plant/unit. Plant/unit control systems also should be operated so that the desired unit response will occur and be sustained. Comments:
3. Do you agree that the proposed standard(s) would be applicable to the Reliability Coordinator, Balancing Authority, Generator Owner, and Load-serving Entity?
$\boxtimes$ Yes
$\square$ No
However, the standard applies to each entity in different ways. The lion's share of responsibility lies with the BA to insure that the aggregate of the Gen Owners responses provide the response needed. Comments:
4. The current standard on Bias requires a Balancing Authority to carry a minimum bias equal to $1 \%$ of peak load. As an example, in the Eastern Interconnection, this value is double current natural frequency response. Should the standard provide an incentive, such that a Balancing Authority can use a bias equal to their
natural response, but less than $1 \%$ of peak, if the response is above an acceptable target?
$\boxtimes$ YesNo
Calculation of each BA's bias should be based on a rigorous analysis which demonstrates that the BA can provide the expected response, regardless of peak load. This is consistent with the proposed requirements - 'technicallysound calculation and report of frequency response' and 'Will not mandate a given amount of frequency response'. Comments:
5. Several commenters suggested response should be measured for an extended period after a frequency excursion, up to the point where automatic generation control (AGC) would take over. This was to ensure initial response wasn't withdrawn prematurely. Should the standard measure out to 60 seconds following an excursion?

Q Yes
At least. Based on the words in the SAR Purpose statement, 'this proposed standard coordinates with and complements the Balance Resources and Demand standards, which addresses Interconnection frequency control generally 5 minutes and longer', it seems that this standard should cover out to the 5 minute mark of an event. AGC actions will commence at the first scan cylcle or two after the event (5-15 secs), but the actual generation response may not settle out for several minutes, depending on the type and amount of generation on AGC at the time. Comments:
6. Do you have other comments on the SAR?

Comments:

Because the changes to the SAR were so extensive, there is no 'red line' version to show the changes from the first draft.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that comments from the first posting of the SAR were adequately addressed?
$\boxtimes$ Yes
Comments:
2. Do you agree with the list of proposed requirements included in the detailed description of the revised SAR?Yes
$\boxtimes$ No
The SAR identifies Load-Serving Entities as a function that will be affected by any requirements that are developed from this SAR. Question three, on this comment form, goes one step further and asked the industry if the proposed standard would be applicable to Load-Serving Entities. ATC was unable to determine from the detailed description section any requirements that would apply to a Load-Serving Entity. With that being said ATC suggests that language be added to the SAR that would require the Load-Serving Entities to be responsible for procurement of adequate frequency response.

ATC found bullet number six lacks a clear description of the standard that could be developed. ATC recommends that this bullet be rewritten to better inform the industry of the type of standard the SAR requestor wants developed. Is the SAR requestor requesting a standard that will not mandate frequency response, but instead recommend a frequency response? ATC, in general, feels that standards should require something not make recommendation. or, Is the SAR requestor requesting that a standard be develop that would set long-term Interconnection target levels and then require the industry to meet those target-levels? ATC is in support of a standard that would require entities to set long-term target levels and require other entities to meet the determined target levels. ATC is not in support of a standard that requires functions to set long-term target levels but not require other entities to meet those levels. Lastly, this bullet should clearly identify who are the responsible entities.

ATC is concerned that Generator Owners could be allowed to categories the same generating units differently. A Generator Owner that aggregates their units for purposes of determining a voltage schedule (VAR-001-1) should then
not be allowed to individualize their units for this standard to escape under the nameplate rating of 10 MW . Comments:
3. Do you agree that the proposed standard(s) would be applicable to the Reliability Coordinator, Balancing Authority, Generator Owner, and Load-serving Entity?

Q YesNo
Please see comment in questions two about the Load-serving Entity. Comments:
4. The current standard on Bias requires a Balancing Authority to carry a minimum bias equal to $1 \%$ of peak load. As an example, in the Eastern Interconnection, this value is double current natural frequency response. Should the standard provide an incentive, such that a Balancing Authority can use a bias equal to their natural response, but less than $1 \%$ of peak, if the response is above an acceptable target?
$\boxtimes$ YesNo
Although ATC is in support of this recommendation, we feel that it should be classified as an "allowable exemption" not an "incentive". Comments:
5. Several commenters suggested response should be measured for an extended period after a frequency excursion, up to the point where automatic generation control (AGC) would take over. This was to ensure initial response wasn't withdrawn prematurely. Should the standard measure out to 60 seconds following an excursion?

Q Yes
No

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that comments from the first posting of the SAR were adequately addressed?
$\boxtimes$ Yes
Comments:
2. Do you agree with the list of proposed requirements included in the detailed description of the revised SAR?
$\boxtimes$ YesNo
Re Bullet 7 - BAs must be free to operate their automatic generation control in any method they desire. The tie-line frequeency bias is used for complinace monitoring, but should not be a requirement for the actual automatic generation algorithm. Recommend this be modified to state : Balancing authorities will calculate an Area Control Error for compliance reporting purposes using tie-line frequency bias. Comments:
3. Do you agree that the proposed standard(s) would be applicable to the Reliability Coordinator, Balancing Authority, Generator Owner, and Load-serving Entity?
$\boxtimes$ YesNo
The proposed standards may apply to LSEs when demand side resources are utilized for frequency control, but will not apply to many of the LSEs. There may also be cases where Generator Operators have obligations under the standard. Comments:
4. The current standard on Bias requires a Balancing Authority to carry a minimum bias equal to $1 \%$ of peak load. As an example, in the Eastern Interconnection, this value is double current natural frequency response. Should the standard provide an incentive, such that a Balancing Authority can use a bias equal to their natural response, but less than $1 \%$ of peak, if the response is above an acceptable target?
$\boxtimes$ YesNo

The 1\% minimum frequency bias should be evaluated to take into account the reliability requirements of the interconnections. frequency response over recent years. We suggest that the minimum bias be addressed during the development of the Frequency Response Standard. It is unclear what the word "incentive" means above.

Comments:
5. Several commenters suggested response should be measured for an extended period after a frequency excursion, up to the point where automatic generation control (AGC) would take over. This was to ensure initial response wasn't withdrawn prematurely. Should the standard measure out to 60 seconds following an excursion?

区 Yes
$\boxtimes$ No
AGC response begins within only a few seconds after the disturbance with a maximum ramp rate achieved within three to five minutes. Governor response and load frequency response typically peak within 30 seconds. There is logic to monitoring governor respone for sustainability past its initial peak and this should be investigated during standard development.

Comments:
6. Do you have other comments on the SAR?

In our opinion, this SAR, or one like it, is required to ensure that the primary frequency response of the interconnections and the BAs do not deteriorate to a point where 1) the interconnection can not adequately respond to major generator trips (including potential multiple contingencies which, though rare, do happen) and 2) primary frequency response of the BAs is inadequate to support islanding during severe local disturbances, thus allowing local disturbances to cascade into regional or interconnection wide disturbances. Primary frequency response is declining in all Interconnections, Eastern, Western and ERCOT. WECC and ERCOT have taken a proactive approach to addressing this problem, but there is no similar work being done in the Eastern Interconnection. This SAR, or one like it, is needed.

$\square$ Yes
Comments:
2. Do you agree with the list of proposed requirements included in the detailed description of the revised SAR?YesNo
Comments:
3. Do you agree that the proposed standard(s) would be applicable to the Reliability Coordinator, Balancing Authority, Generator Owner, and Load-serving Entity?Yes
$\boxtimes$ No
Since the standard is concerned with governor regulated frequency response of generating units that applicability should also apply to the Generator Operator (currently this box is not checked). It will ultimately be the Generator Operators responsibility to ensure frequency responsiveness of the units, e.g. ensuring that the unit is not operating in Valve Wide Open mode. Comments:
4. The current standard on Bias requires a Balancing Authority to carry a minimum bias equal to $1 \%$ of peak load. ## Background Information

Please review the drafting team's consideration of the comments submitted with the first draft of the Frequency Response SAR and then review the drafting team's conforming changes made to SAR. Because the changes to the SAR were so extensive, there is no 'red line' version to show the changes from the first draft.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that comments from the first posting of the SAR were adequately addressed?
$\boxtimes$ YesNo
Comments:
2. Do you agree with the list of proposed requirements included in the detailed description of the revised SAR?
$\boxtimes$ YesNo
However some bullets need further clarification
Bullet 2: The standards process allows for regional differences. What more flexibility is needed?

Bullet 6: Keep this bullet simple by simply stating target levels will be set for BAs and RROs to take actions cited. Also a sub-bullet needs to be added on what are options to get additional frequency response; specifically for the BAs. In particular what can the BAs do if the Generation Owners do not provide adequate response. The BAs don't have generation interconnection agreements, the transmission owners do.

Comments:
3. Do you agree that the proposed standard(s) would be applicable to the Reliability Coordinator, Balancing Authority, Generator Owner, and Load-serving Entity?
$\boxtimes$ YesNo
Also pertains to Generator Operator Comments:
4. The current standard on Bias requires a Balancing Authority to carry a minimum bias equal to $1 \%$ of peak load. As an example, in the Eastern Interconnection, this value is double current natural frequency response. Should the standard provide an incentive, such that a Balancing Authority can use a bias equal to their natural response, but less than $1 \%$ of peak, if the response is above an acceptable target?

X YesNo
However this requirement still does not address the need for enough frequency response on the system. Comments:
5. Several commenters suggested response should be measured for an extended period after a frequency excursion, up to the point where automatic generation control (AGC) would take over. This was to ensure initial response wasn't withdrawn prematurely. Should the standard measure out to 60 seconds following an excursion?
$\qquad$ Yes
No
Needs to be verified with a field trial. Comments:
6. Do you have other comments on the SAR?

Reliability and Market Interface Principles 3, 5 and 6 should be checked as well.

Comments:

## Background:

The Frequency Response SAR Drafting Team thanks all commenters who submitted comments on the first draft of the SAR for Frequency Response. This SAR was posted for a 30-day public comment period from April 4, 2006-May 3, 2006. The SAR DT asked stakeholders to provide feedback on the SAR through a special SAR Comment Form. There were 16 sets of comments, including comments from more than 59 different people from more than 41 companies representing 6 of the 9 Industry Segments as shown in the table on the following pages.

The primary changes to the SAR were made based on comments:

- Clarification on the role of the LSE and Generator Operator.
- Inclusion of the applicability of Reliability Principles 3,5 and 6.
- Reduced the scope to address only the collection of data needed to model Frequency Response in North America.

In this 'Consideration of Comments’ document stakeholder comments have been organized so that it is easier to see the responses associated with each question. All comments received on the SAR can be viewed in their original format at:

## http://www.nerc.com/~filez/standards/Frequency_Response.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Gerry Adamski at 609-452-8060 or at gerry.adamski@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process. ${ }^{1}$

## Update:

The original SAR on Frequency Response was submitted in large part due to a study that showed a $10+\%$ decline in Eastern Interconnection Frequency Response over a 5 year period, when response should be increasing over time as an Interconnection grows. The drafting team posted a whitepaper along with the SAR to outline the need for a standard.

The NERC Resources Subcommittee recently updated their estimate of Eastern Interconnection Frequency Response and found it to be on the order of $2800 \mathrm{MW} / 0.1 \mathrm{~Hz}$ and still trending downward.

[^17]
## Decline in Beta Over 5 Year Period

Figure 1 Original Eastern Interconnection Frequency Response Study (Ingleson and Nagle)

Figure 2 Updated Eastern Interconnection Frequency Response (NERC Resources Subcommittee)
Based on these observations, at its June, 2006 meeting, the NERC Operating Committee endorsed developing a frequency response standard that includes the following goals and objectives:

- Improving Interconnection frequency response event cataloging and benchmarking
- Calculating balancing authority frequency response and requiring balancing authorities to analyze those cases where the response is significantly below the norm
- Establishing time limits to complete the analyses
- Tabulating non-responsive generators
- Measuring generator response (including those units on line)
- Including regional participation and review

Unfortunately, the stakeholders who responded to the second draft of the proposed SAR offered a wide range of opinions on what should be in the standard, without a clear consensus. Given this, the drafting team revised the SAR to only require collection of data needed to model frequency response in each of the interconnections. Once frequency response has been modeled and analyzed, the Resources Subcommittee and the industry will be in a better position to recommend specific frequency response targets for each Interconnection.

This revised SAR was reviewed and supported by the NERC Resources Subcommittee on December 4, 2006.

Balancing Authority, Generator Owner, and Load-serving Entity? ............................................... 22
4. The current standard on Bias requires a Balancing Authority to carry a minimum bias equal to $1 \%$ of peak load. As an example, in the Eastern Interconnection, this value is double current natural frequency response. Should the standard provide an incentive, such that a Balancing Authority can use a bias equal to their natural response, but less than 1\% of peak, if the response is above an acceptable target?
5. Several commenters suggested response should be measured for an extended period after a
frequency excursion, up to the point where automatic generation control (AGC) would take over.
This was to ensure initial response wasn't withdrawn prematurely. Should the standard measure
out to 60 seconds following an excursion? ..... 28
6. Do you have other comments on the SAR? ..... 32

## 1. Do you agree that comments from the first posting of the SAR were adequately addressed?

Summary Consideration: Most commenters indicated that the SAR drafting team did provide an adequate response to the comments submitted with the first posting of the SAR.

| Commenter | Yes | No | Comment |
| :--- | :--- | :--- | :--- |
| Energy Mark, Inc. (8) <br> Howard F. Illian |  | $\checkmark$ | There is an expectation apparent in the first set of responses that indicates that the drafting <br> team believes they have more knowledge of the solutions that will be required than the final <br> standard will contain. The two greatest areas of insufficient understanding lie in the <br> measurement of Frequency Response at less than the full interconnection level and the effect of <br> the standard as envisioned on markets. These two problems are addressed in the comments to <br> later questions in this comment form. |
| Response: There were varying opinions on the scope of the second draft of the SAR. The drafting team revised the scope of the SAR again to <br> focus solely on collection of data needed to model frequency response in each of the interconnections. Once that data is collected and analyzed, <br> a standard can be proposed that includes performance requirements that will motivate entities to operate in ways that keep frequency response <br> within an acceptable range. |  |  |  |

## Commenter <br> Yes <br> No <br> Comment

Response: We agree that there needs to be additional studies and investigation. There were varying opinions on the scope of the second draft of the SAR. The drafting team revised the scope of the SAR again to focus solely on collection of data needed to model frequency response in each of the interconnections. Once that data is collected and analyzed, a standard can be proposed that includes performance requirements that will motivate entities to operate in ways that keep frequency response within an acceptable range.

PJM Corporate Development
Div. (2)

Al DiCaprio
Joseph D. Willson
Mark Kuras

The Resources Subcommittee in a response to the first draft states "A primary purpose of this standard is to collect information so informed decisions can be made before there is a problem." It is clear from that reply that the Resources Subcommittee wishes to undertake an analysis of the system and needs to collect additional information. This data collection effort may be laudable but it does not rise to the level of being a federally enforced mandatory standard. What if later on the 'data' were to show there is no problem, then there will be a need to rescind the standard and repay those who were non-compliant to a data collection effort.
In their response to the first draft, the Resources Subcommittee cite a WECC study. But they have no similar study for the East. The Resources Subcommittee still has not shown that the decrease in sub-minute response is either (1) a problem or (2) nothing more than an indication that a larger system has more inertia and therefore less response that the smaller system in the past.
This SAR, with its present theoretical focus, posits the BA as the responsible entity for governor response. Even those who agreed with the first posting that Frequency Response is an important issue - stated that a standard cannot define fixed norms (MRO, NYISO, IESO (2) ). The BA is not responsible to instantaneous response -at best it can establish a capacity obligation but it can't guarantee continuous response.

Response: There were varying opinions on the scope of the second draft of the SAR. The drafting team revised the scope of the SAR again to focus solely on collection of data needed to model frequency response in each of the interconnections. Once that data is collected and analyzed, a standard can be proposed that includes performance requirements that will motivate entities to operate in ways that keep frequency response within an acceptable range.

| IESO (2) <br> Ron Falsetti | $\checkmark$ | $\checkmark$ | Yes, with respect to the responses to the IESO's comments. However, the revised SAR appears <br> to get somewhat mixed up between sub-minute frequency response performance with a longer <br> term (> 1 minute) performance, and lacks clarity on what the proposed standard is intended to <br> stipulate. <br> Is the proposed standard intended to stipulate: <br> (a) a minimum frequency response performance level with which to determine if follow-up <br> analysis is to be conducted, or, <br> (b) requirements for calculating, measuring, reporting and analyzing frequency response, or, <br> (c) both, in addition to, <br> (d) requirements for generators to be equipped with governors and if so, the target to be <br> responding to? |
| :--- | :--- | :--- | :--- |

| Commenter | Yes | No | Comment |
| :---: | :---: | :---: | :---: |
|  |  |  | If (a) is not specified in the standard, we see a difficulty in stipulating the threshold for (b) and the target for (d). <br> From the SDT's response to our previous comments ("The new requirements may need to be field tested for an extended duration before compliance with the requirements becomes mandatory. A long field test with extensive data collection may be needed before justifiable minimum performance standards can be identified"). It is our belief the standard is intended to stipulate (b) only. We see this as a necessary first step. However, it may then beg the question of the need of having a standard to develop the basis for a future standard. Might there not be other alternatives to achieve (b) such as by means of a request from the standing committees or NERC to the BAs and the regions to compile this information? |
| Response: There were varying opinions on the scope of the second draft of the SAR. The drafting team revised the scope of the SAR again to focus solely on collection of data needed to model frequency response within each interconnection. Once that data is collected and analyzed, a standard can be proposed that includes performance requirements that will motivate entities to operate in ways that keep frequency response within an acceptable range. |  |  |  |
| BPA (1, 3, 5, 6) <br> Bart McManus <br> John Anasis <br> Lynn Aspaas <br> Mike Viles | $\checkmark$ |  | We are still concerned with a NERC standard countering some aspects of the standard we are in the process of drafting in WECC, so will continue to be active on the drafting team to insure it does not adversely impact the WECC standard. |
| Response: We encourage WECC to be actively involved in the drafting of the standard. Note that the drafting team revised the scope of the SAR so that the SAR focuses solely on the collection of data needed to model frequency response in each interconnection. This should not conflict with WECC's work on its frequency response standard. |  |  |  |

## 2. Do you agree with the list of proposed requirements included in the detailed description of the revised SAR?

Summary Consideration: Most commenters disagreed with the proposed requirements included in the second draft of the SAR. The drafting team revised the SAR to focus solely on the collection of data needed to model frequency response in each interconnection. Additional SARs may be proposed in the future to propose requirements for operating in ways that support frequency response.

| Commenter | Yes | No | Comment |
| :---: | :---: | :---: | :---: |
| Arizona Public Service Co. $(1,5)$ Baj Agrawal |  |  | The requirements on individual generator are unnecessary. The requirements should be on a group of generators in a control area to achieve a desired response. Thus, one could have some generators which are being operated as non responsive and the others which are responding well to offset for those which are not responsive. <br> Additionally, the 10 MW size requirements are too restrictive and unnecessary. It should be plant based and should apply to plants of 100 MW or more aggregate capacity. In any realistic scenario, the smaller plants are not expected to contribute much to frequency response and hence subjecting them to frequency response requirements is uneconomic. |
| Response: The SAR was revised and will address only the collection of data needed to model frequency response in each interconnection. Once more is known about frequency response, additional SARs may be proposed with specific performance requirements for generators. |  |  |  |
| IESO(1) <br> Anita Lee |  | $\checkmark$ | The purpose is definitely suggested for under frequency conditions. However, when specifying that the generators shall have governors with droop etc... the role of the governor is for both high and low frequency conditions and not just underfrequency FRR. In a market environment it is very possible that not every generator will provide FRR services. Thus, the governor and governor deadband should be a requirement to interconnect to a power system. Generators that provide FRR shall have responsive governor and prime mover. The standard is based on balancing area response which will include generators and in some jurisdications will include load. So is the intent that whatever load is considered, additional FRR resources such as generators are used to provide the required FRR? <br> What about load as FRR providers? Some industrial facilities are capable to dynamically vary the load of the facility to frequency (ie virtual governor). The standard should apply to FRR providers which can be generators and loads. <br> We agree that generator owners have an obligation to have working governors or provide explanations why not. The "10 MW" requirement should be evaluated for consistency with other standards. This should not hold up the progress of the SAR, but should be evaluated by the ultimate standard drafting team. |
| Response: The SAR drafting team agrees that governors must work for both high and low frequency events. One methodology under discussion would monitor both high and low events. The logic behind capturing low frequency (typically associated with trips of large generators) is that these events are much more common than large loss of load. |  |  |  |

| Commenter | Yes | No | Comment |
| :---: | :---: | :---: | :---: |
| We agree that all generators may not need to provide frequency response. As envisioned, as long as the BA had adequate response, it would have had some flexibility under the proposed standard. Note, however, that the SAR has been revised and no longer includes these performance requirements. The SAR was revised and will address only the collection of data needed to model frequency response in each interconnection. Once more is known about frequency response, additional SARs may be proposed with specific performance requirements for generators. <br> As each new standard is developed, greater attention will be paid on the 'applicability'. The threshold of ' 10 MW ' will need to be reviewed from a reliability-related perspective rather than 'consistency across all standards' perspective. |  |  |  |
| IESO (2) <br> Ron Falsetti |  | $\checkmark$ | The intent of some of the requirements is again unclear to the IESO, for example. <br> (i) Does Bullet \#2 mean the flexibility in the calculation and reporting process or in the target/minimum frequency response level? <br> (ii) Assuming Bullet \#4 a requirement, and one which relates to the minimum level of frequency response, how is this requirement stipulated at this time while data collection and follow-up analysis are to be proposed as standard requirements and field testing has yet to commence? Same comment applies to Bullet \#9. <br> (iii) Bullet \#6 appears to go beyond the sub-minute time frame. Further, we are unable to understand the leading sentence "Will not mandate a given amount of frequency response". We feel it is important that if poor frequency response performance in the sub-minute time frame is to be assessed and improved, specific target which may well be the minimum amount of frequency recovery would need to be stipulated. <br> (iv) Bullet \#7 also appears to be beyond the sub-minute time frame, which is to mandate AGC but which should be covered by other BAL standards. <br> (v) Bullets \#8 and \#1 appear to be the main requirements for the proposed standard that are achievable at this time. <br> (vi) As mentioned in (ii) above, we are unable to visualize how the range and target of response be stipulated in the standard before Bullets \#1 and \#8 are implemented. <br> (v) If generators are allowed to seek exception, the standard should provide some basic premise that bounds the exception cases rather than leaving the door wide open and the decision solely to the judgment of the BAs and RROs. |
| Response: "Flexibility to meet the needs of each Interconnection" was intended to mean some flexibility in calculation (for example ERCOT is interested in "point C" (the extreme) of an event, but this point is not observable and has little value in the East. The WECC has expressed |  |  |  |

| Commenter | Yes | No | Comment |
| :---: | :--- | :--- | :--- |
| concern for extended contribution of response (perhaps out several minutes). As envisioned, there would have been different target levels in |  |  |  |

concern for extended contribution of response (perhaps out several minutes). As envisioned, there would have been different target levels in each Interconnection. Interconnections would have been able to choose to have a tighter target droop setting.

Bullet 4 relates to a statistically-sound measurement of frequency response at both the Interconnection and BA level. The data would have been collected and reported each year of the standard. In effect, the data collection in the first year of the standard would have served as the field test.
"Long term target measure" intended to imply that the BA would be measured on many events over the year and its performance would have been evaluated on the whole, not on single events.

It is true operation of AGC goes beyond the sub-minute window of time. The intent of this bullet was that the bias a BA provides should match its natural frequency response. Just as was originally intended in Policy 1, a BA calculates its natural response in one year and uses those observations to operate in the next year. The drafting team envisioned the same would occur in the originally proposed standard. The establishment of the "12 month basis" either on a calendar year or on a rolling 12 month period like CPS1 would have been determined during standard drafting.

Note, however, that the SAR was revised and will address only the collection of data needed to model frequency response in each interconnection. Once more is known about frequency response, additional SARs may be proposed with specific performance requirements for generators.

NPCC CP9 Reliability Standards Working Group

The proposed requirements nor the White Paper adequately make the case that there is a need for a frequency response standard at this time. However, it is recommended that the subject be further investigated. The analysis should evaulate if a frequency response standard that addresses the three major short term frequency control components (inertial response, governor response, and automatic generation control) are required. The report writers should include a broad range of participants including (at least) 3 OEM's (original equipment manufacturers) representing steam, gas and hydro generation control. Some specific issues that should be addressed are:

1. Inertial Response: Evaluate historical changes in the inertial response of the electric grid as a result of changing power equipment designs and types of load. For example, the addition of new industrial and aero-derivative turbine-generators have lower inertia-power ratios than tranditonal nuclear/fossil units and, in addition, they are not base loaded (as a result of more efficient dispatching and improved power plant controls).
2. Governor Response: Evaulate generation governor performance as a result of newer, more configurable prime mover controls. Digital controls provide increased plant reliability, however, this may be at the expense of decreased governor response. For example, the use of main steam pressure controls on steam units and low NOx controls on gas turbines may

| Commenter | Yes | No | Comment |
| :--- | :--- | :--- | :--- |
|  |  |  | produce unexpected droop output responses. <br> 3. Automatic Generation Control (AGC): Perform a control area survey to determine if there <br> is sufficient regulation capacity within control areas to maintain generation and load balance. <br> Include a review of incentives and penalties for generators to respond accurately and reliably <br> to AGC signals. |

## Response:

When the first draft of the SAR was posted for comment, the drafting team asked stakeholders if they felt that there was a reliability-related need for a standard that focuses on frequency response, and most stakeholders indicated there is a reliability-related need for a frequency response standard.

While we don't know the exact amount of frequency response needed for each interconnection, a 12 year decline in response when it is expected to be increasing and without knowledge of where the response is low is a reliability concern.

Failure of generators to follow AGC signals would appear to be either a CPS issue or a business practice.
The SAR was revised and will address only the collection of data needed to model frequency response in each interconnection. Once more is known about frequency response, additional standards may be proposed with specific performance requirements for generators. This will allow analyses to focus on the different types of response and should, eventually, facilitate the development of another standard that includes performance requirements aimed at providing a specified amount of frequency response.

| Energy Mark, Inc. (8) |  | $\checkmark$ | Requirements that apply to individual generators cannot be implemented as indicated in the <br> standard without failing to comply with Market Interface Principle 2. Frequency Response |
| :--- | :--- | :--- | :--- |

Howard F. Illian

Requirements that apply to individual generators cannot be implemented as indicated in the standard without failing to comply with Market Interface Principle 2. Frequency Response (Governor Response) have economic costs associated with standing ready to supply. These costs have been documented in EPRI Reports on Ancillary Services. If any generator is given an exception to not provide a response, that generator will also be given a market advantage resulting from the savings they will receive by not providing a response. The SAR as currently written will create a market advantage for all generators below 10 MW and all generators that are given an exception to the governor response requirement. The alternatives to these generator requirements are either not have a competitive market and decide the provision of frequency response administratively (the old VIU method), or determine who provides frequency response through a competitive market process.

Response: We appreciate the comments on Market Interface Principle 2. As envisioned the original SAR proposed measuring the approximately 140 Balancing Authorities rather than the roughly 4000 individual generators (NERC 2004 Generating Unit Statistical Brochure). The SAR intended to be indifferent to what entity provides response (whether load, large generator or small generator). It was intended to measure the $B A$, with the expectation that the BA would have had to document exceptions that would have been reviewed by the BA and the Region for reliability implications. As envisioned, the drafting team did not expect owners to install many small generators rather than one larger generator to avoid providing data for the standard.

| Commenter | Yes | No | Comment |
| :---: | :---: | :---: | :---: |
| Note that the SAR was revised and will address only the collection of data needed to model frequency response in each interconnection. Once more is known about frequency response, additional standards may be proposed with specific performance requirements for generators. |  |  |  |
| Duke Energy Midwest (1, 3, 6) Jeff Baker |  | $\checkmark$ | Not totally, I need to understand more of what would be required to meet the obligation of Generator owners to equip generating units with nameplate ratings of 10 MW or greater, with a governor capable of providing immediate and sustained response to frequency deviations. |
| Response: As envisioned, all generators would have governors that respond to frequency deviations. The BA and the Region would need be aware of exceptions for study purposes. If the BA's performance were significantly below the norm, an analysis and assessment would have been required. <br> Note, however, that the SAR was revised and will address only the collection of data needed to model frequency response in each interconnection. Once more is known about frequency response, additional standards may be proposed with specific performance requirements for generators. |  |  |  |
| $\operatorname{BPA}(1,3,5,6)$ |  | $\checkmark$ | RE: bullet 2: Instead of flexibility to meet interconnection needs, each interconnection should have its own requirements on frequency response, this is due to the unique frequency response of each interconnection. <br> re bullet 4: This Standard will need to measure frequency response for the duration of the frequency deviation. Measuring it until frequency recovers will overlap with the Balance Resources and Demand standard slightly, but will give much better results than simply going out a few minutes. <br> re bullet 6: Target levels should be BA specific to insure there is not an incentive to lean on other BA's. How will the target levels be calculated? <br> Re bullet 7: BAs must be free to operate their automatic generation control in any method they desire. The tie-line frequency bias is used for compliance monitoring, but must not be a requirement for the actual automatic generation control algorithm. Recommend this be modified to state: Balancing Authorities will calculate an Area Control Error for monitoring purposes using tie-line frequency bias. <br> re bullet 8: WECC should call FRC surveys for WECC instead of NERC. <br> re bullet 9: Recommend generating unit nameplate of 10 MW plus multi-unit installations of 10 MW or greater be required to have a governor(s) capable of providing immediate and sustained response to frequency deviations. <br> Re bullets 9 and 10: Currently wind generation does not have governor response capability. Due to the amount of wind integration planned in the next decade, new installations should have a requirement for frequency responsive units. Historically, requirements have provided incentive for manufacturers to modify machine design (low-voltage ride-through capability, voltage control capability) to meet the requirements. |

Commenter |  | Yes | No |
| :--- | :--- | :--- |

Response: We agree - the proposed standard would have assumed that each interconnection had a unique frequency response.
Regarding bullet 4, some thought would have to be given on how to measure over the entire duration of a frequency disturbance (typically up to 15 minutes for a DCS event) and how to remove AGC response from the estimate of frequency response. Suggestions are welcome. However, the Interconnection would be able to define specific requirements.

Regarding bullet 8, WECC has the right to call FRC Surveys for WECC, as does NERC (historically through the NERC OC and Resources subcommittee)

We agree with your comment regarding bullet 9 .
Regarding wind generation, governor response is normally provided by calling on more energy from the prime mover when frequency drops. We are unsure how this would normally be done with wind, unless the goal would be to under-utilize the wind during normal operation and then call for full available energy when the frequency drops. Again, this standard as originally proposed, was intended to measure BA response- as long as the pool of generation within the BA provided adequate response, it would have allowed the BA flexibility on which generators provide that response.

Note, however, that the SAR was revised and will address only the collection of data needed to model frequency response in each interconnection. Once more is known about frequency response, additional standards may be proposed with specific performance requirements for generators. This will allow analyses to focus on the different types of response and should, eventually, facilitate the development of another standard that includes performance requirements aimed at providing a specified amount of frequency response.

## ATC LLC (1) <br> Jason Shaver

$\checkmark \quad$ The SAR identifies Load-Serving Entities as a function that will be affected by any requirements that are developed from this SAR. Question three, on this comment form, goes one step further and asked the industry if the proposed standard would be applicable to Load-Serving Entities. ATC was unable to determine from the detailed description section any requirements that would apply to a Load-Serving Entity. With that being said ATC suggests that language be added to the SAR that would require the Load-Serving Entities to be responsible for procurement of adequate frequency response.
ATC found bullet number six lacks a clear description of the standard that could be developed. ATC recommends that this bullet be rewritten to better inform the industry of the type of standard the SAR requestor wants developed. Is the SAR requestor requesting a standard that will not mandate frequency response, but instead recommend a frequency response? ATC, in general, feels that standards should require something not make recommendation. or, Is the SAR requestor requesting that a standard be develop that would set long-term Interconnection target levels and then require the industry to meet those targetlevels? ATC is in support of a standard that would require entities to set long-term target levels and require other entities to meet the determined target levels. ATC is not in support

| Commenter | Yes | No | Comment |
| :---: | :---: | :---: | :---: |
|  |  |  | of a standard that requires functions to set long-term target levels but not require other entities to meet those levels. Lastly, this bullet should clearly identify who are the responsible entities. <br> ATC is concerned that Generator Owners could be allowed to categories the same generating units differently. A Generator Owner that aggregates their units for purposes of determining a voltage schedule (VAR-001-1) should then not be allowed to individualize their units for this standard to escape under the nameplate rating of 10 MW . |
| Response: We agree that the LSE is the ultimate beneficiary of frequency response. However, since the standard isn't mandating a particular amount of frequency response for individual events, it would seem inappropriate to have the LSE obtain a given amount of frequency response for any specific event. |  |  |  |
| As originally proposed, this standard would have been primarily a technical/preparedness standard. Initially, the target levels of frequency response would have been based on observed interconnection history. |  |  |  |
| We agree that bullet \# 6 needs additional clarification for it to be understood. The long-term measure was envisioned to be an annual metric, based on a calendar year or on a rolling 12 month basis like CPS1 that captures many events over the year to come up with a composite estimate of performance. It was expected that the standard would allow interconnections to set their own frequency response limits. Absent specific frequency response bounds for an interconnection, the standard would have used recent history. The standard was intended to focus on the frequency response needs of each interconnection, and would have allocated a portion of each interconnection's frequency response responsibility to each of the interconnection's Balancing Authorities. |  |  |  |
| Note that the SAR was revised and will address only the collection of data needed to model frequency response in each interconnection. Once more is known about frequency response, additional standards may be proposed with specific performance requirements for generators. This will allow analyses to focus on the different types of response and should, eventually, facilitate the development of another standard that includes performance requirements aimed at providing a specified amount of frequency response. |  |  |  |
| PJM Corporate Development Div. (2) |  | $\checkmark$ | The SAR is still not clear about what is to be developed in the standard. Of the ten bulleted items several seem to show a misunderstanding between a sub-minute frequency response obligation and Automatic Generation control. The RS must make clear what it wants to do. Sub-minute frequency response occurs with or without frequency bias; sub-minute frequency response is not helped or hurt by having AGC. This is a major problem with the proposal. It is not clear and it is not definitive. <br> Item 1 indicates the standard will be a Report <br> Item 2 states the standard will be flexible (that is mandated in the Process Manual) <br> Item 3 seems to indicate that non-compliance will be met with a requirement to analyze the incident (if this is standard is so important why isn't every event critical?) <br> Item 5 is the most unusual - the standard will not mandate a response but will provide |

| :--- | :--- | :--- | :--- | :--- |

| Commenter |  | No | Commen |
| :---: | :---: | :---: | :---: |
| Regarding item 10, the SAR was not proposing that generators may opt out of participation. As envisioned, generators were expected to have governors that respond to frequency. Exceptions would have been documented. Nevertheless, the standard would have measured overall BA response. <br> Note, however, that the SAR was revised and will address only the collection of data needed to model frequency response in each interconnection. Once more is known about frequency response, additional standards may be proposed with specific performance requirements for generators. This will allow analyses to focus on the different types of response and should, eventually, facilitate the development of another standard that includes performance requirements aimed at providing a specified amount of frequency response. |  |  |  |
| Duke Energy Carolinas (1, 3, 5, <br> 6) <br> Tom Pruitt |  |  | Generally, yes, but more clarity is desired on a number of points, e.g., who decides which generators will be granted exemptions - the BA or the RRO; who sets the criteria - BA or RRO. In addition, I think some of the proposed requirements may conflict with each other as details are driven out; if a number of a BA's generators applied for and were granted exemptions from governor response, the (anticipated) $5 \%$ droop range may need to be adjusted for the generators which do provide governor response for the BA. <br> Governor response is not the only equipment consideration at the plant/unit. Plant/unit control systems also should be operated so that the desired unit response will occur and be sustained. |
| Response: The SAR was revised and will address only the collection of data needed to model frequency response in each interconnection. Once more is known about frequency response, additional standards may be proposed with specific performance requirements for generators. This will allow analyses to focus on the different types of response and should, eventually, facilitate the development of another standard that includes performance requirements aimed at providing a specified amount of frequency response. |  |  |  |
| NERC Resources Subcommittee | $\checkmark$ |  | Re Bullet 7 - BAs must be free to operate their automatic generation control in any method they desire. The tie-line frequeency bias is used for complinace monitoring, but should not be a requirement for the actual automatic generation algorithm. Recommend this be modified to state : Balancing authorities will calculate an Area Control Error for compliance reporting purposes using tie-line frequency bias. |
| Response: Based on comments, the Resources Subcommittee recommends this requirement more appropriately belongs in the AGC standard. <br> The SAR was revised and will address only the collection of data needed to model frequency response in each interconnection. Once more is known about frequency response, additional standards may be proposed with specific performance requirements for generators. This will allow analyses to focus on the different types of response and should, eventually, facilitate the development of another standard that includes performance requirements aimed at providing a specified amount of frequency response. |  |  |  |
| ITC Transmission (1) Jim Cyrulewski | $\checkmark$ |  | However some bullets need further clarification <br> Bullet 2: The standards process allows for regional differences. What more flexibility is needed? |

| Commenter | Yes | No | Comment |
| :---: | :---: | :---: | :---: |
| Beth Howell Mike Moltane Van Greening |  |  | Bullet 6: Keep this bullet simple by simply stating target levels will be set for BAs and RROs to take actions cited. Also a sub-bullet needs to be added on what are options to get additional frequency response; specifically for the BAs. In particular what can the BAs do if the Generation Owners do not provide adequate response. The BAs don't have generation interconnection agreements, the transmission owners do. |
| Response: As originally envision there might be more than one aut <br> We agree that transmission owne practices" provisions. <br> The SAR was revised and will ad known about frequency response allow analyses to focus on the dif performance requirements aimed | have |  | differences would have been at the Interconnection level. For example, it was envisioned that that could be used by a BA to calculate response. <br> nection agreements that provide leverage to get generators to perform through "good utility <br> llection of data needed to model frequency response in each interconnection. Once more is dards may be proposed with specific performance requirements for generators. This will sponse and should, eventually, facilitate the development of another standard that includes pecified amount of frequency response. |
| Midwest Reliability Organization (2) | $\checkmark$ |  | In particular we agree that generator owners have an obligation to have working governors or provide explanations why not. The 10 MW requirement should be evaluated for consistency with other standards. This should not hold up the progress of the SAR, but should be evaluated by the ultimate standard drafting team. |
| Response: The SAR was revised and will address only the collection of data needed to model frequency response in each interconnection. Once more is known about frequency response, additional standards may be proposed with specific performance requirements for generators. This will allow analyses to focus on the different types of response and should, eventually, facilitate the development of another standard that includes performance requirements aimed at providing a specified amount of frequency response. <br> With respect to the 10 MW threshold - As each new standard is developed, greater attention will be paid on the 'applicability'. The threshold of '10 MW' will need to be reviewed from a reliability-related perspective rather than 'consistency across all standards' perspective. |  |  |  |
| Southern Company Transm. (1) | $\checkmark$ |  |  |

## 3. Do you agree that the proposed standard(s) would be applicable to the Reliability Coordinator, Balancing Authority, Generator Owner, and Load-serving Entity?

Summary Consideration: Although most commenters agreed with the proposed applicability, the drafting team has reduced the scope of the proposed standard, and the proposed applicability has been changed. The revised SAR shows that, in addition to the functional entities listed above, the Generator Operator may have some requirements in the proposed standard.

| Commenter | Yes | No | Comment |
| :---: | :---: | :---: | :---: |
| Tri-State G\&T (1) Bruce Sembeck |  | $\checkmark$ | Since the standard is concerned with governor regulated frequency response of generating units that applicability should also apply to the Generator Operator (currently this box is not checked). It will ultimately be the Generator Operators responsibility to ensure frequency responsiveness of the units, e.g. ensuring that the unit is not operating in Valve Wide Open mode. |
| Response: Note that the SAR was revised and will address only the collection of data needed to model frequency response in each interconnection. <br> We will include generator operator as an applicable entity. |  |  |  |
| PJM Corporate Development Div. (2) |  | $\checkmark$ | This question would require an assumption of what the standard would be. If the standard is to provide sub-minute frequency response, then the only entity should be the generator owner. |
| Response: The SAR was revised and will address only the collection of data needed to model frequency response in each interconnection. |  |  |  |
| IESO. (2) <br> Ron Falsetti |  | $\checkmark$ | Not having a good handle on what the standard is intended to achieve and stipulate, we are unable to comment on whom the standard should apply to. Among the ones included in the question, we are unclear on the role of the $R C$ in requiring anyone to install devices or take actions to improve frequency response in day to day operation. |
| Response: The SAR was revised and will address only the collection of data needed to model frequency response in each interconnection. We expect the Reliability Coordinator's role to be limited (most likely only alerting other Reliability Coordinators of generation or load events causing significant frequency excursions) |  |  |  |
| Duke Energy Midwest (1, 3, 6) Jeff Baker |  | $\checkmark$ |  |
| IESO (1) <br> Anita Lee | $\checkmark$ | $\checkmark$ | The Generator Operator may also have some responsibilities, such as the selection of control modes. <br> We're not sure what the LSE can do regarding the standard. They cannot control response from load. The exception may be coordination of frequency response with UFLS. <br> Planners may have some responsibilities with regard to new interconnections and also using observed frequency response in models as opposed to theoretical response. |

| Commenter | Yes | No | Comment |
| :---: | :---: | :---: | :---: |
| Response: The SAR was revised and will address only the collection of data needed to model frequency response in each interconnection. The LSE does need to provide some of this data and is listed as an applicable entity in the revised SAR. |  |  |  |
| $\operatorname{BPA}(1,3,5,6)$ | $\checkmark$ | $\checkmark$ | The only portion we can think of that would applicable to the Load-serving entity is for the load-serving entity to report their underfrequency load shedding settings. We believe LSEs should be removed as applicable entities. |
| Response: The SAR was revised and will address only the collection of data needed to model frequency response in each interconnection. The LSE does need to provide some of this data and is listed as an applicable entity in the revised SAR. |  |  |  |
| Duke Energy Carolinas (1, 3, 5, 6) Tom Pruitt | $\checkmark$ |  | However, the standard applies to each entity in different ways. The lion's share of responsibility lies with the BA to insure that the aggregate of the Gen Owners responses provide the response needed. |
| Response: The SAR was revised and will address only the collection of data needed to model frequency response in each interconnection. |  |  |  |
| WECC Reliability Coordination Subc. | $\checkmark$ |  | The only portion we can think of that would applicable to the Load-serving entity is for the load-serving entity to report their underfrequency load shedding settings. We believe LSEs should be removed as applicable entities. |
| Response: The SAR was revised and will address only the collection of data needed to model frequency response in each interconnection. The Load-serving Entity does need to provide some of this data and is listed as an applicable entity in the revised SAR. |  |  |  |
| ATC LLC (1) Jason Shaver | $\checkmark$ |  | Please see comment in questions two about the Load-serving Entity. |
| Response: Please see the response to your comment on question 2. |  |  |  |
| Midwest Reliability Organization (2) | $\checkmark$ |  | The Generator Operator may also have some responsibilities, such as the selection of control modes. <br> We're not sure what the LSE can do regarding the standard. They cannot control response from load. The exception may be coordination of frequency response with UFLS. Planners may have some responsibilities with regard to new interconnections and also using observed frequency response in models as opposed to theoretical response. |
| Response: The SAR was revised and will address only the collection of data needed to model frequency response in each interconnection. The Load-serving Entity does need to provide some of this data and is listed as an applicable entity in the revised SAR. |  |  |  |
| NERC Resources Subcommittee | $\checkmark$ |  | The proposed standards may apply to LSEs when demand side resources are utilized for frequency control, but will not apply to many of the LSEs. There may also be cases where Generator Operators have obligations under the standard. |
| Response: The SAR was revised and will address only the collection of data needed to model frequency response in each interconnection. The Load-serving Entity does need to provide some of this data and is listed as an applicable entity in the revised SAR. |  |  |  |
| Energy Mark, Inc. (8) | $\checkmark$ |  | The requirements applicable to the Generator Owner and Load-serving Entity may only |

| :--- | :--- | :--- | :--- |
| Howard F. Illian |  |  | Comment <br> include requirements for measurement processes, not necessairly requirements to provide <br> any frequency response. |
| Response: The SAR was revised and will address only the collection of data needed to model frequency response in each interconnection. <br> The Load-serving Entity does need to provide some of this data and is listed as an applicable entity in the revised SAR. |  |  |  |
| NPCC CP9 Reliability <br> Standards Working Group | $\checkmark$ |  | If required. |
| Response: Thank you. |  |  |  |
| ITC Transmission (1) <br> Jim Cyrulewski <br> Beth Howell <br> Mike Moltane <br> Van Greening |  |  | Also pertains to Generator Operator. |
| Response: The SAR was revised and will address only the collection of data needed to model frequency response in each interconnection. In <br> the revised SAR, the Generator Operator is responsible for providing data when the BA's performance is below an Interconnection target. |  |  |  |
| Southern Company Transm. (1) | $\checkmark$ |  |  |

4. The current standard on Bias requires a Balancing Authority to carry a minimum bias equal to $1 \%$ of peak load. As an example, in the Eastern Interconnection, this value is double current natural frequency response. Should the standard provide an incentive, such that a Balancing Authority can use a bias equal to their natural response, but less than $1 \%$ of peak, if the response is above an acceptable target?

Summary Consideration: While most commenters supported this suggestion, there was not consensus on the scope of the proposed requirements, and the drafting team revised the SAR to focus solely on collecting data needed to model frequency response in each of the interconnections. The drafting team will forward these comments to the Director of Standards Development so that they can be addressed by the Balance Resources and Demand standard drafting team or another drafting team. This shall serve as a summary response to all comments provided.

| Commenter | Yes | No | Comment |
| :--- | :--- | :--- | :--- |
| IESO. (2) <br> Ron Falsetti |  | $\checkmark$ | (i) The question seems to get the sub-minute and longer-term targets intertwined. We are <br> unclear on which "standard be provided an incentive". Is it the proposed sub-minute <br> standard which has yet to be determined or the current standard on Bias? If it is the <br> former, then this question seems a bit premature as we don't even know what the <br> performance target for sub-minute response should be. If it's the latter, then the issue <br> belongs to other BAL standards. |
|  |  | $\checkmark$ | The RS again is avoiding the issue of what sub-minute frequency response it MUST <br> mandate. The 1\% is related to the frequency bias setting (basically a long term average <br> response). The BRD deals with the longer term issue of frequency response - this <br> standard was designed for the shorter-term response. <br> If the RS is willing to accept under-biased systems then it would seem to be going against <br> conventional wisdom, and should explain why it would even consider such an idea. If the <br> real intent of this frequency SAR is to establish a minimum frequency response value <br> then the SAR needs to state that. <br> Perhaps the SAR should establish a minimum 1 minute response for every generator (if <br> they can't provide it they are obligated to contract for it from another unit) and maybe a 1 <br> minute average over a week, month, or year if a longer term value is needed. However, <br> since the SAR authors state the problem is sub-minute response, it is suggested that the <br> long term response is better be addressed by the BRD standard. <br> In addition the SAR does not adequately address the load portion of the frequency <br> response. The standard seems to presuppose the solution is having governors. |
| BPA (1, 3, 5, 6) |  |  |  |

| Commenter | Yes | No | Comment |
| :---: | :---: | :---: | :---: |
| Southern Company Transm. (1) | $\checkmark$ |  | The 1\% minimum frequency bias is obsolete and does not take into account the changes in interconnection frequency response over recent years. If not modified, it will lead to increased frequency oscillations within the interconnections and needless maneuvering of generating assets with associated wear and tear on these assets. |
| IESO(1) <br> Anita Lee | $\checkmark$ |  | There should be a safeguard in place, such that if frequency performance declines, the industry reverts to the $1 \%$ minimum. |
| Midwest Reliability Organization (2) | $\checkmark$ |  | There should be a safeguard in place, such that if frequency performance declines, the industry reverts to the $1 \%$ minimum. |
| Energy Mark, Inc. (8) Howard F. Illian | $\checkmark$ |  | There is a minimum frequency response below which the interconnection will be less reliable than acceptable. We currently do not know what this value is but we do know that a value exists. We also know that this value is less than the $1 \%$ of peak load specificed in the current standards. A standard that arbitrairly requires a $1 \%$ of peak load response without a technical justification based on reliability cannot be called a reliabiltiy standard. However, even though we do not know the minimum frequency response below which the interconnection will be less reliable than acceptable, we can perform the work necessary to estimate a reasonable value for a minimum frequency response and assign responsibility for that response among the Balancing Authorities on an interconnection. A Frequency Response Standard without this characteristic cannot maintain reliability of the interconnection. |
| Duke Energy Midwest (1, 3, 6) Jeff Baker | $\checkmark$ |  | I believe that an incentive should be included in the standard. |
| Duke Energy Carolinas (1, 3, 5, 6) Tom Pruitt | $\checkmark$ |  | Calculation of each BA's bias should be based on a rigorous analysis which demonstrates that the BA can provide the expected response, regardless of peak load. This is consistent with the proposed requirements - 'technically-sound calculation and report of frequency response' and 'Will not mandate a given amount of frequency response'. |
| ATC LLC (1) Jason Shaver | $\checkmark$ |  | Although ATC is in support of this recommendation, we feel that it should be classified as an "allowable exemption" not an "incentive". |
| NERC Resources Subcommittee | $\checkmark$ |  | The 1\% minimum frequency bias should be evaluated to take into account the reliability requirements of the interconnections. frequency response over recent years. We suggest that the minimum bias be addressed during the development of the Frequency Response Standard. It is unclear what the word "incentive" means above. |
| ITC Transmission (1) <br> Jim Cyrulewski <br> Beth Howell | $\checkmark$ |  | However this requirement still does not address the need for enough frequency response on the system. |

| Commenter | Yes | No |  |
| :--- | :--- | :--- | :--- |
| Mike Moltane <br> Van Greening |  |  |  |

5. Several commenters suggested response should be measured for an extended period after a frequency excursion, up to the point where automatic generation control (AGC) would take over. This was to ensure initial response wasn't withdrawn prematurely. Should the standard measure out to $\mathbf{6 0}$ seconds following an excursion?

Summary Consideration: There was not consensus on the scope of the proposed requirements, and the drafting team revised the SAR to focus solely on collecting data needed to model frequency response in each of the interconnections. The drafting team modified the SAR to specify that data will be collected to measure response over a period up to 5 minutes. This window may be reduced during the standard drafting phase. This should provide sufficient data to analyze frequency response and should help identify the window of time where frequency response appears to be masked by Automatic Generation Control action.

| Commenter | Yes | No | Comment |
| :---: | :---: | :---: | :---: |
| Duke Energy Midwest (1, 3, 6) Jeff Baker |  |  | I did not provide an answer but believe that this is a decision that could be made over time and not necessarily with the inception of the standard. |
| Response: We agree. |  |  |  |
| Arizona Public Service Co. $(1,5)$ Baj Agrawal |  | $\checkmark$ | Most of the frequency recovery happens in first 30 seconds. Thus anything more than 30 seconds is unnecessary. It is also seen that the response of a unit varies greatly within that 30 seconds period. Thus, it is very important that the measured response be the average response over the 30 seconds period and not be the response at 30 seconds. |
| Response: We agree that frequency response should be measured over a period of time (as opposed to a measure for a single event). |  |  |  |
| Southern Company Transm. (1) |  | $\checkmark$ | AGC response begins within only a few seconds after the disturbance with a maximum ramp rate achieved within three to five minutes. Governor response and load frequency response typically peak within 30 seconds. There is some logic to monitoring governor respone for sustainability past its initial peak, but we have not seen anything about that in this SAR. |
| Response: There was no consensus on this matter. The drafting team modified the SAR to specify that data will be collected to measure response over a period up to 5 minutes. This should provide sufficient data to analyze frequency response and should help identify the window of time where frequency response appears to be masked by AGC action. |  |  |  |
|  |  | $\checkmark$ | The standard should measure out to when the frequency recovers. This could be up to the 15 minute DCS limit. AGC control may or may not kick in within 60 seconds depending on deadbands, etc. However, generators on setpoint control may hold for between 10 and 60 seconds then drop back off prior to AGC pulses reaching the generator. In order to see the full response of a BA it is necessary to see data for the full event rather than just the first minute. Rather than overlapping the BRD standard, this will work hand-in-hand with this standard. |
| Response: There was no consensus on this matter. The drafting team modified the SAR to specify that data will be collected to measure response over a period up to 5 minutes. This should provide sufficient data to analyze frequency response and should help identify the window |  |  |  |

| Commenter | Yes | No | Comment |
| :---: | :---: | :---: | :---: |
| of time where frequency response appears to be masked by AGC action. |  |  |  |
| NPCC CP9 Reliability Standards Working Group |  | $\checkmark$ | This question is not clear. AGC control pulses generation every 5 seconds, therefore, the measurement should be based on the amount of time it takes to restore the generation load balance. |
| Response: In general, following a unit trip, frequency will not recover until the contingent BA has replaced the energy that was lost. This typically takes up to 15 minutes. Unless over-biased, a non-contingent BA will not contribute AGC response to a frequency event. |  |  |  |
| PJM Corporate Development Div. (2) |  | $\checkmark$ | Unsure as to what is being suggested here. The SAR drafters need to be specific about what requirements are needed and how they will be measured. The details contained in the white paper are supporting information but they do not define the standard that is being proposed. |
| Response: There was no consensus on the scope of the proposed requirements, and the drafting team revised the SAR to focus solely on collecting data needed to model frequency response in each of the interconnections. |  |  |  |
| NERC Resources Subcommittee | $\checkmark$ | $\checkmark$ | AGC response begins within only a few seconds after the disturbance with a maximum ramp rate achieved within three to five minutes. Governor response and load frequency response typically peak within 30 seconds. There is logic to monitoring governor response for sustainability past its initial peak and this should be investigated during standard development. |
| Response: We agree with this comment. The drafting team modified the SAR to specify that data will be collected to measure response over a period up to 5 minutes. This should provide sufficient data to analyze frequency response and should help identify the window of time where frequency response appears to be masked by AGC action. |  |  |  |
| IESO(1) <br> Anita Lee | $\checkmark$ |  | Sixty seconds is a reasonable balance to capture the period prior to AGC response. |
| Response: Agree - However, several commenters indicated there may be value in analyzing response for several minutes and the drafting team modified the SAR to specify that data will be collected to measure response over a period up to 5 minutes. This should provide sufficient data to analyze frequency response and should help identify the window of time where frequency response appears to be masked by AGC action. |  |  |  |
| IESO. (2) <br> Ron Falsetti | $\checkmark$ |  | This should cover the entire spectrum of immediate response before AGC kicks in. |
| Response: Agree However, several commenters indicated there may be value in analyzing response for several minutes and the drafting team modified the SAR to specify that data will be collected to measure response over a period up to 5 minutes. This should provide sufficient data to analyze frequency response and should help identify the window of time where frequency response appears to be masked by AGC action. |  |  |  |
| Energy Mark, Inc. (8) Howard F. Illian | $\checkmark$ |  | There are two issues associated with this question. The first is that the change in instantaneous frequency be limited to within a range that limits the risk of a cascading outage on the interconnection. The second is that each generation technology provides a different response characteristic within the first minute after a sudden frequency excursion. Work |

| Commenter | Yes | No | Comment |
| :---: | :---: | :---: | :---: |
|  |  |  | performed at NIPSCo and published by IEEE indicated that a measurement interval of one to two minutes worked well for the measurement of frequency response. Without specific knowledge of the nature of the individual responses that make up the sustained frequency response to an excursion, it may be difficult to justify the selection of a measurement interval shorter than one-minute that might put some generation technologies at a disadvantage with respect to the measurement method. This is a subject that the drafting team should technically evaluate before including a specific measurement period in the standard. |
| Response: Several commenters indicated there may be value in analyzing response for several minutes and the drafting team modified the SAR to specify that data will be collected to measure response over a period up to 5 minutes. This should provide sufficient data to analyze frequency response and should help identify the window of time where frequency response appears to be masked by AGC action. |  |  |  |
| Duke Energy Carolinas (1, 3, 5, 6) Tom Pruitt | $\checkmark$ |  | At least. Based on the words in the SAR Purpose statement, 'this proposed standard coordinates with and complements the Balance Resources and Demand standards, which addresses Interconnection frequency control generally 5 minutes and longer', it seems that this standard should cover out to the 5 minute mark of an event. AGC actions will commence at the first scan cylcle or two after the event ( $5-15$ secs), but the actual generation response may not settle out for several minutes, depending on the type and amount of generation on AGC at the time. |
| Response: Several commenters indicated there may be value in analyzing response for several minutes and the drafting team modified the SAR to specify that data will be collected to measure response over a period up to 5 minutes. This should provide sufficient data to analyze frequency response and should help identify the window of time where frequency response appears to be masked by AGC action. |  |  |  |
| Midwest Reliability Organization (2) | $\checkmark$ |  | This is a significant issue, because if the governor system withdraws the unit's support prior to the recovery of frequency, this does have a problematic impact. A period of at least 60 seconds should be considered, and 60 seconds may not be adequate as often frequency recovery of the interconnection extends beyond the initial 60 seconds. |
| Response: Several commenters indicated there may be value in analyzing response for several minutes and the drafting team modified the SAR to specify that data will be collected to measure response over a period up to 5 minutes. This should provide sufficient data to analyze frequency response and should help identify the window of time where frequency response appears to be masked by AGC action. |  |  |  |
| ITC Transmission (1) Jim Cyrulewski <br> Beth Howell <br> Mike Moltane <br> Van Greening | $\checkmark$ |  | Needs to be verified with a field trial. |
| Response: Several commenters indicated there may be value in analyzing response for several minutes and the drafting team modified the SAR to specify that data will be collected to measure response over a period up to 5 minutes. This should provide sufficient data to analyze frequency response and should help identify the window of time where frequency response appears to be masked by AGC action. Note that the |  |  |  |

| Commenter | Yes | No | Comment |
| :--- | :--- | :--- | :--- |
| drafting team modified the scope of the entire SAR to focus solely on collecting data needed to model frequency response in each of the <br> interconnections. |  |  |  |
| ATC LLC (1) <br> Jason Shaver | $\checkmark$ |  |  |

## 6. Do you have other comments on the SAR?

| Commenter | Comment |
| :---: | :---: |
| ITC Transmission (1) Jim Cyrulewski <br> Beth Howell <br> Mike Moltane <br> Van Greening | Reliability and Market Interface Principles 3, 5 and 6 should be checked as well. |
| Response: We made this change. |  |
| PJM Corporate Development Div. (2) | Please be clear about the terminology. Frequency response comes in many flavors - sub-minute; several minutes; and hours. The RS seems to touch on all of them in this proposal. |
| Response: There was no consensus on the scope of the proposed requirements, and the drafting team revised the SAR to focus solely on collecting data needed to model frequency response in each of the interconnections. The data collection will include data to model and analyze frequency response up to five minutes. |  |
| Southern Company Transm. (1) | In our opinion, this SAR, or one like it, is required to ensure that the primary frequency response of the interconnections and the BAs do not deteriorate to a point where 1) the interconnection can not adequately respond to major generator trips (including potential multiple contingencies which, though rare, do happen) and 2) primary frequency response of the BAs is inadequate to support islanding during severe local disturbances, thus allowing local disturbances to cascade into regional or interconnection wide disturbances. Primary frequency response is declining in at least the Eastern and Western Interconnections. WECC has taken a proactive approach to addressing this problem, but there is no similar work being done in the Eastern Interconnection. This SAR, or one like it, is needed to take the best practices in the industry, wherever they may be found, and utilize them to protect the interconnections from disturbances that could be avoided if we take action now rather than waiting until the problems actually occur. |
| Response: There was no consensus on the scope of the proposed requirements, and the drafting team revised the SAR to focus solely on collecting data needed to model frequency response in each of the interconnections. Your support is very much appreciated. |  |
| IESO. (2) <br> Ron Falsetti | (i) The SAR does not address the load portion of the frequency response but it indicates that the standard would apply to the LSEs as well. Please clarify or eliminate LSE from the Reliability Function check list. <br> (ii) We feel that the SAR needs to be very clear on what the proposed standard is intended and what will be included. Conducting calculation, measuring and report on frequency excursion events followed by analysis would help to ascertain whether or not poor performance exists. However, the determination of poor performance also relies on having a minimally acceptable level to gauge. If the standard is to provide requirements for calculation, reporting and conducting analysis only, then there |

Commenter

## Comment

needs to be some general guideline on the threshold for reporting and analyzing, which in turn begs the question of should this "guideline" be included as the initial standard, whose compliance would not be enforced until sufficient experience has been gained and field test conducted, with possible revision as experience and field test so suggest. Absent a minimum performance level, the requirements for governor setting would be difficult to determine.

Response: There was no consensus on the scope of the proposed requirements, and the drafting team revised the SAR to focus solely on collecting data needed to model frequency response in each of the interconnections. The Load-serving Entity will need to provide some of the data needed to model frequency response.

Energy Mark, Inc. (8)
Howard F. Illian

The current measurement methods for determining individual Balancing Authority Frequency Response may not be reliable. This is because the current measurement methods only capture a small sample of the frequency responses provided limited to only several minutes per year. The metering methods we currently use on the interconnection can shed some light on this problem. Since the each BA measures its Tie Line Error with common metering with adjancent BAs, the sum of the Tie Line Errors over the total interconnection must equal zero at all times. Each tie line has a positive error for one BA and a negative error of equal value to the other BA that the tie line connects. If the errors must sum to zero, then the change in errors must also sum to zero between any two points in time. Since the Frequency on an interconnection is the same throughtout the interconnection at any point in time for the purpose of the frequency response measurement, the change in frequency between two points in time must also be the same throughout the interconnection. Therefore, the change in tie-line error divided by the change in frequency must indicate a total frequency response for the interconnection as measured by the sum of the individual BA frequency responses must be equal to zero. In other words, there is a BA or a set of BAs that cause each frequency response on the interconnection. Only knowledge of the distribution of individual frequency responses among BAs will provide the necessary information to determine whether or not the frequency response indicated by current measurement methods will maintain adequate reliablity. It may not be the average frequency response to large events that indicates interconnection reliability, but the distribution of frequency responses among BAs including both the positive and negative responses. Therefore, the measurement methods included in the standard should have the goal of capturing the distribution of both positive and negative frequency responses over the entire range of frequency operation should be a goal of standard. The measurement methods suggested will not accomplish this goal.

Response: We agree with the concerns on errors induced in the measurement process. The standard will be designed to capture enough events to provide a statistically-sound estimate of Balancing Authority response. We also agree that the distribution of responses needs to be considered.

| Duke Energy Midwest $(1,3,6)$ <br> Jeff Baker | I believe we have to address the frequency issue, but feel that it can be developed over time proactivly. |
| :--- | :--- |

Response: The revised SAR focuses solely on the collection of data needed to model frequency response. The data can be analyzed and additional standards can be developed that build on the results of those analyses. This supports your suggestion that the standard(s) be

| Commenter | Comment |

## Purpose/Industry Need

Frequency Response, a measure of an Interconnection's ability to stabilize frequency immediately following the sudden loss of generation or load, is a critical component to the reliable operation of the bulk power system, particularly during disturbances and restoration. The proposed standard's intent is to collect data needed to accurately model existing Frequency Response. There is evidence of continuing decline in Frequency Response in the three Interconnections over the past 10 years, but no confirmed reason for the apparent decline. The proposed standard requires entities to provide data so that Frequency Response in each of the Interconnections can be modeled, and the reasons for the decline in Frequency Response can be identified. Once the reasons for the decline in Frequency Response are confirmed, requirements can be written to control Frequency Response to within defined reliability parameters.

Reliability Functions
The Standard will Apply to the Following Functions（Check box for each one that applies by
double clicking the grey boxes．）

| 区 | Reliability Coordinator | Responsible for the real－time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator＇s wide area view． |
| :---: | :---: | :---: |
| 区 | Balancing Authority | Integrates resource plans ahead of time，and maintains load－interchange－ resource balance within its metered boundary and supports system frequency in real time |
| $\square$ | Interchange Authority | Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced interchange schedules between Balancing Authority Areas． |
| $\square$ | Planning Coordinator | Assesses the longer－term reliability of its Planning Coordinator Area． |
| $\square$ | Resource Planner | Develops a long－term（＞1year）plan for the resource adequacy of specific loads within its portion of a Planning Coordinator Area． |
| $\square$ | Transmission Planner | Develops a（＞one year）plan for the reliability of the interconnected Bulk Electric System within its portion of the Planning Coordinator Area． |
| $\square$ | Transmission Service Provider | Administers the transmission tariff and provides transmission services under applicable transmission service agreements（e．g．，the pro forma tariff）． |
| $\square$ | Transmission Owner | Owns and maintains transmission facilities． |
| $\square$ | Transmission Operator | Ensures the real－time operating reliability of the transmission assets within a Transmission Operator Area． |
| $\square$ | Distribution Provider | Delivers electrical energy to the End－use customer． |
| ® | Generator Owner | Owns and maintains generation facilities． |
| ® | Generator Operator | Operates generation unit（s）to provide real and reactive power． |
| $\square$ | Purchasing－ Selling Entity | Purchases or sells energy，capacity，and necessary reliability－related services as required． |
| $\square$ | Market Operator | Interface point for reliability functions with commercial functions． |
| 区 | Load－Serving Entity | Secures energy and transmission service（and related reliability－related services）to serve the End－use Customer． |

Reliability and Market Interface Principles

|  | s．） |
| :---: | :---: |

| 区 | 3．Information necessary for the planning and operation of interconnected bulk electric systems shall be made available to those entities responsible for planning and operating the systems reliably． |
| $\square$ | 4．Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed，coordinated，maintained and implemented． |
| 区 | 5．Facilities for communication，monitoring and control shall be provided，used and maintained for the reliability of interconnected bulk electric systems． |
| ® | 6．Personnel responsible for planning and operating interconnected bulk electric systems shall be trained，qualified and have the responsibility and authority to implement actions． |
| 区 | 7．The security of the interconnected bulk electric systems shall be assessed maintained on a wide area basis． |
| Does the proposed Standard comply with all of the following Market Interface Principles？（Select＇yes＇or＇no＇from the drop－down box by double clicking the grey area．） |  |
| 1．The planning and operation of bulk electric systems shall recognize that reliability is an essential requirement of a robust North American economy．Yes |  |
| An Organization Standard shall not give any market participant an unfair competitive advantage．Yes |  |
| 3．An Organization Standard shall neither mandate nor prohibit any specific market structure．Yes |  |
| 4．An Organization Standard shall not preclude market solutions to achieving compliance with that Standard．Yes |  |
|  | An Organization Standard shall not require the public disclosure of commercially sensitive information．All market participants shall have equal opportunity to access commercially non－ sensitive information that is required for compliance with reliability standards．Yes |

## Detailed Description (Provide enough detail so that an independent entity familiar with the industry could draft, modify, or withdraw a Standard based on this description.) The proposed technical/preparedness standard will require or provide the following:

1. Each Balancing Authority shall collect and provide data [scan rate tie deviation and frequency for up to 5* minutes per event] needed to model its sub-minute Frequency Response to loss of large generating units and load.
2. Each Balancing Authority shall report each loss of generation or load greater than the respective Interconnection reporting threshold to its Reliability Coordinator.
3. Each Reliability Coordinator shall relay Frequency Response Standard (FRS) event information to other Reliability Coordinators in its Interconnection. The Interconnection Time Monitor will maintain a log of $F R S$ events.
4. NERC shall annually post a list of $F R S$ events. These events shall be used by Balancing Authorities to calculate and report their annual Frequency Response and Bias.
5. NERC, in conjunction with the respective Regions, shall establish a Target Frequency Response for each Interconnection. Absent an agreement, the observed Frequency Response in the first year of the FRS shall be used as a target.
6. Balancing Authorities with less than [75\%]* of their share of Target Frequency Response shall provide generation-level data to their Region for use by Transmission Planners and Planning Coordinators.
a. Each Generator Operator that operates a generator larger than [10 MW]*, shall provide data to its Balancing Authority, as required in item 6, to support this standard and for use in developing models of Frequency Response in the associated Interconnection.
b. Load Serving Entities shall provide data, as required in item 6, to their BA and Region to support the standard.
*These values are representative and will be refined based on stakeholder input during the standard drafting phase.

## TO: REGISTERED BALLOT BODY

Ladies and Gentlemen:

## Announcement: Comment Periods Open for three SARs

## System Restoration and Blackstart SAR (February 8-March 9, 2007)

The second draft of the System Restoration and Blackstart SAR has been posted for a 30-day comment period from February 8 through March 9, 2007. The SAR calls for the modification of the following standards:

EOP-005 - System Restoration Plans
EOP-006 - Reliability Coordination - System Restoration
EOP-007 - Establish, Maintain, and Document a Regional Blackstart Capability Plan
EOP-009 - Documentation of Blackstart Generating Unit Test Results
This project involves upgrading the overall quality of the four standards; eliminating some gaps in the requirements, ambiguity, and "fill-in-the-blank" components.

The development may include other improvements to the standards deemed appropriate by the drafting team, with the consensus of stakeholders, consistent with establishing high-quality, enforceable, and technically sufficient bulk power system reliability standards.

Please use the comment form to provide comments on this SAR.

## Underfrequency Load Shedding SAR (February 8-March 9, 2007)

The second draft of the Underfrequency Load Shedding SAR has been posted for a 30 -day comment period from February 8 through March 9, 2007. The SAR calls for the modification of the following standards:

PRC-006 - Development and Documentation of Regional Reliability Organizations’ Underfrequency Load Shedding Programs

PRC-007 - Assuring Consistency with Regional UFLS Programs
PRC-009 - UFLS Performance Following an Underfrequency Event
This project involves upgrading the overall quality of the four standards; eliminating some gaps in the requirements, ambiguity, and "fill-in-the-blank" components.

The development may include other improvements to the standards deemed appropriate by the drafting team, with the consensus of stakeholders, consistent with establishing high-quality, enforceable, and technically sufficient bulk power system reliability standards.

Please use the comment form to provide comments on this SAR.

## Frequency Response SAR (February 8-March 9, 2007)

The third draft of the Frequency Response SAR has been posted for a 30-day comment period from February 8 through March 9, 2007. The SAR calls for the collection of data needed to model each interconnection's frequency response.

Please use the comment form to provide comments on this SAR.

## Standards Development Process

The Reliability Standards Development Procedure contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate. If you have any questions, please contact me at 813-468-5998 or maureen.long@nerc.net.

Sincerely,
Maverer F. Lang

## Background I nformation:

The original SAR on Frequency Response was submitted in large part due to a study that showed a 10+\% decline in Eastern Interconnection Frequency Response over a 5-year period, when response should be increasing over time as the Interconnection grows. Other Interconnections were observing similar declines. The drafting team posted a white paper along with the SAR to outline the need for a standard.

The NERC Resources Subcommittee recently updated their estimate of Eastern Interconnection Frequency Response and found it still trending downward. Response in 2006 was on the order of $2,800 \mathrm{MW} / 0.1 \mathrm{~Hz}$ (compared to $3,750 \mathrm{MW} / 0.1 \mathrm{~Hz}$ in 1994). Frequency Response for larger events (greater than 35 mHz ) in 2006 may be as low as $2,600 \mathrm{MW} / 0.1 \mathrm{~Hz}$. Below is an independently calculated estimate of the trend in Eastern Interconnection Frequency Response provided by the New York ISO. Note: Response is stated in engineering terms ( $\mathrm{MW} / \mathrm{mHz}$ ) as opposed to the traditional $\mathrm{MW} / 01 . \mathrm{Hz}$.

The proposed Frequency Response standard (FRS) is a technical standard. Technical standards are described in the Reliability Standards Development Procedure. The FRS is not proposed to be a performance standard and does not propose a minimum Frequency Response, below which penalties are applied.

Industry commenters agreed there is a reliability need for the FRS. Comments varied on the technical details of the standard. Because of the divergent views on the details of the FRS SAR, the NERC Standards Committee (SC) directed the SAR drafting team to revise the SAR to focus only on the data collection needed to support the development of accurate models of Frequency Response in North America.

The SAR drafting team has tried to meet the Standards Committee's directive with this third version of the SAR.

The Version 3 of the Frequency Response SAR represents the changes requested by the NERC Standards Committee, while still meeting the June 2006 direction of the NERC Operating Committee. Specifically, the Operating Committee endorsed developing a Frequency Response standard that includes the following goals and objectives:

- Improving Interconnection Frequency Response event cataloging and benchmarking.
- Calculating balancing authority Frequency Response and requiring balancing authorities to analyze those cases where the response is significantly below the norm.
- Establishing time limits to complete the analyses.
- Tabulating non-responsive generators.
- Measuring generator response (those units on line).
- Including regional participation and review.

This revised SAR was reviewed and supported by the NERC Resources Subcommittee on December 4, 2006. The major changes between Draft 2 and Draft 3 include:

- Clarification on the role of the Load-serving Entity and Generator Operator.
- Inclusion of the applicability of Reliability Principles 3,5, and 6.
- Reduced the scope to address only the collection of data needed to model Frequency Response in North America.
- Clarified that the data collected to model frequency response over a period of up to 5 minutes per event to help identify the window of time where frequency response appears to be masked by AGC action.
Note that because the changes to the SAR were quite significant, no redline showing the changes from Version 2 to Version 3 will be posted.

Please review the revised SAR and then answer the questions on the following page. Comments must be submitted by March 9, 2007. You may submit the completed form by e-mail to sarcomm@nerc.com with the words "FR SAR Draft 3" in the subject line.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree with the reduced scope of this SAR - focusing only on the data collection needed to support the development of accurate models of Frequency Response in North America?
$\boxtimes$ Yes
$\square$ No
Comments:
2. The proposed standard would have requirements for the following functional entities:

Reliability Coordinator, Balancing Authority, Generator Owner, Generator Operator, and Load-serving Entity. Do you agree that these are the right functional entities for the proposed standard?
$\boxtimes$ YesNo
Comments:
3. The SAR drafting team modified the SAR to clarify that data will be collected to model up to 5 minutes of frequency response. This should help identify the window of time where frequency response appears to be masked by AGC action. Do you agree with this clarification?
$\boxtimes$ Yes
$\square$ N
Comments: With the caveat that more data may be collected if the need arises (out to 10 or 15 minutes)
4. Should a field trial be initiated, whereby a set of events for each Interconnection is posted throughout the year, to be used by BAs to calculate their 2007 Frequency Response?Yes
$\boxtimes$ No
Comments: BPA does not believe a field trial is needed for this standard. The standard should be written and implemented with the levels of noncompliance structured around data submittal.
5. Please provide any other comments (that you have not already provided in response to the first three questions on this form) that you have on the revised SAR. Comments: BPA agrees with the necessity of a frequency response standard. BPA highly encourages that this effort be implemented as soon as possible.

Please use this form to submit comments on the third draft of the Frequency Response SAR. Comments must be submitted by March 9, 2007. You may submit the completed form by e-mail to sarcomm@nerc.com with the words "FR SAR Draft 3" in the subject line. If you have questions please contact Maureen Long at maureen.long@nerc. net or by telephone at 813-468-5998.

## Background I nformation:

The original SAR on Frequency Response was submitted in large part due to a study that showed a 10+\% decline in Eastern Interconnection Frequency Response over a 5-year period, when response should be increasing over time as the Interconnection grows. Other Interconnections were observing similar declines. The drafting team posted a white paper along with the SAR to outline the need for a standard.

The NERC Resources Subcommittee recently updated their estimate of Eastern Interconnection Frequency Response and found it still trending downward. Response in 2006 was on the order of $2,800 \mathrm{MW} / 0.1 \mathrm{~Hz}$ (compared to $3,750 \mathrm{MW} / 0.1 \mathrm{~Hz}$ in 1994). Frequency Response for larger events (greater than 35 mHz ) in 2006 may be as low as $2,600 \mathrm{MW} / 0.1 \mathrm{~Hz}$. Below is an independently calculated estimate of the trend in Eastern Interconnection Frequency Response provided by the New York ISO. Note: Response is stated in engineering terms ( $\mathrm{MW} / \mathrm{mHz}$ ) as opposed to the traditional MW/01.Hz.

The proposed Frequency Response standard (FRS) is a technical standard. Technical standards are described in the Reliability Standards Development Procedure. The FRS is not proposed to be a performance standard and does not propose a minimum Frequency Response, below which penalties are applied.

Industry commenters agreed there is a reliability need for the FRS. Comments varied on the technical details of the standard. Because of the divergent views on the details of the FRS SAR, the NERC Standards Committee (SC) directed the SAR drafting team to revise the SAR to focus only on the data collection needed to support the development of accurate models of Frequency Response in North America.

The SAR drafting team has tried to meet the Standards Committee's directive with this third version of the SAR.

The Version 3 of the Frequency Response SAR represents the changes requested by the NERC Standards Committee, while still meeting the June 2006 direction of the NERC Operating Committee. Specifically, the Operating Committee endorsed developing a Frequency Response standard that includes the following goals and objectives:

- Improving Interconnection Frequency Response event cataloging and benchmarking.
- Calculating balancing authority Frequency Response and requiring balancing authorities to analyze those cases where the response is significantly below the norm.
- Establishing time limits to complete the analyses.
- Tabulating non-responsive generators.
- Measuring generator response (those units on line).
- Including regional participation and review.

This revised SAR was reviewed and supported by the NERC Resources Subcommittee on December 4, 2006. The major changes between Draft 2 and Draft 3 include:

- Clarification on the role of the Load-serving Entity and Generator Operator.
- Inclusion of the applicability of Reliability Principles 3,5, and 6.
- Reduced the scope to address only the collection of data needed to model Frequency Response in North America.
- Clarified that the data collected to model frequency response over a period of up to 5 minutes per event to help identify the window of time where frequency response appears to be masked by AGC action.

Note that because the changes to the SAR were quite significant, no redline showing the changes from Version 2 to Version 3 will be posted.

Please review the revised SAR and then answer the questions on the following page.
Comments must be submitted by March 9, 2007. You may submit the completed form by e-mail to sarcomm@nerc.com with the words "FR SAR Draft 3" in the subject line.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree with the reduced scope of this SAR - focusing only on the data collection needed to support the development of accurate models of Frequency Response in North America?Yes
$\boxtimes$ No
Comments: The primary objective of this SAR is to collect data; to analyze the data; and only then to recommend a performance value. The SAR DT insists that collecting data is a Technical Standard. The RSDP states:
"Technical standards...will contain Measures (not measuring - AMD) of physical parameters..." At this point this SAR proposal does not contain such a measure, it does not even assert that the measure is really needed (hence the need to analyze the data).

Page 19 (of 43) of the RSPM states "The drafting team may recommend the scope of the standard be reduced to allow the effort to move forward, while still remaining within the scope of the SAR. Reducing the scope of the SAR is acceptable if the drafting team finds, for instance, THAT ADDITIONAL TECHNICAL RESEARCH IS NEEDED PRIOR TO DEVELOPING (emphasis added) a portion of the standard or issues need to be resolved before consensus can be achieved on a portion of the standard. "The highlighted section applies directly to the scope of this SAR. The SAR Team recognizes work is needed. There is no question about that. The Team should do that work BEFORE proposing a mandatory standard.
PJ M supports the concept of doing such a study, and would encourage NERC to assign a group to do such a study, but PJM does not agree that collecting data rises to the level of a valid NERC reliability standard.
2. The proposed standard would have requirements for the following functional entities: Reliability Coordinator, Balancing Authority, Generator Owner, Generator Operator, and Load-serving Entity. Do you agree that these are the right functional entities for the proposed standard?
$\square$ Yes
$\boxtimes$ No
Comments: The proposal as written appears to be headed towards mandating a given unit response. As such there would be an obligation on the Generator Operator - there does not seem to be any requirements that would apply to the Generator Owner unless of course the requestor includes a requirement to install a governor (this has, to date, be an implied obligation just as having a turbine has been an implied obligation). If the requestor does intend to assert an obligation on the Generator Owner to install a governor then the question arises should that be a standard or should that be a part of the Certification of a GO?

It is not clear what the LSE requirements are in this proposal.
3. The SAR drafting team modified the SAR to clarify that data will be collected to model up to 5 minutes of frequency response. This should help identify the window of time where frequency response appears to be masked by AGC action. Do you agree with this clarification?Yes
$\boxtimes$ No
Comments: As noted above PJM does not consider collecting data in order to decide what a requirement should be as grounds for a standard. Thus the sampling period which is outside of a NERC standard, can be defined in whatever way the group doing the sampling desires.
4. Should a field trial be initiated, whereby a set of events for each Interconnection is posted throughout the year, to be used by BAs to calculate their 2007 Frequency Response?
$\square$ Yes
No
Comments: There are field trials for standards (which this question is directed) and there are field trials for good ideas. This proposed SAR would seem to fall into the second category; and while posting events is interesting, it does not rate being a NERC standard. Collecting and posting data can be effected without a standard.
5. Please provide any other comments (that you have not already provided in response to the first three questions on this form) that you have on the revised SAR.
Comments: PJM would also note that the proposal references two distinct parameters the Natural response of a BA; and the natural response of a unit. It is not clear how the requestor intends to link the two parameters. The sum of the units' natural responses will not equal the natural response of the BA. Does the requestor intend to link the two, or to keep them separate? As written it appears that the requestor intends for the BA to be held responsible for an annual measured value. The SAR DT does not recognize that during different times there are different number of units opperating and available to respond. The SAR DT makes no mention of whether or not a BA(?) would have to shed load to maintain such frequency response (for those periods when all units are at full load). The SAR DT makes no mention of distance from an event. An event in NE will effect more response in NE then in Florida - how will that be addressed? PJ M would ask for clarification on what the requestor would intend to mandate.

FERC has recognized the need to include suppliers that use load control - how does this SAR intend to address such 'natural response suppliers'?

As written this proposal becomes an ambiguous standard as it obligates a BA to get data from a generator ( as opposed to directly obligating generators to supply the data to the analysis team - this is important from the perspective of who would be noncompliant if the data were not supplied - the BA or the GO?).

PJ M would suggest that NERC create a Frequency Project, budget the project through its members rather then create a standard and risk imposing non-compliance penalities for what potentially could be a non-issue. Deal with this for what it is - a research activity.

Please use this form to submit comments on the third draft of the Frequency Response SAR. Comments must be submitted by March 9, 2007. You may submit the completed form by e-mail to sarcomm@nerc.com with the words "FR SAR Draft 3" in the subject line. If you have questions please contact Maureen Long at maureen. long@nerc. net or by telephone at 813-468-5998.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree with the reduced scope of this SAR - focusing only on the data collection needed to support the development of accurate models of Frequency Response in North America?
$\boxtimes$ No
Comments: Do not agree with the notion in point 5 regarding the need for a Target Frequency Response for each interconnection at this time. It is beyond the scope of this technical SAR to propose anything other than collection of data to support the study.

Do not agree with point 6 of the description. In order to get a handle on what is really going on, all Balancing Authorities should be required to produce data valid to the study. Also the language in point 6 is poorly worded compared to the right wording in 6 a and 6 b . 6 a and 6 b should be included in the SAR and 6 should be removed.
2. The proposed standard would have requirements for the following functional entities: Reliability Coordinator, Balancing Authority, Generator Owner, Generator Operator, and Load-serving Entity. Do you agree that these are the right functional entities for the proposed standard?Yes
$\boxtimes$ No
Comments: A standard can not be imposed on the response of load to frequency. Load Serving Entities can only provide data.
3. The SAR drafting team modified the SAR to clarify that data will be collected to model up to 5 minutes of frequency response. This should help identify the window of time where frequency response appears to be masked by AGC action. Do you agree with this clarification?
® No
Comments: The 5 minute time is adaquate, but it lacks substance. Small changes in load and generation due to frequency response are very difficult to separate from normal load changes and AGC action on generation units (as was pointed out). It is important to include in the description of data collection that the 5 minutes should include 1 minute of data prior to a study event and 4 minutes after a study event. It is also important to include a sample rate, such as 4 seconds (obviously, faster samples are better, but may not be practicle).

The SAR, as written, lacks specifics on what data is required to perform a valid study. Some examples of necessary data may include, but are not limited to, AGC pulses, special protection systems, generator MW, tie line MW, frequency, etc.
4. Should a field trial be initiated, whereby a set of events for each Interconnection is posted throughout the year, to be used by BAs to calculate their 2007 Frequency Response?
$\boxtimes$ Yes
$\square$ No
Comments:
5. Please provide any other comments (that you have not already provided in response to the first three questions on this form) that you have on the revised SAR. Comments: The reasoning for this technical standard is based on the perception that the frequency response of the electrical system is declining and a concern that the interconnect's ability to arrest significant system disturbances is slowly being compromised. Although it is not disagreeable that a study be conducted to determine if an actual decline in frequency response is occuring and then to determine cause, it is diagreeable to propose a potential remedy for a problem that may not exist or, dependent on the findings, in inappropriate remedy.

Types of generating units online (e.g., wind generation, combined cycle, etc) and their subsequent loading will have an influence on the frequency response of the system. As long as Balancing Authorities are maintaining their reserve obligations, even large contingencies should be manageable. However, over the years because of the trend to get more out of invested generation resources, it would give the appearance of a decline in frequency response since most frequency degradations are a result of losses of generation and a resultant decline in system frequency and those are what is studied and scrutinized. The August 14, 2003 disturbance was an opportunity to study the frequency response of all on-line generating units due to the frequency event resulting in a high frequency. High frequency is the only event where all on-line generating units will respond.

Proposing the establishment of a Target Frequency Response for the interconnect before concluding if an actual decline in frequency response is occuring and the cause(s) for the decline is finding a solution before defining the problem. Any standards involving frequency response need to also consider the role system reserves play in the interconnect as well as the frequency response of generators and system load to frequency. As long as generating reserve obligations are being met in accordance with current Reliability Standards and Regional Operating Criteria there may not be a need to go further dependent on the outcome of the study proposed by this SAR.

Please use this form to submit comments on the third draft of the Frequency Response SAR. Comments must be submitted by March 9, 2007. [^22] comments. Regional acronyms and segment numbers are shown on prior page.

## Background I nformation:

The original SAR on Frequency Response was submitted in large part due to a study that showed a 10+\% decline in Eastern Interconnection Frequency Response over a 5-year period, when response should be increasing over time as the Interconnection grows. Other Interconnections were observing similar declines. The drafting team posted a white paper along with the SAR to outline the need for a standard.

The NERC Resources Subcommittee recently updated their estimate of Eastern Interconnection Frequency Response and found it still trending downward. Response in 2006 was on the order of $2,800 \mathrm{MW} / 0.1 \mathrm{~Hz}$ (compared to $3,750 \mathrm{MW} / 0.1 \mathrm{~Hz}$ in 1994). Frequency Response for larger events (greater than 35 mHz ) in 2006 may be as low as $2,600 \mathrm{MW} / 0.1 \mathrm{~Hz}$. Below is an independently calculated estimate of the trend in Eastern Interconnection Frequency Response provided by the New York ISO. Note: Response is stated in engineering terms ( $\mathrm{MW} / \mathrm{mHz}$ ) as opposed to the traditional MW/01.Hz.

The proposed Frequency Response standard (FRS) is a technical standard. Technical standards are described in the Reliability Standards Development Procedure. The FRS is not proposed to be a performance standard and does not propose a minimum Frequency Response, below which penalties are applied.

Industry commenters agreed there is a reliability need for the FRS. Comments varied on the technical details of the standard. Because of the divergent views on the details of the FRS SAR, the NERC Standards Committee (SC) directed the SAR drafting team to revise the SAR to focus only on the data collection needed to support the development of accurate models of Frequency Response in North America.

The SAR drafting team has tried to meet the Standards Committee's directive with this third version of the SAR.

The Version 3 of the Frequency Response SAR represents the changes requested by the NERC Standards Committee, while still meeting the June 2006 direction of the NERC Operating Committee. Specifically, the Operating Committee endorsed developing a Frequency Response standard that includes the following goals and objectives:

- Improving Interconnection Frequency Response event cataloging and benchmarking.
- Calculating balancing authority Frequency Response and requiring balancing authorities to analyze those cases where the response is significantly below the norm.
- Establishing time limits to complete the analyses.
- Tabulating non-responsive generators.
- Measuring generator response (those units on line).
- Including regional participation and review.

This revised SAR was reviewed and supported by the NERC Resources Subcommittee on December 4, 2006. The major changes between Draft 2 and Draft 3 include:

- Clarification on the role of the Load-serving Entity and Generator Operator.
- Inclusion of the applicability of Reliability Principles 3,5, and 6.
- Reduced the scope to address only the collection of data needed to model Frequency Response in North America.
- Clarified that the data collected to model frequency response over a period of up to 5 minutes per event to help identify the window of time where frequency response appears to be masked by AGC action.

Note that because the changes to the SAR were quite significant, no redline showing the changes from Version 2 to Version 3 will be posted.

Please review the revised SAR and then answer the questions on the following page.
Comments must be submitted by March 9, 2007. You may submit the completed form by e-mail to sarcomm@nerc.com with the words "FR SAR Draft 3" in the subject line.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree with the reduced scope of this SAR - focusing only on the data collection needed to support the development of accurate models of Frequency Response in North America?Yes
$\square$ No
Comments:
2. The proposed standard would have requirements for the following functional entities:

Reliability Coordinator, Balancing Authority, Generator Owner, Generator Operator, and Load-serving Entity. Do you agree that these are the right functional entities for the proposed standard?YesNo
Comments:
3. The SAR drafting team modified the SAR to clarify that data will be collected to model up to 5 minutes of frequency response. This should help identify the window of time where frequency response appears to be masked by AGC action. Do you agree with this clarification?YesNo
Comments:
4. Should a field trial be initiated, whereby a set of events for each Interconnection is posted throughout the year, to be used by BAs to calculate their 2007 Frequency Response?YesNo
Comments:
5. Please provide any other comments (that you have not already provided in response to the first three questions on this form) that you have on the revised SAR. Comments:
Specific to the Requirement 6 a which states:
Each Generator Operator that operates a generator larger than [10 MW]*, shall provide data to its Balancing Authority, as required in item 6, to support this standard and for use in developing models of Frequency Response in the associated Interconnection.

Balancing Authorities may seek Speed Droop characteristics for our generators. Speed Droop is a design characteristic of the steam turbine (or the prime mover's governor response in the case of a combustion turbine or diesel).

Our concern is the only data we may be able to provide would be turbine manufacturer design data. For our older units where turbine control systems have been retrofitted and upgraded with more modern controls, we may not really know the speed droop characteristic of the unit. Collecting performance data to demonstrate the speed droop is extremely difficult if not impossible on a large unit. (Requires the grid connection frequency be allowed to "droop" as the generator is loaded). Hence, as now written, Constellation Generation is not clear how we could comply.

Please use this form to submit comments on the third draft of the Frequency Response SAR. Comments must be submitted by March 9, 2007. You may submit the completed form by e-mail to sarcomm@nerc.com with the words "FR SAR Draft 3" in the subject line. If you have questions please contact Maureen Long at maureen. long@nerc. net or by telephone at 813-468-5998.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree with the reduced scope of this SAR - focusing only on the data collection needed to support the development of accurate models of Frequency Response in North America?
$\boxtimes$ Yes
$\square$ No
Comments: At this time information is not available that would provide a sound technical basis for the development of a performance standard. However, with the recent increased interest in Frequency Response, new data and analysis could become available at any time that would change the focus from a technical standard to a performance standard. If new information and analysis becomes available during the development of the technical standard, consideration should be given to how the development of the technical standard could delay the development and implementation of a performance standard. Must the technical standard be completed and approved before work can start on a performance standard?
2. The proposed standard would have requirements for the following functional entities: Reliability Coordinator, Balancing Authority, Generator Owner, Generator Operator, and Load-serving Entity. Do you agree that these are the right functional entities for the proposed standard?
Q Yes
】 No
Comments: I agree that the proposed list includes those entities that would be affected by a technical standard. However, there are many questions that must be resolved before any standard that affects the Generation Owner, Generation Operator or Loadserving Entity can be implemented. These questions relate to how a performance standard can or should be implemented. If there is no reasonable expectation that they would be included in a future performance standard, it would be unreasonable to implement a technical standard that requires these three functional entities to provide data. In a fair market that allows voluntary participation by Generation Owners, Generation Operators and Load-serving Entities, the direct application of a Frequency Response Performance Standard to these entities is not currently possible without creating unreasonable inequities in the market. Any standard applied directly to one generator but not another will create unreasonble inequities in a market. Since each generation technology has different Frequency Response capabilities, only a solution that provides Frequency Response through a market based mechanism can be fairly implimented in a market. Under these conditions, the measurement methods and data collection for a technical standard should only be applied to those entities that would have resposibilities under a performance standard. The correct alternative for collecting data from these entities is to collect it indirectly through the Balancing Authority or Reliability Coordinator that would be directly affected by a performance standard. The inclusion of Generation Owner, Generation Operator, and Load-serving Entity directly in the data collection will lead to the development of data collection systems that will need to be replaced, if and when, a performance standard is developed. This is an inefficient way to develop the technology for a new standard.
3. The SAR drafting team modified the SAR to clarify that data will be collected to model up to 5 minutes of frequency response. This should help identify the window of time where frequency response appears to be masked by AGC action. Do you agree with this clarification?
$\boxtimes$ Yes
$\boxtimes$ No
Comments: I agree with the concept of measuring Frequency Response for an extended period after a disturbance, but I do not agree that the reason is related to masking by AGC action. If the Frequency Bias for a Balancing Authority is set to a value that approximates the actual Frequency Response, the AGC action will always provide the correct response for reliable interconnection performance. The Frequency Response should be measured for an extended period after a disturbance to identify entities that are prematurely withdrawing their expected frequency response support from the interconnection. This has been demonstrated for entities that have outer loop control that only includes scheduled deliveries without adjustment for frequency response.
4. Should a field trial be initiated, whereby a set of events for each Interconnection is posted throughout the year, to be used by BAs to calculate their 2007 Frequency Response?
Q Yes
$\boxtimes$ No
Comments: This would be a good way to insure that every entity select a similar set of events for calculation of their Frequency Response, but it will not insure conformity of the results. The difficulty with any method for selecting a common set of events is that each of those events is caused by a disturbance within one or more of the Balancing Authorities on the interconnection. Those entities that cause the disturbance will experience a different frequency response than those entities that are responding. The net effect is that the sum of the responses for all of the entities on the interconnection must sum to zero. This means that each entity must eliminate those disturbances for which they are the cause, from the set of disturbances they use to estimate their response. The real advantage is an entity cannot influence the results of the measurement through selection of the events they choose to include in the calculation.
5. Please provide any other comments (that you have not already provided in response to the first three questions on this form) that you have on the revised SAR.
Comments: One of my concerns is a majority of entities in NERC must agree that there is a need for a standard before the standard process moves forward. This could have undesirable long-term results with respect to the quality of the standards that are developed. This standard provides a good example of this problem. From what I have observed, both the Texas and Western Interconnections have concluded that there is a reliability need for a Frequency Response Standard on their interconnections. Unfortunately, reasonable opposition from the Eastern Interconnection will prevent the development of a common standard for those two interconnections. The only alternative will be for the Texas and Western Interconnections to each develop their own standards for Frequency Response without considering ways of making those two standards similar to each other. If the Eastern Interconnection, after a few years, finds that it needs a Frequency Response Standard, it will then become necessary for a new
standard to be developed that applies to all three interconnections. If each interconnection has a different Frequency Response Standard, it means there is no standard at all, but three different rules for NERC. The next logical step is to develop a common standard for all three interconnections requiring the first two standards developed by the Texas and Western Interconnections separately be modified to conform to a North American Standard on Frequency Response. Combining these three separate needs into a single standard will result in a natural opposition to change by those interconnections that have already implemented an interconnection standard that meets their individual needs. This will make it very difficult to gain the support necessary to enact a common standard for NERC. This multi-step development can only be avoided by having all three interconnections participate and contribute to standards identified and developed by individual interconnections. I believe that NERC needs to find a way to address this problem. If they do not, the standard development and approval process will lead to fractured standards and an unacceptable fractured standard process for NERC. One alternative might be to find a way for all interconnections to participate in the solution of individual interconnection problems as part of the standard development process.

## Background I nformation:

The original SAR on Frequency Response was submitted in large part due to a study that showed a 10+\% decline in Eastern Interconnection Frequency Response over a 5-year period, when response should be increasing over time as the Interconnection grows. Other Interconnections were observing similar declines. The drafting team posted a white paper along with the SAR to outline the need for a standard.

The NERC Resources Subcommittee recently updated their estimate of Eastern Interconnection Frequency Response and found it still trending downward. Response in 2006 was on the order of $2,800 \mathrm{MW} / 0.1 \mathrm{~Hz}$ (compared to $3,750 \mathrm{MW} / 0.1 \mathrm{~Hz}$ in 1994). Frequency Response for larger events (greater than 35 mHz ) in 2006 may be as low as $2,600 \mathrm{MW} / 0.1 \mathrm{~Hz}$. Below is an independently calculated estimate of the trend in Eastern Interconnection Frequency Response provided by the New York ISO. Note: Response is stated in engineering terms ( $\mathrm{MW} / \mathrm{mHz}$ ) as opposed to the traditional MW/01.Hz.

The proposed Frequency Response standard (FRS) is a technical standard. Technical standards are described in the Reliability Standards Development Procedure. The FRS is not proposed to be a performance standard and does not propose a minimum Frequency Response, below which penalties are applied.

Industry commenters agreed there is a reliability need for the FRS. Comments varied on the technical details of the standard. Because of the divergent views on the details of the FRS SAR, the NERC Standards Committee (SC) directed the SAR drafting team to revise the SAR to focus only on the data collection needed to support the development of accurate models of Frequency Response in North America.

The SAR drafting team has tried to meet the Standards Committee's directive with this third version of the SAR.

The Version 3 of the Frequency Response SAR represents the changes requested by the NERC Standards Committee, while still meeting the June 2006 direction of the NERC Operating Committee. Specifically, the Operating Committee endorsed developing a Frequency Response standard that includes the following goals and objectives:

- Improving Interconnection Frequency Response event cataloging and benchmarking.
- Calculating balancing authority Frequency Response and requiring balancing authorities to analyze those cases where the response is significantly below the norm.
- Establishing time limits to complete the analyses.
- Tabulating non-responsive generators.
- Measuring generator response (those units on line).
- Including regional participation and review.

This revised SAR was reviewed and supported by the NERC Resources Subcommittee on December 4, 2006. The major changes between Draft 2 and Draft 3 include:

- Clarification on the role of the Load-serving Entity and Generator Operator.
- Inclusion of the applicability of Reliability Principles 3,5, and 6.
- Reduced the scope to address only the collection of data needed to model Frequency Response in North America.
- Clarified that the data collected to model frequency response over a period of up to 5 minutes per event to help identify the window of time where frequency response appears to be masked by AGC action.

Note that because the changes to the SAR were quite significant, no redline showing the changes from Version 2 to Version 3 will be posted.

Please review the revised SAR and then answer the questions on the following page.
Comments must be submitted by March 9, 2007. You may submit the completed form by e-mail to sarcomm@nerc.com with the words "FR SAR Draft 3" in the subject line.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree with the reduced scope of this SAR - focusing only on the data collection needed to support the development of accurate models of Frequency Response in North America?
$\boxtimes$ Yes
$\square$ No
Comments:
2. The proposed standard would have requirements for the following functional entities:

Reliability Coordinator, Balancing Authority, Generator Owner, Generator Operator, and Load-serving Entity. Do you agree that these are the right functional entities for the proposed standard?
$\boxtimes$ YesNo
Comments:
3. The SAR drafting team modified the SAR to clarify that data will be collected to model up to 5 minutes of frequency response. This should help identify the window of time where frequency response appears to be masked by AGC action. Do you agree with this clarification?
$\boxtimes$ Yes
$\square$ No
Comments: This time frame should be sufficient for determination of frequency response. If it is intended that this data should also be useful for evaluating generating unit governor functioning, a longer time may be appropriate.
4. Should a field trial be initiated, whereby a set of events for each Interconnection is posted throughout the year, to be used by BAs to calculate their 2007 Frequency Response?
$\boxtimes$ YesNo
Comments: A field trial would be beneficial to ensure that no gaps in the need for data exist. This could relate to whether other data is needed or whether data for a longer time is needed.
5. Please provide any other comments (that you have not already provided in response to the first three questions on this form) that you have on the revised SAR. Comments:

## Background I nformation:

The original SAR on Frequency Response was submitted in large part due to a study that showed a 10+\% decline in Eastern Interconnection Frequency Response over a 5-year period, when response should be increasing over time as the Interconnection grows. Other Interconnections were observing similar declines. The drafting team posted a white paper along with the SAR to outline the need for a standard.

The NERC Resources Subcommittee recently updated their estimate of Eastern Interconnection Frequency Response and found it still trending downward. Response in 2006 was on the order of $2,800 \mathrm{MW} / 0.1 \mathrm{~Hz}$ (compared to $3,750 \mathrm{MW} / 0.1 \mathrm{~Hz}$ in 1994). Frequency Response for larger events (greater than 35 mHz ) in 2006 may be as low as $2,600 \mathrm{MW} / 0.1 \mathrm{~Hz}$. Below is an independently calculated estimate of the trend in Eastern Interconnection Frequency Response provided by the New York ISO. Note: Response is stated in engineering terms ( $\mathrm{MW} / \mathrm{mHz}$ ) as opposed to the traditional MW/01.Hz.

The proposed Frequency Response standard (FRS) is a technical standard. Technical standards are described in the Reliability Standards Development Procedure. The FRS is not proposed to be a performance standard and does not propose a minimum Frequency Response, below which penalties are applied.

Industry commenters agreed there is a reliability need for the FRS. Comments varied on the technical details of the standard. Because of the divergent views on the details of the FRS SAR, the NERC Standards Committee (SC) directed the SAR drafting team to revise the SAR to focus only on the data collection needed to support the development of accurate models of Frequency Response in North America.

The SAR drafting team has tried to meet the Standards Committee's directive with this third version of the SAR.

The Version 3 of the Frequency Response SAR represents the changes requested by the NERC Standards Committee, while still meeting the June 2006 direction of the NERC Operating Committee. Specifically, the Operating Committee endorsed developing a Frequency Response standard that includes the following goals and objectives:

- Improving Interconnection Frequency Response event cataloging and benchmarking.
- Calculating balancing authority Frequency Response and requiring balancing authorities to analyze those cases where the response is significantly below the norm.
- Establishing time limits to complete the analyses.
- Tabulating non-responsive generators.
- Measuring generator response (those units on line).
- Including regional participation and review.

This revised SAR was reviewed and supported by the NERC Resources Subcommittee on December 4, 2006. The major changes between Draft 2 and Draft 3 include:

- Clarification on the role of the Load-serving Entity and Generator Operator.
- Inclusion of the applicability of Reliability Principles 3,5, and 6.
- Reduced the scope to address only the collection of data needed to model Frequency Response in North America.
- Clarified that the data collected to model frequency response over a period of up to 5 minutes per event to help identify the window of time where frequency response appears to be masked by AGC action.

Note that because the changes to the SAR were quite significant, no redline showing the changes from Version 2 to Version 3 will be posted.

Please review the revised SAR and then answer the questions on the following page.
Comments must be submitted by March 9, 2007. You may submit the completed form by e-mail to sarcomm@nerc.com with the words "FR SAR Draft 3" in the subject line.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree with the reduced scope of this SAR - focusing only on the data collection needed to support the development of accurate models of Frequency Response in North America?
$\boxtimes$ Yes
$\boxtimes$ No
Comments: HQT believe there might be other means than Reliability Standards to accomplish this data collection.
2. The proposed standard would have requirements for the following functional entities: Reliability Coordinator, Balancing Authority, Generator Owner, Generator Operator, and Load-serving Entity. Do you agree that these are the right functional entities for the proposed standard?Yes
$\boxtimes$ No
Comments: We question the need to include the applicability to the LSEs in this SAR and requests the drafting team to explain the purpose.
3. The SAR drafting team modified the SAR to clarify that data will be collected to model up to 5 minutes of frequency response. This should help identify the window of time where frequency response appears to be masked by AGC action. Do you agree with this clarification?
$\boxtimes$ Yes
$\boxtimes$ No
Comments: We requests clarification as to what data and at what periodicity will be collected from the identitified entities.
4. Should a field trial be initiated, whereby a set of events for each Interconnection is posted throughout the year, to be used by BAs to calculate their 2007 Frequency Response?
$\boxtimes$ YesNo
Comments:
5. Please provide any other comments (that you have not already provided in response to the first three questions on this form) that you have on the revised SAR.
Comments: Being a single Balancing Authority Interconnection, there might be a need for a «regional»difference for the Québec Interconnection when specific value will be established. Same as ERCOT, frequency response will be based on the change in generation (or load) rather than Tie-Line deviation.

Please use this form to submit comments on the third draft of the Frequency Response SAR. Comments must be submitted by March 9, 2007. You may submit the completed form by e-mail to sarcomm@nerc.com with the words "FR SAR Draft 3" in the subject line. If you have questions please contact Maureen Long at maureen. long@nerc. net or by telephone at 813-468-5998.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree with the reduced scope of this SAR - focusing only on the data collection needed to support the development of accurate models of Frequency Response in North America?
$\boxtimes$ No
Comments:
We do not agree with the reduced scope of this SAR. It does not require a standard to enable a data collection task(s). Data collection procedures and processes, charged by a standing committee, e.g. the OC, or respective working groups, would be more than sufficient.
2. The proposed standard would have requirements for the following functional entities: Reliability Coordinator, Balancing Authority, Generator Owner, Generator Operator, and Load-serving Entity. Do you agree that these are the right functional entities for the proposed standard?
$\square$ Yes
$\boxtimes$ No
Comments:
For the purpose of data collection, assigning responsibility to the Balancing Authority, Generator Operator and Load-serving Entity would suffice.
3. The SAR drafting team modified the SAR to clarify that data will be collected to model up to 5 minutes of frequency response. This should help identify the window of time where frequency response appears to be masked by AGC action. Do you agree with this clarification?
$\boxtimes$ YesNo
Comments:
4. Should a field trial be initiated, whereby a set of events for each Interconnection is posted throughout the year, to be used by BAs to calculate their 2007 Frequency Response?YesNo
Comments: A field test is a must and would definitely provide useful information on the types of event that would necessiate such data collection (The threshold needs to be clarified though - e.g. should it be >10MW loss of generator or some other threshold?), and any specific areas that need to be worked on in order to ensure that all relevant and required data is collected.
5. Please provide any other comments (that you have not already provided in response to the first three questions on this form) that you have on the revised SAR. Comments:

While we felt that the previous SAR was unclear on the intent, this SAR has such a reduced scope that the intended task does not require a reliability standard to achieve . A task team charged by a standing committee (the OC), would suffice. The requirements proposed in the SAR can be set as conditions for completing the data collection effort by the task team.

Please use this form to submit comments on the third draft of the Frequency Response SAR. Comments must be submitted by March 9, 2007. You may submit the completed form by e-mail to sarcomm@nerc.com with the words "FR SAR Draft 3" in the subject line. If you have questions please contact Maureen Long at maureen. long@nerc. net or by telephone at 813-468-5998.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree with the reduced scope of this SAR - focusing only on the data collection needed to support the development of accurate models of Frequency Response in North America?
$\boxtimes$ No
Comments: Do not agree with the notion in point 5 regarding the need for a Target Frequency Response for each interconnection at this time. It is presumptuous to advance a remedy prior to determining cause of the perceived decline in frequency response. Allow the techincal SAR to perform its function to determine cause. Any appropriate remedy in operating standards should become apparent.

Do not agree with point 6 of the description. In order to get a handle on what is really going on, all Balancing Authorities should be required to produce data valid to the study. Also the language in point 6 is poorly worded compared to the right wording in $6 a$ and $6 b$. $6 a$ and $6 b$ should be included in the SAR and 6 should be removed.
2. The proposed standard would have requirements for the following functional entities: Reliability Coordinator, Balancing Authority, Generator Owner, Generator Operator, and Load-serving Entity. Do you agree that these are the right functional entities for the proposed standard?
$\boxtimes$ Yes
$\square$ No
Comments:
3. The SAR drafting team modified the SAR to clarify that data will be collected to model up to 5 minutes of frequency response. This should help identify the window of time where frequency response appears to be masked by AGC action. Do you agree with this clarification?
$\boxtimes$ No
Comments: The 5 minute time is adaquate, but it lacks substance. Small changes in load and generation due to frequency response are very difficult to separate from normal load changes and AGC action on generation units (as was pointed out). It is important to include in the description of data collection that the 5 minutes should include 1 minute of data prior to a study event and 4 minutes after a study event. It is also important to include a sample rate, such as 4 seconds (obviously, faster samples are better, but may not be practicle).
4. Should a field trial be initiated, whereby a set of events for each Interconnection is posted throughout the year, to be used by BAs to calculate their 2007 Frequency Response?
5. Please provide any other comments (that you have not already provided in response to the first three questions on this form) that you have on the revised SAR.
Comments: The reasoning for this technical standard is based on the perception that the frequency response of the electrical system is declining and a concern that the interconnect's ability to arrest significant system disturbances is slowly being compromised. Although it is not disagreeable that a study be conducted to determine if an actual decline in frequency response is occuring and then to determine cause, it is diagreeable to propose a potential remedy for a problem that may not exist or, dependent on the findings, in inappropriate remedy.

One reason a decline in frequency response may be perceived occuring is a result of more on-line generating units being fully loaded. That means when a frequency decline occurs there are less units able to respond because they are already loaded. That does not mean the interconnection is at risk. As long as Balancing Authorities are maintaining their reserve obligations, even large contingencies should be manageable. However, over the years because of the trend to get more out of invested generation resources, it would give the appearance of a decline in frequency response since most frequency degradations are a result of losses of generation and a resultant decline in system frequency and those are what is studied and scrutinized. The August 14, 2003 disturbance was an opportunity to study the frequency response of all on-line generating units due to the frequency event resulting in a high frequency. High frequency is the only event where all on-line generating units will respond.

Proposing the establishment of a Target Frequency Response for the interconnect before concluding if an actual decline in frequency response is occuring and the subsequent cause(s) for the decline is finding a solution before defining the problem. Any standards involving frequency response needs to also consider the role system reserves play in the interconnect as well as the frequency response of generators and system load to frequency. As long as generating reserve obligations are being met to meet current Reliability Standards and Regional Operating Criteria there may not be a need to go further dependent on the outcome of the study proposed by this SAR.

Please use this form to submit comments on the third draft of the Frequency Response SAR．Comments must be submitted by March 9，2007．You may submit the completed form by e－mail to sarcomm＠nerc．com with the words＂FR SAR Draft 3＂in the subject line． If you have questions please contact Maureen Long at maureen．long＠nerc．net or by telephone at 813－468－5998．

## Background I nformation:

The original SAR on Frequency Response was submitted in large part due to a study that showed a 10+\% decline in Eastern Interconnection Frequency Response over a 5-year period, when response should be increasing over time as the Interconnection grows. Other Interconnections were observing similar declines. The drafting team posted a white paper along with the SAR to outline the need for a standard.

The NERC Resources Subcommittee recently updated their estimate of Eastern Interconnection Frequency Response and found it still trending downward. Response in 2006 was on the order of $2,800 \mathrm{MW} / 0.1 \mathrm{~Hz}$ (compared to $3,750 \mathrm{MW} / 0.1 \mathrm{~Hz}$ in 1994). Frequency Response for larger events (greater than 35 mHz ) in 2006 may be as low as $2,600 \mathrm{MW} / 0.1 \mathrm{~Hz}$. Below is an independently calculated estimate of the trend in Eastern Interconnection Frequency Response provided by the New York ISO. Note: Response is stated in engineering terms ( $\mathrm{MW} / \mathrm{mHz}$ ) as opposed to the traditional MW/01.Hz.

The proposed Frequency Response standard (FRS) is a technical standard. Technical standards are described in the Reliability Standards Development Procedure. The FRS is not proposed to be a performance standard and does not propose a minimum Frequency Response, below which penalties are applied.

Industry commenters agreed there is a reliability need for the FRS. Comments varied on the technical details of the standard. Because of the divergent views on the details of the FRS SAR, the NERC Standards Committee (SC) directed the SAR drafting team to revise the SAR to focus only on the data collection needed to support the development of accurate models of Frequency Response in North America.

The SAR drafting team has tried to meet the Standards Committee's directive with this third version of the SAR.

The Version 3 of the Frequency Response SAR represents the changes requested by the NERC Standards Committee, while still meeting the June 2006 direction of the NERC Operating Committee. Specifically, the Operating Committee endorsed developing a Frequency Response standard that includes the following goals and objectives:

- Improving Interconnection Frequency Response event cataloging and benchmarking.
- Calculating balancing authority Frequency Response and requiring balancing authorities to analyze those cases where the response is significantly below the norm.
- Establishing time limits to complete the analyses.
- Tabulating non-responsive generators.
- Measuring generator response (those units on line).
- Including regional participation and review.

This revised SAR was reviewed and supported by the NERC Resources Subcommittee on December 4, 2006. The major changes between Draft 2 and Draft 3 include:

- Clarification on the role of the Load-serving Entity and Generator Operator.
- Inclusion of the applicability of Reliability Principles 3,5, and 6.
- Reduced the scope to address only the collection of data needed to model Frequency Response in North America.
- Clarified that the data collected to model frequency response over a period of up to 5 minutes per event to help identify the window of time where frequency response appears to be masked by AGC action.

Note that because the changes to the SAR were quite significant, no redline showing the changes from Version 2 to Version 3 will be posted.

Please review the revised SAR and then answer the questions on the following page.
Comments must be submitted by March 9, 2007. You may submit the completed form by e-mail to sarcomm@nerc.com with the words "FR SAR Draft 3" in the subject line.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree with the reduced scope of this SAR - focusing only on the data collection needed to support the development of accurate models of Frequency Response in North America?
$\boxtimes$ Yes
$\square$ No
Comments:
2. The proposed standard would have requirements for the following functional entities:

Reliability Coordinator, Balancing Authority, Generator Owner, Generator Operator, and Load-serving Entity. Do you agree that these are the right functional entities for the proposed standard?
$\boxtimes$ YesNo
Comments:
3. The SAR drafting team modified the SAR to clarify that data will be collected to model up to 5 minutes of frequency response. This should help identify the window of time where frequency response appears to be masked by AGC action. Do you agree with this clarification?
$\boxtimes$ Yes
$\square$ No
Comments: Ten minutes might be more useful, especially in any areas where it appears to take a long time to settle down after a frequency deviation event. This could be left up to the discretion of operators and balancing authorities in any areas where slow or bumpy returns to normal frequency levels are experienced.
4. Should a field trial be initiated, whereby a set of events for each Interconnection is posted throughout the year, to be used by BAs to calculate their 2007 Frequency Response?YesNo
Comments: Only if field trials are deemed to have very high probability of not causing significant difficulties on overly sensitive network area.
5. Please provide any other comments (that you have not already provided in response to the first three questions on this form) that you have on the revised SAR. Comments:

Comments must be submitted by March 9, 2007. You may submit the completed form by e-mail to sarcomm@nerc.com with the words "FR SAR Draft 3" in the subject line.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree with the reduced scope of this SAR - focusing only on the data collection needed to support the development of accurate models of Frequency Response in North America?
$\boxtimes$ Yes
$\square$ No
Comments: This standard would be a start, at least, at bringing to light where and why response is being lost. It may well be that exposure and peer pressure, as well as the tiered reporting requirements, will keep plant and operations personnel abreast of their obligations for providing reserves of all types.
2. The proposed standard would have requirements for the following functional entities: Reliability Coordinator, Balancing Authority, Generator Owner, Generator Operator, and Load-serving Entity. Do you agree that these are the right functional entities for the proposed standard?
$\boxtimes$ Yes
Comments:
3. The SAR drafting team modified the SAR to clarify that data will be collected to model up to 5 minutes of frequency response. This should help identify the window of time where frequency response appears to be masked by AGC action. Do you agree with this clarification?
$\boxtimes$ Yes
$\square$ No
Comments:
4. Should a field trial be initiated, whereby a set of events for each Interconnection is posted throughout the year, to be used by BAs to calculate their 2007 Frequency Response?
$\boxtimes$ No
Comments: This is not a new concept. I support institution of the standard as written so a start can be made to identify and, with luck, remediate the decline in frequency response.
5. Please provide any other comments (that you have not already provided in response to the first three questions on this form) that you have on the revised SAR. Comments: I have concern about the "shall"s in the standard, in that there is no apparent enforcement behind the requirements for data submittals. If I'm wrong in
this, then I would be comfortable with the effectiveness possible. If I'm right, what is to be done with an entity which finds it convenient not to report?

Please use this form to submit comments on the third draft of the Frequency Response SAR. Comments must be submitted by March 9, 2007. You may submit the completed form by e-mail to sarcomm@nerc.com with the words "FR SAR Draft 3" in the subject line. If you have questions please contact Maureen Long at maureen.long@nerc. net or by telephone at 813-468-5998.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree with the reduced scope of this SAR - focusing only on the data collection needed to support the development of accurate models of Frequency Response in North America?
$\boxtimes$ Yes
$\square$ No
Comments:
2. The proposed standard would have requirements for the following functional entities:

Reliability Coordinator, Balancing Authority, Generator Owner, Generator Operator, and Load-serving Entity. Do you agree that these are the right functional entities for the proposed standard?
$\boxtimes$ YesNo
Comments:
3. The SAR drafting team modified the SAR to clarify that data will be collected to model up to 5 minutes of frequency response. This should help identify the window of time where frequency response appears to be masked by AGC action. Do you agree with this clarification?
$\boxtimes$ Yes
$\boxtimes$ No
Comments: Five minutes is acceptable. There may be merit in collecting 15 minutes of data to cover the DCS window. The data should be readily available since the BAs are already examining this data to determine their compliance with the DCS standard. The final decision can be made during the standards drafting phase.
4. Should a field trial be initiated, whereby a set of events for each Interconnection is posted throughout the year, to be used by BAs to calculate their 2007 Frequency Response?
$\boxtimes$ YesNo
Comments: This should not be a problem as BAs should already be performing this calculation in the annual determination of their frequency bias.
5. Please provide any other comments (that you have not already provided in response to the first three questions on this form) that you have on the revised SAR. Comments:

## Background I nformation:

The original SAR on Frequency Response was submitted in large part due to a study that showed a 10+\% decline in Eastern Interconnection Frequency Response over a 5-year period, when response should be increasing over time as the Interconnection grows. Other Interconnections were observing similar declines. The drafting team posted a white paper along with the SAR to outline the need for a standard.

The NERC Resources Subcommittee recently updated their estimate of Eastern Interconnection Frequency Response and found it still trending downward. Response in 2006 was on the order of $2,800 \mathrm{MW} / 0.1 \mathrm{~Hz}$ (compared to $3,750 \mathrm{MW} / 0.1 \mathrm{~Hz}$ in 1994). Frequency Response for larger events (greater than 35 mHz ) in 2006 may be as low as $2,600 \mathrm{MW} / 0.1 \mathrm{~Hz}$. Below is an independently calculated estimate of the trend in Eastern Interconnection Frequency Response provided by the New York ISO. Note: Response is stated in engineering terms ( $\mathrm{MW} / \mathrm{mHz}$ ) as opposed to the traditional MW/01.Hz.

The proposed Frequency Response standard (FRS) is a technical standard. Technical standards are described in the Reliability Standards Development Procedure. The FRS is not proposed to be a performance standard and does not propose a minimum Frequency Response, below which penalties are applied.

Industry commenters agreed there is a reliability need for the FRS. Comments varied on the technical details of the standard. Because of the divergent views on the details of the FRS SAR, the NERC Standards Committee (SC) directed the SAR drafting team to revise the SAR to focus only on the data collection needed to support the development of accurate models of Frequency Response in North America.

The SAR drafting team has tried to meet the Standards Committee's directive with this third version of the SAR.

The Version 3 of the Frequency Response SAR represents the changes requested by the NERC Standards Committee, while still meeting the June 2006 direction of the NERC Operating Committee. Specifically, the Operating Committee endorsed developing a Frequency Response standard that includes the following goals and objectives:

- Improving Interconnection Frequency Response event cataloging and benchmarking.
- Calculating balancing authority Frequency Response and requiring balancing authorities to analyze those cases where the response is significantly below the norm.
- Establishing time limits to complete the analyses.
- Tabulating non-responsive generators.
- Measuring generator response (those units on line).
- Including regional participation and review.

This revised SAR was reviewed and supported by the NERC Resources Subcommittee on December 4, 2006. The major changes between Draft 2 and Draft 3 include:

- Clarification on the role of the Load-serving Entity and Generator Operator.
- Inclusion of the applicability of Reliability Principles 3,5, and 6.
- Reduced the scope to address only the collection of data needed to model Frequency Response in North America.
- Clarified that the data collected to model frequency response over a period of up to 5 minutes per event to help identify the window of time where frequency response appears to be masked by AGC action.

Note that because the changes to the SAR were quite significant, no redline showing the changes from Version 2 to Version 3 will be posted.

Please review the revised SAR and then answer the questions on the following page.
Comments must be submitted by March 9, 2007. You may submit the completed form by e-mail to sarcomm@nerc.com with the words "FR SAR Draft 3" in the subject line.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree with the reduced scope of this SAR - focusing only on the data collection needed to support the development of accurate models of Frequency Response in North America?
$\boxtimes$ Yes
$\boxtimes$ No
Comments: Many of NPCC's participating members believe there are other means to accomplish this phase of the initiative and that appropriate revisions to existing standard(s) may address the issue determined by the data analysis could be proposed.
2. The proposed standard would have requirements for the following functional entities: Reliability Coordinator, Balancing Authority, Generator Owner, Generator Operator, and Load-serving Entity. Do you agree that these are the right functional entities for the proposed standard?
$\boxtimes$ No
Comments: NPCC participating members question the need to include the applicability to the LSEs in this SAR and requests the drafting team to explain this.
3. The SAR drafting team modified the SAR to clarify that data will be collected to model up to 5 minutes of frequency response. This should help identify the window of time where frequency response appears to be masked by AGC action. Do you agree with this clarification?
$\square$ Yes
$\boxtimes$ No
Comments: It is not clear what type of data is going to be collected from this requirement. AGC response is continuous. What is the justification for the specific "five minutes" reffered to? Since AGC control is every 4 seconds, five minutes appears to be too long a period to collect this data. Imposing this requirement will require the installation of local data storage retention facilities \& telemetering equipment that may not be necessary and NPCC participating members would like the drafting team to explain why 5 minutes is necessary.

Also, when requesting data from a generator what is expected scan-rate/exception reporting clarity of the data?
4. Should a field trial be initiated, whereby a set of events for each Interconnection is posted throughout the year, to be used by BAs to calculate their 2007 Frequency Response?
【 Yes
Comments:
5. Please provide any other comments (that you have not already provided in response to the first three questions on this form) that you have on the revised SAR. Comments:

[^33] comments. Regional acronyms and segment numbers are shown on prior page.

## Background I nformation:

The original SAR on Frequency Response was submitted in large part due to a study that showed a 10+\% decline in Eastern Interconnection Frequency Response over a 5-year period, when response should be increasing over time as the Interconnection grows. Other Interconnections were observing similar declines. The drafting team posted a white paper along with the SAR to outline the need for a standard.

The NERC Resources Subcommittee recently updated their estimate of Eastern Interconnection Frequency Response and found it still trending downward. Response in 2006 was on the order of $2,800 \mathrm{MW} / 0.1 \mathrm{~Hz}$ (compared to $3,750 \mathrm{MW} / 0.1 \mathrm{~Hz}$ in 1994). Frequency Response for larger events (greater than 35 mHz ) in 2006 may be as low as $2,600 \mathrm{MW} / 0.1 \mathrm{~Hz}$. Below is an independently calculated estimate of the trend in Eastern Interconnection Frequency Response provided by the New York ISO. Note: Response is stated in engineering terms ( $\mathrm{MW} / \mathrm{mHz}$ ) as opposed to the traditional MW/01.Hz.

The proposed Frequency Response standard (FRS) is a technical standard. Technical standards are described in the Reliability Standards Development Procedure. The FRS is not proposed to be a performance standard and does not propose a minimum Frequency Response, below which penalties are applied.

Industry commenters agreed there is a reliability need for the FRS. Comments varied on the technical details of the standard. Because of the divergent views on the details of the FRS SAR, the NERC Standards Committee (SC) directed the SAR drafting team to revise the SAR to focus only on the data collection needed to support the development of accurate models of Frequency Response in North America.

The SAR drafting team has tried to meet the Standards Committee's directive with this third version of the SAR.

The Version 3 of the Frequency Response SAR represents the changes requested by the NERC Standards Committee, while still meeting the June 2006 direction of the NERC Operating Committee. Specifically, the Operating Committee endorsed developing a Frequency Response standard that includes the following goals and objectives:

- Improving Interconnection Frequency Response event cataloging and benchmarking.
- Calculating balancing authority Frequency Response and requiring balancing authorities to analyze those cases where the response is significantly below the norm.
- Establishing time limits to complete the analyses.
- Tabulating non-responsive generators.
- Measuring generator response (those units on line).
- Including regional participation and review.

This revised SAR was reviewed and supported by the NERC Resources Subcommittee on December 4, 2006. The major changes between Draft 2 and Draft 3 include:

- Clarification on the role of the Load-serving Entity and Generator Operator.
- Inclusion of the applicability of Reliability Principles 3,5, and 6.
- Reduced the scope to address only the collection of data needed to model Frequency Response in North America.
- Clarified that the data collected to model frequency response over a period of up to 5 minutes per event to help identify the window of time where frequency response appears to be masked by AGC action.

Note that because the changes to the SAR were quite significant, no redline showing the changes from Version 2 to Version 3 will be posted.

Please review the revised SAR and then answer the questions on the following page.
Comments must be submitted by March 9, 2007. You may submit the completed form by e-mail to sarcomm@nerc.com with the words "FR SAR Draft 3" in the subject line.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree with the reduced scope of this SAR - focusing only on the data collection needed to support the development of accurate models of Frequency Response in North America?
$\boxtimes$ Yes
$\square$ No
Comments:
2. The proposed standard would have requirements for the following functional entities:

Reliability Coordinator, Balancing Authority, Generator Owner, Generator Operator, and Load-serving Entity. Do you agree that these are the right functional entities for the proposed standard?
$\boxtimes$ YesNo
Comments:
3. The SAR drafting team modified the SAR to clarify that data will be collected to model up to 5 minutes of frequency response. This should help identify the window of time where frequency response appears to be masked by AGC action. Do you agree with this clarification?
$\boxtimes$ Yes
$\square$ N
Comments:
4. Should a field trial be initiated, whereby a set of events for each Interconnection is posted throughout the year, to be used by BAs to calculate their 2007 Frequency Response?
$\boxtimes$ Yes
$\square$ No
Comments: A field trial may indicate the need for more or different data for the proper calculation of a BAs Frequency Response.
5. Please provide any other comments (that you have not already provided in response to the first three questions on this form) that you have on the revised SAR. Comments: Frequency Response of Resources is vital to the reliability of an interconnection. Large differences between the measured Frequency Response of a BA, its Bias setting and the models of Frequency Response may indicate a reliability risk. Updating the models with accurate Frequency Response data will improve the evaluation of this reliability risk. Please implement this process as soon as possible.

Please use this form to submit comments on the third draft of the Frequency Response SAR. Comments must be submitted by March 9, 2007. You may submit the completed form by e-mail to sarcomm@nerc.com with the words "FR SAR Draft 3" in the subject line. If you have questions please contact Maureen Long at maureen. long@nerc. net or by telephone at 813-468-5998.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree with the reduced scope of this SAR - focusing only on the data collection needed to support the development of accurate models of Frequency Response in North America?
$\boxtimes$ Yes
$\boxtimes$ No
Comments: The NYISO is uncertain if this is the appropriate means to require data collection for purposes of developing models. A review should be made to be certain that this proposed scope meets the criteria for a standard.
2. The proposed standard would have requirements for the following functional entities: Reliability Coordinator, Balancing Authority, Generator Owner, Generator Operator, and Load-serving Entity. Do you agree that these are the right functional entities for the proposed standard?
$\boxtimes$ Yes
Comments:
3. The SAR drafting team modified the SAR to clarify that data will be collected to model up to 5 minutes of frequency response. This should help identify the window of time where frequency response appears to be masked by AGC action. Do you agree with this clarification?
$\boxtimes$ Yes
$\boxtimes$ No
Comments: It is not clear what type of data is going to be collected from this requirement. AGC response is continuous. What is the justification for the specific "five minutes" reffered to? Since AGC control is every 4 seconds, five minutes appears to be too long a period to collect this data. Imposing this requirement will require the installation of local data storage retention facilities \& telemetering equipment that may not be necessary and NPCC participating members would like the drafting team to explain why 5 minutes is necessary.

Also, when requesting data from a generator what is expected scan-rate/exception reporting clarity of the data?
4. Should a field trial be initiated, whereby a set of events for each Interconnection is posted throughout the year, to be used by BAs to calculate their 2007 Frequency Response?
Q Yes
$\square$ No
Comments:

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree with the reduced scope of this SAR - focusing only on the data collection needed to support the development of accurate models of Frequency Response in North America?
$\boxtimes$ Yes
$\square$ No
Comments: Frequency response and its dynamic behavior is a complex issue that requires detailed analysis and study to understand. This in turn requires sufficient high quality data be obtained to support the development of models and concepts. The data could be collected voluntarily, but without the force of NERC standards behind it not many people are going to devote the resources required to collect the data. We strongly support this effort.
2. The proposed standard would have requirements for the following functional entities: Reliability Coordinator, Balancing Authority, Generator Owner, Generator Operator, and Load-serving Entity. Do you agree that these are the right functional entities for the proposed standard?
$\boxtimes$ YesNo
Comments:
3. The SAR drafting team modified the SAR to clarify that data will be collected to model up to 5 minutes of frequency response. This should help identify the window of time where frequency response appears to be masked by AGC action. Do you agree with this clarification?
$\boxtimes$ YesNo
Comments:
4. Should a field trial be initiated, whereby a set of events for each Interconnection is posted throughout the year, to be used by BAs to calculate their 2007 Frequency Response?
$\boxtimes$ Yes
$\square$ No
Comments: Currently BAs in the Eastern Interconnection have little, if any, way to actually calculate their frequency responses. As a result, most default to the one percent minimum. A good database of disturbance events will provide the information to calculate BA frequency response more accurately while at the same time allowing the NERC OC/RS to determine if the one percent minimum is appropriate in the El today.
5. Please provide any other comments (that you have not already provided in response to the first three questions on this form) that you have on the revised SAR.
Comments: This SAR starts the process toward understanding frequency behavior, particularly in the Eastern Interconnection. In our opinion this is a necessary first step in determining whether we need frequency response allocations or other measures to ensure the sustained frequency performance that is required for reliable operations.

Wherever possible, the scope and extent of data collection required for generators, their dynamic models including all associated control devices, and any other system data parameters covered under this SAR be limited such that it should not duplicate or exceed system modeling data requirements of any other NERC standard. One important system modeling parameter not emphasized in this SAR is the characteristic behavior of load at each substation (constant power, constant current, etc.), which would seem to have a significant effect on overall frequency response of the interconnected system. It is quite possible that advancements in consumer appliances and electronics, and their proliferation of use, have collectively changed the overall characteristics of system load to a composite state that is significantly different from modeling assumptions made within the previous few years.

Please use this form to submit comments on the third draft of the Frequency Response SAR. Comments must be submitted by March 9, 2007. You may submit the completed form by e-mail to sarcomm@nerc.com with the words "FR SAR Draft 3" in the subject line. If you have questions please contact Maureen Long at maureen. long@nerc. net or by telephone at 813-468-5998.

[^37] comments. Regional acronyms and segment numbers are shown on prior page.

## Background I nformation:

The original SAR on Frequency Response was submitted in large part due to a study that showed a 10+\% decline in Eastern Interconnection Frequency Response over a 5-year period, when response should be increasing over time as the Interconnection grows. Other Interconnections were observing similar declines. The drafting team posted a white paper along with the SAR to outline the need for a standard.

The NERC Resources Subcommittee recently updated their estimate of Eastern Interconnection Frequency Response and found it still trending downward. Response in 2006 was on the order of $2,800 \mathrm{MW} / 0.1 \mathrm{~Hz}$ (compared to $3,750 \mathrm{MW} / 0.1 \mathrm{~Hz}$ in 1994). Frequency Response for larger events (greater than 35 mHz ) in 2006 may be as low as $2,600 \mathrm{MW} / 0.1 \mathrm{~Hz}$. Below is an independently calculated estimate of the trend in Eastern Interconnection Frequency Response provided by the New York ISO. Note: Response is stated in engineering terms ( $\mathrm{MW} / \mathrm{mHz}$ ) as opposed to the traditional MW/01.Hz.

The proposed Frequency Response standard (FRS) is a technical standard. Technical standards are described in the Reliability Standards Development Procedure. The FRS is not proposed to be a performance standard and does not propose a minimum Frequency Response, below which penalties are applied.

Industry commenters agreed there is a reliability need for the FRS. Comments varied on the technical details of the standard. Because of the divergent views on the details of the FRS SAR, the NERC Standards Committee (SC) directed the SAR drafting team to revise the SAR to focus only on the data collection needed to support the development of accurate models of Frequency Response in North America.

The SAR drafting team has tried to meet the Standards Committee's directive with this third version of the SAR.

The Version 3 of the Frequency Response SAR represents the changes requested by the NERC Standards Committee, while still meeting the June 2006 direction of the NERC Operating Committee. Specifically, the Operating Committee endorsed developing a Frequency Response standard that includes the following goals and objectives:

- Improving Interconnection Frequency Response event cataloging and benchmarking.
- Calculating balancing authority Frequency Response and requiring balancing authorities to analyze those cases where the response is significantly below the norm.
- Establishing time limits to complete the analyses.
- Tabulating non-responsive generators.
- Measuring generator response (those units on line).
- Including regional participation and review.

This revised SAR was reviewed and supported by the NERC Resources Subcommittee on December 4, 2006. The major changes between Draft 2 and Draft 3 include:

- Clarification on the role of the Load-serving Entity and Generator Operator.
- Inclusion of the applicability of Reliability Principles 3,5, and 6.
- Reduced the scope to address only the collection of data needed to model Frequency Response in North America.
- Clarified that the data collected to model frequency response over a period of up to 5 minutes per event to help identify the window of time where frequency response appears to be masked by AGC action.

Note that because the changes to the SAR were quite significant, no redline showing the changes from Version 2 to Version 3 will be posted.

Please review the revised SAR and then answer the questions on the following page.
Comments must be submitted by March 9, 2007. You may submit the completed form by e-mail to sarcomm@nerc.com with the words "FR SAR Draft 3" in the subject line.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree with the reduced scope of this SAR - focusing only on the data collection needed to support the development of accurate models of Frequency Response in North America?
$\boxtimes$ Yes
$\square$ No
Comments:
2. The proposed standard would have requirements for the following functional entities: Reliability Coordinator, Balancing Authority, Generator Owner, Generator Operator, and Load-serving Entity. Do you agree that these are the right functional entities for the proposed standard?
$\boxtimes$ YesNo
Comments: Ultimately there may be some impact to the Planning Coordinator and/or Resource Planner if a frequency response requirement is specified. Could there be an extreme scenario where an entity would have to consider shedding load to meet some frequency reserve criteria?
3. The SAR drafting team modified the SAR to clarify that data will be collected to model up to 5 minutes of frequency response. This should help identify the window of time where frequency response appears to be masked by AGC action. Do you agree with this clarification?
$\boxtimes$ YesNo
Comments:
4. Should a field trial be initiated, whereby a set of events for each Interconnection is posted throughout the year, to be used by BAs to calculate their 2007 Frequency Response?
$\boxtimes$ YesNo
Comments:
5. Please provide any other comments (that you have not already provided in response to the first three questions on this form) that you have on the revised SAR.
Comments: The SAR includes some requirement language pertaining to generators greater than 10 MW. Old NERC Policy included language requiring frequency responsive governors "unless restricted by regulatory mandates". This makes sense for most nuclear facilities. Another type of restriction on governors involves small hydro units
that are dependent on water order. For this type of unit there truly is no governor response yet the unit capabilities may exceed 10 MWs. Please consider these types of exemptions as work progresses on this SAR and resulting standard.

Please use this form to submit comments on the third draft of the Frequency Response SAR. Comments must be submitted by March 9, 2007. You may submit the completed form by e-mail to sarcomm@nerc.com with the words "FR SAR Draft 3" in the subject line. If you have questions please contact Maureen Long at maureen.long@nerc. net or by telephone at 813-468-5998.

Below is an independently calculated estimate of the trend in Eastern Interconnection Frequency Response provided by the New York ISO. Note: Response is stated in engineering terms ( $\mathrm{MW} / \mathrm{mHz}$ ) as opposed to the traditional MW/01.Hz.

The proposed Frequency Response standard (FRS) is a technical standard. Technical standards are described in the Reliability Standards Development Procedure. The FRS is not proposed to be a performance standard and does not propose a minimum Frequency Response, below which penalties are applied.

Industry commenters agreed there is a reliability need for the FRS. Comments varied on the technical details of the standard. Because of the divergent views on the details of the FRS SAR, the NERC Standards Committee (SC) directed the SAR drafting team to revise the SAR to focus only on the data collection needed to support the development of accurate models of Frequency Response in North America.

The SAR drafting team has tried to meet the Standards Committee's directive with this third version of the SAR.

The Version 3 of the Frequency Response SAR represents the changes requested by the NERC Standards Committee, while still meeting the June 2006 direction of the NERC Operating Committee. Specifically, the Operating Committee endorsed developing a Frequency Response standard that includes the following goals and objectives:

- Improving Interconnection Frequency Response event cataloging and benchmarking.
- Calculating balancing authority Frequency Response and requiring balancing authorities to analyze those cases where the response is significantly below the norm.
- Establishing time limits to complete the analyses.
- Tabulating non-responsive generators.
- Measuring generator response (those units on line).
- Including regional participation and review.

This revised SAR was reviewed and supported by the NERC Resources Subcommittee on December 4, 2006. The major changes between Draft 2 and Draft 3 include:

- Clarification on the role of the Load-serving Entity and Generator Operator.
- Inclusion of the applicability of Reliability Principles 3,5, and 6.
- Reduced the scope to address only the collection of data needed to model Frequency Response in North America.
- Clarified that the data collected to model frequency response over a period of up to 5 minutes per event to help identify the window of time where frequency response appears to be masked by AGC action.

Note that because the changes to the SAR were quite significant, no redline showing the changes from Version 2 to Version 3 will be posted.

Please review the revised SAR and then answer the questions on the following page.
Comments must be submitted by March 9, 2007. You may submit the completed form by e-mail to sarcomm@nerc.com with the words "FR SAR Draft 3" in the subject line.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree with the reduced scope of this SAR - focusing only on the data collection needed to support the development of accurate models of Frequency Response in North America?
$\boxtimes$ No
Comments: The scope of this SAR is for data collection, and should not include establishing a Target Frequency Response as stated in Paragraph \#5.
2. The proposed standard would have requirements for the following functional entities: Reliability Coordinator, Balancing Authority, Generator Owner, Generator Operator, and Load-serving Entity. Do you agree that these are the right functional entities for the proposed standard?Yes
$\boxtimes$ No
Comments: Load serving entities should not be included due to the characteristics of load and frequency. Load Serving Entities should contribute data to determine FRC.
3. The SAR drafting team modified the SAR to clarify that data will be collected to model up to 5 minutes of frequency response. This should help identify the window of time where frequency response appears to be masked by AGC action. Do you agree with this clarification?Yes
$\boxtimes$ No
Comments: Need more specific information regarding sample rates. The 5 -minutes of frequency response should identify time periods prior to and after the event.
4. Should a field trial be initiated, whereby a set of events for each Interconnection is posted throughout the year, to be used by BAs to calculate their 2007 Frequency Response?
$\boxtimes$ YesNo
Comments:
5. Please provide any other comments (that you have not already provided in response to the first three questions on this form) that you have on the revised SAR.
Comments: Data collection and FRC assessments should also take into account loss of load, not just loss of generation. If load is lost, causing a high frequency excursion, FRC should be observed on heavily loaded generators.

Please use this form to submit comments on the third draft of the Frequency Response SAR. Comments must be submitted by March 9, 2007. You may submit the completed form by e-mail to sarcomm@nerc.com with the words "FR SAR Draft 3" in the subject line. If you have questions please contact Maureen Long at maureen.long@nerc. net or by telephone at 813-468-5998.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree with the reduced scope of this SAR - focusing only on the data collection needed to support the development of accurate models of Frequency Response in North America?
இNo
Comments: We agree with the proposed scope except that items 5 and 6 do not deal specifically with data collection and therefore are beyond the scope of the SAR. We are concerned over establishing a Target Frequency Response. This is presumptious in that it advances a proposed remedy before first meeting the intent of the SAR-determining the cause for the percieved decline in frequency response. We support Items 6a. and 6b. if referenced to item 4 as modified as follows: Modify 4 to require generator level reporting when the Frequency Response for a BA is less than [75]* percent of the Previous Years observed Frequency Response. Delete items 5 and 6.
2. The proposed standard would have requirements for the following functional entities: Reliability Coordinator, Balancing Authority, Generator Owner, Generator Operator, and Load-serving Entity. Do you agree that these are the right functional entities for the proposed standard?
$\boxtimes$ Yes
$\square$ No
Comments: To the extent information is needed from these entities, they are appropriate to list. It is possible that the LSE is not required.
3. The SAR drafting team modified the SAR to clarify that data will be collected to model up to 5 minutes of frequency response. This should help identify the window of time where frequency response appears to be masked by AGC action. Do you agree with this clarification?Yes
$\boxtimes$ No
Comments: Further clarification is needed around the time period for which data will be collected. It important to note that description of the 5 minutes data collection period should include 1 minute before and 4 minutes after the event.
4. Should a field trial be initiated, whereby a set of events for each Interconnection is posted throughout the year, to be used by BAs to calculate their 2007 Frequency Response?
$\boxtimes$ Yes
$\square$ No
Comments:
5. Please provide any other comments (that you have not already provided in response to the first three questions on this form) that you have on the revised SAR.
Comments: Establishing a Target Frequency Response is premature. It advances a proposed remedy in advance of first meeting the intent of the SAR-determining the cause for the percieved decline in frequency response. It is our view that the percieved decline of frequency response, if that turns out to be the confirmed as a true decline, of itself does not necessarily indicate an significantly increased threat to reliability. As long as generating reserve obligations are being met to meet Reliability Standards and the real time regulating reserves are being carried, also to meet Standards, there may not be a need to go further depending on the outcome of the study proposed by the SAR.

Please use this form to submit comments on the third draft of the Frequency Response SAR. Comments must be submitted by March 9, 2007. You may submit the completed form by e-mail to sarcomm@nerc.com with the words "FR SAR Draft 3" in the subject line. If you have questions please contact Maureen Long at maureen. long@nerc. net or by telephone at 813-468-5998.

## Background I nformation:

The original SAR on Frequency Response was submitted in large part due to a study that showed a 10+\% decline in Eastern Interconnection Frequency Response over a 5-year period, when response should be increasing over time as the Interconnection grows. Other Interconnections were observing similar declines. The drafting team posted a white paper along with the SAR to outline the need for a standard.

The NERC Resources Subcommittee recently updated their estimate of Eastern Interconnection Frequency Response and found it still trending downward. Response in 2006 was on the order of $2,800 \mathrm{MW} / 0.1 \mathrm{~Hz}$ (compared to $3,750 \mathrm{MW} / 0.1 \mathrm{~Hz}$ in 1994). Frequency Response for larger events (greater than 35 mHz ) in 2006 may be as low as $2,600 \mathrm{MW} / 0.1 \mathrm{~Hz}$. Below is an independently calculated estimate of the trend in Eastern Interconnection Frequency Response provided by the New York ISO. Note: Response is stated in engineering terms ( $\mathrm{MW} / \mathrm{mHz}$ ) as opposed to the traditional MW/01.Hz.

The proposed Frequency Response standard (FRS) is a technical standard. Technical standards are described in the Reliability Standards Development Procedure. The FRS is not proposed to be a performance standard and does not propose a minimum Frequency Response, below which penalties are applied.

Industry commenters agreed there is a reliability need for the FRS. Comments varied on the technical details of the standard. Because of the divergent views on the details of the FRS SAR, the NERC Standards Committee (SC) directed the SAR drafting team to revise the SAR to focus only on the data collection needed to support the development of accurate models of Frequency Response in North America.

The SAR drafting team has tried to meet the Standards Committee's directive with this third version of the SAR.

The Version 3 of the Frequency Response SAR represents the changes requested by the NERC Standards Committee, while still meeting the June 2006 direction of the NERC Operating Committee. Specifically, the Operating Committee endorsed developing a Frequency Response standard that includes the following goals and objectives:

- Improving Interconnection Frequency Response event cataloging and benchmarking.
- Calculating balancing authority Frequency Response and requiring balancing authorities to analyze those cases where the response is significantly below the norm.
- Establishing time limits to complete the analyses.
- Tabulating non-responsive generators.
- Measuring generator response (those units on line).
- Including regional participation and review.

This revised SAR was reviewed and supported by the NERC Resources Subcommittee on December 4, 2006. The major changes between Draft 2 and Draft 3 include:

- Clarification on the role of the Load-serving Entity and Generator Operator.
- Inclusion of the applicability of Reliability Principles 3,5, and 6.
- Reduced the scope to address only the collection of data needed to model Frequency Response in North America.
- Clarified that the data collected to model frequency response over a period of up to 5 minutes per event to help identify the window of time where frequency response appears to be masked by AGC action.

Note that because the changes to the SAR were quite significant, no redline showing the changes from Version 2 to Version 3 will be posted.

Please review the revised SAR and then answer the questions on the following page.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree with the reduced scope of this SAR - focusing only on the data collection needed to support the development of accurate models of Frequency Response in North America?
$\boxtimes$ Yes
$\square$ No
Comments:
2. The proposed standard would have requirements for the following functional entities:

Reliability Coordinator, Balancing Authority, Generator Owner, Generator Operator, and Load-serving Entity. Do you agree that these are the right functional entities for the proposed standard?
$\boxtimes$ YesNo
Comments:
3. The SAR drafting team modified the SAR to clarify that data will be collected to model up to 5 minutes of frequency response. This should help identify the window of time where frequency response appears to be masked by AGC action. Do you agree with this clarification?Yes
$\boxtimes$ No
Comments: Five minutes of data seems arbitrary. If the collection period were extended to 15 minutes, it would coincide with the Disturbance Control period.
4. Should a field trial be initiated, whereby a set of events for each Interconnection is posted throughout the year, to be used by BAs to calculate their 2007 Frequency Response?
$\boxtimes$ YesNo
Comments:
5. Please provide any other comments (that you have not already provided in response to the first three questions on this form) that you have on the revised SAR. Comments:

Please use this form to submit comments on the third draft of the Frequency Response SAR. Comments must be submitted by March 9, 2007. You may submit the completed form by e-mail to sarcomm@nerc.com with the words "FR SAR Draft 3" in the subject line. If you have questions please contact Maureen Long at maureen. long@nerc. net or by telephone at 813-468-5998.

## Background I nformation:

The original SAR on Frequency Response was submitted in large part due to a study that showed a 10+\% decline in Eastern Interconnection Frequency Response over a 5-year period, when response should be increasing over time as the Interconnection grows. Other Interconnections were observing similar declines. The drafting team posted a white paper along with the SAR to outline the need for a standard.

The NERC Resources Subcommittee recently updated their estimate of Eastern Interconnection Frequency Response and found it still trending downward. Response in 2006 was on the order of $2,800 \mathrm{MW} / 0.1 \mathrm{~Hz}$ (compared to $3,750 \mathrm{MW} / 0.1 \mathrm{~Hz}$ in 1994). Frequency Response for larger events (greater than 35 mHz ) in 2006 may be as low as $2,600 \mathrm{MW} / 0.1 \mathrm{~Hz}$. Below is an independently calculated estimate of the trend in Eastern Interconnection Frequency Response provided by the New York ISO. Note: Response is stated in engineering terms ( $\mathrm{MW} / \mathrm{mHz}$ ) as opposed to the traditional MW/01.Hz.

The proposed Frequency Response standard (FRS) is a technical standard. Technical standards are described in the Reliability Standards Development Procedure. The FRS is not proposed to be a performance standard and does not propose a minimum Frequency Response, below which penalties are applied.

Industry commenters agreed there is a reliability need for the FRS. Comments varied on the technical details of the standard. Because of the divergent views on the details of the FRS SAR, the NERC Standards Committee (SC) directed the SAR drafting team to revise the SAR to focus only on the data collection needed to support the development of accurate models of Frequency Response in North America.

The SAR drafting team has tried to meet the Standards Committee's directive with this third version of the SAR.

The Version 3 of the Frequency Response SAR represents the changes requested by the NERC Standards Committee, while still meeting the June 2006 direction of the NERC Operating Committee. Specifically, the Operating Committee endorsed developing a Frequency Response standard that includes the following goals and objectives:

- Improving Interconnection Frequency Response event cataloging and benchmarking.
- Calculating balancing authority Frequency Response and requiring balancing authorities to analyze those cases where the response is significantly below the norm.
- Establishing time limits to complete the analyses.
- Tabulating non-responsive generators.
- Measuring generator response (those units on line).
- Including regional participation and review.

This revised SAR was reviewed and supported by the NERC Resources Subcommittee on December 4, 2006. The major changes between Draft 2 and Draft 3 include:

- Clarification on the role of the Load-serving Entity and Generator Operator.
- Inclusion of the applicability of Reliability Principles 3,5, and 6.
- Reduced the scope to address only the collection of data needed to model Frequency Response in North America.
- Clarified that the data collected to model frequency response over a period of up to 5 minutes per event to help identify the window of time where frequency response appears to be masked by AGC action.

Note that because the changes to the SAR were quite significant, no redline showing the changes from Version 2 to Version 3 will be posted.

Please review the revised SAR and then answer the questions on the following page.
Comments must be submitted by March 9, 2007. You may submit the completed form by e-mail to sarcomm@nerc.com with the words "FR SAR Draft 3" in the subject line.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree with the reduced scope of this SAR - focusing only on the data collection needed to support the development of accurate models of Frequency Response in North America?
$\boxtimes$ Yes
$\square$ No
Comments:
2. The proposed standard would have requirements for the following functional entities:

Reliability Coordinator, Balancing Authority, Generator Owner, Generator Operator, and Load-serving Entity. Do you agree that these are the right functional entities for the proposed standard?
$\boxtimes$ YesNo
Comments: The role of the load serving entity in item 6 b is unclear.
3. The SAR drafting team modified the SAR to clarify that data will be collected to model up to 5 minutes of frequency response. This should help identify the window of time where frequency response appears to be masked by AGC action. Do you agree with this clarification?
$\boxtimes$ Yes
$\square \mathrm{N}$
Comments:
4. Should a field trial be initiated, whereby a set of events for each Interconnection is posted throughout the year, to be used by BAs to calculate their 2007 Frequency Response?
$\boxtimes$ YesNo
Comments:
5. Please provide any other comments (that you have not already provided in response to the first three questions on this form) that you have on the revised SAR. Comments:

NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

## Consideration of Comments on $3^{\text {rd }}$ Posting of Frequency Response SAR

The Frequency Response SAR Requesters thank all commenters who submitted comments on Draft 3 of the Frequency Response SAR. This SAR was posted for a 30-day public comment period from February 8 through March 9, 2007. The requesters asked stakeholders to provide feedback on the standard through a special standard Comment Form. There were 26 sets of comments, including comments from more than 59 different people from 39 companies representing 9 of the 10 Industry Segments as shown in the table on the following pages.

Based on the comments received, the drafting team did not make any changes to the SAR (except to update the descriptions of the Reliability Functions to match the latest version of the Functional Model) and is recommending that the Standards Committee authorize moving this SAR forward to standard drafting.

In this "Consideration of Comments" document stakeholder comments have been organized so that it is easier to see the responses associated with each question. All comments received on the standards can be viewed in their original format at:

## http://www.nerc.com/~filez/standards/Frequency Response.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Director of Standards, Gerry Adamski, at 609-452-8060 or at gerry.adamski@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process. ${ }^{1}$

## Index to Questions, Comments, and Responses

1. Do you agree with the reduced scope of this SAR - focusing only on the data collection needed to support the development of accurate models of Frequency Response in North America?
2. The proposed standard would have requirements for the following functional entities: Reliability Coordinator, Balancing Authority, Generator Owner, Generator Operator, and Load-serving Entity. Do you agree that these are the right functional entities for the proposed standard?
3. The SAR drafting team modified the SAR to clarify that data will be collected to model up to 5 minutes of frequency response. This should help identify the window of time where frequency response appears to be masked by AGC action. Do you agree with this clarification?17
4. Should a field trial be initiated, whereby a set of events for each Interconnection is posted throughout the year, to be used by BAs to calculate their 2007 Frequency Response? ... 22
5. Please provide any other comments (that you have not already provided in response to the first three questions on this form) that you have on the revised SAR.

## 1. Do you agree with the reduced scope of this SAR - focusing only on the data collection needed to support the development of accurate models of Frequency Response in North America?

## Summary Consideration:

The majority of the comments agreed with the reduced scope of the SAR, which now focuses only on the data collection that is needed to support the development of accurate models of Frequency Response in North America. For most of the commenters that did not support the reduced scope, the SAR Drafting Team believes there may be a misunderstanding with respect to the use of the Target Frequency Response. The SAR Drafting Team explained to those commenters that the Target Frequency Response does not set a minimum for any particular Balancing Authority. Rather it sets a benchmark, beyond which additional data is needed from the Balancing Authority.

| Question \# 1 |  |  |  |
| :---: | :---: | :---: | :---: |
| Commenter | Yes | No | Comment |
| SWPA |  | $\checkmark$ | The scope of this SAR is for data collection, and should not include establishing a Target Frequency Response as stated in Paragraph \#5. |
| Response: The SAR Drafting Team appreciates your input, but disagrees with your conclusion. There should always be a purpose for going to the trouble and expense of capturing and analyzing data. The SAR Drafting Team considers the establishment of a Target Frequency Response for each Interconnection as vital for the reliability of the Interconnections and one of the two fundamental reasons why this SAR was initially drafted. The SAR Drafting Team believes there may be a misunderstanding with respect to Target Frequency Response, which does not set a minimum for any particular Balancing Authority. The Target Frequency Response sets a benchmark, beyond which additional data is needed from the Balancing Authority. |  |  |  |
| Xcel Energy Services |  |  | We agree with the proposed scope except that items 5 and 6 do not deal specifically with data collection and therefore are beyond the scope of the SAR. We are concerned over establishing a Target Frequency Response. This is presumptious in that it advances a proposed remedy before first meeting the intent of the SAR-determining the cause for the percieved decline in frequency response. We support Items 6 a . and 6 b . if referenced to item 4 as modified as follows: Modify 4 to require generator level reporting when the Frequency Response for a BA is less than [75]* percent of the Previous Years observed Frequency Response. Delete items 5 and 6. |
| Response: In response to your first comment on Paragraph 5, the SAR Drafting Team considers the establishment of a Target Frequency Response for each Interconnection as vital for the reliability of the Interconnections and one of the two fundamental reasons why this SAR was drafted initially. The reason for establishing the target frequency response is to determine the point at which additional data is needed from a given Balancing Authority. |  |  |  |
| In response to your comment on Paragraph 6, the SAR Drafting Team does not view the provisions of Paragraph 6 as presumptive or proscriptive, but as a necessary step in identifying and understanding potential frequency response variations within a given Interconnection. No specific action is required by the Balancing Authority or the Generation Owner at this |  |  |  |

## Question \#1

> | Commenter | Yes | No | Comment |
| :--- | :--- | :--- | :--- |

point in the process beyond supplying the data needed for NERC to understand why variations in Frequency Response occur in different regions and to determine if further actions are required, via the NERC Reliability Standards Process, to address them.

## PJM

The primary objective of this SAR is to collect data; to analyze the data; and only then to recommend a performance value. The SAR DT insists that collecting data is a Technical Standard. The RSDP states:
"Technical standards...will contain Measures (not measuring - AMD) of physical parameters..." At this point this SAR proposal does not contain such a measure, it does not even assert that the measure is really needed (hence the need to analyze the data).

Page 19 (of 43) of the RSPM states "The drafting team may recommend the scope of the standard be reduced to allow the effort to move forward, while still remaining within the scope of the SAR. Reducing the scope of the SAR is acceptable if the drafting team finds, for instance, THAT ADDITIONAL TECHNICAL RESEARCH IS NEEDED PRIOR TO DEVELOPING (emphasis added) a portion of the standard or issues need to be resolved before consensus can be achieved on a portion of the standard. "The highlighted section applies directly to the scope of this SAR. The SAR Team recognizes work is needed. There is no question about that. The Team should do that work BEFORE proposing a mandatory standard.

PJM supports the concept of doing such a study, and would encourage NERC to assign a group to do such a study, but PJM does not agree that collecting data rises to the level of a valid NERC reliability standard.

## Response: NERC's Reliability Standards Development Plan: 2007-2009 describes the characteristics of a Reliability

 Standard as follows: " Although reliability standards have a common format and process, several types of reliability standards may exist, each with a different approach to measurement:- Technical standards related to the provision, maintenance, operation, or state of bulk power systems will likely contain measures of physical parameters and will often be technical in nature.
- Performance standards related to the actions of entities providing for or impacting the reliability of the bulk power systems will likely contain measures of the result of such actions, or the nature of the performance of such actions".
Collecting, correlating and analyzing data on a continental scale is not a simple matter. The SAR Drafting Team believes that the scale of this project and the potential importance of the conclusions to be developed per the specifications in Paragraphs 5 and 6 more than warrant the use of the NERC Reliability Standards Process to address them. Directed research can be

| Question \#1 |  |  |
| :---: | :---: | :---: |
| om |  | Comment |
| estig |  |  |
| IESO |  | We do not agree with the reduced scope of this SAR. It does not require a standard to enable a data collection task(s). Data collection procedures and processes, charged by a standing committee, e.g. the OC, or respective working groups, would be more than sufficient. |
| Response: The SAR Drafting Team believes that the scale of this project, the ongoing nature, and the potential importance of the conclusions to be developed per the specifications in Paragraphs 5 and 6 more than warrant the use of the NERC Reliability Standards Process to address them. We believe the Standing Committees would play a vital role in evaluating the initial results of the standard. |  |  |
| SPP ORWG | V | Do not agree with the notion in point 5 regarding the need for a Target Frequency Response for each interconnection at this time. It is beyond the scope of this technical SAR to propose anything other than collection of data to support the study. <br> Do not agree with point 6 of the description. In order to get a handle on what is really going on, all Balancing Authorities should be required to produce data valid to the study. Also the language in point 6 is poorly worded compared to the right wording in 6a and 6 b . 6 a and 6 b should be included in the SAR and 6 should be removed. |
| Response: The SAR Drafting Team appreciates your input, but disagrees with your conclusion. The SAR Drafting Team considers the establishment of a Target Frequency Response for each Interconnection as vital for the reliability of the Interconnections and one of the two fundamental reasons why this SAR was drafted initially. The reason for establishing the target frequency response is to determine the point at which additional data is needed from a given Balancing Authority. |  |  |
| With respect to your comment on Paragraph 6, the SAR Drafting Team does not view the provisions of Paragraph 6 as presumptive or proscriptive, but as a necessary step in identifying and understanding potential frequency response variations within a given Interconnection. No specific action is required by the Balancing Authority or the Generation Owner at this point in the process beyond supplying the data needed for NERC to understand why variations in Frequency Response occur in different regions and to determine if further actions are required, via the NERC Reliability Standards Process, to address them. The intent of the Target Frequency Response is to determine the point where additional data is required. The SAR Drafting Team does not recognize the specific wording that you are referring to in Paragraph 6 and request clarification. |  |  |
| KCPQL | マ | Do not agree with the notion in point 5 regarding the need for a Target Frequency Response for each interconnection at this time. It is presumptuous to advance a remedy prior to determining cause of the perceived decline in frequency response. Allow the techincal SAR to perform its function to determine cause. Any appropriate remedy in operating standards should become apparent. <br> Do not agree with point 6 of the description. In order to get a handle on what is really |

|  |  |  | on, all Balancing Authorities should be required to produce data valid to the study. |
| Response: We appreciate your input, but disagree with your conclusion. The SAR Drafting Team considers the establishment of a Target Frequency Response for each Interconnection as vital for the reliability of the Interconnections and one of the two fundamental reasons why this SAR was drafted initially. The reason for establishing the target frequency response is to determine the point at which additional data is needed from a given Balancing Authority. |  |  |  |
| In response to your comment on Paragraph 6, the SAR Drafting Team does not view the provisions of Paragraph 6 as presumptive or proscriptive, but as a necessary step in identifying and understanding potential frequency response variations within a given Interconnection. No specific action is required by the Balancing Authority or the Generation Owner at this point in the process beyond supplying the data needed for NERC to understand why variations in Frequency Response occur in different regions and to determine if further actions are required, via the NERC Reliability Standards Process, to address them. The intent of the Target Frequency Response is to determine the point where additional data is required. The SAR Drafting Team does not recognize the specific wording that you are referring to in Paragraph 6 and request clarification. |  |  |  |
|  | V | - | HQT believe there might be other means than Reliability Standards to accomplish this data collection. |
| Response: The SAR Drafting Team agrees that there may be methods other than the use of the NERC Reliability Standards Process to address this issue. However, due to the scale of this project and the potential importance of the conclusions to be developed per the specifications in Paragraphs 5 and 6 , the SAR Drafting Team believes that the use of the NERC Reliability Standards Process is appropriate. |  |  |  |
| NPCC CP9 |  |  | Many of NPCC's participating members believe there are other means to accomplish this phase of the initiative and that appropriate revisions to existing standard(s) may address the issue determined by the data analysis could be proposed. |
| Response: The SAR Drafting Team agrees that there may be methods other than the use of the NERC Reliability Standards Process to address this issue. However, due to the scale of this project and the potential importance of the conclusions to be developed per the specifications in Paragraphs 5 and 6, the SAR Drafting Team believes that the use of the NERC Reliability Standards Process is appropriate. |  |  |  |
| NYISO | - | - | The NYISO is uncertain if this is the appropriate means to require data collection for purposes of developing models. A review should be made to be certain that this proposed scope meets the criteria for a standard. |
| Response: The SAR Drafting Team agrees that there may be methods other than the use of the NERC Reliability Standards Process to address this issue. However, due to the scale of this project and the potential importance of the conclusions to be developed per the specifications in Paragraphs 5 and 6, the SAR Drafting Team believes that the use of the NERC Reliability Standards Process is appropriate. Note that the NERC Standards Committee and the industry as a whole are currently performing just such a review, as you request, by commenting on this draft SAR. |  |  |  |

| Question \#1 |  |  |  |
| :---: | :---: | :---: | :---: |
| Commenter | Yes | No | Comment |
| Energy Mark, Inc. | $\square$ |  | At this time information is not available that would provide a sound technical basis for the development of a performance standard. However, with the recent increased interest in Frequency Response, new data and analysis could become available at any time that would change the focus from a technical standard to a performance standard. If new information and analysis becomes available during the development of the technical standard, consideration should be given to how the development of the technical standard could delay the development and implementation of a performance standard. Must the technical standard be completed and approved before work can start on a performance standard? |
| Response: The SAR Drafting Team agrees that there may be technical issues which may allow the Standard Drafting Team to accomplish the functional purpose of this SAR differently than anticipated by the SAR Drafting Team. This is allowed for in the NERC Reliability Standards Process Manual, page 19, as noted by PJM above. |  |  |  |
| It is anticipated by the SAR Drafting Team that the work set forth in the SAR will aid in determining if a Performance Standard is required and, if so, how the standard should be structured. A SAR for a Frequency Response Performance Standard can be written and submitted to the NERC Standards Committee at any time. |  |  |  |
| MidAmerican Energy Co. | $\square$ |  | This standard would be a start, at least, at bringing to light where and why response is being lost. It may well be that exposure and peer pressure, as well as the tiered reporting requirements, will keep plant and operations personnel abreast of their obligations for providing reserves of all types. |
| Response: The SAR Drafting Team appreciates your support. |  |  |  |
| Southern | $\square$ |  | Frequency response and its dynamic behavior is a complex issue that requires detailed analysis and study to understand. This in turn requires sufficient high quality data be obtained to support the development of models and concepts. The data could be collected voluntarily, but without the force of NERC standards behind it not many people are going to devote the resources required to collect the data. We strongly support this effort. |
| Response: The SAR Drafting Team appreciates your support. |  |  |  |

2. The proposed standard would have requirements for the following functional entities: Reliability Coordinator, Balancing Authority, Generator Owner, Generator Operator, and Load-serving Entity. Do you agree that these are the right functional entities for the proposed standard?

## Summary Consideration:

The majority of the commenters supported the functional entities for which the proposed standard would be applicable, specifically the Reliability Coordinator, Balancing Authority, Generator Owner, Generator Operator, and Load-Serving Entity. All commenters that responded that they did not agree to the proposed functional entities requested clarification on the applicability to a Load-serving Entity (LSE).
The SAR Drafting Team explained that the LSE functional entity was added in response to stakeholder comments received on the first draft of the SAR. The SAR Drafting Team also explained to commenters that various industry experts estimate that as much as $1 / 3$ of the total Interconnection Frequency Response may be supplied by Load Frequency Response (the other $2 / 3$ is supplied from Turbine Governor Support). Thus information from the LSE concerning the composition and variations of load served within the Interconnection can be critical in understanding total Interconnection Frequency Response.
One commenter suggested that if there is a future performance standard, it would be unreasonable to implement a technical standard that requires functional entities to provide data. The SAR Drafting Team does not see the linkage between requiring data from entities in order to qualify and quantify Frequency Response with the interconnections and NOT including all these entities in a Frequency Response Performance Standard.

| Question \#2 |  |  |  |
| :--- | :--- | :--- | :--- |
| Commenter | Yes | No | Comment |
| PJM |  | $\boxed{V}$ | The proposal as written appears to be headed towards mandating a given unit response. <br> As such there would be an obligation on the Generator Operator - there does not seem <br> to be any requirements that would apply to the Generator Owner - unless of course the <br> requestor includes a requirement to install a governor (this has, to date, be an implied <br> obligation just as having a turbine has been an implied obligation). If the requestor does <br> intend to assert an obligation on the Generator Owner to install a governor then the <br> question arises should that be a standard or should that be a part of the Certification of <br> a GO? |
| Response: The stated purpose of this SAR is to collect and analyze data in order to determine the Frequency Response for |  |  |  |
| each Interconnection, recommend a target Frequency Response for each Interconnection and determine the cause of any |  |  |  |
| significant variations in Frequency Response within each of the Interconnections. |  |  |  |

\hline
\end{array}
$$

Governor Support). Thus information from the LSE concerning the composition and variations of load served within the Interconnection can be critical in understanding total Interconnection Frequency Response. The applicability to LSEs was added at the specific request of commenters in a previous version of the SAR.

| SWPA |  | $\boxed{ }$ | Load serving entities should not be included due to the characteristics of load and <br> frequency. Load Serving Entities should contribute data to determine FRC. |
| :--- | :--- | :--- | :--- |

Response: Various industry experts estimate that as much as $1 / 3$ of the total Interconnection Frequency Response may be supplied by Load Frequency Response (the other $2 / 3$ is supplied from Turbine Governor Support). Thus information from the LSE concerning the composition and variations of load served within the Interconnection can be critical in understanding total Interconnection Frequency Response. The applicability to LSEs was added at the specific request of commenters in a previous version of the SAR. Note that your two statements seem to contradict each other.

| NPCC CP9 |  | $\nabla$ | NPCC participating members question the need to include the applicability to the LSEs in <br> this SAR and requests the drafting team to explain this. |
| :--- | :--- | :--- | :--- |

Response: Various industry experts estimate that as much as $1 / 3$ of the total Interconnection Frequency Response may be supplied by Load Frequency Response (the other $2 / 3$ is supplied from Turbine Governor Support). Thus information from the LSE concerning the composition and variations of load served within the Interconnection can be critical in understanding total Interconnection Frequency Response. The applicability to LSEs was added at the specific request of commenters in a previous version of the SAR.

\section*{| NYSRC |  | $\square$ | Explain the applicability of the SAR to LSEs. |
| :--- | :--- | :--- | :--- |}

Response: Various industry experts estimate that as much as $1 / 3$ of the total Interconnection Frequency Response may be supplied by Load Frequency Response (the other $2 / 3$ is supplied from Turbine Governor Support). Thus information from the LSE concerning the composition and variations of load served within the Interconnection can be critical in understanding total Interconnection Frequency Response. The applicability to LSEs was added at the specific request of commenters in a previous version of the SAR.

| SPP ORWG |  | $\boxed{ }$ | A standard can not be imposed on the response of load to frequency. Load Serving <br> Entities can only provide data. |
| :--- | :--- | :--- | :--- |

Response: The SAR Drafting Team agrees that the role of the LSE will primarily be to supply data concerning the composition and variations of load served within the Interconnection. There is nothing in the SAR imposing a response requirement on any of the functional entities.

| Hydro Québec |  | $\boxed{ }$ | We question the need to include the applicability to the LSEs in this SAR and requests |
| :--- | :--- | :--- | :--- | TransÉnergie the drafting team to explain the purpose.

Response: Various industry experts estimate that as much as $1 / 3$ of the total Interconnection Frequency Response may be supplied by Load Frequency Response (the other $2 / 3$ is supplied from Turbine Governor Support). Thus information from the LSE concerning the composition and variations of load served within the Interconnection can be critical in understanding total Interconnection Frequency Response. The applicability to LSEs was added at the specific request of commenters in a previous version of the SAR.

| Question \#2 |  |  |  |
| :---: | :---: | :---: | :---: |
| Commenter | Yes | No | Comment |
| IESO |  | $\checkmark$ | For the purpose of data collection, assigning responsibility to the Balancing Authority, Generator Operator and Load-serving Entity would suffice. |
| Response: Most of the data will be collected from the entities you list. However, the SAR Drafting Team believes the other entities included in the SAR have some of the data that is needed for this standard. For example the Generator Owner might have relevant data that may not be available from the Generator Operator. |  |  |  |
| ISO New England |  | $\square$ | ISO New England does not see a need to include the applicability to the LSEs in this SAR and requests the drafting team to explain this. |
| Response: Various industry experts estimate that as much as $1 / 3$ of the total Interconnection Frequency Response may be supplied by Load Frequency Response (the other $2 / 3$ is supplied from Turbine Governor Support). Thus information from the LSE concerning the composition and variations of load served within the Interconnection can be critical in understanding total Interconnection Frequency Response. The applicability to LSEs was added at the specific request of commenters in a previous version of the SAR. |  |  |  |
| American Transmission Co. |  | $\checkmark$ | ATC does not see the need to identify the Load Serving Entity in the Applicability section. The SDT should provide an explanation as to the reasoning behind the selection of Load Serving Entities. |
| Response: Various industry experts estimate that as much as $1 / 3$ of the total Interconnection Frequency Response may be supplied by Load Frequency Response (the other $2 / 3$ is supplied from Turbine Governor Support). Thus information from the LSE concerning the composition and variations of load served within the Interconnection can be critical in understanding total Interconnection Frequency Response. The applicability to LSEs was added at the specific request of commenters in a previous version of the SAR. |  |  |  |
| Energy Mark, Inc. | $\square$ | $\checkmark$ | I agree that the proposed list includes those entities that would be affected by a technical standard. However, there are many questions that must be resolved before any standard that affects the Generation Owner, Generation Operator or Load-serving Entity can be implemented. These questions relate to how a performance standard can or should be implemented. If there is no reasonable expectation that they would be included in a future performance standard, it would be unreasonable to implement a technical standard that requires these three functional entities to provide data. In a fair market that allows voluntary participation by Generation Owners, Generation Operators and Load-serving Entities, the direct application of a Frequency Response Performance Standard to these entities is not currently possible without creating unreasonable inequities in the market. Any standard applied directly to one generator but not another will create unreasonble inequities in a market. Since each generation technology has different Frequency Response capabilities, only a solution that provides Frequency Response through a market based mechanism can be fairly implimented in a market. Under these conditions, the measurement methods and data collection for a technical standard should only be applied to those entities that would have resposibilities under a |

| Question \#2 |  |  |  |
| :---: | :---: | :---: | :---: |
| Commenter | Yes | No | Comment |
|  |  |  | performance standard. The correct alternative for collecting data from these entities is to collect it indirectly through the Balancing Authority or Reliability Coordinator that would be directly affected by a performance standard. The inclusion of Generation Owner, Generation Operator, and Load-serving Entity directly in the data collection will lead to the development of data collection systems that will need to be replaced, if and when, a performance standard is developed. This is an inefficient way to develop the technology for a new standard. |
| Response: The SAR Drafting Team appreciates your input, but disagrees with some of your conclusions. |  |  |  |
| The SAR Drafting team does not see the linkage between requiring data from entities in order to qualify and quantify Frequency Response with the interconnections and NOT including all these entities in a Frequency Response Performance Standard. |  |  |  |
| Available Frequency Response and its distribution within an Interconnection may require that certain generators be treated differently than others due to their location and electrical characteristics. How this difference is compensated is neither within the scope of this SAR nor within NERC's authority. |  |  |  |
| The SAR drafting team agrees with your statement about the data collection being performed in the most efficient manner. |  |  |  |
| Salt River Project | $\checkmark$ |  | Ultimately there may be some impact to the Planning Coordinator and/or Resource Planner if a frequency response requirement is specified. Could there be an extreme scenario where an entity would have to consider shedding load to meet some frequency reserve criteria? |
| Response: The SAR Drafting Team does not anticipate that the standard resulting from this SAR will contain any requirement for specific Frequency Responses from the Interconnections or the Balancing Authorities. Future standards are beyond the scope of this SAR. The SAR Drafting Team would expect that in any standard (whether dealing with transmission, dynamics or reserves) load shedding only makes sense if the entity cannot withstand the next contingency. |  |  |  |
| Xcel Energy Services | $\checkmark$ |  | To the extent information is needed from these entities, they are appropriate to list. It is possible that the LSE is not required. |
| Response: Various industry experts estimate that as much as $1 / 3$ of the total Interconnection Frequency Response may be supplied by Load Frequency Response (the other $2 / 3$ is supplied from Turbine Governor Support). Thus information from the LSE concerning the composition and variations of load served within the Interconnection can be critical in understanding total Interconnection Frequency Response. The applicability to LSEs was added at the specific request of commenters in a previous version of the SAR. |  |  |  |
| American Electric Power | $\checkmark$ |  | The role of the load serving entity in item 6b is unclear. |
| Response: Various industry experts estimate that as much as $1 / 3$ of the total Interconnection Frequency Response may be supplied by Load Frequency Response (the other $2 / 3$ is supplied from Turbine Governor Support). Thus information from the |  |  |  |

3. The SAR drafting team modified the SAR to clarify that data will be collected to model up to 5 minutes of frequency response. This should help identify the window of time where frequency response appears to be masked by AGC action. Do you agree with this clarification?

## Summary Consideration:

Most comments agreed that the clarification helped to identify the window of time when frequency response appears to be masked by AGC action. Several commenters requested more specific information on the sample rates and the specific data that would be collected. The SAR Drafting Team explained that this type of information will be developed in the standard development process and not captured in the SAR. The SAR drafting team agreed to forward these comments to the Director of Standards Development so that they can be addressed by the Frequency Response Standard Drafting Team.

| Question \#3 |  |  |  |
| :---: | :---: | :---: | :---: |
| Commenter | Yes | No | Comment |
| SWPA |  | $\checkmark$ | Need more specific information regarding sample rates. The 5-minutes of frequency response should identify time periods prior to and after the event. |
| Response: The SAR Drafting Team agrees with the comment. Specific information, such as sampling rate and specific data requirements, will be developed in the standard development process and not captured in the SAR. The five minute period was proposed based on comments to a prior version of the SAR. Some commenters were concerned that governors were withdrawing response shortly after the initial excursion. The SAR drafting team will forward these comments to the Director of Standards so that they can be addressed by the Frequency Response Standard Drafting Team. We expect the data sampling rate to be on existing SCADA periodicity. |  |  |  |
| SPP ORWG |  | $\checkmark$ | The 5 minute time is adequate, but it lacks substance. Small changes in load and generation due to frequency response are very difficult to separate from normal load changes and AGC action on generation units (as was pointed out). It is important to include in the description of data collection that the 5 minutes should include 1 minute of data prior to a study event and 4 minutes after a study event. It is also important to include a sample rate, such as 4 seconds (obviously, faster samples are better, but may not be practical). <br> The SAR, as written, lacks specifics on what data is required to perform a valid study. Some examples of necessary data may include, but are not limited to, AGC pulses, special protection systems, generator MW, tie line MW, frequency, etc. |
| Response: The SAR Drafting Team agrees with the comment. Specific information, such as sampling rate and specific data requirements, will be developed in the standard development process and not captured in the SAR. The five minute period was proposed based on comments to a prior version of the SAR. Some commenters were concerned that governors were withdrawing response shortly after the initial excursion. The SAR drafting team will forward these comments to the Director of Standards so that they can be addressed by the Frequency Response Drafting Team. We expect the data sampling rate to |  |  |  |

| Question \# |  |  |
| :---: | :---: | :---: |
| Commenter |  |  |
| be on existing SCADA periodicity |  |  |
| Xcel Energy Services | V | Further clarification is needed around the time period for which data will be collected important to note that description of the 5 minutes data collection period should includ 1 minute before and 4 minutes after the event. |
| Response: In response to your first comment, the SAR Drafting Team agrees with the comment. Specific information, such as sampling rate and specific data requirements, will be developed in the standard development process and not captured in the SAR. The five minute period was proposed based on comments to a prior version of the SAR. Some commenters were concerned that governors were withdrawing response shortly after the initial excursion. The SAR drafting team will forward these comments to the Director of Standards so that they can be addressed by the Frequency Response Standard Drafting Team. We expect the data sampling rate to be on existing SCADA periodicity. |  |  |
| In response to your second comment, the SAR Drafting team agrees that data is required both before and after the contingency to be analyzed. |  |  |
| ITC Transco |  | Five minutes of data seems arbitrary. If the collection period were extended to 15 minutes, it would coincide with the Disturbance Control period. |
| Response: Thank you for your comment. The SAR Drafting Team agrees with the comment. Specific information, such as sampling rate and specific data requirements, will be developed in the standard development process and not in the SAR. The five minute period was proposed based on comments to a prior version of the SAR. Some commenters were concerned that governors were withdrawing response shortly after the initial excursion. The SAR drafting team will forward these comments to the Director of Standards so that they can be addressed by the Frequency Response Drafting Team. We expect the data sampling rate to be on existing SCADA periodicity. |  |  |
|  |  | As noted above PJM does not consider collecting data in order to decide what a requirement should be as grounds for a standard. Thus the sampling period which is outside of a NERC standard, can be defined in whatever way the group doing the sampling desires. |
| Response: Specific information, such as sampling rate and specific data requirements, will be developed in the standard development process and not captured in the SAR. The five minute period was proposed based on comments to a prior version of the SAR. |  |  |
| NYSRC | マ | It is not clear what type of data is going to be collected from this requirement. AGC response is continuous. What is the justification for the specific "five minutes" reffered to? Since AGC control is every 4 seconds, five minutes appears to be too long a period to collect this data. Imposing this requirement will require the installation of local data storage retention facilities \& telemetering equipment that may not be necessary. |
| Response: The SAR Drafting Team agrees with the comment. Specific information, such as sampling rate and specific data requirements, will be developed in the standard development process and not captured in the SAR. The five minute period was proposed based on comments to a prior version of the SAR. Some commenters were concerned that governors were |  |  |

| Question \#3 |  |  |  |
| :---: | :---: | :---: | :---: |
| Commenter | Yes | 0 | Comment |
|  |  |  | reliable interconnection performance. The Frequency Response should be measured for an extended period after a disturbance to identify entities that are prematurely withdrawing their expected frequency response support from the interconnection. This has been demonstrated for entities that have outer loop control that only includes scheduled deliveries without adjustment for frequency response. |
| Response: The SAR Drafting Team agrees with the comment. Specific information, such as sampling rate and specific data requirements, will be developed in the standard development process and not captured in the SAR. The five minute period was proposed based on comments to a prior version of the SAR. Some commenters were concerned that governors were withdrawing response shortly after the initial excursion. The SAR drafting team will forward these comments to the Director of Standards so that they can be addressed by the Frequency Response Standard Drafting Team. We expect the data sampling rate to be on existing SCADA periodicity. |  |  |  |
| Hydro Québec TransÉnergie | $\checkmark$ | $\checkmark$ | We requests clarification as to what data and at what periodicity will be collected from the identified entities. |
| Response: The SAR Drafting Team agrees with the comment. Specific information, such as sampling rate and specific data requirements, will be developed in the standard development process and not captured in the SAR. The five minute period was proposed based on comments to a prior version of the SAR. Some commenters were concerned that governors were withdrawing response shortly after the initial excursion. The SAR drafting team will forward these comments to the Director of Standards so that they can be addressed by the Frequency Response Standard Drafting Team. | Response: The SAR Drafting Team agrees with the comment. Specific information, such as sampling rate and specific data requirements, will be developed in the standard development process and not captured in the SAR. The five minute period was proposed based on comments to a prior version of the SAR. Some commenters were concerned that governors were withdrawing response shortly after the initial excursion. The SAR drafting team will forward these comments to the Director of Standards so that they can be addressed by the Frequency Response Standard Drafting Team. We expect the data sampling rate to be on existing SCADA periodicity. |  |  |  |
| MISO | $\checkmark$ | $\square$ | Five minutes is acceptable. There may be merit in collecting 15 minutes of data to cover the DCS window. The data should be readily available since the BAs are already examining this data to determine their compliance with the DCS standard. The final decision can be made during the standards drafting phase. |
| Response: The SAR Drafting Team agrees with the comment. Specific information, such as sampling rate and specific data requirements, will be developed in the standard development process and not captured in the SAR. The five minute period was proposed based on comments to a prior version of the SAR. Some commenters were concerned that governors were withdrawing response shortly after the initial excursion. | sampling rate to be on existing SCADA periodicity. |  |  |  |

## Consideration of Comments on $3^{\text {rd }}$ Posting of Frequency Response SAR

4. Should a field trial be initiated, whereby a set of events for each Interconnection is posted throughout the year, to be used by BAs to calculate their 2007 Frequency Response?

## Summary Consideration:

Most commenters indicated that a field trial should be initiated whereby a set of events for each Interconnection is posted throughout the year, to be used by Bias to calculate their 2007 Frequency Response.

| Question \#4 |  |  |  |
| :---: | :---: | :---: | :---: |
| Commenter | Yes | No | Comment |
| Manitoba Hydro |  |  | Only if field trials are deemed to have very high probability of not causing significant difficulties on overly sensitive network area. |
| Response: The SAR Drafting Team agrees that no field trial should adversely impact the reliability of the Bulk Power System. |  |  |  |
| MidAmerican Energy Co. |  | $\checkmark$ | This is not a new concept. I support institution of the standard as written so a start can be made to identify and, with luck, remediate the decline in frequency response. |
| Response: Thank you for your support. |  |  |  |
| Bonneville Power Administration |  | V | BPA does not believe a field trial is needed for this standard. The standard should be written and implemented with the levels of noncompliance structured around data submittal. |
| Response: Thank you for your support. |  |  |  |
| PJM |  | $\checkmark$ | There are field trials for standards (which this question is directed) and there are field trials for good ideas. This proposed SAR would seem to fall into the second category; and while posting events is interesting, it does not rate being a NERC standard. Collecting and posting data can be effected without a standard. |
| Response: Thank you for your comment. |  |  |  |
| NYSRC |  | $\square$ |  |
| Energy Mark, Inc. | $\square$ | $\square$ | This would be a good way to insure that every entity select a similar set of events for calculation of their Frequency Response, but it will not insure conformity of the results. The difficulty with any method for selecting a common set of events is that each of those events is caused by a disturbance within one or more of the Balancing Authorities on the interconnection. Those entities that cause the disturbance will experience a different frequency response than those entities that are responding. The net effect is that the sum of the responses for all of the entities on the interconnection must sum to zero. This means that each entity must eliminate those disturbances for which they are the cause, from the set of disturbances they use to estimate their response. The real advantage is an entity cannot influence the results of the measurement through selection of the events they choose to include in the calculation. |

| Question \＃4 |  |  |  |
| :---: | :---: | :---: | :---: |
| Commenter | Yes | No | Comment |
| Response：Thank you for your comment．The SAR drafting team will forward these comments to the Director of Standards so that they can be addressed by the Frequency Response Standard Drafting Team． |  |  |  |
| MISO | V |  | This should not be a problem as BAs should already be performing this calculation in the annual determination of their frequency bias． |
| Response：Thank you for your comment． |  |  |  |
| NRG Texas | V |  | A field trial may indicate the need for more or different data for the proper calculation of a BAs Frequency Response． |
| Response：Thank you for your comment． |  |  |  |
| ERCOT | マ |  | A field trial would be beneficial to ensure that no gaps in the need for data exist．This could relate to whether other data is needed or whether data for a longer time is needed． |
| Response：Thank you for your comment． |  |  |  |
| IESO | マ |  | A field test is a must and would definitely provide useful information on the types of event that would necessiate such data collection（The threshold needs to be clarified though－e．g．should it be＞10MW loss of generator or some other threshold？），and any specific areas that need to be worked on in order to ensure that all relevant and required data is collected． |
| Response：Thank you for your comment．The SAR Drafting Team agrees with the comment．Specific information，such as sampling rate and specific data requirements，will be developed in the standard development process and not in the SAR． The SAR drafting team will forward these comments to the Director of Standards so that they can be addressed by the Frequency Response Standard Drafting Team．We expect the data sampling rate to be on existing SCADA periodicity． |  |  |  |
| Southern | マ |  | Currently BAs in the Eastern Interconnection have little，if any，way to actually calculate their frequency responses．As a result，most default to the one percent minimum．A good database of disturbance events will provide the information to calculate BA frequency response more accurately while at the same time allowing the NERC OC／RS to determine if the one percent minimum is appropriate in the EI today． |
| Response：Thank you for your comment． |  |  |  |

5. Please provide any other comments (that you have not already provided in response to the first three questions on this form) that you have on the revised SAR.

| Question \#5 |  |
| :--- | :--- |
| Commenter | $\quad$ Comment |\(\left.| \begin{array}{l}BPA agrees with the necessity of a frequency response standard. BPA highly encourages that this <br>

effort be implemented as soon as possible.\end{array}\right]\)

| Question \#5 |  |
| :--- | :--- |
| Commenter | If each interconnection has a different Frequency Response Standard, it means there is no standard <br> at all, but three different rules for NERC. The next logical step is to develop a common standard for <br> all three interconnections requiring the first two standards developed by the Texas and Western <br> Interconnections separately be modified to conform to a North American Standard on Frequency <br> Response. Combining these three separate needs into a single standard will result in a natural <br> opposition to change by those interconnections that have already implemented an interconnection <br> standard that meets their individual needs. This will make it very difficult to gain the support <br> necessary to enact a common standard for NERC. This multi-step development can only be avoided <br> by having all three interconnections participate and contribute to standards identified and developed <br> by individual interconnections. I believe that NERC needs to find a way to address this problem. If <br> they do not, the standard development and approval process will lead to fractured standards and an <br> unacceptable fractured standard process for NERC. One alternative might be to find a way for all <br> interconnections to participate in the solution of individual interconnection problems as part of the <br> standard development process. |

| Question \#5 |  |
| :--- | :--- |
| Commenter | One reason a decline in frequency response may be perceived occuring is a result of more on-line <br> generating units being fully loaded. That means when a frequency decline occurs there are less units <br> able to respond because they are already loaded. That does not mean the interconnection is at risk. <br> As long as Balancing Authorities are maintaining their reserve obligations, even large contingencies <br> should be manageable. However, over the years because of the trend to get more out of invested <br> generation resources, it would give the appearance of a decline in frequency response since most <br> frequency degradations are a result of losses of generation and a resultant decline in system <br> frequency and those are what is studied and scrutinized. The August 14, 2003 disturbance was an <br> opportunity to study the frequency response of all on-line generating units due to the frequency event <br> resulting in a high frequency. High frequency is the only event where all on-line generating units will <br> respond. |
|  | Proposing the establishment of a Target Frequency Response for the interconnect before concluding if <br> an actual decline in frequency response is occuring and the subsequent cause(s) for the decline is <br> finding a solution before defining the problem. Any standards involving frequency response needs to <br> also consider the role system reserves play in the interconnect as well as the frequency response of <br> generators and system load to frequency. As long as generating reserve obligations are being met to <br> meet current Reliability Standards and Regional Operating Criteria there may not be a need to go <br> further dependent on the outcome of the study proposed by this SAR. |
| Response: The SAR Drafting Team agrees with you speculations, but strongly believes that actual field data must be |  |
| collected and analyzed to determine the specific processes impacting Frequency Response. It may well be that no further |  |
| action will be required, |  |
| but that is beyond the scope of this SAR. |  |

| Question \#5 |  | $\quad$ Comment |
| :--- | :--- | :--- |
| Commenter | Response: The SAR Drafting Team agrees and thanks you for your support. |  |
| Southern | This SAR starts the process toward understanding frequency behavior, particularly in the Eastern <br> Interconnection. In our opinion this is a necessary first step in determining whether we need <br> frequency response allocations or other measures to ensure the sustained frequency performance <br> that is required for reliable operations. <br> Wherever possible, the scope and extent of data collection required for generators, their dynamic <br> models including all associated control devices, and any other system data parameters covered under <br> this SAR be limited such that it should not duplicate or exceed system modeling data requirements of <br> any other NERC standard. One important system modeling parameter not emphasized in this SAR is <br> the characteristic behavior of load at each substation (constant power, constant current, etc.), which <br> would seem to have a significant effect on overall frequency response of the interconnected system. <br> It is quite possible that advancements in consumer appliances and electronics, and their proliferation <br> of use, have collectively changed the overall characteristics of system load to a composite state that <br> is significantly different from modeling assumptions made within the previous few years. |  |
| Response: The SAR Drafting Team agrees and thanks you for your support. |  |  |
| SPP ORWG | The reasoning for this technical standard is based on the perception that the frequency response of <br> the electrical system is declining and a concern that the interconnect's ability to arrest significant <br> system disturbances is slowly being compromised. Although it is not disagreeable that a study be <br> conducted to determine if an actual decline in frequency response is occuring and then to determine <br> cause, it is diagreeable to propose a potential remedy for a problem that may not exist or, dependent <br> on the findings, in inappropriate remedy. |  |
| Types of generating units online (e.g., wind generation, combined cycle, etc) and their subsequent |  |  |
| loading will have an influence on the frequency response of the system. As long as Balancing |  |  |

## Question \#5

## Commenter

## Comment

consider the role system reserves play in the interconnect as well as the frequency response of generators and system load to frequency. As long as generating reserve obligations are being met in accordance with current Reliability Standards and Regional Operating Criteria there may not be a need to go further dependent on the outcome of the study proposed by this SAR.
Response: The SAR Drafting Team disagrees and believes that a fundamental understanding of frequency response in each of the Interconnections is necessary to ensure reliability of the Bulk Power System. This is particularly important as new, untested technologies are integrated into the Bulk Power System with potentially unanticipated outcomes. Although no follow up Standards may be required after the Frequency Response Standard is developed, there is a potential risk to Interconnection reliability unless we do implement this SAR and Standard and develop a firm understanding of specifically how Frequency Response operates.
It appears that there is a misunderstanding of the Target Frequency Response in that this does not set a minimum for any particular Balancing Authority. The Target Frequency Response sets a benchmark, beyond which additional data is needed from the Balancing Authority.
Salt River Project $\quad$ The SAR includes some requirement language pertaining to generators greater than 10 MW. Old NERC Policy included language requiring frequency responsive governors "unless restricted by regulatory mandates". This makes sense for most nuclear facilities. Another type of restriction on governors involves small hydro units that are dependent on water order. For this type of unit there truly is no governor response yet the unit capabilities may exceed 10 MWs . Please consider these types of exemptions as work progresses on this SAR and resulting standard.
Response: Your comments are good and will be provided to the Standard Drafting Team as it wrestles with the specific details of this project. The SAR does not propose to set a mandatory level of governor response for each generator. The proposed standard requires data and an identification of which generators are not providing response should the Balancing Authority be below the Target Response.
Xcel Energy Services Establishing a Target Frequency Response is premature. It advances a proposed remedy in advance of first meeting the intent of the SAR-determining the cause for the percieved decline in frequency response. It is our view that the percieved decline of frequency response, if that turns out to be the confirmed as a true decline, of itself does not necessarily indicate an significantly increased threat to reliability. As long as generating reserve obligations are being met to meet Reliability Standards and the real time regulating reserves are being carried, also to meet Standards, there may not be a need to go further depending on the outcome of the study proposed by the SAR.
Response: The SAR Drafting Team does not anticipate that a Target Frequency Response will be developed until such time that it can be technically supported as required by the NERC Reliability Standards Process.
PJM
PJM would also note that the proposal references two distinct parameters - the Natural response of a BA; and the natural response of a unit. It is not clear how the requestor intends to link the two parameters. The sum of the units' natural responses will not equal the natural response of the BA.

| Question \#5 | Comment |
| :--- | :--- |
| Commenter | Does the requestor intend to link the two, or to keep them separate? As written it appears that the <br> requestor intends for the BA to be held responsible for an annual measured value. The SAR DT does <br> not recognize that during different times there are different number of units opperating and available <br> to respond. The SAR DT makes no mention of whether or not a BA(?) would have to shed load to <br> maintain such frequency response (for those periods when all units are at full load). The SAR DT <br> makes no mention of distance from an event. An event in NE will effect more response in NE then in <br> Florida - how will that be addressed? PJM would ask for clarification on what the requestor would <br> intend to mandate. |
| FERC has recognized the need to include suppliers that use load control - how does this SAR intend to <br> address such 'natural response suppliers'? |  |
| As written this proposal becomes an ambiguous standard as it obligates a BA to get data from a <br> generator ( as opposed to directly obligating generators to supply the data to the analysis team - this <br> is important from the perspective of who would be non-compliant if the data were not supplied - the <br> BA or the GO?). |  |
| PJM would suggest that NERC create a Frequency Project, budget the project through its members |  |
| rather then create a standard and risk imposing non-compliance penalities for what potentially could |  |
| be a non-issue. Deal with this for what it is - a research activity. |  |

## Standard Authorization Request Form

| Telephone <br> Fax | (317) $249-5463$ <br> (317) $249-5994$ | $\square$ | Withdrawal of existing Standard |
| E-mail | tbilke@midwestiso.org | $\square$ | Urgent Action |

## Purpose/Industry Need

Frequency Response, a measure of an Interconnection's ability to stabilize frequency immediately following the sudden loss of generation or load, is a critical component to the reliable operation of the bulk power system, particularly during disturbances and restoration. The proposed standard's intent is to collect data needed to accurately model existing Frequency Response. There is evidence of continuing decline in Frequency Response in the three Interconnections over the past 10 years, but no confirmed reason for the apparent decline. The proposed standard requires entities to provide data so that Frequency Response in each of the Interconnections can be modeled, and the reasons for the decline in Frequency Response can be identified. Once the reasons for the decline in Frequency Response are confirmed, requirements can be written to control Frequency Response to within defined reliability parameters.

Reliability Functions
The Standard will Apply to the Following Functions（Check box for each one that applies by double clicking the grey boxes．）

| Q | Reliability Authority | Responsible for the real－time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator＇s wide area view． |
| :---: | :---: | :---: |
| 区 | Balancing Authority | Integrates resource plans ahead of time，and maintains load－interchange－ resource balance within a Balancing Authority Area and supports interconnection frequency in real time |
| $\square$ | Interchange Authority | Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation valid and balanced Interchange Schedules between Balancing Authority Areas． |
| $\square$ | Planning Coordinator | Assesses the longer－term reliability of its Planning Coordinator Area． |
| $\square$ | Resource Planner | Develops a＞1year plan for the resource adequacy of its specific loads within a Planning Authority area． |
| $\square$ | Transmission Planner | Develops a＞1 year plan for the reliability of the interconnected Bulk Electric System within its portion of the Planning Coordinator Area． |
| $\square$ | Transmission Service Provider | Administers the transmission tariff and provides transmission services under applicable transmission service agreements（e．g．，the pro forma tariff）． |
| $\square$ | Transmission Owner | Owns and maintains transmission facilities |
| $\square$ | Transmission Operator | Ensures the real－time operating reliability of the transmission assets within a Transmission Operator Area． |
| $\square$ | Distribution Provider | Delivers electrical energy to the End－use customer． |
| 区 | Generator Owner | Owns and maintains generation facilities． |
| 区 | Generator Operator | Operates generation unit（s）to provide real and reactive power． |
| $\square$ | Purchasing－ Selling Entity | Purchases or sells energy，capacity and necessary reliability－related services as required． |
| $\square$ | Market Operator | Interface point for reliability functions with commercial functions． |
| 区 | Load－Serving Entity | Secures energy and transmission service（and reliability－related services）to serve the End－use Customer． |

Reliability and Market Interface Principles

| Applicable Reliability Principles（Check boxes for all that apply by double clicking the grey boxes．） |  |
| :---: | :---: |
| ® | 1．Interconnected bulk electric systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards． |
| 区 | 2．The frequency and voltage of interconnected bulk electric systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand． |
| ® | 3．Information necessary for the planning and operation of interconnected bulk electric systems shall be made available to those entities responsible for planning and operating the systems reliably． |
| $\square$ | 4．Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed，coordinated，maintained and implemented． |
| 区 | 5．Facilities for communication，monitoring and control shall be provided，used and maintained for the reliability of interconnected bulk electric systems． |
| ® | 6．Personnel responsible for planning and operating interconnected bulk electric systems shall be trained，qualified and have the responsibility and authority to implement actions． |
| 区 | 7．The security of the interconnected bulk electric systems shall be assessed，monitored and maintained on a wide area basis． |
| $\square$ | 8．Bulk power systems shall be protected from malicious physical or cyber attacks． |
| Does the proposed Standard comply with all of the following Market Interface Principles？（Select＇yes＇or＇no＇from the drop－down box by double clicking the grey area．） |  |
| 1．The planning and operation of bulk electric systems shall recognize that reliability is an essential requirement of a robust North American economy．Yes |  |
| 2．An Organization Standard shall not give any market participant an unfair competitive advantage．Yes |  |
| 3．An Organization Standard shall neither mandate nor prohibit any specific market structure．Yes |  |
| 4．An Organization Standard shall not preclude market solutions to achieving compliance with that Standard．Yes |  |
|  | An Organization Standard shall not require the public disclosure of commercially sensitive information．All market participants shall have equal opportunity to access commercially non－ sensitive information that is required for compliance with reliability standards．Yes |

## Detailed Description (Provide enough detail so that an independent entity familiar with the industry could draft, modify, or withdraw a Standard based on this description.) The proposed technical/preparedness standard will require or provide the following:

1. Each Balancing Authority shall collect and provide data [scan rate tie deviation and frequency for up to 5* minutes per event] needed to model its sub-minute Frequency Response to loss of large generating units and load.
2. Each Balancing Authority shall report each loss of generation or load greater than the respective Interconnection reporting threshold to its Reliability Coordinator.
3. Each Reliability Coordinator will relay Frequency Response Standard (FRS) event information to other Reliability Coordinators in its Interconnection. The Interconnection Time Monitor will maintain a log of FRS events.
4. NERC will annually post a list of $\operatorname{FRS}$ events. These events will be used by Balancing Authorities to calculate and report their annual Frequency Response and Bias.
5. NERC, in conjunction with the respective Regions, will establish a Target Frequency Response for each Interconnection. Absent an agreement, the observed Frequency Response in the first year of the FRS will be used as a target.
6. Balancing Authorities with less than [75\%]* of their share of Target Frequency Response shall provide generation-level data to their Region for use by Transmission Planners and Planning Coordinators.
a. Each Generator Operator that operates a generator larger than [10 MW]*, shall provide data to its Balancing Authority, as required in item 6, to support this standard and for use in developing models of Frequency Response in the associated Interconnection.
b. Load Serving Entities shall provide data, as required in item 6, to their BA and Region to support the standard.
*These values are representative and will be refined based on stakeholder input during the standard drafting phase.

July 17, 2007

## TO: REGISTERED BALLOT BODY

Ladies and Gentlemen:

## Announcement: Nomination Periods Open for Five New Drafting Teams

The Standards Committee announces the following standards actions:

## Project 2007-04 — Certifying System Operators SAR Drafting Team (July 17-30, 2007)

The Standards Committee is seeking industry experts to serve on the Certifying System Operators SAR Drafting Team. The drafting team will work on the modification of the following standard:
PER-003 - Operating Personnel Credentials

If you are interested in serving on this SAR drafting team, please complete this nomination form and return it to sarcomm@nerc.net by July 30, 2007 with "SO Certification SAR DT" in the subject line. For questions, please contact Linda Clarke at 610-310-7210 or linclrke@msn.com.

## Project 2007-05 — Balancing Authority Controls SAR Drafting Team (July 17-30, 2007)

The Standards Committee is seeking industry experts to serve on the Balancing Authority Controls SAR Drafting Team. The drafting team will work on modifications to the following standards:

- BAL-002 - Disturbance Control Performance
- BAL-004 - Time Error Correction
- BAL-005 - Automatic Generation Control
- BAL-006 - Inadvertent Interchange

If you are interested in serving on this SAR drafting team, please complete this nomination form and return it to sarcomm@nerc.net by July 30, 2007 with "BA Controls SAR DT" in the subject line. For questions, please contact Linda Clarke at 610-310-7210 or linclrke@msn.com.

## Project 2007-09 — Generator Verification Standard Drafting Team (July 17-30, 2007)

The Standards Committee is seeking industry experts to serve on the Generator Verification Standard Drafting Team. If you are interested in serving on this team, please complete this nomination form and return it to sarcomm@nerc.net with "Gen Verification SDT" in the subject line by July 30, 2007. For questions, please contact David Taylor at 609-651-5089 or david.taylor@nerc.net.

The drafting team will work on finalizing the following Phase III \& IV standards:

REGISTERED BALLOT BODY
July 17, 2007
Page Two

- PRC-019 - Coordination of Generator Voltage Regulator Controls with Unit Capabilities and Protection
- PRC-024 - Generator Performance during Frequency and Voltage Excursions
- MOD-026 - Verification of Models and Data for Generator Excitation System Functions
- MOD-027 - Verification of Generator Unit Frequency Response

The drafting team will also work on revising two existing standards that were not approved by the FERC because of their "fill-in-the-blank" elements:

- MOD-024 - Verification of Generator Gross and Net Real Power Capability
- MOD-025 - Verification of Generator Gross and Net Reactive Power Capability

## Project 2007-12 — Frequency Response Standard Drafting Team (July 17-30, 2007)

The Standards Committee is seeking industry experts to serve on the Frequency Response Standard Drafting Team. The drafting team will work to develop a standard that requires entities to provide data so that Frequency Response in each of the Interconnections can be modeled, and the reasons for the decline in Frequency Response can be identified.

If you are interested in serving on this standard drafting team, please complete this nomination form and return it to sarcomm@nerc.net by July 30, 2007 with "FR SDT" in the subject line. For questions, please contact Linda Clarke at 610-310-7210 or linclrke@msn.com.

Project 2007-23 — Violation Severity Levels Drafting Team (July 17-30, 2007)
The Standards Committee is seeking industry experts to serve on the Violation Severity Levels SAR Drafting Team. The drafting team will work to achieve consensus on a set of criteria for assigning Violation Severity Levels, and will work (with other existing drafting teams) to replace "Levels of Non-compliance" with "Violation Severity Levels" in the 83 standards approved by the FERC. FERC directed NERC to replace "Levels of Non-compliance" with "Violation Severity Levels' so that the ERO's Sanctions Guidelines can be used as intended.

If you are interested in serving on this standard drafting team, please complete this nomination form and return it to sarcomm@nerc.net by July 30, 2007 with "VSL DT" in the subject line. For questions please contact Al Calafiore at 678-524-1188 or al.calafiore@nerc.net or Stephen Crutchfield at 609-651-9455 or stephen.crutchfield@nerc.net.

## Standards Development Process

The Reliability Standards Development Procedure contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate. If you have any questions, please contact me at 813-468-5998 or maureen.long@nerc.net.

[^44]
## Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

## Single Event Frequency Response Data (SEFRD)

The individual sample of event data from a Balancing Authority which represents the change in Net Actual Interchange $\left(\mathrm{NI}_{\mathrm{A}}\right)$, divided by the change in frequency, expressed in $\mathrm{MW} / 0.1 \mathrm{~Hz}$.

## Frequency Response Measure (FRM)

The median of all Single Event Frequency Response Data observations reported annually on FRS Form 1.

## Frequency Response Obligation (FRO)

The Balancing Authority's contribution to the total aggregate Frequency Response needed for reliable operation of an Interconnection assigned by the ERO.

## Frequency Bias Setting (redline showing proposed changes to approved definition)

A value, (either a fixed or variable Frequency Bias), usually expressed in MW/0.1 Hz, set into a Balancing Authority Area Control Error algorithm-equation that allows the Balancing Authority to contribute its frequency Frequency $£$ Response to the Interconnection.

## A. Introduction

## Title: Frequency Response and Frequency Bias Setting

Number: BAL-003-1
Purpose: To require sufficient Frequency Response from the Balancing Authority to maintain Interconnection Frequency within predefined bounds by arresting frequency deviations and supporting frequency until the frequency is restored. To schedule and provide consistent methods for measuring Frequency Response and determining the Frequency Bias Setting.

## Applicability:

1.1. Balancing Authority
1.2. Reserve Sharing Group (where applicable)

## Effective Date:

1.3. In those jurisdictions where regulatory approval is required, Requirements R2, R3 and R4 of this standard shall become effective the first calendar day of the first calendar quarter 12 months after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, Requirements R2 and R3 of this standard shall become effective the first calendar day of the first calendar quarter 12 months after Board of Trustees adoption.
1.4. In those jurisdictions where regulatory approval is required, Requirements R1 of this standard shall become effective the first calendar day of the first calendar quarter 24 months after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, Requirements R1 of this standard shall become effective the first calendar day of the first calendar quarter 24 months after Board of Trustees adoption.

## B. Requirements

R1. Each Balancing Authority shall achieve a Frequency Response Measure (FRM) (as detailed in Attachment A and calculated on FRS Form 1) that is equal to or more negative than its Frequency Response Obligation (FRO). [Risk Factor: ][Time Horizon: Operations Assessment]

R2. Each Balancing Authority shall implement the Frequency Bias Setting (fixed or variable) provided by the ERO into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effective coordinated secondary control, using the results from the calculation methodology detailed in Attachment A. [Risk Factor: ][Time Horizon: Operations Planning]

R3. Each Balancing Authority shall operate its Automatic Generation Control (AGC) on Tie Line Bias, unless such operation would have an Adverse Reliability Impact on the Balancing Authority's Area. [Risk Factor: ][Time Horizon: Real-time Operations]
R4. Each Balancing Authority that is performing Overlap Regulation Service shall increase its Frequency Bias Setting in its ACE calculation by combining the Frequency Bias

Settings for the entire Balancing Authority Area being controlled. [Risk Factor: $\mathcal{K}$ Time Horizon: Operations Planning\}

## C. Measures

Measures for each Requirement will be provided in the second posting of the proposed standard.

## D. Compliance

## 1. Compliance Monitoring Process

### 1.1. Compliance Enforcement Authority

The Regional Entity shall serve as the Compliance Enforcement Authority.

### 1.2. Compliance Monitoring and Assessment Processes:

Compliance Audits
Self-Certifications
Spot Checking
Compliance Violation Investigations
Self-Reporting
Complaints
Periodic Data Submittals

### 1.3. Data Retention

Data Retention periods for Requirement R1 through Requirement R4 will be defined in the second posting of the proposed standard.

If a Balancing Authority is found non-compliant, it shall keep information related to the non-compliance until found compliant or for the time period specified above, whichever is longer.
The Compliance Enforcement Authority shall keep the last audit records and all subsequent requested and submitted records.

### 1.4. Additional Compliance Information

## R1 Supplemental Information

Each Balancing Authority shall report its previous year's Frequency Response Measure (FRM) to the ERO on Form 1 by January 10 each year. If the ERO posts the official list of events after December 10, Balancing Authorities will be given 45 days from the date the ERO posts the official list of events to submit their FRS Form 1.

A Balancing Authority may elect to fulfill its Frequency Response Obligation by participating as a member of a Reserve Sharing Group (RSG). If a Balancing

Authority elects to report as an RSG, the total of the participating Balancing Authorities' FRO will be compared to the total of the participating Balancing Authorities' FRM.

## R2 Supplemental Information.

Each Balancing Authority shall report its current year requested Frequency Bias Setting and Frequency Bias type (fixed or variable) to the ERO on FRS-Form 1 by January 10 each year. If the ERO posts the official list of events after December 10, Balancing Authorities will be given 45 days from the date NERC posts the official list of events to submit their FRS Form 1. Once the FRM and Frequency Bias Settings have been validated by the ERO, the ERO will disseminate the Frequency Bias Settings Report for all Balancing Authorities in each Interconnection along with the implementation date.
Balancing Authorities with variable Frequency Bias Settings shall calculate monthly average Frequency Bias Settings. The previous year's monthly averages will be reported annually on FRS Form 1.

### 2.0 Violation Severity Levels (To be added later)

| R\# | Lower VSL | Medium VSL | High VSL | Severe VSL |

## BAL-003 - Attachment A <br> Background Document

## Introduction

This draft document provides background to explain the requirements in the draft Frequency Response Standard (BAL-003-1). This document will evolve on the basis of Industry comments on the standard and is expected to become Attachment A to the standard.

## Requirement 1

R1. Each Balancing Authority shall achieve a Frequency Response Measure (FRM) (as detailed in Attachment A and calculated on FRS Form 1) that is equal to or more negative than its Frequency Response Obligation (FRO).

## Frequency Bias Setting vs. Frequency Response

The Frequency Response Measure (FRM) for the upcoming year is based on the same data collected for the Balancing Authorities’ annual Frequency Bias Setting calculation. A final listing of official events to be used in the calculation will be available from NERC by December 10 each year. Once a list is distributed to Balancing Authorities, each BA has one month to assemble its data and calculate the FRM.

The ERO will use the following criteria for the selection of events to be analyzed.

1. At least 25 events will be used for the calculation of FRM. If a year occurs in which there are not 25 events that meet the remaining criteria below, then the most recent 25 events (as defined below) will be used for determination of an entity's compliance with the FRM requirement and storage of SEFRD.
2. Two limits will be used to determine if a frequency event has occurred for the purposes of determining FRM:
$a$. The frequency at the arresting frequency (Point C ) must exceed the frequency deviation event threshold specified for the Interconnection. (As of 2010, the governor deadband setting for the Eastern and Western Interconnections will be assumed to be near or greater than 36 MHz , although there is no stated requirement defined in NERC standards). The Point C value is the minimum of frequency samples within 8 seconds after the start of the rapid change in frequency.
b. The time from the start of the rapid change in frequency until the point at which Frequency has largely stabilized should be less than 18 seconds.
3. Typically, the Point A frequency should be relatively steady and near 60.000 Hz . Point A is computed as an average over the period from -16 seconds to 0 seconds before initial frequency decline.
4. Any indication or evidence of a secondary event occurrence after Point $C$ should be reviewed for inclusion based on having sufficient information to perform a full analysis of the event.
5. Events occurring during periods in which either significant interchange schedule ramping or load ramping is likely, should be excluded if other events are available for measurement purposes.
Additional events included in Frequency Response survey for interconnection analysis: The ERO has the discretion to request a frequency survey for events that differ significantly from criteria 3, 4, or 5. These events will not be included on FRS Form 1 used for calculation of frequency response.

The report will be done via FRS Form 1.
Sliding of the reporting deadline from that found in previous versions of BAL-003 is due to the increased number of samples required and is intended to avoid burdening NERC and the Balancing Authorities with working over holiday periods for no added value to reliability.

Frequency Bias Settings and acceptable Frequency Response are negative numbers by definition. In other words, as frequency drops, the Balancing Authority is expected to contribute MWs to the Interconnection (or take fewer MWs in).

The current BAL-003 has a minimum Frequency Bias Setting (in MW/0.1Hz) that is in absolute terms equal to $1 \%$ of the Balancing Authority's projected peak. An early researcher ${ }^{1}$ noted that the ideal state is where the Frequency Bias Setting is exactly equal to natural Frequency Response. Researchers have also noted that over-bias is preferable to under-bias. The current ( $1 \%$ of peak) $/ 0.1 \mathrm{~Hz}$ floor for the Frequency Bias Setting is significantly more negative than most Balancing Authorities’ natural Frequency Response. This can lead to over-control , particularly in the Eastern Interconnection, and force the industry to require too much secondary control resulting in degraded performance and increased operating cost compared to requiring an appropriate balance of primary and secondary control.

Changes to the Frequency Bias Setting that move it closer to the natural Frequency Response will improve the quality and accuracy of ACE and all ACE based systems and measures, including: the CERTS Automatic Frequency Events Identification and Frequency Response Evaluation System; the CPS1 measure; the CPS2 measure; the DCS measure; the BAAL measure; and, AGC Systems in general.

[^45]
## Frequency Bias Setting Floor

The FR SDT is proposing a gradual transition to bring Frequency Bias Settings and natural Frequency Response closer. The Frequency Response Field Test Document describes the gradual replacement of a floor by natural Frequency Response for Frequency Bias Setting.

## Frequency Response Obligation and Allocation

The SDT is initially proposing that the Interconnection Frequency Response Obligation (FRO) be a discretely administered determination.

For this administered approach each Interconnection will have a target contingency protection criteria based on the largest category C event ( $\mathrm{N}-2$ ). The protection criteria will assure that Point C will not encroach on the first step UFLS.

Under development - The SDT is evaluating a risk based approach to establishing an Interconnection Frequency Response Obligation which can be based on a probability function.

The ERO and the NERC RS will manage the administrative procedure to assign an FRO to each BA for the upcoming year.

Each Balancing Authority will receive a proportional slice of the Interconnection’s Frequency Response Obligation based on (peak generation + peak load)/2. The reasoning for this allocation method is that Balancing Authorities carry differing proportions of load and generation. In fact, some Balancing Authorities have only load with no native generation, while others have only generation with no native load. One of the reasons for using 2010 event data as part of a field trial of the standard is to evaluate the allocation methodology.

## Methods of Obtaining Response

A Balancing Authority may elect to fulfill its Frequency Response Obligation by participating as a member of a Reserve Sharing Group.

There are two considerations under the option of meeting compliance by participation in a Reserve Sharing Group (RSG). First, although spinning reserve is not a part of this standard, it should be noted that RSGs typically define the amount of spinning reserve carried by Balancing Authorities. Second, allowing the RSG option addresses the FERC Order No. 693 directive to define methods of obtaining frequency response.

As long as all BAs within the RSG use the same events for calculating FRM, BAs within the RSG may allocate a portion of their FRM to another RSG participant.

The SDT is soliciting comments on methods of obtaining Frequency Response to meet the Order 693 directive (markets, incentive programs, tariff changes, interconnection agreements, innovative technology, resource standard).

## Measure and Compliance Information

This will be added in the second posting.

## Requirement 2

R2. Each Balancing Authority shall implement the Frequency Bias Setting (fixed or variable) provided by the ERO into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effective coordinated secondary control, using the results from the calculation methodology detailed in Attachment A.

## Background and Rationale

The traditional process for implementing new Frequency Bias Settings is for Balancing Authorities to submit their upcoming annual Frequency Bias Setting value by January 1. NERC and the Resources Subcommittee validate Frequency Bias Setting values, perform error checking and use these values to calculate L10 values for CPS2. Once the L10 values are validated, NERC posts the L10 values and sends a letter to Balancing Authorities giving a date on which to implement the new Frequency Bias Settings. This data collection and validation process can take up to two months. It is expected NERC will send out the L10 and Frequency Bias Setting notification generally in February for March 1 implementation.

## Measure and Compliance Information

This will be added in the second posting.

## Requirement 3

R3. Each Balancing Authority shall operate its Automatic Generation Control (AGC) on Tie Line Bias, unless such operation would have an Adverse Reliability Impact on the Balancing Authority's Area.

## Background and Rationale

This requirement has existed in NERC Policy 1 and BAL-003 for years. Operating out of Tie Line Bias control can lead to uncoordinated control that may result in unreliable operations.

## Measure and Compliance Information

This will be added in the second posting.

## Requirement 4

R4. Each Balancing Authority that is performing Overlap Regulation Service shall increase its Frequency Bias Setting in its ACE calculation by combining the Frequency Bias Settings for the entire Balancing Authority Area being controlled.

## Background and Rationale

This requirement has existed in NERC Policy 1 and BAL-003 for years. Overlap regulation service provides ACE control for compliance from another BA authority performing the overlap service thus the frequency bias used by the BA purchasing the service needs to be added to the providers frequency bias which will provide the ACE control for the Balancing Authority. Supplemental service is a schedule to provide a portion of the control for another BA using a portion of the ACE which does not require changing the frequency bias.

## Measure and Compliance Information

This will be added in the second posting.

## A. Introduction

1. Title: Frequency Response and Bias
2. Number: BAL-003-0
3. Purpose:

This standard provides a consistent method for calculating the Frequency Bias component of ACE.
4. Applicability:
4.1. Balancing Authorities
5. Effective Date: April 1, 2005

## B. Requirements

R1. Each Balancing Authority shall review its Frequency Bias Settings by January 1 of each year and recalculate its setting to reflect any change in the Frequency Response of the Balancing Authority Area.

R1.1. The Balancing Authority may change its Frequency Bias Setting, and the method used to determine the setting, whenever any of the factors used to determine the current bias value change.
R1.2. Each Balancing Authority shall report its Frequency Bias Setting, and method for determining that setting, to the NERC Operating Committee.
R2. Each Balancing Authority shall establish and maintain a Frequency Bias Setting that is as close as practical to, or greater than, the Balancing Authority's Frequency Response.
Frequency Bias may be calculated several ways:
R2.1. The Balancing Authority may use a fixed Frequency Bias value which is based on a fixed, straight-line function of Tie Line deviation versus Frequency Deviation. The Balancing Authority shall determine the fixed value by observing and averaging the Frequency Response for several Disturbances during on-peak hours.
R2.2. The Balancing Authority may use a variable (linear or non-linear) bias value, which is based on a variable function of Tie Line deviation to Frequency Deviation. The Balancing Authority shall determine the variable frequency bias value by analyzing Frequency Response as it varies with factors such as load, generation, governor characteristics, and frequency.
R3. Each Balancing Authority shall operate its Automatic Generation Control (AGC) on Tie Line Frequency Bias, unless such operation is adverse to system or Interconnection reliability.
R4. Balancing Authorities that use Dynamic Scheduling or Pseudo-ties for jointly owned units shall reflect their respective share of the unit governor droop response in their respective Frequency Bias Setting.
R4.1. Fixed schedules for Jointly Owned Units mandate that Balancing Authority (A) that contains the Jointly Owned Unit must incorporate the respective share of the unit governor droop response for any Balancing Authorities that have fixed schedules (B and C). See the diagram below.

R4.2. The Balancing Authorities that have a fixed schedule (B and C) but do not contain the Jointly Owned Unit shall not include their share of the governor droop response in their Frequency Bias Setting.

R5. Balancing Authorities that serve native load shall have a monthly average Frequency Bias Setting that is at least $1 \%$ of the Balancing Authority's estimated yearly peak demand per 0.1 Hz change.
R5.1. Balancing Authorities that do not serve native load shall have a monthly average Frequency Bias Setting that is at least $1 \%$ of its estimated maximum generation level in the coming year per 0.1 Hz change.
R6. A Balancing Authority that is performing Overlap Regulation Service shall increase its Frequency Bias Setting to match the frequency response of the entire area being controlled. A Balancing Authority shall not change its Frequency Bias Setting when performing Supplemental Regulation Service.

## C. Measures

M1. Each Balancing Authority shall perform Frequency Response surveys when called for by the Operating Committee to determine the Balancing Authority's response to Interconnection Frequency Deviations.
D. Compliance

Not Specified.

## E. Regional Differences

None identified.

The information in this Supplemental SAR identifies the modifications to RELIABILITY CORPORATION BAL-003-0 that were originally part of Project 2007-18 - Reliabilitybased Control. The Standards Committee authorized the transfer of this work from Project 2007-18 to Project 2007-12 during its October 13-14, 2010 meeting.

## Standard Authorization Request Form

Title of Proposed Standard BAL-003-1 Frequency Response and Frequency Bias Setting Supplemental to SAR dated 30J un2007
SC Approved the transfer of work identified in this SAR from Project 2007-18 to Project 2007-12 during its October 13-14, 2010 meeting.
The supplemental SAR outlining the work that was transferred was accepted by the SC EC on February 2, 2011

| SAR Requester Information | SAR Type (Check a box for each one <br> that applies.) |  |
| :--- | :--- | :--- |
| Name Frequency Response Standard <br> Drafting Team | $\square$ | New Standard |
| Primary Contact Bill Herbsleb - PJ M | X | Revision to existing Standard |
| Telephone 610.666.8874 <br> Fax | $\square$ | Withdrawal of existing Standard |
| E-mail herbslhw@pjm.com | $\square$ | Urgent Action |

Purpose (Describe what the standard action will achieve in support of bulk power system reliability.)
To require sufficient Frequency Response from the Balancing Authority to maintain Interconnection Frequency within predefined bounds by arresting frequency deviations and supporting frequency until the frequency is restored to schedule and to provide consistent methods for measuring Frequency Response and determining the Frequency Bias Setting.

Industry Need (Provide a justification for the development or revision of the standard, including an assessment of the reliability and market interface impacts of implementing or not implementing the standard action.)
Frequency Response, a measure of an Interconnection's ability to stabilize frequency immediately following the sudden loss of generation or load, is a critical component to the reliable operation of the bulk power system, particularly during disturbances and restoration. There is evidence of continuing decline in Frequency Response in the three Interconnections over the past 10 years, but no confirmed reason for the apparent decline.

Brief Description (Provide a paragraph that describes the scope of this standard action.)
To provide a minimum Frequency Response Obligation for the Balancing Authority to
achieve, methods to obtain Frequency Response and provide a consistent method for calculating the Frequency Bias Setting for a Balancing Authority. In addition, the standard will specify the optimal periodicity of Frequency Response surveys.
Detailed Description (Provide a description of the proposed project with sufficient details for the standard drafting team to execute the SAR.)

This SAR proposes to retire BAL-003-0 when BAL-003-1 is implemented. Below are excerpts from documents relevant to this SAR.

From FERC Order 693:
369 - With respect to the frequency of frequency response surveys, EEI states that NERC currently conducts an annual frequency response characteristic survey that appears to address the Commission's concern. The Commission disagrees. The surveys that were performed on a yearly basis are not available on NERC's website and the ISO/RTO Council believes that more frequent analysis after large frequency disturbances is appropriate. The Commission understands that the last analysis was performed in 2002. Currently, Measure M1 only requires balancing authorities to perform surveys when requested by the NERC operating committee. As identified in Order No. 672, the Reliability Standards should be based on actual data. Therefore, on further consideration, instead of requiring yearly surveys as proposed in the NOPR, the Commission believes that the frequency of these surveys should be based on the data requirements that will assist the ERO to determine if the balancing authorities are providing adequate and equitable frequency response to disturbances on the Bulk-Power System. Accordingly, we direct the ERO to determine the optimal periodicity of frequency response surveys necessary to ensure that Requirement R2 and other Requirements of the Reliability Standard are being met and to modify Measure M1 based on this determination.

372 - The Commission is not persuaded by the commenters. We conclude that the minimum frequency response needed for Reliable Operation should be defined and methods of obtaining the frequency response identified. In addition to the ERCOT experience, EEI provides an additional example that underscores the Commission's concern in this area with its discussion of the ISO-NE frequency oscillations resulting from the August 14, 2003 blackout. Severe oscillations were observed in the ISO-NE frequency when it separated from the Eastern Interconnection during the August 14, 2003 blackout. The ISO-NE operators acted quickly to reduce the bias setting so as to eliminate the self-induced frequency oscillations before they affected system reliability. This apparent mismatch between the bias and the actual frequency response might have caused the ISO-NE system to cascade if it had not been for the quick actions of its operators. Therefore, we direct the ERO to either modify this Reliability Standard or develop a new Reliability Standard that defines the necessary amount of frequency response needed for Reliable Operation and methods of obtaining and measuring that frequency response is available.

## Reliability Functions

The Standard will Apply to the Following Functions (Check box for each one that applies.)

| $\square$ | Reliability <br> Assurer | Monitors and evaluates the activities related to planning and <br> operations, and coordinates activities of Responsible Entities to <br> secure the reliability of the bulk power system within a Reliability <br> Assurer Area and adjacent areas. |
| :---: | :--- | :--- |
| $\square$ | Reliability <br> Coordinator | Responsible for the real-time operating reliability of its Reliability <br> Coordinator Area in coordination with its neighboring Reliability <br> Coordinator's wide area view. |
| x | Balancing <br> Authority | Integrates resource plans ahead of time, and maintains load- <br> interchange-resource balance within a Balancing Authority Area <br> and supports Interconnection frequency in real time. |
| $\square$ | Interchange <br> Authority | Ensures communication of interchange transactions for reliability <br> evaluation purposes and coordinates implementation of valid and <br> balanced interchange schedules between Balancing Authority <br> Areas. |
| $\square$ | Planning <br> Coordinator | Assesses the longer-term reliability of its Planning Coordinator <br> Area. |
| $\square$ | Resource <br> Planner | Develops a >one year plan for the resource adequacy of its <br> specific loads within its portion of the Planning Coordinator's Area. |
| $\square$ | Transmission <br> Owner | Owns and maintains transmission facilities. |
| $\square$ | Transmission <br> Operator | Ensures the real-time operating reliability of the transmission <br> assets within a Transmission Operator Area. |
| $\square$ | Transmission <br> Planner | Develops a >one year plan for the reliability of the interconnected <br> Bulk Electric System within the Transmission Planner Area. |
| $\square$ | Transmission <br> Service <br> Provider | Administers the transmission tariff and provides transmission <br> services under applicable transmission service agreements (e.g., <br> the pro forma tariff). |
| $\square$ | Distribution <br> Provider | Delivers electrical energy to the End-use customer. |
| $\square$ | Generator <br> Owner | Owns and maintains generation facilities. <br> Generator <br> Operator | | Operates generation unit(s) to provide real and reactive power. |
| :--- |
| Selling Entity |$\quad$| Purchases or sells energy, capacity, and necessary reliability- |
| :--- |
| related services as required. |

## Reliability and Market Interface Principles

| Applicable Reliability Principles (Check box for all that apply.) |  |
| :---: | :--- |
| X | 1. Interconnected bulk power systems shall be planned and operated in a coordinated <br> manner to perform reliably under normal and abnormal conditions as defined in the <br> NERC Standards. |
| X | 2.The frequency and voltage of interconnected bulk power systems shall be controlled <br> within defined limits through the balancing of real and reactive power supply and <br> demand. <br> X3. Information necessary for the planning and operation of interconnected bulk power <br> systems shall be made available to those entities responsible for planning and <br> operating the systems reliably. |
| $\square$ | 4. Plans for emergency operation and system restoration of interconnected bulk power <br> systems shall be developed, coordinated, maintained and implemented. |
| X | 5. Facilities for communication, monitoring and control shall be provided, used and <br> maintained for the reliability of interconnected bulk power systems. |
| $\square$ | 6. Personnel responsible for planning and operating interconnected bulk power systems <br> shall be trained, qualified, and have the responsibility and authority to implement <br> actions. |
| X | 7.The security of the interconnected bulk power systems shall be assessed, monitored <br> and maintained on a wide area basis. <br> $\square$8. Bulk power systems shall be protected from malicious physical or cyber attacks. <br> Does the proposed Standard comply with all of the following Market Interface <br> Principles? (Select 'yes' or 'no' from the drop-down box.) <br> 1. A reliability standard shall not give any market participant an unfair competitive <br> advantage. Yes |
| 2. A reliability standard shall neither mandate nor prohibit any specific market structure. Yes |  |
| 3. A reliability standard shall not preclude market solutions to achieving compliance with that |  |
| standard. Yes |  |

## Balancing Authority FRS Form 1 Background and Instructions

## Subsections

## A. Frequency Response Characteristics and their Measurement

1. Frequency Response
2. Response to Internal and External Generation/Load Imbalances
3. Frequency Bias Setting versus Frequency Response
4. Effects of a Disturbance on all Balancing Authorities External to the Contingent Balancing Authority
5. Effects of a Disturbance on the Contingent Balancing Authority
6. Effects of a Disturbance on the Contingent Balancing Authority with a Jointly-Owned Unit
7. Effects of a Disturbance on the Non-Contingent Balancing Authority with a Jointly-Owned Unit

## B. FRS Form 1 Instructions

This document includes the purpose and description of the Frequency Response Survey (FRS) Form 1, including specific instructions to complete the survey form.

## A. Frequency Response Characteristics and their Measurement

Disturbances can cause frequency to either increase from loss of load or decrease from loss of generation; Frequency Response characteristics should be evaluated for both types of events.

Accurate measurement of Frequency Response for an Interconnection or for individual Balancing Authorities is difficult unless the frequency deviation resulting from a system disturbance is significant. Therefore, it is better to analyze response only when significant frequency deviations occur.

1. Frequency Response - For any change in generation/load balance in the Interconnection, a frequency change occurs. Each Balancing Authority in the Interconnection will respond to this frequency change through:

- A load change resulting from the load's Frequency Response ${ }^{1}$ that acts to arrest frequency changes, and varies with frequency in a continuous and inverse relationship,
- A generation change resulting from governor action that acts to arrest frequency changes, and varies with frequency in a continuous and inverse relationship, and
- A change in energy consumption or production from other devices resulting from the device's control system that acts to arrest frequency changes, and varies with frequency in a continuous and inverse relationship.

[^46]Frequency responsive resources (generation, load, and other devices as above described) produce these responses. The net effect of these actions is the Balancing Authority's response to the frequency change, that is, its Frequency Response. The combined response of all Balancing Authorities in the Interconnection will cause the Interconnection frequency to settle at some value different from the pre-disturbance value and maintain it there. Frequency will remain different until the Balancing Authority with the generation/load imbalance (referred to as the "contingent Balancing Authority") corrects that imbalance, thus returning the Interconnection frequency to its pre-disturbance value.
2. Response to Internal and External Generation/Load Imbalances - Most of a Balancing Authority's Frequency Response will be reflected in a change in its actual net interchange. By monitoring frequency error (the difference between actual and scheduled frequency) and the change in actual interchange in response to the frequency deviation, a Balancing Authority's automatic generation control (AGC) can determine whether the imbalance in load and generation is internal or external to its system. If internal, the Balancing Authority's AGC and/or deployment of Contingency Reserve should gradually correct the imbalance. If external, the Balancing Authority's AGC should allow its frequency responsive resources to continue responding (as allowed by its Frequency Bias Setting contribution in its ACE equation) until the contingent Balancing Authority corrects its imbalance, which should return frequency to its predisturbance value.
3. Frequency Response versus Frequency Bias Setting- If the Balancing Authority's Frequency Bias Setting matches its Frequency Response in its AGC ACE equation, the Balancing Authority's Frequency Bias Setting allowance term would exactly offset the change in tie line flow included in the ACE that results from frequency responsive resource action countering a frequency deviation on the Interconnection. The following sections discuss effects of Frequency Bias Settings on control action. The discussion explains control action by all Balancing Authorities external to the contingent Balancing Authority (the Balancing Authority that experienced the sudden generation/load imbalance) and by the contingent Balancing Authority itself.

While this discussion deals with loss of generation, it applies equally to loss of load, or any sudden contingency resulting in a generation/load mismatch. Each Balancing Authority's Frequency Response will vary with each disturbance because generation and load characteristics change continuously. This discussion also assumes that frequency error from 60 Hz was zero (all ACE values were zero) just prior to the sudden generation/load imbalance.

For further explanation of the ACE equation, refer to the Area Interchange Error Training Document.
4. Effects of a Disturbance on all Balancing Authorities External to the Contingent Balancing Authority - When a loss of generation occurs, Interconnection frequency declines because machine speed must decrease to supply a portion of the energy shortfall from rotating kinetic energy. Initially, rotating kinetic energy from all rotating machines with direct mechanical-toelectrical coupling addresses the entire shortfall by lowering machine speed, and hence frequency, of the Interconnection ${ }^{2}$. Over time, Balancing Authorities' frequency responsive

[^47]resources should respond to frequency error and change energy to stabilize frequency accordingly. This will cause a change in the Balancing Authorities’ actual net interchange. In other words, the Actual Net Interchange $\left(N I_{\mathrm{A}}\right)$ generally should be greater than its value before the contingency for all but the contingent Balancing Authority, and the result should be an increase in flow out of non-contingent Balancing Authorities (or a decrease in flow into noncontingent Balancing Authorities). The resulting tie flow error ( $N I_{\mathrm{A}}-N I_{\mathrm{S}}$ ) will be counted as Inadvertent Interchange.

If Balancing Authorities were using only tie line flow error (i.e., flat tie control ignoring the frequency error), this non-zero ACE would cause their AGC to reduce generation until $N I_{\mathrm{A}}$ was equal to $N I_{S}$; returning their ACE to zero. However, doing this would not help arrest Interconnection frequency decline because the Balancing Authorities would not be helping to temporarily replace some of the generation deficiency in the Interconnection. With the tie-line bias method, the Balancing Authorities’ AGC should allow their frequency responsive resources to continue responding to the frequency deviation until the contingent Balancing Authority replaces the generation it has lost.

For the AGC to allow frequency responsive resource action to continue to support frequency, a frequency bias contribution term is added to the ACE equation to offset the tie flow error. This bias contribution term is equal in magnitude and opposite in direction to the frequency responsive resource action and should ideally be equal to each Balancing Authority's Frequency Response measured in MW/0.1 Hz. Then, when multiplied by the frequency error, ideally the Frequency Bias Setting should exactly be offset by the tie flow error portion of the ACE calculation, allowing continued support of frequency responsive resource action to support system frequency while maintaining ACE at zero.

The ACE equation is then:

$$
A C E=\left(N i_{A}-N i_{S}\right)-10 B\left(f_{A}-f_{S}\right)-I_{M E}
$$

Where:

- The factor 10 converts the Frequency Bias Setting (B) from MW/0.1 Hz to MW/Hz.
- $\mathrm{I}_{\mathrm{ME}}$ is a meter error correction estimate; this term should normally be very small or zero

NOTE: Frequency Response and Frequency Bias Settings are often referred to as positive values (such as "our bias is $50 \mathrm{MW} / 0.1 \mathrm{~Hz}$ "). Frequency Response and Frequency Bias Settings are actually negative values.

If the Frequency Bias Setting is greater (as an absolute value) than the Balancing Authority's actual Frequency Response, then its AGC will increase generation beyond the primary frequency responsive resource response in order to achieve $\mathrm{ACE}=0$, which further helps arrest the frequency decline, but increases Inadvertent Interchange. Likewise, if the Frequency Bias Setting contribution term is less (as an absolute value) than actual Frequency Response, its AGC will reduce generation in order to achieve $\mathrm{ACE}=0$, thereby reducing the Balancing Authority's contribution to arresting frequency change.
5. Effects of a Disturbance on the Contingent Balancing Authority - In the contingent Balancing Authority where the generation deficiency occurred, most of the replacement power comes from the Interconnection over its tie lines from Frequency Response contributions by other Balancing Authorities in the Interconnection, as allowed by Frequency Bias Settings. A small portion will be made up internally from the contingent Balancing Authority's own frequency responsive resource response. In this case, the change in $N I_{\mathrm{A}}$ for the contingent Balancing Authority is much greater than its Frequency Bias Setting component. Its ACE will be negative (if the loss is generation), and its AGC will begin to increase generation.

$$
\begin{aligned}
& N I_{\mathrm{A}} \text { - drops by the total generation lost less the contingent Balancing Authority's own } \\
& N I_{\mathrm{S}} \text { - does not change }
\end{aligned}
$$

The energy supplied from the Interconnection appears in the contingent Balancing Authority’s inadvertent balance.
6. Effects of a Disturbance on the Contingent Balancing Authority with a Jointly-Owned Unit ${ }^{3}$ - When a generation deficiency occurs within a Balancing Authority on a jointly-owned unit (with dynamically scheduled shares being exported), the effects on the tie line component ( $N I_{\mathrm{A}}-$ $N I_{\mathrm{S}}$ ) of their ACE equation are more complicated. The $N I_{\mathrm{A}}$ drops by the total amount of the generator lost, while the $N I_{\mathrm{S}}$ is reduced only by the dynamic reduction in the shares being exported.
$N I_{\mathrm{A}}$ - drops by the total generation lost less the contingent Balancing Authority's own
frequency responsive resource response
$N I_{\mathrm{S}}$ - decreases by the reduction in dynamic shares being exported

The net effect is that the tie line bias component reflects only the response by the contingent Balancing Authority for its share of the lost generation. Most of the replacement power comes from the Interconnection over its tie lines from Frequency Response contributions by other Balancing Authorities in the Interconnection.
7. Effects of a Disturbance on a Balancing Authority with a Contingent Jointly-Owned Unit ${ }^{4}$ Geographically-Located in an External Balancing Authority - In a Balancing Authority whose generation deficiency occurred on a jointly-owned unit in another Balancing Authority (with dynamically scheduled shares being exported from the other BA), the effects on the tie line component ( $N I_{\mathrm{A}}-N I_{\mathrm{S}}$ ) of their ACE equations are also complicated. The $N I_{\mathrm{A}}$ increases by the Balancing Authority's own Frequency Response, while the $N I_{\mathrm{S}}$ is reduced only by the dynamic reduction in the share the BA is importing from the unit.
$N I_{\mathrm{A}}$ — increases by the Balancing Authority's own frequency responsive resource response
$N I_{\mathrm{S}}$ - decreases by the BA's dynamic share of the jointly-owned unit.
The net effect is that the tie line bias component reflects only the response by the contingent Balancing Authority for its share of the lost generation. Most of the replacement power comes from the Interconnection over its tie lines from Frequency Response contributions of other Balancing Authorities in the Interconnection.

[^48]
## B. BAL-003-FRS Form 1 Instructions

Figure 1 - Class ic Frequency Excursion and Recovery
A sample frequency chart is shown in Figure 1 with points A, B, and C labeled. Point A represents the interconnected system frequency immediately before the disturbance. Point B represents the interconnected system frequency at the point immediately after frequency stabilizes due to Frequency Response but before the contingent Balancing Authority takes corrective AGC action. Point C represents the interconnected system frequency at its maximum deviation. All dynamic adjustments as cited bulleted items 4 through 6 needs to be made to $\mathrm{NI}_{\mathrm{A}}$.

## Balancing Authority FRS Form 1 Background and Instructions

## Line-by-line instructions for the survey form follow:

| FRS Form 1 Date/Time |  | Point "A" | nformation | Point "B" | formation | SEFRD | Internal |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Column A | Column B | Corumn C | Column D | Column E | column F | Column G | Column I | Column J |
| (XXXX <br> Prevailing) | DelFreq | Load | NAI | Load | NAI | (MW/0.1Hz) | Contingency | Unit |
| $\begin{aligned} & 12 / 20 / 2008 \\ & 2: 12 \end{aligned}$ | -0.058 | 2869.1 | -117.0 | 2861.2 | -93.8 | -40.2 | $N$ |  |
| 12/27/2008 | -0.006 | 2553.6 | -138.5 | 2576.9 | -110.8 | -41.9 | N |  |
| $\begin{aligned} & \text { 4:18 } \\ & \text { 1/5/2009 9:26 } \end{aligned}$ | 0.040 | 2838.7 | -99.2 | 2857.8 | -88.5 | 26 | N |  |
| 1/27/2009 0:39 | -0.053 | 2524.7 | -94.4 | 2522.3 | -13.8 | -153.6 | N |  |

Point A values are averages over the period from -16 seconds to 0 seconds before initial frequency decline.

Point B values are averages over the period from 18 seconds to 52 seconds after the first scan indicating an initial frequency decline

## Data Values

The times of events are approximate; your local observations may vary in time due to the proximity to the loss of generation and SCADA scan rates. The time skew of your observations may be several seconds and your data should be reported accordingly.

Similarly, Delta Frequency values are approximate.
Note: The following table shows the data cells for a Generation Only Balancing Authority

Modified Heading for Generation only BA

Notes: Add any necessary notes to the response. Please note that Excel allows a maximum of 256 characters for a cell.
All other data on the survey form is calculated.

## Implementation Plan for BAL-003-1 - Frequency Response \& Frequency Bias

## Prerequisite Approvals

There are no other reliability standards or Standard Authorization Requests (SARs), in progress or approved, that must be implemented before this standard can be implemented.

## Modified Standards

BAL-003-0 Requirements R1, R2, R3, R4 and R6 should be retired when BAL-003-1 becomes effective.
BAL-003-0 Requirement R5 should be retired as outlined in the following table.

For those Balancing Authorities that serve native load:

- May 2011 through December 2011
- January 2012 through December 2012
- January 2013 through December 2013
- January 2014 through December 2014
- January 2015 through
$-0.8 \%$ of peak/ 0.1 Hz
$-0.6 \%$ of peak/ 0.1 Hz
$-0.4 \%$ of peak/ 0.1 Hz
$-0.2 \%$ of peak/ 0.1 Hz
$-0.0 \%$ of peak/ 0.1 Hz

For those Balancing Authorities that do not serve native load:

- May 2011 through December 2011 generation/ 0.1 Hz
- January 2012 through December 2012 generation/0.1 Hz
- January 2013 through December 2013 generation/0.1 Hz
- January 2014 through December 2014 generation/0.1 Hz
- January 2015 through generation/0.1 Hz
$-0.8 \%$ of upcoming years maximum
$-0.6 \%$ of upcoming years maximum
$-0.4 \%$ of upcoming years maximum
$-0.2 \%$ of upcoming years maximum
$-0.0 \%$ of upcoming years maximum

The FRR drafting team, NERC and the NERC Resources Subcommittee will observe the impact on frequency and will implement a reversion plan should frequency performance decline.

## Compliance with Standards

Once this standard becomes effective, the responsible entities identified in the applicability section of the standard must comply with the requirements. These include:

- Balancing Authorities

## Proposed Effective Date

Compliance with BAL-003-1 shall be implemented over a two-year period, as follows:

- In those jurisdictions where regulatory approval is required, Requirements R1, R3 and R4 of this standard shall become effective the first calendar day of the first calendar quarter 12 months after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, Requirements R1, R3 and R4 of this standard shall become effective the first calendar day of the first calendar quarter 12 months after Board of Trustees adoption.
- In those jurisdictions where regulatory approval is required, Requirements R2 of this standard shall become effective the first calendar day of the first calendar quarter 24 months after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, Requirements R2 of this standard shall become effective the first calendar day of the first calendar quarter 24 months after Board of Trustees adoption.

# Unofficial Comment Form for BAL-003-1 Frequency Response and Frequency Bias Standard 

Please DO NOT use this form to submit comments on the $1^{\text {st }}$ draft of BAL-003-1 Frequency Response and Frequency Bias Setting. Comments must be submitted by March 7, 2011. If you have questions please contact Darrel Richardson by email at darrel.richardson@nerc.net or by telephone at 609.613.1848.

## Background Information:

Frequency Response, a measure of an Interconnection's ability to stabilize frequency immediately following the sudden loss of generation or load, is a critical component to the reliable operation of the bulk power system, particularly during disturbances and restoration. The proposed standard's intent is to collect data needed to accurately analyze existing Frequency Response, set a minimum Frequency Response obligation, provide a uniform calculation of Frequency Bias Settings that transition to values closer to Frequency Response, and encourage coordinated AGC operation. There is evidence of continuing decline in Frequency Response over the past 10 years, but no confirmed reason for the apparent decline. The proposed standard requires entities to provide data so that Frequency Response in each of the Interconnections can be analyzed, and the reasons for the decline in Frequency Response can be identified. Once Frequency Response has been analyzed and confirmed, requirements can be modified to maintain reliability.
The Drafting Team would like to receive industry comments on this standard. Please submit your comments using the electronic form by March 7, 2011.

## You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. The SDT has developed three new terms to be used with this standard.

Single Event Frequency Response Data (SEFRD)
The individual sample of event data from a Balancing Authority which represents the change in Net Actual Interchange ( $\mathrm{NI}_{\mathrm{A}}$ ), divided by the change in frequency, expressed in MW/0.1Hz.
Frequency Response Measure (FRM)
The median of all Single Event Frequency Response Data observations reported annually on FRS Form 1.
Frequency Response Obligation (FRO)
The Balancing Authority's contribution to the total aggregate Frequency Response needed for reliable operation of an Interconnection assigned by the ERO.

Do you agree with the proposed definitions in this standard? If not, please explain in the comment area.Yes
$\square$ No
Comments:
2. The SDT has modified the definition for the term Frequency Bias Setting. The new definition is shown below in redline to show the changes proposed.

Frequency Bias Setting
A value, (either a fixed or variable Frequency Bias), usually expressed in MW/0.1 Hz, set into a Balancing Authority Area Control Error algorithm-equation that allows the Balancing Authority to contribute its frequency-Frequency $f$ Response to the Interconnection.

Do you agree with this new definition for Frequency Bias Setting? If not, please explain in the comment area.YesNo
Comments:
3. The proposed purpose statement in the draft standard is:

To require sufficient Frequency Response from the Balancing Authority to maintain Interconnection Frequency within predefined bounds by arresting frequency deviations and supporting frequency until the frequency is restored to schedule. To provide consistent methods for measuring Frequency Response and determining the Frequency Bias Setting.

Do you agree with this purpose? If not, please explain in the comment area.Yes
Comments:
4. Requirement 1 identifies a minimum level of Frequency Response.

R1. Each Balancing Authority shall achieve a Frequency Response Measure (FRM) (as detailed in Attachment A and calculated on FRS Form 1) that is equal to or more negative than its Frequency Response Obligation (FRO).

Do you agree with the concept that a Balancing Authority should be required to achieve a minimum level of Frequency Response and the method for measurement? If not, please explain in the comment area.YesNo
Comments:
5. Requirement 2 identifies when the Balancing Authority must implement its Frequency Bias Setting.

R2. Each Balancing Authority shall implement the Frequency Bias Setting (fixed or variable) provided by the ERO into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effective coordinated secondary control, using the results from the calculation methodology detailed in Attachment A.

Do you agree with this implementation? If not, please explain in the comment area.
$\square$ No
Comments:
6. Requirement 3 mandates that a Balancing Authority operate its Automatic Generation Control (AGC) on Tie Line Bias unless it becomes adverse to the integrity of its system.

R3. Each Balancing Authority shall operate its Automatic Generation Control (AGC) on Tie Line Bias, unless such operation would have an Adverse Reliability Impact on the Balancing Authority's Area.
Do you agree that a Balancing Authority should operate its AGC on Tie Line Bias unless it becomes adverse to its system? If not, please explain in the comment area below.Yes
$\square$ No
Comments:
7. Do you agree with the proposed Implementation Plan for this standard? If not, please explain in the comment area.
$\square$ No
Comments:
8. This standard proposes to eliminate the $1 \%$ minimum Frequency Bias over a period of 4 years as outlined in the Implementation Plan. Do you agree that the elimination of the $1 \%$ minimum will bring Frequency Bias closer or equal to natural Frequency Response? If not, please explain in the comment area.Yes
$\square$ No
Comments:
9. Do you agree with the drafting team that this standard should be field tested? If not, please explain in the comment area.

$\square$ No
Comments:
10. Attachment A of the proposed standard describes the criteria for selecting events to be analyzed. Do you agree with the criteria as described in Attached A? If not, please explain in the comment area.No
Comments:
11. The proposed standard has a document attached to it that describes the SDT's reasoning for the Requirements (Attachment A - Frequency Response Background Document). Do you agree with the SDT that this document is useful and provides a clear understanding of the Requirements? If not, please explain in the comment area.YesNo
Comments:
12. The proposed standard requires the use of FRS Form 1 for calculating a Balancing Authority's FRM. Do you agree with the SDT that this is the proper method to calculate its FRM? If not, please explain in the comment area and if possible provide an alternate method to calculate FRM.Yes
Comments:
13. The proposed standard requires the use of FRS Form 1 for calculating a Balancing Authority's Frequency Bias Setting. Do you agree with the SDT that this is the proper method to calculate its Frequency Bias Setting? If not, please explain in the comment area and if possible provide an alternate method to calculate Frequency Bias Setting.
$\square$ No
Comments:
14. The SDT has provided a document (FRS Form 1 Instructions) describing how to use FRS Form 1 for calculating FRM and Frequency Bias Setting. Do you agree with the SDT that this document provides a clear understanding of how to use the form? If not, please explain in the comment area.Yes
No
Comments:
15. The SDT is soliciting comments on methods of obtaining Frequency Response to meet the FERC Order 693 directive. If possible please provide any thoughts you may have on this subject.

Comments:
16. If you are aware of any conflicts between the proposed standard and any regulatory function, rule order, tariff, rate schedule, legislative requirement, or agreement please identify the conflict here.

Comments:
17. Please provide any other comments (that you have not already provided in response to the questions above) that you have on the draft standard BAL-003-1.
Comments:

## NERC

NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

## Frequency Response Standard Field Test Document

February 2011

February 2011

## Need for a Field test

To expedite the delivery of a Frequency Response Standard ${ }^{1}$ the draft BAL-003-1 is built upon the traditional annual Frequency Bias Setting calculation. This approach will enable using 2010 event data as a field test of specific aspects of the standard that have never been validated industry-wide. The proposed field test is intended to facilitate the delivery of a technically sound standard as soon as possible. The reasoning and approach for the components of the field test are described below. The field test will be modified if the draft standard changes on the basis of industry comments.

## Frequency Bias Setting Floor

BAL-003-1 proposes to bring Frequency Bias Settings closer to Frequency Response. The drafting team proposes to reduce the minimum Frequency Bias Settings over a period of years. The drafting team proposes to establish a new minimum Frequency Bias Setting in 2011 (-0.8\% of peak $/ 0.1 \mathrm{~Hz}$, compared to the present $-1 \%$ of peak $/ 0.1 \mathrm{~Hz}$ ). The drafting team, NERC and the Resources Subcommittee will observe the impact on frequency and will implement a reversion plan as necessary.

## Impact on other Balancing Standards

Changes in Frequency Bias Settings may have secondary impacts on calculated performance in other balancing standards. For example, with a reduced bias, L10 values tighten. The drafting team will evaluate the impact on other balancing standards.

## Evaluating Other Options

The drafting team is evaluating other approaches to evaluate risk and performance obligation. This evaluation will be done in parallel during the field test period using the same underlying data and other data (such as ACE) that will be available without additional effort on the part of Balancing Authorities.

## Confirm Calculation and Allocation Methodologies

While the general principles of Frequency Response are understood by Balancing Authorities, there has never been a common methodology for measuring and analyzing Frequency Response. The drafting team will evaluate the following aspects of the standard during the field test:

- The measurement methodology for Balancing Authorities with large amounts of nonconforming load. This is because the impact of non conforming load on $\mathrm{NI}_{\mathrm{A}}$ for a small Balancing Authority can be an order of magnitude greater than the Balancing Authority's Frequency Response. The drafting team will solicit volunteer Balancing Authorities to test a

[^49]secondary measure that may be superior for measuring Frequency Response in these situations.

- The validity of the measurement methodology for the full spectrum of Balancing Authorities (fixed vs. variable Frequency Bias Settings, large vs. small, load-only, generation-only).
- The variability of calculated Frequency Response (load’s Frequency Response, governor response, plus Frequency Response from other technologies).
- Evaluate the event-selection criteria (differences in starting and settling frequency).

NORTH AMERICAN ELECTRIC

## Standards Announcement

## Project 2007-12 Frequency Response <br> Comment Period Open February 4 - March 7, 2011

Now available at: http://www.nerc.com/filez/standards/Frequency Response.html

## Formal 30-day Comment Period Open through 8 p.m. on March 7, 2011

BAL-003-1 - Frequency Response and Frequency Bias Setting, and associated documents including the required Form 1, Instructions for Form 1, Attachment A, proposal for a field test, and implementation plan have been posted for a 30-day formal comment period.

## Instructions

Please use this electronic form to submit comments. If you experience any difficulties in using the electronic form, please contact Monica Benson at monica.benson@nerc.net. An off-line, unofficial copy of the comment form is posted on the project page: http://www.nerc.com/filez/standards/Frequency_Response.html

## Next Steps

The drafting team will consider all comments and determine whether to make additional changes to the standard. The team will post its response to comments and, if changes are made to the standard and supporting documents, submit the revised documents for quality review prior to the next posting.

## Project Background

Frequency Response, a measure of an Interconnection's ability to stabilize frequency immediately following the sudden loss of generation or load, is a critical component to the reliable operation of the bulk power system, particularly during disturbances and restoration. The proposed standard's intent is to collect data needed to accurately analyze existing Frequency Response, set a minimum Frequency Response obligation, provide a uniform calculation of Frequency Bias Settings that transition to values closer to Frequency Response, and encourage coordinated AGC operation. There is evidence of continuing decline in Frequency Response over the past 10 years, but no confirmed reason for the apparent decline. The proposed standard requires entities to provide data so that Frequency Response in each of the Interconnections can be analyzed, and the reasons for the decline in Frequency Response can be identified. Once Frequency Response has been analyzed and confirmed, requirements can be modified to maintain reliability.

## Standards Process

The Standard Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

For more information or assistance, please contact Monica Benson, Standards Process Administrator, at monica.benson@nerc.net or at 609.452.8060.

| A Balancing Authority's frequency response is based upon a "median" value calculated from analyzing multiple events. |
| Frequency response during some of these events is better than others, depending on the system conditions at the time |
| and the amount system loading and unloaded generation online at the time of the event. Given these circumstances a |
| BA's actual response could vary by event (better or worse than median), thus compliance measurement per event to a |
| frequency response obligation based on the median response (over multiple events) could put BA's in non-compliant |
| situations unjustly. |
| Yes |

## Yes

No
Comment 9: I agree that each BA should be required to provide a minimum level of Frequency Response to provide for its share of the total Frequency Response required for interconnection reliability. Comment 10: I also agree with the methods used to measure SEFRD subject to my comments on FRS Form 1. Comment 11: I do not agree that the method suggested for setting the FRO will achieve the desired goal of maintaining interconnection reliability. The measurement method offered only evaluates the supply of Frequency Response. It does not evaluate the demand (need) for Frequency Response. Since frequency error is the difference between the demand and supply any effective measure for maintaining reliability due to frequency error must include both the demand and supply parts of this balance. As a consequence, the method will be blind to changes (good or bad) in the demand for Frequency Response. Changes in the demand for Frequency Response will require subsequent changes in the supply for Frequency Response that this standard fails to address until the following year and leaves the interconnection at risk for unreliable operation. Comment 12: The requirements associated with Frequency Response as defined in this standard will not assure interconnection reliability. Frequency Response is a two part service. The first part of this service is the rate at which energy is supplied in proportion to frequency error. This first part is commonly represented as the Frequency Response and the corresponding Frequency Bias Setting. The second part of the service is the amount of capacity that the BA stands ready to supply at this stated proportion in response to frequency error. Failure to effectively specify and measure the amount of capacity that the BA stands ready to supply at the stated proportion could put the interconnection at reliability risk when the required amount of capacity is not included in the operating plan.
No
Comment 13: I agree that the BA shall implement the Frequency Bias Setting provided by the ERO into it Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effective coordinated secondary control. Comment 14: I do not agree that the results from the calculation methodology detailed in Attachment $A$ will provide the correct Frequency Bias Setting. My comments on the calculation methodology are included elsewhere in my comments on Attachment A and FRS Form 1.
No
Comment 15: Requirement 3 as written is unenforceable because it is too difficult to define "unless such operation would have an Adverse Reliability Impact on the Balancing Authority's Area." Comment 16: What if operation out of Tie line Bias control does not have an Adverse Reliability Impact on the Balancing Authority's Area, but does have an Adverse Reliability Impact on another BA? Comment 17: A document follows that provides an initial starting justification for the elimination of this Requirement. See following "Requirements for AGC Operation, January 25, 2011."
Requirements for AGC Operation, January 25, 2011 Introduction: As of the date of these comments there are two requirements in the NERC Standards that address the operation of AGC. The first is in BAL-003-0.1b - Frequency Response and Bias, Requirement R3. R3. Each Balancing Authority shall operate its Automatic Generation Control (AGC) on Tie Line Frequency Bias, unless such operation is adverse to system or Interconnection reliability. The second is in BAL-005-0.1b - Automatic Generation Control, Requirement R7. R7. The Balancing Authority shall operate AGC continuously unless such operation adversely impacts the reliability of the Interconnection. If AGC has become inoperative, the Balancing Authority shall use manual control to adjust generation to maintain the Net Scheduled Interchange. These requirements are misdirected and, for compliance purposes, they are difficult to measure effectively. This paper provides the technical basis for replacing these requirements with new requirements that will not only achieve the intent of these requirements, but do so in a more effective and measurable manner. Background: Automatic Generation Control (AGC) is a computer control system contained in the Control Center EMS that performs a number of critical functions related to the balancing function necessary to maintain frequency and associated reliability. Among the functions it performs are: 1) the collection of telemetered and local data useful for determining the appropriate control actions, 2) the calculation of Area Control Error (ACE), 3) determination of desired control actions that should be sent to those resources available for automatic dispatch, and 4) sending the actual control signals to implement that dispatch. Most AGC Systems have three basic modes of operation, 1) Tie-line Frequency Bias, 2) Constant Net Interchange and 3) Constant Frequency. The ACE Equation is the basis for all three modes of operation. In the Tie-line Frequency Bias mode, all of the ACE Equation is used as an input to control action determination. In the Constant Net Interchange mode, only the Tie-line Error portion of the ACE Equation is used as an input to control action determination. The Constant Net Interchange mode would normally be used when there is no information available to indicate interconnection frequency. In the Constant Frequency mode, only the Frequency Bias portion of the ACE Equation is used as an input to control action determination. The Constant Frequency mode of operation would be used when the Tie-line Error is known to be misleading, inaccurate or unavailable. It is also used when there are no tie-lines in service as in the case of a single BA interconnection or during islanded operation. AGC Systems have been used in the industry since before the development of digital computers. Initially AGC Systems did little more than send instructions to generators based on evaluation of the ACE Equation. They have become more sophisticated since their inception and implement greater complexity in their evaluations of appropriate dispatch actions to the point that they include forecasting, reliability and economics within their algorithms. Modern AGC Systems determine control actions based on the collection of much more data than is included in the ACE Equation. This additional data includes: short-term load forecasts and forecast error estimates as influenced by weather; individual
non-conforming load forecasts and forecast error; forecast interchange transaction information; generating unit ramp and response rates; generating unit economic operating points including valve position; generating unit incremental economic costs including start-up and maintenance; Hydro unit river flow limits as related to the operation of other units on the same waterway; energy storage capabilities and available energy; Inadvertent Interchange energy account balances; time error; and current control performance scores. As AGC Systems have evolved, the control mode in which they are operating, Tie-line Frequency Bias, Constant Net Interchange, or Constant Frequency, provides less and less information about the control actions that they implement. In a modern AGC System the control mode provides little information about how control actions are being determined and implemented. In fact, only someone experienced in AGC programming and implementation would have the knowledge necessary to determine whether or not an AGC System is providing reasonable control actions or control actions consistent with Tie-line Frequency Bias Control. Even someone with the necessary experience observing the operation of a modern AGC System for a short period of time will be incapable of determining whether or not that system is providing effective or adequate control. Therefore, neither of the two requirements is effectively enforceable from a practical point of view. Perspective: A couple of examples are offered to add perspective to the problem. Example 1: R3 includes the requirement, "Each Balancing Authority shall operate its Automatic Generation Control (AGC) on Tie Line Frequency Bias, unless such operation is adverse to system or Interconnection reliability." There are three conditions when operation on Tie-line Frequency Bias control may be adverse to the system or Interconnection reliability. 1. The first is when the Tie-line Error data used in the ACE Equation is incorrect. The ACE Equation will be incorrect when there are errors in the Actual or Scheduled Tie-line flow values. This condition will occur when there is telemetry failure of one or more tielines, when there is an unidentified scheduling error, or when there is a separation that causes a tie-line metering point to be located on a separate island due to interconnection separation or islanding. Telemetry failure will be indicated by the quality bits associated with the Tie-line telemetry. If AGC is disabled to identify a scheduling error, there should be an operating log entry. If AGC is disabled because of a separation, there will also be a log entry. 2. The second is when the actual frequency is determined to be incorrect. If measured frequency is incorrect, this condition should be indicated by an operating log entry and transfer to the redundant frequency device to provide measured frequency. When the actual frequency fails, this condition will be indicated by the quality bits associated with the measured frequency value and transfer to the redundant frequency device to provide measured frequency. 3. The third is when operation of AGC would provide control different from the desired control to address some emergency condition in the BA or elsewhere on the interconnection. If the operation of AGC would be adverse to system or Interconnection reliability and is disabled for this reason, this condition should be indicated by an operating log entry. In all cases, there should be a record of the reason for the use of other than Tie-line Frequency Bias control and records indicating the reason for the use of other control modes. In all cases, other than the third indicated above, an error in the value of ACE is the reason for not using Tie-line Bias Control and the quality bits for ACE or ACE component data should provide a reasonable explanation for the condition. The third case occurs with such infrequency that there should be no need for a special rule to address this condition. Example 2: R7 includes the requirement, "...If AGC has become inoperative, the Balancing Authority shall use manual control to adjust generation to maintain the Net Scheduled Interchange." Cases have been observed of an AGC System that does not perform as well as the manual dispatch used when the AGC System is inoperative. If a BA has a CPS1 score of $120 \%$ when using AGC and a CPS1 score of $125 \%$ when performing manual dispatch, should that BA be penalized for not having its AGC continuously operating? What is the goal? Is the goal to operate on AGC regardless of the result or is the goal to operate in a manner that provides the best measured control? Alternatives: Since these requirements are not effectively measurable or enforceable, can a requirement or requirements be written to provide an equivalent to the intent of the old requirements addressing AGC operation? The industry has three alternatives to address this issue: 1. Retain requirements that are directed at the AGC System understanding that they are effectively not measureable or enforceable. 2. Eliminate requirements that are directed at the AGC System with the understanding that they were not contributing to reliability. 3. Determine an alternative method to evaluate, measure and enforce a requirement that will achieve a goal similar to the goal originally intended by the implementation of the AGC System requirements. Elimination of the requirement is an appropriate solution. However, if it is determined that a replacement measure is required, then the solution to this problem lies with the third alternative above. Solution: There is already a requirement that effectively enforces the intent of the above requirements. Instead of requiring the BA to control in a particular manner, CPS1, BAAL and DCS require the BA to achieve specific results with their control actions. All three measures require the BA to calculate ACE using Tie-line Frequency Bias for determination of their Reporting ACE. The requirements specify that at least $50 \%$ of the data must be valid for the one-minute average data to be included in the measures. The requirements for redundant frequency measurement devices assure that the BA will have the actual frequency data available to perform the necessary calculations. The data retention requirements specify the data they must retain to demonstrate that their control achieved the stated goals. Finally, this approach is consistent with the White House Executive Order on Improving Regulation and Regulatory Review in Section 1(b)(4) stating that regulatory agencies must: "to the extent feasible, specify performance objectives, rather than specifying the behavior or manner of compliance that the regulated entities must adopt;..."
No
Comment 18: The Proposed Effective Date in the implementation plan is inconsistent with the Effective Data in the Draft Standard. Comment 19: The completion of the implementation plan does not occur until 2015. This lengthy plan stems from a standard that only measures reliability annually and provides only an annual window for changing parameters such as Minimum Frequency Response. Alternative methods that measure reliability more frequently could me implemented with a shorter implementation plan.

Frequency Bias Setting A value, (either a fixed or variable Frequency Bias), usually expressed in MW/0.1 Hz, set into a Balancing Authority Area Control Error algorithm equation that allows the Balancing Authority to contribute its frequency Frequency rResponse to the Interconnection. Comments: Not sure the word "allows" is the right word. Perhaps use something in terms of preventing withdrawal of Primary Frequency Response with words like "...equation that prevents the withdrawal of the Balancing Authority's Primary Frequency Response to the Interconnection." Yes

No
Comments: Proposed Standard Comment 1: BAL-003-1, Requirement R1. The requirement should be made less prescriptive by removing references to Attachment A and FRS Form 1. The responsible entity should understand the fundamental and basic requirement - to achieve a Frequency Response Measure. Where the methodology is specified or how the BA is supposed to achieve it should be a matter of compliance and/or implementation and not a part of the basic requirement. Proposed language is as follows: Each Balancing Authority shall achieve a Frequency Response Measure (FRM) that is equal to or more negative than its Frequency Response Obligation (FRO).
No
Comments: Comment 2: BAL-003-1, Requirement R2. The requirement should be made less prescriptive by removing references to the calculation methodology and Attachment $A$. The responsible entity should understand the fundamental and basic requirement - to implement the Frequency Bias Setting into its Areas Control Error calculation. Proposed language is as follows: Each Balancing Authority shall implement the Frequency Bias Setting (fixed or variable) provided by the ERO into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effective coordinated secondary control. Comment 3: BAL-003-1, Requirement R2 and Section 1.4 Additional Compliance Information. The SDT should consider whether or not the ERO has compliance obligations pursuant to the obligations mentioned in the proposed Standard. Requirement R2, states that the ERO should provide the BA with the Frequency Bias Setting and the specified date to begin the calculation. The R1 Supplemental Information section states that the ERO is obligated to post the official list of events. The R2 Supplemental Information section states that the ERO is obligated to validate the FRM and Frequency Bias Settings and disseminate the Frequency Bias Settings Report along with the implementation date. These obligations should be confirmed and properly incorporated into Standard if appropriate.
No
Comments: Agree only to the extent that an accurate frequency measurement is available to the BA . If not frequency measurement is available, then that should be considered an adverse condition and thus TLB is not appropriate. In other words, one small BA maintaining TLB may not cause the condition in the Glossary definition of Adverse Reliability Impact but it is still not appropriate for them to stay on TLB.
Yes
We did not want to vote on Question 7, but clicked 'yes' in error.

No
For FRM, why is median used rather than average? The method in the standard for dsetermining FRM needs to allow for excluding some events due to non-conforming loads, scan rates, intermittent resources, large interchange ramps, etc that may cause the actual response during the 16 seconds to actually be opposite of the expected response.
No
We propose the following: A value, (either a fixed or variable), expressed in MW/0.1 Hz, set into a Balancing Authority Area Control Error equation that allows the Balancing Authority to contribute its SECONDARY Frequency Response to the Interconnection.
Yes
No
The lagging measure is a concern. The ERO should be required to provide an updated proposed/possible list of frequency events monthly so BA's can determine their FRM through out the year so corrective action can be taken if needed. Prior year events should be excluded (just to get to 25 events). This could result in begin non-compliant twice for the same events.
Yes

Yes

Yes
Yes, if field testing validates the standard.

definition should be: The Balancing Authority's annual median frequency response as assigned by the ERO (or NERC). The word "contribution" should be considered to be replaced with "the balancing authority piece of the total....." The standard does not explain who will determine the value of each BA's FRO nor the method used to determine the FRO value. Should the definition of Frequency Response Measure be a median or mean value?
No
We suggest the following changes to the definition: 1. Delete the word "usually" 2. Replace "set into" with "as part of". 3. Replace the remainder of the sentence following "Area Control Error equation" with "that influences its Automatic Generation Control (AGC) to provide its frequency response while Interconnection frequency is not at its scheduled value" - (The frequency bias does not allow a BA to contribute its frequency response to the Interconnection. The frequency bias term only affects the AGC response of the BA, which is part of its frequency response usually minutes after the initial event and is dependent upon generation units being on AGC control and capable of responding.) 4. The suggested changes would result in the following definition: A value, (either a fixed or variable Frequency Bias), expressed in MW/0.1 hertz as part of a Balancing Authority's Area Control Error (ACE) equation that influences its Automatic Generation Control (AGC) to provide its frequency response while Interconnection frequency is not at its scheduled value.
No
The proposed purpose statement as provided in this question is not the same as the purpose statement for BAL-003-1 as posted on the Project 2007-12 page of the NERC website. The posted purpose on the NERC website is: To require sufficient Frequency Response from the Balancing Authority to maintain Interconnection Frequency within predefined bounds by arresting frequency deviations and supporting frequency until the frequency is restored. To schedule and provide consistent methods for measuring Frequency Response and determining the Frequency Bias Setting. The version posted in the question appears to correct errors in the last sentence of the purpose statement given in the project page. We do not agree with the purpose statement as posted on the project page. In addition, we suggest the following edits to what appears to be a corrected purpose statement as provided in this question: To require sufficient Frequency Response from the Balancing Authority to maintain Interconnection Frequency within predefined bounds by arresting frequency deviations due to contingencies on the interconnected BES and supporting frequency until the frequency is restored to schedule. To provide consistent methods for measuring Frequency Response and determining the Frequency Bias Setting. As NERC/FERC has differentiated Frequency Response from Frequency Regulation, the standards addressing Frequency Response should clearly be related to unplanned contingencies occurring on the interconnected BES.

The concept seems reasonable but since the measure of compliance (FRM) is determined only after the 25 events are identified; it is a lagging indicator. The BA may have to ensure it measures all frequency excursions and develops its own leading indicator to ensure compliance following year end. A sample CPS bounds report should be considered, perhaps based on 2010 numbers, to demonstrate how FRM submitted would translate to FRO frequency bias settings and how it will affect the L10 values
No
It is not clear what the methodology (should be method) is in Attachment A. Is the frequency bias setting the BA's prior year FRM with a minimum value being a percentage of estimated yearly peak load or upcoming year maximum generation? What does "provided by the ERO" mean? Perhaps it should be verified or approved by the ERO (NERC).
No
BAL-003-0, Requirement 3 requires operation of AGC on Tie Line Frequency Bias. BAL-005-0.1b, Requirement 6 requires the BA to compare total Net Interchange to total Net Scheduled Interchange plus Frequency Bias obligation to determine the Balancing Authority's ACE. We suggest that Requirement 3 be restated to "shall operate its Automatic Generation Control (AGC) on Tie Line Frequency Bias, unless ........" Tie Line bias is the (Ia-Is) term and frequency bias is the -10B(Fa-Fs) term. This should be coordinated with BARCSDT modifications to BAL-005.
No
The implementation plan has specific dates for reducing the bias settings currently defined in Requirement 5 over several years. Perhaps these dates should not be specific but tied to months following regulatory approval. Attachment A should be modified to match what is in the proposed standard. The values currently shown as percent "of peak/0.1 Hz " should be changed to percent of estimated yearly peak demand per 0.1 Hz change. For BAs that do not serve native load, percent "of upcoming years maximum generation/ 0.1 Hz should be changed to percent of its estimated maximum generation level in the coming year/ 0.1 Hz change

No
The proposed definition for SEFRD assumes that there is no change in the Net Scheduled Interchange (NIS) as a result of the event. However, a dynamic schedule for load or generation based on data obtained with a two second scan rate will impact the NIS, and therefore the corresponding load or generation response will offset the change to NIA. Therefore, the definition of SEFRD should replace "NIA" with "change in NIA minus NIS".

No
A bias, either fixed or variable, usually expressed in MW/0.1 Hz, included in a Balancing Authority's Area Control Error equation to account for the Balancing Authority's Frequency Response contribution to the interconnection, and prevent response withdrawal through secondary control systems. The changes suggested are to clarify that biasing of the ACE equation "allow[s]" primary frequency response to continue beyond the initial event window by accounting for it in the ACE input to secondary control systems (i.e. AGC). It's important to note that Primary Frequency Response will occur no matter what the Bias value is set to in the ACE equation, and biasing "supports" the response until the frequency is restored".

## Yes

No
Progress Energy believes the Eastern Interconnection does not have the same issues with frequency experienced in the other two interconnections, and that load response is significant enough in the interconnection to arrest and stabilize frequency as long as BAs do not withdraw that effect (accurate biasing of the ACE equation). We also believe this standard should reference standrd PRC-024 related to accurate relay settings to allow out of bounds operations related to frequency and voltage deviations.
Yes
Yes
No
We agree with the graduated implementation for the FRO portion of the standard, but feel NERC needs to losen the minimum frequency bias requirement immediately so that it matches the newly required frequency response. There are also other areas within the EMS the besides BA's frequency bias that should be addressed such as secondary frequency response systems that should also be included in this standard. Additionally, if the industry was truly concerned with matching bias values to actual response, they would swich to variable frequency bias. Variable bias requires additional up front work along with general maintenance, but it truly is the best way to accurately bias the ACE equation.

No
The definition of SEFRD will not work as described for a single BA Interconnection. There is no change in NI for frequency deviations. Similarly, the definition assumes all response is provided by change in Interchange and does not really reflect the frequency response of a contingent BA. Either the definition needs to be changed to accommodate single BA Interconnections (such as ERCOT and Hydro Quebec), or regional variances for them need to be written by the SDT. A BA's frequency response is composed of load frequency response, governor response, and, for BAs external to the resource loss, change in Net Interchange. Some approximation may be achieved by recognizing that the magnitude of frequency deviation is attenuated by load frequency response and governor response (or frequency activated demand response to reduce load). The definition of FRM specifies the median of all SEFRD observations reported annually. What is the technical basis for selecting the median rather than the mean? The definition of FRO raises questions. The discretely administered determination of FRO described in the draft Attachment A sets too stringent a requirement; particularly for the smaller Interconnections which may also have large size generation resources just as do the larger Interconnections. To "assure that Point C will not encroach on the first step UFLS" is significantly more stringent than existing and historical performance for those smaller Interconnections. Such assurance will assuredly prove to be very expensive. In fact, we question the need to define FRM and FRO since they can easily be stipulated in the standard requirements. Having them defined and added to the ever-growing NERC glossary creates unnecessary work to maintain the glossary, unless these terms are used by other NERC standards for which consistent meaning need to be established. For example, R1 can easily be reworded as: "R1: Each Balancing Authority shall achieve a median of all Single Event Frequency Response Data observations reported annually on FRS Form 1 that is equal to or more negative than its contribution obligation to the total aggregate Frequency Response needed for reliable operation of an Interconnection assigned by the ERO." Similar wording changes can be made to the FRS Form 1 to eliminate the need to define these two terms. Further, the Attachment A states that the SDT is evaluating a risk based approach to establishing an Interconnection Frequency Response Obligation which can be based on a probability function. If the N-2 criteria is established, it will be unlikely to be possible to change that if the new approach is viewed as a reduction in required performance. As an example, in the ERCOT Interconnection, it is recognized that the present level of required frequency responsive reserve cannot in all scenarios assure that Point C will not encroach the first step of UFLS. The system conditions that exist for the encroachment to occur represent a small likelihood and would require the $\mathrm{N}-2$ contingency to occur on something like the minimum hour of the minimum load day of the year. It has occurred one time in the history of ERCOT. Thus, it is less than once in ten years based upon actual history. The cost of precluding such an event would be astronomical.

No
The definition appears to be accurate, but where is "fixed" and "variable" Frequency Bias defined in the context of these requirements? Should it be Frequency Bias Setting, instead? "Fixed" seems to be straightforward, but what is "variable"? How often must Frequency Bias Setting change in order to be considered to be "variable"?
No
If this is really intended to be a Field Trial, it should be written as such and the standard should not be developed or promulgated until the Field Trial has accomplished its purpose and the performance criteria and measures have been determined. We request that the results of the Field Trial should be published and discussed BEFORE any changes are made. The standard should be put into place later; it is premature at this time. Since this is to be a data gathering process to be used to determine appropriate performance parameters, the purpose statement of the Field Trial should be changed to read as follows: To determine require sufficient Frequency Response arranged by from the Balancing Authority to maintain Interconnection Frequency within predefined bounds by responding to and arresting frequency deviations and supporting frequency until the frequency is restored to schedule. To identify and establish provide consistent methods for measuring Frequency Response and determining the Frequency Bias Setting and Frequency Response Obligation. We should not write the new standard and its requirements until this Field Trial work has been accomplished; to do so possibly would result in difficulty changing the standard requirements based upon Field Trial results. Further, while we do not have any issue with the general intent of the scope statement, we have a difficulty seeing the BA being the only entity held responsible for maintaining interconnection frequency and arresting frequency deviations. When there is a sudden and sizable change to system resource or demand, the first response to a frequency deviation caused by this change would be the generators' governors. This will provide a mitigating effect for the immediate seconds up to minutes. The frequency bias setting will then kick in to supplement the mitigation need. The governors are owned by the Generator Owners; the BAs do not own these facilities and hence can do little to address frequency response during this initial period. To hold only the BA responsible for maintaining interconnection frequency and arresting frequency deviations would be inappropriate. The industry needs to have a discussion to determine who should be held responsible for providing governor responses immediately following an event, and by what mechanism, and for implementing additional measures thereafter. We suggest that BAL-003 development be withheld until this discussion takes place and a decision is made on who and how the governor response shall be provided.
No
The SRC agrees that a Frequency Response of some minimum level for each Interconnection should be achieved. However, the measure as described does not apply to all Interconnections. It does not apply to single BA Interconnections such as ERCOT and Hydro Quebec. This requirement should be added later-not included now; and it should clarify what the BA must do and what the response providers must do. BAs do not own and operate the resources. An entity which does own or operate the resources may also be registered as a BA, but an entity which does not own or operate resources may also be registered as a BA. Therefore, it is important to detail what a BA must do and also to detail what the resource owner or operator must do. The resource owner may be registered as a GO or a TO or even a DP. The resource operator may be registered as a GOP, a TOP, or a LSE. The BA must establish an operations plan, using data provided to it by the resource owners and or operators, that will meet the performance requirements. The BA must then deploy the proper amount of response through AGC or verbal instructions to supplement the automatic responses that the resources will provide, must calculate the actual responses after-the-fact, and report the performance as required. The resources must, as standards already provide, comply with the deployments and instructions provided by the BA. However, if an entity which is functioning as a BA does not own its resources, nor does it directly operate those resources, the BA cannot ensure the achievement. The standard must not create an organizational or contractual arrangement that dictates how the compliance is provided. It should state what must be done, not how. If entities choose to write and enter into such arrangements, that should be permissible, but not required. Specific to R1, the wording does not correspond to the figures shown in the FRS (Form 1) in that the FRM (the median) is -14.5 whereas the FRO is -15.8 . The FRO is more negative than the FRM, which does not seem to correspond to what's stipulated in R1 (FRM to be equal or more negative than its FRO).
No
It is not clear how the ERO uses the FRM to determine the required Frequency Bias Settings. It should not be necessary for the ERO to do the determination for all the Interconnections. There are already in place methods for this by the existing ERCOT and WECC Interconnections. The SRC suggests that the ERO may not be the appropriate technical entity. The ERO may be the appropriate entity to serve as the receiver of the forms and analyze results for the Eastern Interconnection, but existing processes are already in place elsewhere. It should be sufficient that those processes continue and submit copies of Form 1 to the ERO. This may also be appropriate for Hydro Quebec. In addition, whichever entity determines the Frequency Bias Setting must provide implementation time for the BAs to implement the settings. The proposed language says only that the BA shall implement it on the date specified, but it doesn't address the need for that date to include some implementation time.

## No

Single BA Interconnections do not operate on Tie Line Bias. The requirement should be modified to accommodate this or regional variances should be written by the SDT to address existing differences. In addition this requirement, as written, does not provide for momentary cessation of AGC for any reason, nor for reasonable system maintenance, repair, or updates. As written, it seems to sav that anv duration of operation off Tie Line Bias is unacceptable and, thus.

| would be a violation. |  |
| :---: | :---: |
| No |  |
| What is the technical basis for the phase-out schedule? Making the standard requirements effective earlier than the schedule shown could result in the unintended consequence of non-compliance enforcement for performance that is caused by the change rather than by the non-performance of the functional entity. Also, the effective dates given in the Implementation differ from those in the draft standard. Different requirement numbers are expressed in each. Some of the implementation steps (retiring R5 of BAL-003-0) presented in the implementation plan start as early as May 2011. We do not believe that the BAL-003-1 standard will be approved by the industry or the NERC BoT at that time and that does not even take into account regulatory approval (or 12 months after BoT adoption in those jurisdictions where no regulatory approval is required). How can a standard begins to phase out while the successor standard is not anywhere near becoming effective? If the SDT wants to propose a gradual replacement of the current R5, we would suggest that the phase-out steps be tied to the date that the standard becomes effective. |  |

| For Frequency Response Measure, the drafting team should consider using average rather than median. Because median is literally the middle value, a Balancing Authority could have 12 really bad Single Event Frequency Response Data points and still comply. Average values would prevent this from happening. Should FRM be clear that it includes at least 25 events in the definition? While that can be garnered from Attachment $A$, it is not specified in the Form 1 instructions. We are concerned that the regulators may argue that 25 events do not apply because an attachment is not part of the standard. |  |
| No |  |
| Given that frequency response is "contributed" long before AGC has an impact, "contribute" should probably be changed to "maintain." The goal is to ensure AGC does not withdraw frequency response and that it is maintained while frequency is depressed. We are not sure if Frequency Response has a precise enough definition and it is part of the definition of Frequency Bias Setting. The current NERC Glossary definition of Frequency Response really just reflects how it is measured, it does not define Frequency Response. Frequency Response is the dynamic real power response of load, generation, and other devices to a perturbation in frequency. The drafting team should also consider resolving the definition of Frequency Bias. Is it needed? It is often confused with Frequency Bias Setting and is often used interchangeably with Frequency Response even though the meanings are slightly different. |  |
| No |  |
| In general, we don't have significant issues with a standard that attempts to establish a minimum Frequency Response performance level. However, we caution the drafting team that the minimum level established needs to be determined based on an extensive data analysis, field trial data, the Frequency Response Initiative Work Plan that NERC filed in response to the Commission's September 23 technical conference, and the plan outlined in NERC's October 25, 2010 compliance filing. |  |

| Flexibility established in the date is better than the existing currently defined date in the standards. It is better to allow the ERO to specify the date to allow some flexibility in implementation. It appears that the responsibility for identifying Frequency Bias Setting is being removed from the Balancing Authority. There is an implied obligation that the ERO will determine the Frequency Bias Setting but it is not stated explicitly. Thus, we are left wondering who has the responsibility for determining the Frequency Bias Setting. Frequency Response of the interconnection is constantly changing. As a result, the Frequency Bias Setting will never match the Frequency Response exactly. It is better to over-bias than under-bias to prevent withdrawal of frequency response by AGC. Historically, the $1 \%$ floor for frequency bias setting was chosen to ensure that BAs are always over-biased. The standard needs to allow some margin in the frequency bias setting to ensure that the bias setting is over-biased. |  |

We agree with the plan to phase out BAL-003-0.1b R5 over a period of years rather than abruptly terminate it because it will take several years to assess the impact. We recommend a wording change to the implementation plan. Please change 'BAL-003-0 Requirement 5 should be retired as outlined in the following table," to "BAL-003-0.1b Requirement 5 should be phased out by reducing the minimum frequency bias setting per the table." It is not clear if the minimum frequency bias setting can be modified without modifying the existing BAL-003-0.1b standard. Is this being accomplished through the field trial? The implementation plan makes no mention of a field trial. It should. Please change all BAL-003-0 to BAL-003-0.1b.

Yes
For the definition of FRM, we are not clear as to the rationale for choosing the median value instead of the mean. Yes
Although we support the definition, we suggest the word "contribute" be changed to "maintain".

between the separate versions of the standard. Rather than create and prolong this type of situation over a 4 year time period, BPA asks that BAL-003-0 be retired in its entirety and that the contents of BAL-003-1 be expanded to also include R5, as specified in BAL-003-0. This change resolves the identified issues while also ensuring that all requirements of BAL-005 are in effect, as originally intended. The Implementation Plan for BAL-003-1 also includes a proposal to modify the specified limiting percentage of Native Load on a sliding scale over a 4 year time period. BAL-003-3 R5, as approved, explicitly specifies $1 \%$ as a minimum value for monthly average Frequency Bias Setting. As such, changing this value results in a change in the requirement itself. Instead of being done through an Implementation Plan, these types of changes should be made as specific modifications to the requirement in question. To resolve this issue, BPA asks that the sliding scale specified for percentage of peak load specified in the Implementation Plan be incorporated directly into BAL-003-1 as a part of the specified text of R5. This change meets the intended goal of applying a sliding scale to this value over time while assuring that the underlying change is implemented as a change to the requirement through the Standards Development Process.

If "the proposed standard's intent is to collect data needed to accurately analyze existing Frequency Response, set a minimum Frequency Response obligation, provide a uniform calculation of Frequency Bias Settings that transition to values closer to Frequency Response, and encourage coordinated AGC operation", it appears the current and stated definition is precluding the process for determination of the Frequency Bias Setting itself. I believe it is too early to state in definition the frequency bias setting to be based on $M W / 0.1 \mathrm{~Hz}$, when this appears to be more of the expected response. Using the word usually does not appear to be defining anything. To eventually get to an acceptable performance measure with reliability basis the project needs to be expanded to also address associated governor droop issues, which inherently affect response. When the current definition references using "either a fixed or variable Frequency Bias", it does not state whether or not to be applied in the calculation to either load or generation. The current Standard uses 1\% of yearly estimated peak demand for BAs that serve load, when the actual load at time of disturbance could be greatly different. Response is more directly related to the amount of Generation on-line and active AGC within the BA at time of trip. MW/0.1 Hz states more of expected result of response than defining Frequency Bias Setting.
No
AEP believes the statement should read "To require sufficient Frequency Response from governors and AGC of Generators within the Balancing Authority to maintain Interconnection Frequency within predefined bounds by arresting frequency deviations and supporting frequency until the frequency is restored to schedule.To provide consistent methods for measuring Frequency Response from governors and AGC of Generators within the Balancing Authority for determining the overall Frequency Bias Setting threshold. Since Generators are directly responsible for response, applicability must be added to Generator Operators.
No
Between the definition and the requirement in Attachment A, it is unclear if FRM is a reliability-supported, performancebased measure, or instead, if it is a calculated number based on previous performance. As written, it is unclear if this is a performance-based requirement, or simply a calculation that should be utilized in some way. In any event, the requirement needs to be re-written to clarify its intent.
No
It appears this standard deviates from past practice for calculating frequency bias. It is unclear how this might affect the CPS Bounds L10 calculation.
Yes

No
It is unprecedented that an implementation plan would require following some (but not all) requirement(s) within multiple versions of the same standard. This would make following the standard very difficult. Having to piece together multiple documents into a coherent requirement would be very difficult to achieve. There needs to be a definitive start and stop date for each version, rather than a phase in and phase out across multiple versions. We disagree with setting preselected dates beginning months away. Timing should be driven by applicable regulatory approval, as opposed to dates which appear to be arbitrarily selected. Going from $100 \%$ of the load-based, frequency bias calculation to $0 \%$ is unclear without correlating it to something else being phased in over time. It is very hard to follow how BAL-003-0 R5 relates to BAL-003-1. More work needs to be done by the SDT to explain how these relate to one another.

Duke Energy

No
The definition of SEFRD would conflict with any alternative measurement of frequency response. The SEFRD makes no provision for the impacts of generation loss experienced by a contingent BA, impacts of non-conforming loads, or impacts of schedule ramps. The FRM also makes no such provisions. The resulting FRM for a BA experiencing one or more of these impacts for one or more SEFRDs will be skewed and completely miss the intended measurement of the BA's response to frequency excursions. In addition, as it is not yet clear how provision of Frequency Response by one BA to meet a portion of another BA's requirement would be achieved, Duke Energy cannot say that a simple measure of the NIA against the frequency deviation will capture the net of the response desired. Regarding the definition of FRO, the industry should agree on the methodology which would be used for the ERO to determine the response desired for the Interconnection that is used for allocation of the FRO, and not leave it as a parameter subject to change outside of the standards process. The definition is only acceptable if the assignment by the ERO is based upon a methodology supported by the industry and subject to change only through the standards process.
No
Duke Energy would suggest not using "Frequency Bias" in the definition of "Frequency Bias Setting". In addition, Duke Energy would like to point out that ACE does not allow Frequency Response; response will occur with or without the ACE equation. The Frequency Bias Setting is needed so that the AGC does not negate what may be provided in frequency response. The bias component of ACE provides the feedback so that a BA may sustain the intended amount of response with secondary control as long as Actual Frequency deviates from Scheduled Frequency. Duke Energy would suggest the following: "A fixed or variable value usually expressed in MW/0.1 Hz, set into a Balancing Authority Area Control Error equation to bias the control of resources so that Interconnection frequency is driven toward the Scheduled Frequency."
Yes
No
Duke Energy agrees that a BA should be required to achieve a minimum level of Frequency Response, however Duke Energy believes the method for measurement needs improvement - please see comments to 1 and 2 above. Duke Energy agrees with the concept that a Balancing Authority should be required to achieve a minimum level of Frequency Response however the method for measurement should also allow exclusion of certain events, such as when the frequency deviation is associated with the BA's contingent loss of generation, or when an event is coincident with a significant change in ramped interchange. It is not clear how the FRO will be determined - Duke Energy believes that the industry should agree on the methodology which would be used for the ERO to determine the response desired for the Interconnection and how the allocation for the FRO would be determined for each Balancing Authority. The calculation of FRO allocation (in Attachment 1) is not clear on whether the peak load and generation data used is historic data or forecasted data. It is also not clear how the assignment of the FRO would accommodate a mid-year change in Balancing Authority size or other attribute that could change the calculated response. Duke Energy questions if a BA providing better response than its allocated FRO in any year should be held to achieving that in the following year - Duke Energy believes that should be the decision of the BA if it chooses to achieve more than the minimum requirement applied to others.
No
Duke Energy believes that this needs to be restated. Will the ERO perform the calculations to determine each BA's Bias? Will the ERO provide ample time between publication of the settings and the date of implementation? If effective coordinated secondary control is desired, other related operational parameters (e.g., L10) need to be set at the same time. Since measurement and reporting of operational performance is primarily on a monthly basis (e.g., CPS1/CPS2), the implementation date should be on or near the first of a month, but during normal working hours (so that adequate support personnel are available).
No
Duke Energy agrees to the simple statement posed in the question; however, the requirement goes beyond that by using a defined term, Adverse Reliability Impact, which has a relatively narrow focus on extreme conditions. If a single BA lost a significant amount of its tie-line telemetry or its frequency sources, cascading outages and/or grid separation would not necessarily be imminent but it would be imprudent to remain in Tie Line Bias mode. Go back to the original language for the requirement - "Each Balancing Authority shall operate its Automatic Generation Control (AGC) on Tie Line Frequency Bias, unless such operation is adverse to system or Interconnection reliability."
No
Duke Energy does not agree with having prescribed dates for the gradual reduction of the minimum Frequency Bias Setting, as the implementation may drive significant issues which could delay, or halt the implementation at a certain level. It is not clear what process would be used to give the "go-ahead" to move to the next level (agree?).

SPP Standards Development
Robert Rhodes
No
In the past tie line flow changes that did not have the expected response for the qiven frequency deviation have been
excluded from the determination of Frequency Bias. It appears that this exclusion does not carry forth in the determination of Frequency Response Measure. Therefore, non-conforming loads, intermittent resources and other events/issues within a Balancing Authority could very well mask its natural frequency repsonse thereby setting the Balancing Authority's Frequency Bias and its Frequency Response Obligation incorrectly. Then the Balancing Authority is obligated to respond and will be measured for compliance against an incorrect value. This being the case, we can support the definition of Single Event Frequency Response Data but have reservations about Frequency Response Measure and Frequency Response Obligation.
No
We would suggest inserting 'secondary' in front of Frequency Response at the end of the sentence and delete 'Frequency Bias' following 'variable' at the beginning of the sentence.
Yes

Yes

No
We would suggest ending the sentence at the second ERO, deleting the phrase '...to ensure effective coordinated secondary control, using the results from the calculation methodology detailed in Attachment A.' This phrase is more of an explanation of why this is being done rather than a part of an actual requirement.
Yes
Yes

Patterson Consulting, Inc.
No
SEFRD: From the definition, it is not clear whether SEFRD is a Balancing Authority's 1) data collected for each frequency event, 2) calculated Frequency Response for a selected event, 3) Net Actual Interchange divided by the change in frequency for a selected event, or 4) some combination of these interpretations. If the SDT determines that adjustments to Net Actual Interchange should be made such as adjustments for joint-owned generation and nonconforming loads as suggested in the field test document, then since this definition requires Frequency Response to be determined from Net Actual Interchange, this definition would require changing to allow those adjustments. I suggest defining SEFRD as "The individual sample of event data from a Balancing Authority that is necessary to calculate its Frequency Response on FRS Form 1, expressed in MW/0.1Hz." FRM: This definition and its calculation in FRS Form 1 do not match. FRS Form 1 calculates FRM as "The median of Single Event Frequency Response Data observations reported annually on FRS Form 1 [for events external to the Balancing Authority]." (Brackets added for emphasis.) The FRS Form 1 calculation appears more appropriate based on data collected, since data are not reported and calculations are not adjusted to compensate for contingencies within the Balancing Authority. Regardless, the difference between definition and calculation makes it impossible for a Balancing Authority to know the expected performance measure. FRO: The definition should be changed to remove the opposing concepts of performance and obligation. For example: FRO is defined to be "The Balancing Authority's contribution to the total aggregate Frequency Response..." FRM, not FRO, is the Balancing Authority's contribution toward the aggregated Frequency Response. FRO is "The Balancing Authority's allocation of the interconnection's required Frequency Response..." or "The Balancing Authority's required Frequency Response needed for reliable operation of an Interconnection ..." Yes

No
The purpose should not expect Frequency Response to maintain frequency beyond a few minutes, perhaps 15 minutes for example. This purpose statement suggests the requirements will be "...to maintain Interconnection Frequency within predefined bounds by arresting frequency deviations and support frequency until the frequency is restored to schedule..." The phrase "until the frequency is restored to schedule" is problematic since regulation must bring frequency to schedule. Frequency Response, and the associated requirements, should not be expected to substitute for poor regulation beyond the first few minutes.
No
Requiring a Balancing Authority to provide Frequency Response and measuring that Frequency Response consistently, is critical to maintaining reliability. The requirement is long overdue and the concept is a good one. The method for measurement in FRS Form 1 is not consistent with the definition of FRM. The desired "averaging" of input data over specific time ranges by the Balancing Authority as it completes FRS Form 1 appears only in the background and instructions for FRS Form 1. Since this "instruction" document will not be a part of the standard, it is not obvious that Balancing Authoritv's will be compelled to provide consistent data. Therefore, the standard will fail to achieve the
stated purpose of providing "...consistent methods for measuring Frequency Response...". Attachment A, other than the section providing guidance regarding event selection, appears to be explanatory, contextual, and instructional in content. These aspects are important, but should not be requirements. Attachment A should include only the event selection process and calculations associated with requirements, including an explanation of what is necessary if variable Frequency Bias Settings are implemented. If other "requirements" are included in Attachment $A$, they should be moved to the standard. FRS Form 1 should be an attachment to the standard as this form contains and performs the required calculations. The remaining information in Attachment A should become either a standalone (technical) document, or be combined with information such as "FRS Form 1 Background and Instructions" and renamed. As further clarification regarding the ambiguity identified in the previous paragraph, Attachment A could be interpreted as additional requirements on the Balancing Authority, ERO, or both. The language and scope is not sufficiently clear to identify whether statements are informative or requirements. This lack of clarity makes it impossible for entities to identify requirements, acquire appropriate tools and resources related to requirements, and to provide suitable performance to meet requirements. For example, the statement "A final listing of official events to be used in the calculation will be available from NERC by December 10 each year." may be intended as a requirement rather than a statement suggesting a typical schedule. Further, if the previous statement is a typical schedule, then the statement "The ERO will use the following criteria for the selection of events to be analyzed." could be interpreted as merely the typical process to be used, but not a binding one.
No
The concept of requiring a Balancing Authority to implement its Frequency Bias Setting at a specific time and using a specific calculation is meaningful. This requirement is not clearly worded, however. If the intent of Requirement 2 is to identify "...when the Balancing Authority must implement its Frequency Bias Setting..." the requirement should stop after "...on the date specified by the ERO." The remaining portion of the requirement explains the need for the requirement and should be moved to supporting material. Attachment A does not have a "calculation methodology" associated with the Frequency Bias Setting unless the language describing historical practice and the benefits of moving a Frequency Bias Setting closer to a Balancing Authority's natural Frequency Response are intended to constitute a "calculation methodology." FRS Form 1 has the "calculation methodology" of using the minimum (since the value is negative) of last year's FRM, next year's FRO, and percentage of next year's peak load or generation. Attachment A does not mention this methodology and the requirement does not mention FRS Form 1. The clause "..., using the results from the calculation methodology detailed in Attachment A." appears to place an obscure requirement on the ERO since the ERO is the entity providing the Frequency Bias Setting to be implemented by the Balancing Authority. If the ERO is intended to use the value from FRS Form 1, after verifying data and calculations, then state that expectation explicitly and clearly. Otherwise, the ERO could set Frequency Bias Settings in another manner after observing the Form 1 values. The requirement for the ERO to provide a Frequency Bias Setting to each Balancing Authority begs the question of how variable bias will be implemented. Historically, the Balancing Authority implements its algorithm with oversight from NERC (Resources Subcommittee). The manner and expectation for providing data and algorithms related to variable bias are inadequate.
No
While this requirement is in the existing standard, it places a significant reporting burden on a Balancing Authority to demonstrate compliance during audits for little reliability gain. In addition for single Balancing Authority interconnections, operating in this AGC mode is functionally equivalent to operating in flat frequency mode. This may cause some interconnections to seek a variance, just to avoid compliance complications. Perhaps this requirement could be replaced with a requirement for Balancing Authorities to contribute to frequency performance as well as balance commitments and resources, or to calculate the ACE it uses to report in other standards in a specific manner. As written, it could be interpreted to create a violation when AGC suspends or is offline.
No
The implementation plan should address implementing these requirements at the same time for all Balancing Authorities within an interconnection, regardless of regulatory approvals. The present implementation plan will require some Balancing Authorities within an interconnection to operate to the new standard while other Balancing Authorities operate to the old standard if multiple regulatory jurisdictions exist as they do within two interconnections. This could lead to uncoordinated and unreliable operation within an interconnection.

No
The definition of SEFRD will not work as described for a single BA Interconnection. There is no change in NI for frequency deviations. Similarly, the definition assumes all response is provided by change in Interchange and does not really reflect the frequency response of a contingent BA. Either the definition needs to be changed to accommodate single BA Interconnections (such as ERCOT and Hydro Quebec), or regional variances for them need to be written by the SDT. A BA's frequency response is composed of load frequency response, governor response, and, for BAs external to the resource loss, change in Net Interchange. Some approximation may be achieved by recognizing that the magnitude of frequency deviation is attenuated by load frequency response and governor response (or frequency activated demand response to reduce load). The definition of FRM specifies the median of all SEFRD observations
reported annually. What is the technical basis for selecting the median rather than the mean? The definition of FRO raises questions. The discretely administered determination of FRO described in the draft Attachment A sets too stringent a requirement; particularly for the smaller Interconnections which may also have large size generation resources just as do the larger Interconnections. To "assure that Point C will not encroach on the first step UFLS" is significantly more stringent than existing and historical performance for those smaller Interconnections. Such assurance will assuredly prove to be very expensive. In fact, we question the need to define FRM and FRO since they can easily be stipulated in the standard requirements. Having them defined and added to the ever-growing NERC glossary creates unnecessary work to maintain the glossary, unless these terms are used by other NERC standards for which consistent meaning need to be established. For example, R1 can easily be reworded as: "R1: Each Balancing Authority shall achieve a median of all Single Event Frequency Response Data observations reported annually on FRS Form 1 that is equal to or more negative than its contribution obligation to the total aggregate Frequency Response needed for reliable operation of an Interconnection assigned by the ERO." Similar wording changes can be made to the FRS Form 1 to eliminate the need to define these two terms. Further, the Attachment A states that the SDT is evaluating a risk based approach to establishing an Interconnection Frequency Response Obligation which can be based on a probability function. If the $\mathrm{N}-2$ criteria is established, it will be unlikely to be possible to change that if the new approach is viewed as a reduction in required performance. As an example, in the ERCOT Interconnection, it is recognized that the present level of required frequency responsive reserve cannot in all scenarios assure that Point C will not encroach the first step of UFLS. The system conditions that exist for the encroachment to occur represent a small likelihood and would require the $\mathrm{N}-2$ contingency to occur on something like the minimum hour of the minimum load day of the year. It has occurred one time in the history of ERCOT. Thus, it is less than once in ten years based upon actual history. The cost of precluding such an event would be astronomical.
No
The definition appears to be accurate, but where is "fixed" and "variable" Frequency Bias defined in the context of these requirements? Should it be Frequency Bias Setting, instead? "Fixed" seems to be straightforward, but what is "variable"? How often must Frequency Bias Setting change in order to be considered to be "variable"?
No
If this is really intended to be a Field Trial, it should be written as such and the standard should not be developed or promulgated until the Field Trial has accomplished its purpose and the performance criteria and measures have been determined. We request that the results of the Field Trial should be published and discussed BEFORE any changes are made. The standard should be put into place later; it is premature at this time. Since this is to be a data gathering process to be used to determine appropriate performance parameters, the purpose statement of the Field Trial should be changed to read as follows: To determine require sufficient Frequency Response arranged by from the Balancing Authority to maintain Interconnection Frequency within predefined bounds by responding to and arresting frequency deviations and supporting frequency until the frequency is restored to schedule. To identify and establish provide consistent methods for measuring Frequency Response and determining the Frequency Bias Setting and Frequency Response Obligation. We should not write the new standard and its requirements until this Field Trial work has been accomplished; to do so possibly would result in difficulty changing the standard requirements based upon Field Trial results. Further, while we do not have any issue with the general intent of the scope statement, we have a difficulty seeing the BA being the only entity held responsible for maintaining interconnection frequency and arresting frequency deviations. When there is a sudden and sizable change to system resource or demand, the first response to a frequency deviation caused by this change would be the generators' governors. This will provide a mitigating effect for the immediate seconds up to minutes. The frequency bias setting will then kick in to supplement the mitigation need. The governors are owned by the Generator Owners; the BAs do not own these facilities and hence can do little to address frequency response during this initial period. To hold only the BA responsible for maintaining interconnection frequency and arresting frequency deviations would be inappropriate. The industry needs to have a discussion to determine who should be held responsible for providing governor responses immediately following an event, and by what mechanism, and for implementing additional measures thereafter. We suggest that BAL-003 development be withheld until this discussion takes place and a decision is made on who and how the governor response shall be provided.
No
The SRC agrees that a Frequency Response of some minimum level for each Interconnection should be achieved. However, the measure as described does not apply to all Interconnections. It does not apply to single BA Interconnections such as ERCOT and Hydro Quebec. This requirement should be added later-not included now; and it should clarify what the BA must do and what the response providers must do. BAs do not own and operate the resources. An entity which does own or operate the resources may also be registered as a BA, but an entity which does not own or operate resources may also be registered as a BA. Therefore, it is important to detail what a BA must do and also to detail what the resource owner or operator must do. The resource owner may be registered as a GO or a TO or even a DP. The resource operator may be registered as a GOP, a TOP, or a LSE. The BA must establish an operations plan, using data provided to it by the resource owners and or operators, that will meet the performance requirements. The BA must then deploy the proper amount of response through AGC or verbal instructions to supplement the automatic responses that the resources will provide, must calculate the actual responses after-the-fact, and report the performance as required. The resources must, as standards already provide, comply with the deployments and instructions provided by the BA. However, if an entity which is functioning as a BA does not own its resources, nor does it directly operate those resources, the BA cannot ensure the achievement. The standard must not
create an organizational or contractual arrangement that dictates how the compliance is provided. It should state what must be done, not how. If entities choose to write and enter into such arrangements, that should be permissible, but not required. Specific to R1, the wording does not correspond to the figures shown in the FRS (Form 1) in that the FRM (the median) is -14.5 whereas the FRO is -15.8 . The FRO is more negative than the FRM, which does not seem to correspond to what's stipulated in R1 (FRM to be equal or more negative than its FRO).
No
It is not clear how the ERO uses the FRM to determine the required Frequency Bias Settings. Please clarify. Also, it should not be necessary for the ERO to do the determination for all the Interconnections. There are already in place methods for this by the existing ERCOT and WECC Interconnections. The SRC suggests that the ERO may not be the appropriate technical entity. The ERO may be the appropriate entity to serve as the receiver of the forms and analyze results for the Eastern Interconnection, but existing processes are already in place elsewhere. It should be sufficient that those processes continue and submit copies of Form 1 to the ERO. This may also be appropriate for Hydro Quebec. In addition, whichever entity determines the Frequency Bias Setting must provide implementation time for the BAs to implement the settings. The proposed language says only that the BA shall implement it on the date specified, but it doesn't address the need for that date to include some implementation time.
No
Single BA Interconnections do not operate on Tie Line Bias. The requirement should be modified to accommodate this or regional variances should be written by the SDT to address existing differences. In addition this requirement, as written, does not provide for momentary cessation of AGC for any reason, nor for reasonable system maintenance, repair, or updates. As written, it seems to say that any duration of operation off Tie Line Bias is unacceptable and, thus, would be a violation.
No
What is the technical basis for the phase-out schedule? Making the standard requirements effective earlier than the schedule shown could result in the unintended consequence of non-compliance enforcement for performance that is caused by the change rather than by the non-performance of the functional entity. Also, the effective dates given in the Implementation differ from those in the draft standard. Different requirement numbers are expressed in each. Some of the implementation steps (retiring R5 of BAL-003-0) presented in the implementation plan start as early as May 2011.
We do not believe that the BAL-003-1 standard will be approved by the industry or the NERC BoT at that time and that does not even take into account regulatory approval (or 12 months after BoT adoption in those jurisdictions where no regulatory approval is required). How can a standard begins to phase out while the successor standard is not anywhere near becoming effective? If the SDT wants to propose a gradual replacement of the current R5, we would suggest that the phase-out steps be tied to the date that the standard becomes effective.
Individual

No
We suggest the SDT consider defining SEFRD as: The calculated frequency response by a Balancing Authority for a specific frequency excursion event as identified by the ERO (or NERC). As a comment, how frequency response is calculated needs to be defined and may not always be the Net Actual Interchange (NIa) divided by the change in frequency expressed in hertz. For example, the Nla may need to be adjusted for known generation and load changes that do not represent frequency response for the period being measured such as known generation and load ramp changes. Change in frequency needs to be more specific, such as the frequency difference between $B$ and $A$ measured at B. If Frequency Response Obligation (FRO) is a targeted value, then perhaps the definition should be: The Balancing Authority's annual median frequency response as assigned by the ERO (or NERC). The word "contribution" should be considered to be replaced with "the balancing authority piece of the total....." The review team is concerned that the FRO and FRM definitions do not contain enough clarity as to how the BAs will be held accountable. Also, the definitions do not explain who will determine the value of each BA's FRO and the method used to determine the FRO value. Should the definition of Frequency Response Measure be a median or mean value? May need to clarify what FRS stands for.
We suggest the following changes to the definition: 1. Delete "Frequency Bias" in the parenthetical expression ("Frequency Bias" should not be used to define Frequency Bias) 2. Delete the word "usually" 3. Replace "set into" with "as part of" as defined in BAL-001. 4. Replace the remainder of the sentence following "Area Control Error equation" with "that influences its Automatic Generation Control (AGC) to provide its frequency response while Interconnection frequency is not at its scheduled value" - (The frequency bias does not allow a BA to contribute its frequency response to the Interconnection. The frequency bias term only affects the AGC response of the BA, which is part of its frequency response usually minutes after the initial event and is dependent upon generation units being on AGC control and capable of responding.) 5 . The suggested changes would result in the following definition" A value, fixed or variable, expressed in MW/0.1 hertz as part of a Balancing Authority's Area Control Error (ACE) equation that influences its Automatic Generation Control (AGC) to provide its frequency response while Interconnection frequency is not at its scheduled value.
Yes

|  | No |
| :---: | :---: |
| The concept seems reasonable but since the measure of compliance (FRM) is determined only after the 25 events are identified; it is a lagging indicator. The BA may have to ensure it measures all frequency excursions and develops its own leading indicator to ensure compliance following year end. A sample CPS bounds report should be considered, perhaps based on 2010 numbers, to demonstrate how FRM submitted would translate to FRO frequency bias settings and how it will affect the L10 values. |  |
| No |  |
| It is not clear what the methodology (should be method) is in Attachment A. Is the frequency bias setting the BA's prior year FRM with a minimum value being a percentage of estimated yearly peak load or upcoming year maximum generation? What does "provided by the ERO" mean? Perhaps it should be verified or approved by the ERO (NERC). We suggest defining the date as by the end of the first business day following the deadline for Frequency Bias Setting implementation. |  |
| No |  |
| BAL-003-0, Requirement 3 requires operation of AGC on Tie Line Frequency Bias. BAL-005-0.1b, Requirement 6 requires the BA to compare total Net Interchange to total Net Scheduled Interchange plus Frequency Bias obligation to determine the Balancing Authority's ACE. We suggest that Requirement 3 be restated to "shall operate its Automatic Generation Control (AGC) on Tie Line Frequency Bias, unless ........" Tie Line bias is the (Ia-Is) term and frequency bias is the -10 B (Fa-Fs) term. This should be coordinated with BARCSDT modifications to BAL-005. |  |
| No |  |
| The implementation plan has specific dates for reducing the bias settings currently defined in Requirement 5 over several years. Perhaps these dates should not be specific but tied to months following regulatory approval. Attachment A should be modified to match what is in the proposed standard. The values currently shown as percent "of peak/0.1 Hz " should be changed to percent of estimated yearly peak demand per 0.1 Hz change. For BAs that do not serve native load, percent "of upcoming years maximum generation $/ 0.1 \mathrm{~Hz}$ should be changed to percent of its estimated maximum generation level in the coming year/ 0.1 Hz change. |  |

| 1) SEFRD - I had to read this definition several times because "The individual sample of event data" is actually an internally calculated value derived from a set of event sample data, and not really a "sample" value at all. So, I believe the SEFRD definition needs further work. 2) FRM is defined by undefined terms "FRS" and "FRS Form 1". 3) FRO fine 4) FRS - "Frequency Response Survey" |  |
|  | No |

1) SEFRD - I had to read this definition several times because "The individual sample of event data" is actually an internally calculated value derived from a set of event sample data, and not really a "sample" value at all. So, I believe the SEFRD definition needs further work.

response to such deviation would be the generators' governors. This will provide a mitigating effect for the immediate seconds up to minutes. The frequency bias setting will then kick in to supplement the mitigation need. To hold only the BA responsible for maintaining interconnection frequency arresting frequency deviations would be only part of the solution. The industry needs to have a discussion to determine who should be held responsible for providing governor responses, and by what mechanism. We suggest that BAL-003 development be withheld until this discussion takes place and a decision is made on who and how the governor response shall be provided.
Yes
We agree with the BA being one of the responsible entities to achieve a minimum level of FR, and the method of measurement. However, R1 does not correspond to the figures shown in the FRS (Form 1) in that the FRM (the median) is -14.5 whereas the FRO is -15.8 . The FRO is more negative than the FRM, which does not seem to correspond to what's stipulated in R1 (FRM to be equal or more negative than its FRO).

## Yes

Yes

We suggest the SDT consider defining SEFRD as: The calculated frequency response by a Balancing Authority for a specific frequency excursion event as identified by the ERO (or NERC). As a comment, how frequency response is calculated needs to be defined and may not always be the Net Actual Interchange (NIa) divided by the change in frequency expressed in hertz. For example, the Nla may need to be adjusted for known generation and load changes that do not represent frequency response for the period being measured such as known generation and load ramp changes. Change in frequency needs to be more specific, such as the frequency difference between $B$ and $A$ measured at $B$. If Frequency Response Obligation (FRO) is a targeted value, then perhaps the definition should be: The Balancing Authority's annual median frequency response as assigned by the ERO (or NERC). The word "contribution" should be considered to be replaced with "the balancing authority piece of the total....." The review team is concerned that the FRO and FRM definitions do not contain enough clarity as to how the BAs will be held accountable. Also, the definitions do not explain who will determine the value of each BA's FRO and the method used to determine the FRO value. Should the definition of Frequency Response Measure be a median or mean value? No
We suggest the following changes to the definition: 1. Delete "Frequency Bias" in the parenthetical expression ("Frequency Bias" should not be used to define Frequency Bias) 2. Delete the word "usually" 3. Replace "set into" with "as part of" as defined in BAL-001. 4. Replace the remainder of the sentence following "Area Control Error equation" with "that influences its Automatic Generation Control (AGC) to provide its frequency response while Interconnection frequency is not at its scheduled value" - (The frequency bias does not allow a BA to contribute its frequency response to the Interconnection. The frequency bias term only affects the AGC response of the BA, which is usually minutes after the initial event and is dependent upon generation units being on AGC control and capable of responding.) 5. The suggested changes would result in the following definition" A value, fixed or variable, expressed in MW/O.1 hertz as part of a Balancing Authority's Area Control Error (ACE) equation that influences its Automatic Generation Control

| (AGC) to continue to provide its frequency response while Interconnection frequency is not at its scheduled value. |  |
| :---: | :---: |
|  | Yes |
| No |  |
| The concept seems reasonable but since the measure of compliance (FRM) is determined only after the 25 events are identified; it is a lagging indicator. The BA may have to ensure it measures all frequency excursions and develops its own leading indicator to ensure compliance following year end. A sample CPS bounds report should be considered, perhaps based on 2010 numbers, to demonstrate how FRM submitted would translate to FRO frequency bias settings and how it will affect the L10 values. |  |
| No |  |
| It is not clear what the methodology (should be method) is in Attachment $A$. Is the frequency bias setting the BA's prior year FRM with a minimum value being a percentage of estimated yearly peak load or upcoming year maximum generation? What does "provided by the ERO" mean? Perhaps it should be verified or approved by the ERO (NERC). |  |
| No |  |
| BAL-003-0, Requirement 3 requires operation of AGC on Tie Line Frequency Bias. BAL-005-0.1b, Requirement 6 requires the BA to compare total Net Interchange to total Net Scheduled Interchange plus Frequency Bias obligation to determine the Balancing Authority's ACE. We suggest that Requirement 3 be restated to "shall operate its Automatic Generation Control (AGC) on Tie Line Frequency Bias, unless ........" Tie Line bias is the (Ia-Is) term and frequency bias is the -10B(Fa-Fs) term. This should be coordinated with BARCSDT modifications to BAL-005. |  |
| The implementation plan has specific dates for reducing the bias settings currently defined in Requirement 5 over several years. Perhaps these dates should not be specific but tied to months following regulatory approval. Attachment A should be modified to match what is in the proposed standard. The values currently shown as percent "of peak/0.1 Hz " should be changed to percent of estimated yearly peak demand per 0.1 Hz change. For BAs that do not serve native load, percent "of upcoming years maximum generation $/ 0.1 \mathrm{~Hz}$ should be changed to percent of its estimated maximum generation level in the coming year/ 0.1 Hz change. |  |

| Yes |  |
|  |  |
| Yes |  |
|  |  |
| No |  |
| This purpose statement presumes that each Balancing Authority (BA) will have generation online to meet a predetermined frequency response obligation. There are many small BA's that do not have any generation online and rely on load regulation agreements and energy agreements to provide their energy needs during parts of the year. This purpose statement would not allow a BA to operate without generation online. |  |
| No |  |
| This requirement presumes that each Balancing Authority (BA) will have generation online to meet a predetermined frequency response obligation. There are many small BA's that do not have any generation online and rely on load regulation agreements and energy agreements to provide their energy needs during parts of the year. This requirement would not allow a BA to operate without generation online. Under Requirement 1, item 2a in Attachment A suggests governor deadband as 36 MHz (Megahertz). Suggest what is intended is 36 mHz (millihertz). The Frequency Response Obligation determination for the interconnection as described in Attachment A is a crude method and will result in obligations that will exceed the FRO that is intended. This will result in additional cost to BA's that is unnecessary to achieve the purpose of maintaining sufficient generation online to arrest frequency degradation events caused by loss of generating resources. The current NERC method for calculating a BA's actual frequency response are inaccurate and provide misleading guidance in the actual frequency response of a BA. These methods need considerable improvement before any attempts to hold a BA to an expected level of frequency response as this proposal has stated. |  |
| No |  |
| The Frequency Response Obligation determination for the interconnection as described in Attachment $A$ is a crude method and will result in obligations that will exceed the FRO that is intended. This will result in additional cost to BA's that is unnecessary to achieve the purpose of maintaining sufficient generation online to arrest frequency degradation events caused by loss of generating resources. The current NERC method for calculating a BA's actual frequency response are inaccurate and provide misleading guidance in the actual frequency response of a BA. These methods need considerable improvement before any attempts to hold a BA to an expected level of frequency response as this proposal has stated. |  |
| No |  |
|  | The impact of operating in an inappropriate AGC control mode is bigger than the BA's own balancing area. The control of the area affects other BA's around a BA and if enouqh BA's are involved, can affect an interconnection. Recommend |

## Consideration of Comments

BAL-003-1 - Frequency Response and Frequency Bias Setting Project 2007-12 - $1^{\text {st }}$ Draft

The Frequency Response and Frequency Bias Setting Drafting Team thanks all commenters who submitted comments on the 1st draft of BAL-003-1 - Frequency Response and Frequency Bias Setting. This standard was posted for a 30-day public comment period from

There are a few places where the team missed providing a comment in response to a suggestion - these are highlighted in yellow. In general, the team did a good job of responding! February 4, 2011 through March 7, 2011. The stakeholders were asked to provide feedback on the standards through a special electronic comment form. There were 36 sets of comments, including comments from more than 139 different people from approximately 86 companies representing 10 of the 10 Industry Segments as shown in the table on the following pages.

Based on the comments received the drafting team made the following changes to the proposed Standard:

- Removed the Single Event Frequency Response Data (SEFRD) definition from the standard.
- Modified the definitions for Frequency Response Measure (FRM) and Frequency Response Obligation (FRO).
- Modified the proposed definition of Frequency Bias Setting.
- Modified FRS Form 1 to correct errors, allow for adjustments and provide clarity.
- Separated Attachment A Background Document into two documents; 1) Attachment A - Supporting Document detailing the methodology to be followed for calculations, and 2) Background Document detailing the rational for the development of the requirements.
- Created Attachment B - Process for Adjusting Bias Setting Floor to clarify the methodology to be used in reducing the present 1\% minimum Frequency Bias Setting.
- Added measures, VRFs and VSLs.

There were a couple of minority issues that the team was unable to resolve, including the following:

- A few stakeholders requested the SDT to consider a standard for generators to support the Balancing Authority in achieving the targeted level of Frequency Response. The team stated that this was outside the scope of the industry approved SAR. The SDT further stated that any entity could submit a SAR addressing this issue to the SC for consideration and that the SDT supported this option.
- A couple of comments stated they believed that the standard should support the development of a market for supporting a Balancing Authority in achieving the target Frequency Response. The SDT explained that this standard would provide for the metrics for Frequency Response while the market would define itself. The SDT further stated a market could be created by a region, subregion, ISO, RTO or other entity as appropriate to facilitate compliance however the NERC Reliability Standards do not establish markets.

In this "Consideration of Comments" document stakeholder comments have been organized so that it is easier to see the responses associated with each question. All comments received can be viewed in their original format at:
http://www.nerc.com/filez/standards/Frequency_Response.html
If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herb Schrayshuen, at 404-446-2560 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process. ${ }^{1}$

[^51]
## Index to Questions, Comments, and Responses

1. The SDT has developed three new terms to be used with this standard.

- Single Event Frequency Response Data (SEFRD) The individual sample of event data from a Balancing Authority which represents the change in Net Actual Interchange (NIA), divided by the change in frequency, expressed in $\mathrm{MW} / 0.1 \mathrm{~Hz}$.
- Frequency Response Measure (FRM) The median of all Single Event Frequency Response Data observations reported annually on FRS Form 1.
- Frequency Response Obligation (FRO) The Balancing Authority's contribution to the total aggregate Frequency Response needed for reliable operation of an Interconnection assigned by the ERO.

Do you agree with the proposed definitions in this standard? If not, please explain in the comment area?
2. The SDT has modified the definition for the term Frequency Bias Setting. The current definition and revised definition are shown below to show the changes proposed. Do you agree with this new definition for Frequency Bias Setting? If not, please explain in the comment area.25
3. The proposed purpose statement in the draft standard is: To require sufficient Frequency Response from the Balancing Authority to maintain Interconnection Frequency within predefined bounds by arresting frequency deviations and supporting frequency until the frequency is restored to schedule. To provide consistent methods for measuring Frequency Response and determining the Frequency Bias Setting. Do you agree with this purpose? If not, please explain in the comment area. ....... ..................................................................................................................... 35
4. Requirement 1 identifies a minimum level of Frequency Response. R1. Each Balancing Authority shall achieve a Frequency Response Measure (FRM) (as detailed in Attachment A and calculated on FRS Form 1) that is equal to or more negative than its Frequency Response Obligation (FRO).

Do you agree with the concept that a Balancing Authority should be required to achieve a minimum level of Frequency Response and the method for measurement? If not, please explain in the comment area. 44
5. Requirement 2 identifies when the Balancing Authority must implement its Frequency Bias Setting. R2. Each Balancing Authority shall implement the Frequency Bias Setting (fixed or variable) provided by the ERO into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effective coordinated secondary control, using the results from the calculation methodology detailed in Attachment A.

Do you agree with this implementation? If not, please explain in the comment area.
6. Requirement 3 mandates that a Balancing Authority operate its Automatic Generation Control (AGC) on Tie Line Bias unless it becomes adverse to the integrity of its system.

R3. Each Balancing Authority shall operate its Automatic Generation Control (AGC) on Tie Line Bias, unless such operation would have an Adverse Reliability Impact on the Balancing Authority's Area.

Do you agree that a Balancing Authority should operate its AGC on Tie Line Bias unless it becomes
adverse to its system? If not, please explain in the comment area below.................................. 67
7. Do you agree with the proposed Implementation Plan for this standard? If not, please explain in the comment area. 79
8. This standard proposes to eliminate the $1 \%$ minimum Frequency Bias over a period of 4 years as outlined in the Implementation Plan. Do you agree that the elimination of the $1 \%$ minimum will bring Frequency Bias closer or equal to natural Frequency Response? If not, please explain in the comment area.
9. Do you agree with the drafting team that this standard should be field tested? If not, please explain in the comment area.

99
10. Attachment A of the proposed standard describes the criteria for selecting events to be analyzed. Do you agree with the criteria as described in Attached A? If not, please explain in the comment area.

105
11. The proposed standard has a document attached to it that describes the SDT's reasoning for the Requirements (Attachment A - Frequency Response Background Document). Do you agree with the SDT that this document is useful and provides a clear understanding of the Requirements? If not, please explain in the comment area.
12. The proposed standard requires the use of FRS Form 1 for calculating a Balancing Authority's FRM. Do you agree with the SDT that this is the proper method to calculate its FRM? If not, please explain in the comment area and if possible provide an alternate method to calculate FRM..... .
13. The proposed standard requires the use of FRS Form 1 for calculating a Balancing Authority's Frequency Bias Setting. Do you agree with the SDT that this is the proper method to calculate its Frequency Bias Setting? If not, please explain in the comment area and if possible provide an alternate method to calculate Frequency Bias Setting.
14. The SDT has provided a document (FRS Form 1 Instructions) describing how to use FRS Form 1 for calculating FRM and Frequency Bias Setting. Do you agree with the SDT that this document provides a clear understanding of how to use the form? If not, please explain in the comment area. 142
15. The SDT is soliciting comments on methods of obtaining Frequency Response to meet the FERC Order 693 directive. If possible please provide any thoughts you may have on this subject........ 149
16. If you are aware of any conflicts between the proposed standard and any regulatory function, rule order, tariff, rate schedule, legislative requirement, or agreement please identify the conflict here. 126
17. Please provide any other comments (that you have not already provided in response to the questions above) that you have on the draft standard BAL-003-1 131

## NERC

## The Industry Segments are:

1 - Transmission Owners
2 - RTOs, ISOs
3 - Load-serving Entities
4 - Transmission-dependent Utilities
5 - Electric Generators
6 - Electricity Brokers, Aggregators, and Marketers
7 - Large Electricity End Users
8-Small Electricity End Users
9 - Federal, State, Provincial Regulatory or other Government Entities
10 - Regional Reliability Organizations, Regional Entities

1. The SDT has developed three new terms to be used with this standard.

- Single Event Frequency Response Data (SEFRD) The individual sample of event data from a Balancing Authority which represents the change in Net Actual Interchange (NIA), divided by the change in frequency, expressed in MW/ 0.1 Hz .
- Frequency Response Measure (FRM) The median of all Single Event Frequency Response Data observations reported annually on FRS Form 1.
- Frequency Response Obligation (FRO) The Balancing Authority's contribution to the total aggregate Frequency Response needed for reliable operation of an Interconnection assigned by the ERO.

Do you agree with the proposed definitions in this standard? If not, please explain in the comment area?

Summary Consideration: The majority of the commenters disagreed with the proposed definitions for this standard. The primary concerns cited are the definitions, and the calculations and methodology associated with the definitions, are not clear.

Many commenters expressed concern that the FRM methodology did not allow exclusion of events that, if included, would mask true frequency response. Commenters also indicated that the 'average' and not the 'median' should be used for the FRM calculation. Other observations include inconsistency between the FRM definition and its calculation on FRS Form 1; that proposed language allows the ERO to unilaterally change FRO value; and that definitions seem more focused on the frequency excursion curve point B value and not point C value. Suggestions for improving the standard include making it clear that 25 events are used for determining FRM; that definitions should specify how to calculate each term; and that FRM should take into account nonconforming load.
In response to industry comments, the SDT has deleted the SEFRD definition from the standard; revised the FRO and FRM definitions; and also improved the calculations. With regards to use of the median for calculating FRM, in general, statisticians use the median as the best measure of central tendency when a population has outliers. Two independent reviews by the FR SDT have shown the Median to be less influenced by noise in the measurement process. FRS Form 1 has been modified to allow for adjustments to the load and generation. To allay industry concern over the ERO's role, the SDT is evaluating if a modification to the NERC Rules of Procedure to obligate the ERO to perform the tasks specified in the standard is necessary.
In regards to concerns over the frequency excursion curve point B value, the SDT explained that while point B measurements have some data quality challenges to be mastered, point C measurements are not practical at this time for Balancing Authorities in an Interconnection with more than one Balancing Authority. The SDT intends to study point B and point C relationships of each Interconnection with more than one Balancing Authority to address this issue during the field trial.
The SDT has chosen the deterministic approach detailed in Attachment A as the method to use to allocate the Interconnection FRO to the BAs. The SDT is evaluating a probabilistic method during the field trial.

| Organization | Yes or No | Question 1 Comment |
| :--- | :--- | :--- |

| Organization | Yes or No |  |
| :--- | :---: | :--- |
| Patterson Consulting, Inc. | No | From the definition, it is not clear whether SEFRD is a Balancing Authority's 1) data collected for each <br> frequency event, 2) calculated Frequency Response for a selected event, 3) Net Actual Interchange divided by <br> the change in frequency for a selected event, or 4) some combination of these interpretations. If the SDT <br> determines that adjustments to Net Actual Interchange should be made such as adjustments for joint-owned <br> generation and nonconforming loads as suggested in the field test document, then since this definition requires <br> Frequency Response to be determined from Net Actual Interchange, this definition would require changing to <br> allow those adjustments. I suggest defining SEFRD as <br> "The individual sample of event data from a Balancing Authority that is necessary to calculate its <br> Frequency Response on FRS Form 1, expressed in MW/O.1Hz." |

| Organization | Yes or No | Question 1 Comment |
| :---: | :---: | :---: |
|  |  | Balancing Authority's annual median frequency response as assigned by the ERO (or NERC). The word "contribution" should be considered to be replaced with "the balancing authority piece of the total....."The review team is concerned that the FRO and FRM definitions do not contain enough clarity as to how the BAs will be held accountable. Also, the definitions do not explain who will determine the value of each BA's FRO and the method used to determine the FRO value.Should the definition of Frequency Response Measure be a median or mean value? |
| Response: The SDT agrees with your concern regarding the definition of SEFRD. The SDT has removed the definition from the standard. <br> The SDT also agrees with your concern regarding the definition of FRO and has revised the definition to read "The Balancing Authority's share of the required Frequency Response needed for the reliable operation of an Interconnection." <br> With regards to use of the median for calculating FRM, in general, statisticians use the median as the best measure of central tendency when a population has outliers. Two independent reviews by the FR SDT have shown the Median to be less influenced by noise in the measurement process. |  |  |
|  |  |  |
| LG\&E and KU Energy | No | We suggest the SDT consider defining SEFRD as: The calculated frequency response by a Balancing Authority for a specific frequency excursion event as identified by the ERO (or NERC). As a comment, how frequency response is calculated needs to be defined and may not always be the Net Actual Interchange (Nla) divided by the change in frequency expressed in hertz. For example, the Nla may need to be adjusted for known generation and load changes that do not represent frequency response for the period being measured such as known generation and load ramp changes. Change in frequency needs to be more specific, such as the frequency difference between two physical locations B and A measured at B. Frequency deviation used in the calculation needs to be the deviation observed by the BA performing the calculation. <br> If Frequency Response Obligation (FRO) is a targeted value, then perhaps the definition should be: The Balancing Authority's annual median frequency response as assigned by the ERO (or NERC). The word "contribution" should be considered to be replaced with "the balancing authority piece of the total....."The standard does not explain who will determine the value of each BA's FRO nor the method used to determine the FRO value. <br> Should the definition of Frequency Response Measure be a median or mean value? |

| Organization Yes or No Question 1 Comment <br>   that 25 events do not apply because an attachment is not part of the standard. <br> Response: With regards to use of the median for calculating FRM, in general, statisticians use the median as the best measure of central <br> tendency when a population has outliers. Two independent reviews by the FR SDT have shown the Median to be less influenced by noise in <br> the measurement process. <br> The SDT has been advised by NERC Legal that an attachment explicitly referenced in a Reliability Standard Requirement is enforceable as part of that <br> Requirement.   <br> We Energies No For Frequency Response Measure, the drafting team should consider using average rather than median. <br> Because median is literally the middle value, a Balancing Authority could have 12 really bad Single Event <br> Frequency Response Data points and still comply. Average values would prevent this from   <br> happening.Should FRM be clear that it includes at least 25 events in the definition? While that can be   <br> garnered from Attachment A, it is not specified in the Form 1 instructions. We are concerned that the   <br> regulators may argue that 25 events do not apply because an attachment is not part of the standard.   |
| :--- |

Response: With regards to use of the median for calculating FRM, in general, statisticians use the median as the best measure of central tendency when a population has outliers. Two independent reviews by the FR SDT have shown the Median to be less influenced by noise in the measurement process.

The SDT has been advised by NERC Legal that an attachment explicitly referenced in a Reliability Standard Requirement is enforceable as part of that Requirement.

| Westar Energy | No | For FRM, why is median used rather than average? <br> The method in the standard for dsetermining FRM needs to allow for excluding some events due to non- <br> conforming loads, scan rate, intermittent resources, large interchange ramps, etc that may cause the actual <br> response during the 16 seconds to actually be opposite of the expected response. |
| :--- | :---: | :--- |

Response: With regards to use of the median for calculating FRM, in general, statisticians use the median as the best measure of central tendency when a population has outliers. Two independent reviews by the FR SDT have shown the Median to be less influenced by noise in the measurement process.
The FRS Form 1 has been modified to allow for adjustments (not exclusions) to the load and generation.

| Bonneville Power Administration $\quad$ No |
| :--- | | FRO definition - BPA feels uncomfortable supporting this standard when the ERO is given a blank check to |
| :--- |
| FRO. The methodology for determining the FRO must be spelled out in detail in order to allow all entities an |
| opportunity to comment on that methodology. |

| Organization | Yes or No | Question 1 Comment |
| :--- | :---: | :--- | :--- |
| necessary. | No | In the past tie line flow changes that did not have the expected response for the given frequency deviation <br> have been excluded from the determination of Frequency Bias. It appears that this exclusion does not carry <br> forth in the determination of Frequency Response Measure. Therefore, non-conforming loads, intermittent <br> resources and other events/issues within a Balancing Authority could very well mask its natural frequency <br> repsonse thereby setting the Balancing Authority's Frequency Bias and its Frequency Response Obligation <br> incorrectly. Then the Balancing Authority is obligated to respond and will be measured for compliance against <br> an incorrect value. This being the case, we can support the definition of Single Event Frequency Response <br> Data but have reservations about Frequency Response Measure and Frequency Response Obligation. |

Response: The SDT agrees with your concern regarding the definition of FRO and has revised the definition to read "The Balancing Authority's share of the required Frequency Response needed for the reliable operation of an Interconnection."
With regards to use of the median for calculating FRM, in general, statisticians use the median as the best measure of central tendency when a population has outliers. Two independent reviews by the FR SDT have shown the Median to be less influenced by noise in the measurement process.
The FRS Form 1 has been modified to allow for adjustments (not exclusions) to the load and generation.
Note that based on other stakeholder concerns, the definition of SEFRD has been deleted.

| IRC Standards Review |
| :--- | :--- | :--- |
| Committee |$\quad$ No | The definition of SEFRD will not work as described for a single BA Interconnection. There is no change in NI |
| :--- |
| for frequency deviations. Similarly, the definition assumes all response is provided by change in Interchange |
| and does not really reflect the frequency response of a contingent BA. Either the definition needs to be |
| changed to accommodate single BA Interconnections (such as ERCOT and Hydro Quebec), or regional |
| variances for them need to be written by the SDT. A BA's frequency response is composed of load frequency |
| response, governor response, and, for BAs external to the resource loss, change in Net Interchange. Some |
| approximation may be achieved by reconnizing that the magnitude of frequency deviation is attenuated by |
| load frequency response and governor response (or frequency activated demand response to reduce load). |
| The definition of FRM specifies the median of all SEFRD observations reported annually. What is the |
| technical basis for selecting the median rather than the mean? |
| The definition of FRO raises questions. The discretely administered determination of FRO described in the |
| draft Attachment A sets too stringent a requirement; particularly for the smaller Interconnections which may |
| also have large size generation resources just as do the larger Interconnections. |
| To "assure that Point C will not encroach on the first step UFLS" is significantly more stringent than existing |
| and historical performance for those smaller Interconnections. Such assurance will assuredly prove to be |
| very expensive.In fact, we question the need to define FRM and FRO since they can easily be stipulated in |

| Organization | Yes or No | Question 1 Comment |

evaluating a probabilistic approach during the field trial.

| Progress Energy | No | The proposed definition for SEFRD assumes that there is no change in the Net Scheduled Interchange (NIS) <br> as a result of the event. However, a dynamic schedule for load or generation based on data obtained with a <br> two second scan rate will impact the NIS, and therefore the corresponding load or generation response will <br> offset the change to NIA. Therefore, the definition of SEFRD should replace "NIA" with "change in NIA minus <br> NIS". |
| :--- | :---: | :--- | :--- |
| Response: The SDT agrees with your concern regarding the definition of SEFRD. The SDT has removed the definition from the standard. |  |  |

Response: (1) The SDT thanks you for your affirmative response, however several other stakeholders disagreed with the definition of SEFRD and the drafting team has removed the proposed definition from the revised standard.
$(2,4,5)$ With regards to use of the median for calculating FRM, in general, statisticians use the median as the best measure of central tendency when a population has outliers. Two independent reviews by the FR SDT have shown the Median to be less influenced by noise in the measurement process.
(3) The SDT has corrected FRS Form 1.
(6) Research conducted by the Frequency Response Standard Drafting Team (FR SDT) indicated that a Balancing Authority's FRM will converge to a reasonably stable value with 20 to 25 samples. The FR SDT as well as the NERC Frequency Response Initiative is evaluating other methods of FRM. The SDT is not ignoring methods of proven statistical design and the chosen method does require at least 25

Consideration of Comments: Project 2007-12 BAL-003-1 - $1^{\text {st }}$ Draft

| Organization | Yes or No | Question 1 Comment |
| :---: | :---: | :---: |
| samples. |  |  |
| EKPC | No | These definitions should be revised to include specifics on how to calculate each term. The FRM calculation method should take into account large non-conforming loads. A median will not reflect the true nature of the system. |
| Response: The SDT does not believe the definition should include the specific calculation and therefore has incorporated the calculation methodology in Attachment A. <br> The FRM calculation, using FRS Form 1, has been modified to now include adjustments. <br> Based on analysis of data the SDT has determined that the median value is the proper method to be used in defining FRM. |  |  |
| Duke Energy | No | The definition of SEFRD would conflict with any alternative measurement of frequency response. The SEFRD makes no provision for the impacts of generation loss experienced by a contingent $B A$, impacts of nonconforming loads, or impacts of schedule ramps. <br> The FRM also makes no such provisions. The resulting FRM for a BA experiencing one or more of these impacts for one or more SEFRDs will be skewed and completely miss the intended measurement of the BA's response to frequency excursions. In addition, as it is not yet clear how provision of Frequency Response by one BA to meet a portion of another BA's requirement would be achieved, Duke Energy cannot say that a simple measure of the NIA against the frequency deviation will capture the net of the response desired. <br> Regarding the definition of FRO, the industry should agree on the methodology which would be used for the ERO to determine the response desired for the Interconnection that is used for allocation of the FRO, and not leave it as a parameter subject to change outside of the standards process. The definition is only acceptable if the assignment by the ERO is based upon a methodology supported by the industry and subject to change only through the standards process. |
| Response: The SDT agrees with your concern regarding the definition of SEFRD. The SDT has removed the definition from the standard. <br> The FRS Form 1 has been modified to allow for adjustments (not exclusions) to the load and generation. <br> The methodology that the ERO will use for determining the FRO is now outlined in the new Attachment A. The industry will either accept or reject this methodology in the balloting phase of the standard. |  |  |
| Associated Electric Cooperative, Inc. | No | 1) SEFRD - I had to read this definition several times because "The individual sample of event data" is actually an internally calculated value derived from a set of event sample data, and not really a "sample" value at all. So, I believe the SEFRD definition needs further work. |

| Organization | Yes or No |  |
| :--- | :--- | :--- |
|  |  | 2) FRM is defined by undefined terms "FRS" and "FRS Form 1". |
|  | 3) FRO - fine <br> 4) FRS - "Frequency Response Survey" |  |

Response: The SDT agrees with your concern regarding the definition of SEFRD. The SDT has removed the definition from the standard.
FRS Form 1 is the name of the form to be used for calculating FRM.

| Alberta Electric System Operator | No | The frequency response has 2 aspects: arresting frequency deviation (Point C) and deviation where <br> frequency has settled (Point B). The proposed SEFRD and FRM seem all based on the Point B, however the <br> intention in purpose statement is towards Point C... It is not clear to AESO that these proposed SEFRD and <br> FRM based on settled frequency deviation (Point B) are technically sufficient to address the concern of <br> arresting frequency deviation (Point C). |
| :--- | :---: | :--- |

Response: The SDT recognizes that point C is the primary reliability concern. However, while Point B measurements have some data quality challenges to be mastered, point C measurements are not practical at this time for Balancing Authorities in an Interconnection with more than one Balancing Authority. The SDT intends to study point B and point C relationships of each Interconnection with more than one Balancing Authority to address this issue.
$\left.\begin{array}{|l|l|l|}\hline \begin{array}{l}\text { Independent Electricity System } \\ \text { Operator }\end{array} & \text { No } & \begin{array}{l}\text { We concur with the definitions for SEFRD, FRM and FRO but do not believe that the latter two terms (FRM } \\ \text { and FRO) need to be defined since they can easily be stipulated in the standard requirements. Having them } \\ \text { defined and added to the ever-growing NERC glossary creates unnecessary work to maintain the glossary, }\end{array} \\ \text { unless these terms are used by other NERC standards for which consistent meaning need to be established. } \\ \text { For example, R1 can easily be reworded as:"R1: Each Balancing Authority shall achieve a median of all }\end{array}\right\}$

Response: Several stakeholders indicated concerns with the definition of SEFRD and the team has removed this definition from the revised standard.
The SDT believes that the FRO and FRM definitions will be used in later revisions to the BAL group of standards and therefore is keeping the definitions in the standard so they can be added to the approved NERC Glossary of Terms.

| FirstEnergy | Yes | For the definition of FRM, we are not clear as to the rationale for choosing the median value instead of the <br> mean. |
| :--- | :---: | :--- |

Response: The SDT thanks you for your affirmative response and clarifying comment.

## Organization

Yes or No

## Question 1 Comment

With regards to use of the median for calculating FRM, in general, statisticians use the median as the best measure of central tendency when a population has outliers. Two independent reviews by the FR SDT have shown the Median to be less influenced by noise in the measurement process.

Southern Company Yes
Comments: The Frequency Response Measure should be based on either the median or average of all SEFR's as currently defined. Due to the varied nature of frequency responsive resources online it should never be based on meeting response on a single event.

Response: The SDT thanks you for your affirmative response and clarifying comment.
With regards to use of the median for calculating FRM, in general, statisticians use the median as the best measure of central tendency when a population has outliers. Two independent reviews by the FR SDT have shown the Median to be less influenced by noise in the measurement process.

| Response: Please refer to the SDT response to Question 17. |  |  |

2. The SDT has modified the definition for the term Frequency Bias Setting. The current definition and revised definition are shown below to show the changes proposed.

## Frequency Bias Setting

Current Definition in NERC Glossary: A value, usually expressed in MW/ 0.1 Hz , set into a Balancing Authority ACE algorithm, that allows the Balancing Authority to contribute its frequency response to the Interconnection.

Revised Definition: A value, (either a fixed or variable Frequency Bias), usually expressed in MW/ $0.1 \mathbf{~ H z}$, set into a Balancing Authority Area Control Error equation that allows the Balancing Authority to contribute its Frequency Response to the Interconnection.

Do you agree with this new definition for Frequency Bias Setting? If not, please explain in the comment area.
Summary Consideration: Many of the commenters did not agree with the new definition proposed for Frequency Bias Setting. Several commenters recommend revising the Frequency Bias Setting definition and have offered suggestions for the SDT to consider. In response, the SDT has revised the Frequency Bias Setting definition to better address concerns raised by industry.

The revised definition is:
Frequency Bias Setting: A number, either fixed or variable, usually expressed in $\mathrm{MW} / 0.1 \mathrm{~Hz}$, included in a Balancing Authority's Area Control Error equation to account for the Balancing Authority's Frequency Response contribution to the Interconnection, and discourage response withdrawal through secondary control systems.

Some commenters also questioned if the definition of Frequency Response also needed to be revised, however in reviewing the current definition of Frequency Response the SDT believes that the current definition is both accurate and appropriate. Concern was also raised regarding what constitutes variable bias. - Fixed bias is a value approved by the ERO whereas variable bias is a methodology for determining the Frequency Bias Setting approved by the ERO.

| Organization | Yes or No | Question 2 Comment |
| :--- | :---: | :--- |
| Santee Cooper | No | We suggest the following changes to the definition: A value, fixed or variable, expressed in MW/0.1 hertz, as <br> part of a Balancing Authority's Area Control Error (ACE) equation that influences its Automatic Generation <br> Control (AGC) to provide frequency response without secondary control action withdrawing the response. |
| Response: The SDT has modified the definition. The definition now reads "A number, either fixed or variable, usually expressed in MW/0.1 Hz , included in a <br> Balancing Authority's Area Control Error equation to account for the Balancing Authority's Frequency Response contribution to the Interconnection, and discourage <br> response withdrawal through secondary control systems." |  |  |
| ENBALA Power Networks | No | : ENBALA would modify the above as follows: A value, (either a fixed or variable Frequency Bias), usually |

| Organization | Yes or No | Question 2 Comment |
| :--- | :--- | :--- |
|  |  | expressed in MW/O.1 Hz, set into a Balancing Authority Area Control Error algorithm equation that allows the <br> Balancing Authority AGC System to ignore the export or import caused by the Primary Frequency Response. |

Response: The SDT has modified the definition. The definition now reads "A number, either fixed or variable, usually expressed in $\mathrm{MW} / 0.1 \mathrm{~Hz}$, included in a Balancing Authority's Area Control Error equation to account for the Balancing Authority's Frequency Response contribution to the Interconnection, and discourage response withdrawal through secondary control systems."

| Westar Energy | No | We propose the following:A value, (either a fixed or variable), expressed in MW/0.1 Hz, set into a Balancing <br> Authority Area Control Error equation that allows the Balancing Authority to contribute its SECONDARY <br> Frequency Response to the Interconnection. |
| :--- | :---: | :--- |

Response: The SDT has modified the definition. The definition now reads "A number, either fixed or variable, usually expressed in $\mathrm{MW} / 0.1 \mathrm{~Hz}$, included in a Balancing Authority's Area Control Error equation to account for the Balancing Authority's Frequency Response contribution to the Interconnection, and discourage response withdrawal through secondary control systems."

| EKPC | No | "Frequency Bias" should not be used in the definition."Usually" can be omitted. |
| :--- | :---: | :--- |

Response: The SDT has modified the definition and "frequency bias" is not used in the revised definition. The definition now reads "A number, either fixed or variable, usually expressed in MW/0.1 Hz, included in a Balancing Authority's Area Control Error equation to account for the Balancing Authority's Frequency Response contribution to the Interconnection, and discourage response withdrawal through secondary control systems."

| LG\&E and KU Energy | No | We suggest the following changes to the definition: <br> 1. Delete the word "usually" |
| :--- | :--- | :--- |
|  |  | 2. Replace "set into" with "as part of". <br> 3. Replace the remainder of the sentence following "Area Control Error equation" with "that influences its <br> Automatic Generation Control (AGC) to provide its frequency response while Interconnection frequency is not <br> at its scheduled value" - (The frequency bias does not allow a BA to contribute its frequency response to the <br> Interconnection. The frequency bias term only affects the AGC response of the BA, which is part of its <br> frequency response usually minutes after the initial event and is dependent upon generation units being on <br> AGC control and capable of responding.) |
|  | 4. The suggested changes would result in the following definition:A value, (either a fixed or variable <br> Frequency Bias) expressed in MW/0.1 hertz as part of a Balancing Authority's Area Control Efror (ACE) <br> equation that influences its Automatic Generation Control (AGC) to provide its frequency response while <br> Interconnection frequency is not at its scheduled value. |  |

Response: The SDT did adopt the suggestion to remove, "set into" and replaced this phrase with, "included", however the team did not adopt the suggestion to

Consideration of Comments: Project 2007-12 BAL-003-1 - $1^{\text {st }}$ Draft

| Organization | Yes or No | Question 2 Comment |
| :--- | :--- | :--- |

delete the word, 'usually' as the inclusion of this word recognizes that there may be rare instances when the Frequency Bias Setting could be expressed in other than MW/0.1 Hz. The SDT did not adopt the third proposed change because it can cause confusion since primary Frequency Response cannot be delivered by AGC.

The SDT has modified the definition. The definition now reads "A number, either fixed or variable, usually expressed in $\mathrm{MW} / 0.1 \mathrm{~Hz}$, included in a Balancing Authority's Area Control Error equation to account for the Balancing Authority's Frequency Response contribution to the Interconnection, and discourage response withdrawal through secondary control systems."

| SERC OC Standards Review Group | No | We suggest the following changes to the definition: <br> 1. Delete "Frequency Bias" in the parenthetical expression - ("Frequency Bias" should not be used to define Frequency Bias) <br> 2. Delete the word "usually" <br> 3. Replace "set into" with "as part of" as defined in BAL-001. <br> 4. Replace the remainder of the sentence following "Area Control Error equation" with "that influences its Automatic Generation Control (AGC) to provide its frequency response while Interconnection frequency is not at its scheduled value" - (The frequency bias does not allow a BA to contribute its frequency response to the Interconnection. The frequency bias term only affects the AGC response of the BA, which is usually minutes after the initial event and is dependent upon generation units being on AGC control and capable of responding.) <br> 5. The suggested changes would result in the following definition"A value, fixed or variable, expressed in MW/0.1 hertz as part of a Balancing Authority's Area Control Error (ACE) equation that influences its Automatic Generation Control (AGC) to continue to provide its frequency response while Interconnection frequency is not at its scheduled value. |
| :---: | :---: | :---: |

Response: The SDT has modified the definition and "frequency bias" is not used in the revised definition and the phase, "set into" was replaced with "included". The SDT did not adopt the suggestion to delete the word, "usually' because there may be rare instances when the Frequency Bias Setting is expressed in other than MW/0.1 Hz. The SDT has modified the definition. The definition now reads "A number, either fixed or variable, usually expressed in MW/ 0.1 Hz , included in a Balancing Authority's Area Control Error equation to account for the Balancing Authority's Frequency Response contribution to the Interconnection, and discourage response withdrawal through secondary control systems."

| Midwest ISO Standards <br> Collaborators | No | Given that frequency response is "contributed" long before AGC has an impact, "contribute" should probably <br> be changed to "maintain". The goal is to ensure AGC does not withdraw frequency response and that it is <br> maintained while frequency is depressed. We are not sure if Frequency Response has a precise enough <br> definition and it is part of the definition of Frequency Bias Setting. The definition of Frequency Response <br> really just reflects how it is measured. It does not define what it really is which is the dynamic response of <br> load, generation, and other frequency responsive devices to a perturbation in frequency. |
| :--- | :---: | :--- |

| Organization | Yes or No | Question 2 Comment |
| :--- | :--- | :--- |
|  |  | The drafting team should also consider resolving the definition of Frequency Bias. Is it needed? It is often <br> confused with Frequency Bias Setting and is often used interchangeably with Frequency Response even <br> though the meanings are slightly different. |

Response: The SDT has modified the definition of Frequency Bias Setting. The definition now reads "A number, either fixed or variable, usually expressed in MW/ 0.1 Hz , included in a Balancing Authority's Area Control Error equation to account for the Balancing Authority's Frequency Response contribution to the Interconnection, and discourage response withdrawal through secondary control systems." The SDT believes that based on the modified definition, the use of the term "contribution" better describes the action that has taken place.
The SDT has reviewed the current definition of Frequency Response and believes that the current definition is both accurate and appropriate.

| We Energies | No | Given that frequency response is "contributed" long before AGC has an impact, "contribute" should probably <br> be changed to "maintain." The goal is to ensure AGC does not withdraw frequency response and that it is <br> maintained while frequency is depressed. We are not sure if Frequency Response has a precise enough <br> definition and it is part of the definition of Frequency Bias Setting. The current NERC Glossary definition of |
| :--- | :--- | :--- |
|  |  | Frequency Response really just reflects how it is measured, it does not define Frequency Response. <br> Frequency Response is the dynamic real power response of load, generation, and other devices to a <br> perturbation in frequency. |
|  | The drafting team should also consider resolving the definition of Frequency Bias. Is it needed? It is often <br> confused with Frequency Bias Setting and is often used interchangeably with Frequency Response even <br> though the meanings are slightly different. |  |

Response: The SDT has modified the definition of Frequency Bias Setting. The definition now reads "A number, either fixed or variable, usually expressed in MW/0.1 Hz, included in a Balancing Authority's Area Control Error equation to account for the Balancing Authority's Frequency Response contribution to the Interconnection, and discourage response withdrawal through secondary control systems." The SDT believes that based on the modified definition, the use of the term "contribution" better describes the action that has taken place.
The SDT has reviewed the current definition of Frequency Response and believes that the current definition is both accurate and appropriate.

| SPP Standards Development | No | We would suggest inserting 'secondary' in front of Frequency Response at the end of the sentence and delete <br> 'Frequency Bias' following 'variable' at the beginning of the sentence. |
| :--- | :--- | :--- |

Response: The SDT has modified the definition. The definition now reads "A number, either fixed or variable, usually expressed in $\mathrm{MW} / 0.1 \mathrm{~Hz}$, included in a Balancing Authority's Area Control Error equation to account for the Balancing Authority's Frequency Response contribution to the Interconnection, and discourage response withdrawal through secondary control systems." The SDT believes that the modified definition is more appropriate than the recommended change. The SDT does not believe it is necessary to differentiate between primary and secondary Frequency Response in the definition.

| IRC Standards Review | No | The definition appears to be accurate, but where is "fixed" and "variable" Frequency Bias defined in the |
| :--- | :--- | :--- |

| Organization | Yes or No | Question 2 Comment |
| :--- | :--- | :--- |
| Committee |  | context of these requirements? Should it be Frequency Bias Setting, instead? <br> "Fixed" seems to be straightforward, but what is "variable"? <br> How often must Frequency Bias Setting change in order to be considered to be "variable"? |

Response: The SDT has modified the definition. The definition now reads "A number, either fixed or variable, usually expressed in $\mathrm{MW} / 0.1 \mathrm{~Hz}$, included in a Balancing Authority's Area Control Error equation to account for the Balancing Authority's Frequency Response contribution to the Interconnection, and discourage response withdrawal through secondary control systems."
If the ERO provides the Frequency Bias Setting then it is considered fixed. If the ERO accepts a methodology for determining the Frequency Bias Setting then it is considered variable.

| ERCOT | No | The definition appears to be accurate, but where is "fixed" and "variable" Frequency Bias defined in the <br> context of these requirements? Should it be Frequency Bias Setting, instead? "Fixed" seems to be <br> straightforward, but what is "variable"? How often must Frequency Bias Setting change in order to be <br> considered to be "variable"? |
| :--- | :---: | :--- |

Response: The SDT has modified the definition. The definition now reads "A number, either fixed or variable, usually expressed in $\mathrm{MW} / 0.1 \mathrm{~Hz}$, included in a Balancing Authority's Area Control Error equation to account for the Balancing Authority's Frequency Response contribution to the Interconnection, and discourage response withdrawal through secondary control systems."
If the ERO provides the Frequency Bias Setting then it is considered fixed. If the ERO accepts a methodology for determining the Frequency Bias Setting then it is considered variable.

| Progress Energy | No | A bias, either fixed or variable, usually expressed in MW/0.1 Hz, included in a Balancing Authority's Area <br> Control Error equation to account for the Balancing Authority's Frequency Response contribution to the <br> interconnection, and prevent response withdrawal through secondary control systems. <br> The changes suggested are to clarify that biasing of the ACE equation "allow[s]" primary frequency response <br> to continue beyond the initial event window by accounting for it in the ACE input to secondary control systems <br> (i.e. AGC). It's important to note that Primary Frequency Response will occur no matter what the Bias value is <br> set to in the ACE equation, and biasing "supports" the response until the frequency is restored". |
| :--- | :--- | :--- |

Response: The SDT has modified the definition. The definition now reads "A number, either fixed or variable, usually expressed in $\mathrm{MW} / 0.1 \mathrm{~Hz}$, included in a Balancing Authority's Area Control Error equation to account for the Balancing Authority's Frequency Response contribution to the Interconnection, and discourage response withdrawal through secondary control systems." The SDT believes that the revised definition agrees with your comment related to supporting the response until frequency is restored. The SDT also believes that it is impossible to "prevent" withdrawal and that you can only try to discourage withdrawal.

| NIPSCO | No | Frequency Bias and Frequency Response are not the same thing and that may be why "F" \& "R" were not |
| :--- | :--- | :--- |

| Organization | Yes or No | Question 2 Comment |
| :---: | :---: | :---: |
|  |  | capitalized in the present definition. <br> I think the word "secondary" should appear per R2 finishing something like this: "to contribute to secondary (non-immediate)Interconnection frequency control.", removing Frequency Response altogether.(I do understand that you are bringing the FR and Bias closer together). |
| Response: The SDT has modified the definition. The definition now reads "A number, either fixed or variable, usually expressed in MW/0.1 Hz, included in a Balancing Authority's Area Control Error equation to account for the Balancing Authority's Frequency Response contribution to the Interconnection, and discourage response withdrawal through secondary control systems." The SDT believes that the modified definition is more appropriate than the recommended change. The SDT does not believe it is necessary to differentiate between primary and secondary Frequency Response in the definition. |  |  |
| Energy Mark, Inc. | No | Comment 7: The definition should be:"A value, (either a fixed or variable Frequency Bias), usually expressed in MW/0.1 Hz, set into a Balancing Authority Area Control Error equation that indicates to the Balancing Authority its contribution of Frequency Response to the Interconnection. <br> Comment 8: The Frequency Bias Setting does not allow or disallow the Frequency Response to be contributed. The BA will contribute its natural Frequency Response to the interconnection through the independent actions of its loads and generators. The only influence that the Frequency Bias Setting has is that it causes the AGC System, and hopefully other outer-loop control systems, to include that natural Frequency Response when developing control actions to implement through AGC in response to BA balancing requirements in a time frame well after the Frequency Response has been provided by the independent actions of its loads and generators. |
| Response: The SDT has modified the definition. The definition now reads "A number, either fixed or variable, usually expressed in MW/ 0.1 Hz , included in a Balancing Authority's Area Control Error equation to account for the Balancing Authority's Frequency Response contribution to the Interconnection, and discourage response withdrawal through secondary control systems." <br> The SDT agrees with comment \#8. |  |  |
| American Electric Power | No | If "the proposed standard's intent is to collect data needed to accurately analyze existing Frequency Response, set a minimum Frequency Response obligation, provide a uniform calculation of Frequency Bias Settings that transition to values closer to Frequency Response, and encourage coordinated AGC operation", it appears the current and stated definition is precluding the process for determination of the Frequency Bias Setting itself. <br> I believe it is too early to state in definition the frequency bias setting to be based on MW/0.1 Hz, when this appears to be more of the expected response. <br> Using the word usually does not appear to be defining anything. To eventually get to an acceptable performance measure with reliability basis the project needs to be expanded to also address associated |

| Organization | Yes or No |  |
| :--- | :--- | :--- |
|  |  | Question 2 Comment |
| Governor droop issues, which inherently affect response. <br> When the current definition references using "either a fixed or variable Frequency Bias", it does not state <br> whether or not to be applied in the calculation to either load or generation. The current Standard uses $1 \%$ of <br> yearly estimated peak demand for BAs that serve load, when the actual load at time of disturbance could be <br> greatly different. Response is more directly related to the amount of Generation on-line and active AGC within <br> the BA at time of trip.MW/O.1 Hz states more of expected result of response than defining Frequency Bias <br> Setting. |  |  |

Response: The SDT has modified the definition. The definition now reads "A number, either fixed or variable, usually expressed in $\mathrm{MW} / 0.1 \mathrm{~Hz}$, included in a Balancing Authority's Area Control Error equation to account for the Balancing Authority's Frequency Response contribution to the Interconnection, and discourage response withdrawal through secondary control systems."The " $\mathrm{MW} / 0.1 \mathrm{~Hz}$ " term represents the units of Frequency Bias and is not intended to reference magnitude.
Issues dealing with governor droop are outside of the scope of the industry approved SAR.
The SDT agrees with the last comment which is why the SDT also supports using a variable bias where appropriate.

| Duke Energy | No | Duke Energy would suggest not using "Frequency Bias" in the definition of "Frequency Bias Setting". <br> In addition, Duke Energy would like to point out that ACE does not allow Frequency Response; response will <br> occur with or without the ACE equation. The Frequency Bias Setting is needed so that the AGC does not <br> negate what may be provided in frequency response. The bias component of ACE provides the feedback so <br> that a BA may sustain the intended amount of response with secondary control as long as Actual Frequency <br> deviates from Scheduled Frequency. Duke Energy would suggest the following:"A fixed or variable value <br> usually expressed in MW/O.1 Hz, set into a Balancing Authority Area Control Error equation to bias the control <br> of resources so that Interconnection frequency is driven toward the Scheduled Frequency." |
| :--- | :---: | :--- |

Response: The term Frequency Bias has been removed from the definition.
The SDT has modified the definition. The definition now reads "A number, either fixed or variable, usually expressed in MW/0.1 Hz, included in a Balancing Authority's Area Control Error equation to account for the Balancing Authority's Frequency Response contribution to the Interconnection, and discourage response withdrawal through secondary control systems."

| Associated Electric Cooperative, <br> Inc. | No | SEFRD - I had to read this definition several times because "The individual sample of event data" is actually <br> an internally calculated value derived from a set of event sample data, and not really a "sample" value at all. <br> So, I believe the SEFRD definition needs further work. |
| :--- | :---: | :--- |

Response: The SDT agrees with your concern regarding the definition of SEFRD. The SDT has removed the definition from the standard.

| Manitoba Hydro | Yes |  |
| South Carolina Electric and Gas |  | We suggest the following changes to the definition: 1. Delete "Frequency Bias" in the parenthetical expression <br> - ("Frequency Bias" should not be used to define Frequency Bias) <br> 2. Delete the word "usually" <br> 3. Replace "set into" with "as part of" as defined in BAL-001. <br> 4. Replace the remainder of the sentence following "Area Control Error equation" with "that influences its Automatic Generation Control (AGC) to provide its frequency response while Interconnection frequency is not at its scheduled value" - (The frequency bias does not allow a BA to contribute its frequency response to the Interconnection. The frequency bias term only affects the AGC response of the BA, which is part of its frequency response usually minutes after the initial event and is dependent upon generation units being on AGC control and capable of responding.) <br> 5. The suggested changes would result in the following definition"A value, fixed or variable, expressed in MW/O.1 hertz as part of a Balancing Authority's Area Control Error (ACE) equation that influences its Automatic Generation Control (AGC) to provide its frequency response while Interconnection frequency is not at its scheduled value. |
| Response: The term, "Frequency Bias" was deleted, the phrase, "set into" was replaced with, "included in". The other suggestions were not adopted. The SDT has modified the definition. The definition now reads "A number, either fixed or variable, usually expressed in MW/0.1 Hz, included in a Balancing Authority's Area Control Error equation to account for the Balancing Authority's Frequency Response contribution to the Interconnection, and discourage response withdrawal through secondary control systems." The SDT believes that the modified definition addresses your concerns but provides for additional clarity as to the action that has taken place. |  |  |
| Northeast Power Coordinating Council |  | Refer to the response to Question 17. |

## NERC

## Organization

 Yes or No Question 2 CommentResponse: Please refer to the SDT response to Question 17.
3. The proposed purpose statement in the draft standard is: To require sufficient Frequency Response from the Balancing Authority to maintain Interconnection Frequency within predefined bounds by arresting frequency deviations and supporting frequency until the frequency is restored to schedule. To provide consistent methods for measuring Frequency Response and determining the Frequency Bias Setting.

Do you agree with this purpose? If not, please explain in the comment area.

Summary Consideration: Several of the commenters agree with the purpose statement of the draft standard as written. Most of the feedback received disagreeing with the purpose statement reflects general comments and suggestions for the SDT to consider. A major concern identified is that the minimum level of Frequency Bias Setting established needs to be determined based on extensive data analysis of field trial results. Some commenters even stated that the standard should not be revised until the field trial is completed, performance criteria and measures determined, and results vetted by industry. Several commenters expressed concern with making the Balancing Authority the only entity responsible for maintaining interconnection frequency and arresting frequency decline; with an observation that the purpose statement presumes that each Balancing Authority must have generation online to meet a predetermined frequency response obligation. It was pointed out that on occasion small Balancing Authorities may not have generation online and instead rely on load regulation and energy agreements to meet their energy needs. Another commenter indicated that since NERC and FERC have differentiated Frequency Response from Frequency Regulation, the standard should only apply to unplanned contingencies that occur.
In response to these general comments the SDT notes that the minimum Frequency Response level used during the field trial uses a deterministic approach and the actual level of Frequency Response required in the final version of the draft standard will be based on field trial results. Issues involving governor droop, dead-band settings, and governor operation are outside the scope of the project's approved SAR. The purpose statement does not mandate generation dispatch for Frequency Response. This standard only prescribes a minimum Frequency Response obligation for reliable BES operation. Each entity must determine how to meet its Frequency Response obligation using existing resources and agreements.
Another commenter noted that the purpose statement addresses several concepts that do not share a common timeframe. In response, the SDT has revised Attachment A to explain the relationship for the different time frames associated with these concepts.

| following edits to what appears to be a corrected purpose statement as provided in this question:To require |  |  |
| sufficient Frequency Response from the Balancing Authority to maintain Interconnection Frequency within |  |  |
| predefined bounds by arresting frequency deviations due to contingencies on the interconnected BES and |  |  |
| supporting frequency until the frequency is restored to schedule. To provide consistent methods for |  |  |
| measuring Frequency Response and determining the Frequency Bias Setting. |  |  |
| As NERC/FERC has differentiated Frequency Response from Frequency Regulation, the standards |  |  |

| Organization | Yes or No | Question 3 Comment |
| :---: | :---: | :---: |
|  |  | addressing Frequency Response should clearly be related to unplanned contingencies occurring on the interconnected BES. |
| Response: The SDT believes adequate Frequency Response is important during both normal and emergency operations however it is easier to measure Frequency Response during a contingency which is why the SDT favors this rationale. |  |  |
| IRC Standards Review Committee | No | If this is really intended to be a Field Trial, it should be written as such and the standard should not be developed or promulgated until the Field Trial has accomplished its purpose and the performance criteria and measures have been determined. We request that the results of the Field Trial should be published and discussed BEFORE any changes are made. The standard should be put into place later; it is premature at this time. Since this is to be a data gathering process to be used to determine appropriate performance parameters, the purpose statement of the Field Trial should be changed to read as follows:To determine require sufficient Frequency Response arranged by from the Balancing Authority to maintain Interconnection Frequency within predefined bounds by responding to and arresting frequency deviations and supporting frequency until the frequency is restored to schedule. To identify and establish provide consistent methods for measuring Frequency Response and determining the Frequency Bias Setting and Frequency Response Obligation.We should not write the new standard and its requirements until this Field Trial work has been accomplished; to do so possibly would result in difficulty changing the standard requirements based upon Field Trial results. <br> Further, while we do not have any issue with the general intent of the scope statement, we have a difficulty seeing the BA being the only entity held responsible for maintaining interconnection frequency and arresting frequency deviations. When there is a sudden and sizable change to system resource or demand, the first response to a frequency deviation caused by this change would be the generators' governors. This will provide a mitigating effect for the immediate seconds up to minutes. The frequency bias setting will then kick in to supplement the mitigation need. The governors are owned by the Generator Owners; the BAs do not own these facilities and hence can do little to address frequency response during this initial period.To hold only the BA responsible for maintaining interconnection frequency and arresting frequency deviations would be inappropriate. The industry needs to have a discussion to determine who should be held responsible for providing governor responses immediately following an event, and by what mechanism, and for implementing additional measures thereafter. We suggest that BAL-003 development be withheld until this discussion takes place and a decision is made on who and how the governor response shall be provided. |

Response: The original SAR was for data collection. The SDT developed a supplemental SAR to address the FERC directives.
The project schedule adopted for the development of the BAL-003 standard has been approved by the FERC and includes filing a standard by May, 2012. Modifications to this schedule require both NERC and FERC approval.
This issue concerning the BA being the only entity being held responsible has been discussed and the SDT understands your concern. However, governor droop requirements, dead-band settings and governor operation are outside the scope of the project approved SAR. The SDT believes that the Generator Verification

## ISO New Engand Inc.

No
If this is really intended to be a Field Trial, it should be written as such and the standard should not be developed or promulgated until the Field Trial has accomplished its purpose and the performance criteria and measures have been determined. The standard should be put into place later; it is premature at this time. Since this is to be a data gathering process to be used to determine appropriate performance parameters, the purpose statement of the Field Trial should be changed to read as follows:To determinerequire sufficient Frequency Response arranged by from the Balancing Authority to maintain Interconnection Frequency within predefined bounds by responding to and arresting frequency deviations and supporting frequency until the frequency is restored to schedule. To identify and establishprovide consistent methods for measuring Frequency Response and determining the Frequency Bias Setting and Frequency Response Obligation.We should not write the new standard and its requirements until this Field Trial work has been accomplished; to do so possibly would result in difficulty changing the standard requirements based upon Field Trial results.
Further, while we do not have any issue with the general intent of the scope statement, we have a difficulty seeing the BA being the only entity held responsible for maintaining interconnection frequency and arresting frequency deviations. When there is a sudden and sizable change to system resource or demand, the first response to a frequency deviation caused by this change would be the generators' governors. This will provide a mitigating effect for the immediate seconds up to minutes. The frequency bias setting will then kick in to supplement the mitigation need. The governors are owned by the Generator Owners; the BAs do not own these facilities and hence can do little to address frequency response during this initial period. To hold only the BA responsible for maintaining interconnection frequency and arresting frequency deviations would be inappropriate. The industry needs to have a discussion to determine who should be held responsible for providing governor responses immediately following an event, and by what mechanism, and for implementing additional measures thereafter. We suggest that BAL-003 development be withheld until this discussion takes place and a decision is made on who and how the governor response shall be provided.

Response: The original SAR was for data collection. The SDT developed a supplemental SAR to address the FERC directives.
This issue concerning the BA being the only entity being held responsible has been discussed and the SDT understands your concern. However, governor droop requirements, dead-band settings and governor operation are outside the scope of the project approved SAR. The purpose of the standard is to establish a minimum Frequency Response threshold that prevents unreliable BES operation.
This issue concerning the BA being the only entity being held responsible has been discussed and the SDT understands your concern. However, governor droop requirements, dead-band settings and governor operation are outside the scope of the project approved SAR. The SDT believes that the Generator Verification standards will help address these concerns. The SDT encourages entities to develop a SAR to address generators.

| Kansas City Power \& Light No This purpose statement presumes that each Balancing Authority (BA) will have generation online to meet a <br> predetermined frequency response obligation. There are many small BA's that do not have any generation <br> online and rely on load regulation agreements and energy agreements to provide their energy needs during <br> parts of the year. This purpose statement would not allow a BA to operate without generation online. <br> Response: The purpose statement does not mandate generation dispatch for Frequency Response. This standard only prescribes a minimum Frequency <br> Response obligation for reliable BES operations. Each entity must determine how to meet this obligation using existing resources and agreements.   <br> NIPSCO No Yes, "Interconnection frequency", small "f". <br> Response: The SDT thanks you for this comment and has corrected the error.   <br> American Electric Power No AEP believes the statement should read "To require sufficient Frequency Response from governors and AGC <br> of Generators within the Balancing Authority to maintain Interconnection Frequency within predefined bounds <br> by arresting frequency deviations and supporting frequency until the frequency is restored to schedule.To <br> provide consistent methods for measuring Frequency Response from governors and AGC of Generators   <br> within the Balancing Authority for determining the overall Frequency Bias Setting threshold. Since   <br> Generators are directly responsible for response, applicability must be added to Generator Operators.   |
| :--- |

Response: The drafting team disagrees with this recommendation because the FERC Order 693 requires a technology neutral performance standard for the purpose of providing Frequency Response.
Patterson Consulting, Inc.
No
The purpose should not expect Frequency Response to maintain frequency beyond a few minutes, perhaps 15 minutes for example. This purpose statement suggests the requirements will be "...to maintain Interconnection Frequency within predefined bounds by arresting frequency deviations and support frequency until the frequency is restored to schedule..." The phrase "until the frequency is restored to schedule" is problematic since regulation must bring frequency to schedule. Frequency Response, and the associated requirements, should not be expected to substitute for poor regulation beyond the first few minutes.

Response: The focus of the standard is to establish sustainable primary frequency control which can seamlessly coordinate with secondary frequency control for maintaining system frequency.

| Organization | Yes or No |  |
| :--- | :---: | :--- |
| Independent Electricity System <br> Operator | No | We do not have any issue with the general intent of the scope statement, but have a difficulty in seeing the <br> BA being the only entity held responsible for maintaining interconnection frequency and arresting frequency <br> deviations. When there is a sudden and sizable change to system resource or demand, the system frequency <br> will change. The first response to such deviation would be the generators' governors. This will provide a <br> mitigating effect for the immediate seconds up to minutes. The frequency bias setting will then kick in to <br> supplement the mitigation need. To hold only the BA responsible for maintaining interconnection frequency <br> arresting frequency deviations would be only part of the solution. The industry needs to have a discussion to <br> determine who should be held responsible for providing governor responses, and by what mechanism. |

Response: The SDT thanks you for your comment. This issue concerning the BA being the only entity being held responsible has been discussed and the SDT understands your concern. However, governor droop requirements, dead-band settings and governor operation are outside the scope of the project approved SAR. The SDT believes that the Generator Verification standards will help address these concerns. The SDT encourages entities to develop a SAR to address generators.

For the field trial, the minimum level of response needed uses a deterministic approach. The actual level of response required may be established in the final version of the standard using field trial information obtained.

The SDT does not agree with your comment concerning withholding the development of a standard addressing Frequency Response. The development of a standard addressing Frequency Response was identified in FERC Order 693. FERC further directed the ERO to finalize a standard addressing Frequency Response in an order in February 2010 within six (6) months which they later granted an extension. The project schedule adopted for the development of the BAL-003 standard has been approved by the FERC and includes filing a standard by May, 2012. Modifications to this schedule would require both NERC and FERC approval.

| ENBALA Power Networks | Yes | ENBALA strongly agrees that a Frequency Response standard is necessary to ensure reliable operation of <br> the bulk power system. We fully support all efforts to understand the declining trend, and the development of <br> accurate models, of Frequency Response in each Interconnection. |
| :--- | :---: | :--- |
| Response: The SDT thanks you for your affirmative response and clarifying comment. |  |  |

4. Requirement 1 identifies a minimum level of Frequency Response.

## R1. Each Balancing Authority shall achieve a Frequency Response Measure (FRM) (as detailed in Attachment A and calculated on FRS Form 1) that is equal to or more negative than its Frequency Response Obligation (FRO).

Do you agree with the concept that a Balancing Authority should be required to achieve a minimum level of Frequency Response and the method for measurement? If not, please explain in the comment area.

Summary Consideration: Most commenters supported the concept however a significant majority did not agree with the method for measurement. In general commenters indicated the sample size of 25 events for determining FRM is too small; insufficient information was provided to address the use of variable bias; the FRM and FRO definitions were unclear with questionable determination methods; and the standard should reference Reserve Sharing Groups. Some commenters also indicated that the measure may not apply to a single BA interconnection; that the draft standard dictated how compliance is provided with respect to Attachment A and FRS Form 1 references; that requirements would not allow a BA to operate without generation online; and expressed concern that the BA may not own and operate resources yet will still have the compliance obligation.
The SDT is currently evaluating a probabilistic method for determining the FRO. After consideration of industry comments, the SDT converted Attachment A into two documents - a calculation methodology included with the standard, and a separate supporting document providing requirement rationale. The SDT revised the definitions for FRO \& FRM; incorporated Reserve Sharing Groups into the draft standard; modified FRS Form 1 to allow for adjustments; and clarified how an entity is to show compliance. The SDT also provided an explanation addressing the use of Variable Bias and provided an administrative procedure for the ERO's FRO determination.

R1. Each Balancing Authority or Reserve Sharing Group (RSG) shall achieve an annual Frequency Response Measure (FRM) (as detailed in Attachment A and calculated on FRS Form 1) that is equal to or more negative than its Frequency Response Obligation (FRO) to ensure that sufficient Frequency Response is provided by each BA or RSG to maintain an adequate level of Frequency Response in the Interconnection.

| Organization | Yes or No | Question 4 Comment |
| :--- | :---: | :--- |
| Santee Cooper | No | The concept seems reasonable but since the measure of compliance (FRM) is determined only after the 25 <br> events are identified; it is a lagging indicator. The BA may have to ensure it measures all frequency <br> excursions and develops its own leading indicator to ensure compliance following year end. |
| Response: The SDT agrees that the measure is a lagging indicator and recommends that the list of reportable events be posted on a quarterly basis. |  |  |
| LG\&E and KU Energy | No | The concept seems reasonable but since the measure of compliance (FRM) is determined only after the 25 <br> events are identified; it is a lagging indicator. The BA may have to ensure it measures all frequency |

| Bonneville Power Administration | No | BPA agrees that there should be a minimum level of Frequency Response, but disagree with the way the <br> measure is obtained in the requirement. <br> o R1 - BPA suggests replacing "achieve" with "calculate". Achieve: indicates it is a performance. <br> o R1 - BPA does not agree with the requirements in Attachment A not being in the standard. These should <br> not be modified without full review and voting by members. <br> o R1 - BPA believes that there should be more description on Variable Bias. What variable bias number <br> should we use: average, minimum, peak for the event? BPA feels that the peak bias of each event would be <br> appropriate. |
| :--- | :--- | :--- |

Response: The SDT believes the intent of the standard is for each BA to "achieve" its Frequency Response Obligation.

| Organization | Yes or No | Question 4 Comment |
| :--- | :--- | :--- |

The SDT is not incorporating additional standard requirements by means of Attachment A information however the SDT recognizes the need to convert Attachment A into two documents. The first document will remain part of the standard as Attachment A and describe the calculation methodology utilized. The second document will explain the rationale for the requirements as supplemental standard information.
Variable frequency bias settings are determined by Balancing Authorities using a calculation based on present operating conditions. The SDT agrees Variable Bias requires more description and will review this concern during the field trial.

| IRC Standards Review | No | The SRC agrees that a Frequency Response of some minimum level for each Interconnection should be <br> achieved. However, the measure as described does not apply to all Interconnections. It does not apply to <br> Cingle BA Interconnections such as ERCOT and Hydro Quebec. |
| :--- | :--- | :--- |
| This requirement should be added later-not included now; and it should clarify what the BA must do and what |  |  |
| the response providers must do. BAs do not own and operate the resources. An entity which does own or |  |  |
| operate the resources may also be registered as a BA, but an entity which does not own or operate resources |  |  |
| may also be registered as a BA. Therefore, it is important to detail what a BA must do and also to detail what |  |  |
| the resource owner or operator must do. The resource owner may be registered as a GO or a TO or even a |  |  |
| DP. The resource operator may be registered as a GOP, a TOP, or a LSE. The BA must establish an |  |  |
| operations plan, using data provided to it by the resource owners and or operators, that will meet the |  |  |
| performance requirements. The BA must then deploy the proper amount of response through AGC or verbal |  |  |
| instructions to supplement the automatic responses that the resources will provide, must calculate the actual |  |  |
| responses after-the-fact, and report the performance as required. The resources must, as standards already |  |  |
| provide, comply with the deployments and instructions provided by the BA. However, if an entity which is |  |  |
| functioning as a BA does not own its resources, nor does it directly operate those resources, the BA cannot |  |  |
| ensure the achievement. The standard must not create an organizational or contractual arrangement that |  |  |
| dictates how the compliance is provided. It should state what must be done, not how. If entities choose to |  |  |
| write and enter into such arrangements, that should be permissible, but not required. |  |  |
| Specific to R1, the wording does not correspond to the figures shown in the FRS (Form 1) in that the FRM |  |  |

Response: This standard is intended to apply to all Interconnections. The SDT has modified the definition for FRO to read, "The Balancing Authority's share of the required Frequency Response needed for the reliable operation of an Interconnection."
The standard does not dictate a particular generation dispatch strategy. The standard only prescribes a minimum obligation. The entity must determine how to meet this minimum obligation.
FRS Form 1 has been revised to allow for adjustments.
ERCOT $\quad$ No $\quad$ The SRC agrees that a Frequency Response of some minimum level for each Interconnection should be achieved. However, the measure as described does not apply to all Interconnections. It does not apply to

| :---: | :---: | :---: |
|  |  | single BA Interconnections such as ERCOT and Hydro Quebec. This requirement should be added later-not included now; and it should clarify what the BA must do and what the response providers must do. BAs do not own and operate the resources. An entity which does own or operate the resources may also be registered as a BA, but an entity which does not own or operate resources may also be registered as a BA. Therefore, it is important to detail what a BA must do and also to detail what the resource owner or operator must do. The resource owner may be registered as a GO or a TO or even a DP. The resource operator may be registered as a GOP, a TOP, or a LSE. The BA must establish an operations plan, using data provided to it by the resource owners and or operators, that will meet the performance requirements. The BA must then deploy the proper amount of response through AGC or verbal instructions to supplement the automatic responses that the resources will provide, must calculate the actual responses after-the-fact, and report the performance as required. The resources must, as standards already provide, comply with the deployments and instructions provided by the BA. However, if an entity which is functioning as a BA does not own its resources, nor does it directly operate those resources, the BA cannot ensure the achievement. The standard must not create an organizational or contractual arrangement that dictates how the compliance is provided. It should state what must be done, not how. If entities choose to write and enter into such arrangements, that should be permissible, but not required. Specific to R1, the wording does not correspond to the figures shown in the FRS (Form 1) in that the FRM (the median) is -14.5 whereas the FRO is -15.8 . The FRO is more negative than the FRM, which does not seem to correspond to what's stipulated in R1 (FRM to be equal or more negative than its FRO). |
| Response: This standard is intended to apply to all Interconnections. The SDT has modified the definition for FRO to read, "The Balancing Authority's share of the required Frequency Response needed for the reliable operation of an Interconnection." |  |  |
| The standard does not dictate a particular generation dispatch strategy. The standard only prescribes a minimum obligation. The entity must determine how to meet this minimum obligation. |  |  |
| Kansas City Power \& Light | No | This requirement presumes that each Balancing Authority (BA) will have generation online to meet a predetermined frequency response obligation. There are many small BA's that do not have any generation online and rely on load regulation agreements and energy agreements to provide their energy needs during parts of the year. This requirement would not allow a BA to operate without generation online. <br> Under Requirement 1, item 2a in Attachment A suggests governor deadband as 36MHz (Megahertz). Suggest what is intended is 36 mHz (millihertz). <br> The Frequency Response Obligation determination for the interconnection as described in Attachment A is a crude method and will result in obligations that will exceed the FRO that is intended. This will result in additional cost to BA's that is unnecessary to achieve the purpose of maintaining sufficient generation online to arrest frequency degradation events caused by loss of generating resources. |

| Organization | Yes or No | Question 4 Comment |
| :--- | :--- | :--- |
|  |  | The current NERC method for calculating a BA's actual frequency response are inaccurate and provide <br> misleading guidance in the actual frequency response of a BA. These methods need considerable <br> improvement before any attempts to hold a BA to an expected level of frequency response as this proposal <br> has stated. |

Response: The standard does not dictate a particular generation dispatch strategy. The standard only prescribes a minimum obligation. The entity must determine how to meet this minimum obligation.
The SDT has removed the reference to governor deadband.
The minimum level of response selected for the field trial uses a deterministic approach. The actual level of response specified in the final version of the draft standard may be based on analysis of data obtained from the field trial. The SDT is also evaluating a probabilistic method for determining the FRO.
The SDT has modified FRS Form 1 to correctly calculate Frequency Response.

| Southern Company | No | Comments: Proposed Standard <br> Comment 1: BAL-003-1, Requirement R1. The requirement should be made less prescriptive by removing <br> references to Attachment A and FRS Form 1. The responsible entity should understand the fundamental and <br> basic requirement - to achieve a Frequency Response Measure. Where the methodology is specified or how <br> the BA is supposed to achieve it should be a matter of compliance and/or implementation and not a part of <br> the basic requirement. Proposed language is as follow: Each Balancing Authority shall achieve a Frequency <br> Response Measure (FRM) that is equal to or more negative than its Frequency Response Obligation (FRO). |
| :--- | :--- | :--- |

Response: The SDT believes that Requirement 1 needs to reference FRS Form 1 in order for the calculation methodology to be consistent for all interconnections and has removed the reference to Attachment A. The SDT has also revised FRS Form 1 to correctly calculate Frequency Response and to allow for adjustments.

| Progress Energy | No | Progress Energy believes the Eastern Interconnection does not have the same issues with frequency <br> experienced in the other two interconnections, and that load response is significant enough in the <br> interconnection to arrest and stabilize frequency as long as BAs do not withdraw that effect (accurate biasing <br> of the ACE equation). <br> We also believe this standard should reference standrd PRC-024 related to accurate relay settings to allow <br> out of bounds operations related to frequency and voltage deviations. |
| :--- | :---: | :--- |

Response: Under certain system conditions the response of frequency sensitive load to a frequency excursion may be sufficient to arrest and stabilize frequency following an event. The eastern interconnection may also demonstrate greater stability as compared to the other interconnections. However, frequency stability is not assured to be achieved in this manner for all system conditions, even for the eastern interconnection irrespective of Frequency Bias setting accuracy.
The intent of BAL-003 is independent of PRC-024 intent. Specifically the purpose of BAL-003 is to better match a Balancing Authority's Frequency Bias Setting to its Frequency Response Characteristic, which should also reduce the probability for UFLS activation. The purpose of PRC-024 is to ensure generation remains

| Organization | Yes or No | Question 4 Comment |
| :--- | :--- | :--- |

connected during a tolerable frequency or voltage excursion. Furthermore, consideration of voltage deviations is outside the scope of the approved project.

| NIPSCO | No | Yes and no, similar to BAL-002 I think this should read "Each Balancing Authority or Reserve Sharing Group shall ....., With so many BA's I believe the RSGs will be play a big role in this compliance ... This comment applies to only R1, |
| :---: | :---: | :---: |
| Response: The SDT has revised Requirement R1 to reference Reserve Sharing Groups. |  |  |
| NorthWestern Energy | No | A Balancing Authority's frequency response is based upon a "median" value calculated from analyzing multiple events. Frequency response during some of these events is better than others, depending on the system conditions at the time and the amount system loading and unloaded generation online at the time of the event. Given these circumstances a BA's actual response could vary by event (better or worse than median), thus compliance measurement per event to a frequency response obligation based on the median response (over multiple events) could put BA's in non-compliant situations unjustly. |
| Response: The SDT agrees that compliance should not be based on an individual event but based on a series of events. |  |  |
| Energy Mark, Inc. | No | Comment 9: I agree that each BA should be required to provide a minimum level of Frequency Response to provide for its share of the total Frequency Response required for interconnection reliability. <br> Comment 10: I also agree with the methods used to measure SEFRD subject to my comments on FRS Form 1. <br> Comment 11: I do not agree that the method suggested for setting the FRO will achieve the desired goal of maintaining interconnection reliability. The measurement method offered only evaluates the supply of Frequency Response. It does not evaluate the demand (need) for Frequency Response. Since frequency error is the difference between the demand and supply any effective measure for maintaining reliability due to frequency error must include both the demand and supply parts of this balance. As a consequence, the method will be blind to changes (good or bad) in the demand for Frequency Response. Changes in the demand for Frequency Response will require subsequent changes in the supply for Frequency Response that this standard fails to address until the following year and leaves the interconnection at risk for unreliable operation. <br> Comment 12: The requirements associated with Frequency Response as defined in this standard will not assure interconnection reliability. Frequency Response is a two part service. The first part of this service is the rate at which energy is supplied in proportion to frequency error. This first part is commonly represented as the Frequency Response and the corresponding Frequency Bias Setting. The second part of the service is the amount of capacity that the BA stands ready to supply at this stated proportion in response to frequency error. Failure to effectively specify and measure the amount of capacity that the BA stands ready to supply at the stated proportion could put the interconnection at reliability risk when the required amount of capacity is |

| Organization | Yes or No |  |
| :--- | :---: | :--- |
|  | Question 4 Comment |  |
| Response: Comment 11 - The FRO provides a target for ensuring robust frequency response is achieved by all Balancing Authorities. Both FRO and FRM values <br> are considered by the algorithm determining the Frequency Bias Setting for the next year. While there is mutual dependence between supply and demand with <br> respect to frequency response, the resultant frequency deviation is more important than the cause as it is the effect on system operations realized that <br> determines the magnitude of control response required for reliability. It is expected robust frequency control will yield smaller frequency deviations during events <br> and in turn require less incremental control response than currently realized for maintaining frequency. <br> Comment 12 - Capacity is an important yet independent consideration. First, responsive robust control is necessary. Next, the Frequency Bias Setting must <br> better approximate the Frequency Response Characteristic for improved control response. Adequate capacity is an implicit assumption for reliable grid operation. |  |  |

| Hydro-Quebec TransEnergie | No | The proposed method is good to measure frequency response at point "B". However, point "C" is not taken in <br> consideration in this measure. <br> As for the FRO, a N-2 criteria is more stringent for an Interconnection with less units than a large <br> Interconnection. The risk associated with coincidental events is much higher in a large Interconnection. For <br> this reason, we believe that $N$-1 criteria should be considered for a small Interconnection like Quebec. |
| :--- | :---: | :--- |

Response: The SDT agrees that the size of an Interconnection can make a difference in Frequency Response. This standard is intended to apply to all Interconnections. The SDT has modified the definition for FRO. The definition now reads "The Balancing Authority's share of the required Frequency Response needed for the reliable operation of an Interconnection." A smaller Interconnection can and should request a variance if needed.

| Westar Energy | No | The lagging measure is a concern. The ERO should be required to provide an updated proposed/possible list <br> of frequency events monthly so BA's can determine their FRM through out the year so corrective action can <br> be taken if needed.Prior year events should be excluded (just to get to 25 events). This could result in begin <br> non-compliant twice for the same events. |
| :--- | :---: | :--- |
| Response: The SDT recommends posting selected events quarterly to give BAs time to evaluate their compliance. The SDT has evaluated the method for <br> assessing compliance and has determined compliance is best demonstrated on a quarterly basis using a rolling 12 months data period. |  |  |
| FMPP | No | The proposed Requirement 1 states: Each Balancing Authority shall achieve a Frequency Response Measure <br> (FRM) (as detailed in Attachment A and calculated on FRS Form 1) that is equal to or more negative than its <br> Frequency Response Obligation (FRO).Attachment A states that if a year occurs in which there are not 25 <br> events that meet the remaining criteria below, then the most recent 25 events (as defined below) will be used <br> for determination of an entity's compliance with the FRM requirement and storage of SEFRD. <br> Problem - by using events from last year to determine an entity's compliance with a Requirement for this year <br> puts the entity in double jeopardy for last year's events, which were already used for compliance for last year. |

| Organization | Yes or No | Question 4 Comment |
| :--- | :---: | :---: | :---: |
| Response: The SDT recommends posting selected events quarterly to give BAs time to evaluate their compliance. The SDT has evaluated the method for |  |  | assessing compliance and has determined compliance is best demonstrated on a quarterly basis using a rolling 12 months data period.

| EKPC | No | The method for measurement is not detailed. <br> Also, the method indicates a lagging indicator. Hows is the BA to ensure its compliance through the year? |
| :--- | :--- | :--- |

## Response: FRS Form 1 now details the measurement method.

An entity can use the Criteria for Selecting Events to confirm compliance during the year. The SDT recommends posting selected events quarterly to give BAs time to evaluate their compliance.

| ISO New Engand Inc. | No | We have a difficulty seeing the BA being the only entity held responsible for maintaining interconnection <br> frequency and arresting frequency deviations. When there is a sudden and sizable change to system <br> resource or demand, the first response to a frequency deviation caused by this change would be the <br> generators' governors. This will provide a mitigating effect for the immediate seconds up to minutes. The <br> frequency bias setting will then kick in to supplement the mitigation need. The governors are owned by the <br> Generator Owners; the BAs do not own these facilities and hence can do little to address frequency response <br> during this initial period. |
| :--- | :---: | :--- |

Response: While the SDT has described possible methods for obtaining Frequency Response compliance with this standard, the SDT is not prescribing a particular method for entities to implement. Governor operation is outside the scope of the approved project SAR. Any entity may submit a SAR request to modify or create a standard.

| American Electric Power | No | Between the definition and the requirement in Attachment A, it is unclear if FRM is a reliability-supported, <br> performance-based measure, or instead, if it is a calculated number based on previous performance. As <br> written, it is unclear if this is a performance-based requirement, or simply a calculation that should be utilized <br> in some way. In any event, the requirement needs to be re-written to clarify its intent. |
| :--- | :---: | :--- |
| Response: The SDT has modified the definition of FRM to read "The median of all the Frequency Response observations reported annually on FRS Form 1." " |  |  |
| Duke Energy | No | Duke Energy agrees that a BA should be required to achieve a minimum level of Frequency Response, <br> however Duke Energy believes the method for measurement needs improvement - please see comments to 1 <br> and 2 above.Duke Energy agrees with the concept that a Balancing Authority should be required to achieve a <br> minimum level of Frequency Response however the method for measurement should also allow exclusion of <br> certain events, such as when the frequency deviation is associated with the BA's contingent loss of <br> generation, or when an event is coincident with a significant change in ramped interchange. <br> It is not clear how the FRO will be determined - Duke Energy believes that the industry should agree on the <br> methodology which would be used for the ERO to determine the response desired for the Interconnection and |

| Organization | Yes or No | Question 4 Comment |
| :--- | :--- | :--- |

The FR SDT agrees that mid-year changes need to be addressed and will review this issue during the field trial.
A BA's FRO is not based on the previous year's compliance. FRO is determined using the methodology described in Attachment A.

| Patterson Consulting, Inc. | No | Requiring a Balancing Authority to provide Frequency Response and measuring that Frequency Response consistently, is critical to maintaining reliability. The requirement is long overdue and the concept is a good one. The method for measurement in FRS Form 1 is not consistent with the definition of FRM. <br> The desired "averaging" of input data over specific time ranges by the Balancing Authority as it completes FRS Form 1 appears only in the background and instructions for FRS Form 1. Since this "instruction" document will not be a part of the standard, it is not obvious that Balancing Authority's will be compelled to provide consistent data. Therefore, the standard will fail to achieve the stated purpose of providing "...consistent methods for measuring Frequency Response...". <br> Attachment $A$, other than the section providing guidance regarding event selection, appears to be explanatory, contextual, and instructional in content. These aspects are important, but should not be requirements. Attachment A should include only the event selection process and calculations associated with requirements, including an explanation of what is necessary if variable Frequency Bias Settings are implemented. If other "requirements" are included in Attachment A, they should be moved to the standard. <br> FRS Form 1 should be an attachment to the standard as this form contains and performs the required calculations. The remaining information in Attachment A should become either a standalone (technical) document, or be combined with information such as "FRS Form 1 Background and Instructions" and renamed. As further clarification regarding the ambiguity identified in the previous paragraph, Attachment A |
| :---: | :---: | :---: |

| Organization | Yes or No |  |
| :--- | :--- | :--- |
|  |  | could be interpreted as additional requirements on the Balancing Authority, ERO, or both. The language and <br> scope in not sufficiently clear to identify whether statements are informative or requirements. This lack of <br> clarity makes it impossible for entities to identify requirements, acquire appropriate tools and resources <br> related to requirements, and to provide suitable performance to meet requirements. For example, the |
| statement "A final listing of official events to be used in the calculation will be available from NERC by |  |  |
| December 10 each year." may be intended as a requirement rather than a statement suggesting a typical |  |  |
| schedule. Further, if the previous statement is a typical schedule, then the statement "The ERO will use the |  |  |
| following criteria for the selection of events to be analyzed." could be interpreted as merely the typical process |  |  |
| to be used, but not a binding one. |  |  |

Response: The SDT has modified FRS Form 1 to allow for adjustments.
The SDT has modified the Attachment A documentation to clarify the calculation methodology.
The SDT has modified the Requirements and added measures to clarify how an entity is to show compliance.

| Alberta Electric System Operator | Yes | The AESO agrees that there should be certain minimum requirement(s) of Frequency Response. In <br> Attachment A, it mentioned that it will be based on the protection criteria and Point C, and the FRM is <br> determined based on the settled deviation. The AESO suggests that the SDT describe how the FRM be <br> related with the FRO as they are determined by different time frames. The AESO suggests NERC investigate <br> the measure and method of separate FRM / FRO for different time frames, or provide technical evidence that <br> the proposed FRM / FRO can also address the technical concerns in different time frames. |
| :--- | :--- | :--- |

Response: The FRO is a determined value providing a target for ensuring robust frequency response is achieved by all Balancing Authorities. The FRM is the medium value of observations for the time period. The intent is for FRM to always be equal or more negative than the FRO, signifying robust control resulting in proper frequency response. As such, the determination timeframes does not have to be the same for each value.

| Independent Electricity System Operator | Yes | We agree with the BA being one of the responsible entities to achieve a minimum level of FR, and the method of measurement. However, R1 does not correspond to the figures shown in the FRS (Form 1) in that the FRM (the median) is -14.5 whereas the FRO is -15.8 . The FRO is more negative than the FRM, which does not seem to correspond to what's stipulated in R1 (FRM to be equal or more negative than its FRO). |
| :---: | :---: | :---: |
| Response: FRS Form 1 has been modified to correct calculations and to allow for adjustments (not exclusions) to the load and generation. |  |  |
| Arizona Public Service Company | Yes | What is meant by discretely administered determination, under the heading "Frequency Obligation and Allocation" of Attachment A? Please explain. |
| Response: The SDT has provided an administrative procedure for the ERO to follow in Attachment A. |  |  |

| Organization | Yes or No | Question 4 Comment |  |  |
| :--- | :---: | :--- | :--- | :---: |
| ENBALA Power Networks | Yes | ENBALA does believe that a BA should be responsible for a minimum level of Frequency Response as <br> calculated on Form 1 and reflected in its FRO. Furthermore, we feel that additional data collected on the <br> frequency nadir, such as the metric suggested in the recent Lawrence Berkeley National Laboratory of nadir- <br> based frequency response, would be useful in assessing the current inertial response capabilities and level of <br> risk for under-frequency load shedding. |  |  |
| Response: The FRO is a determined value providing a target for ensuring robust frequency response is achieved by all Balancing Authorities. The FRM is the <br> medium value of observations for the time period. The intent is for FRM to always be equal or more negative than the FRO, signifying robust control resulting in <br> proper frequency response. As such, the determination timeframes does not have to be the same for each value. |  |  |  |  |
| Beacon Power Corporation | Yes | The concept of requiring each Balancing Authority to achieve some level of Frequency Response and <br> calculate it consistently is appropriate and necessary. |  |  |
| Response: The SDT thanks you for your affirmative response and clarifying comment. |  |  |  |  |
| SPP Standards Development | Yes |  |  |  |
| Seattle City Light | Yes |  |  |  |
| Manitoba Hydro | Yes |  |  |  |
| Associated Electric Cooperative, <br> Inc. | Yes |  |  |  |
| Northeast Power Coordinating <br> Council |  |  |  |  |
| Response: Please refer to the SDT response to Question 17. |  |  |  |  |

5. Requirement $\mathbf{2}$ identifies when the Balancing Authority must implement its Frequency Bias Setting.

R2. Each Balancing Authority shall implement the Frequency Bias Setting (fixed or variable) provided by the ERO into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effective coordinated secondary control, using the results from the calculation methodology detailed in Attachment $A$.

Do you agree with this implementation? If not, please explain in the comment area.
Summary Consideration: The majority of the commenters did not agree with the implementation plan specified in Requirement R2. Many of the comments received echo concerns raised in comments for question 4 such as the Attachment A calculation methodology is not clear; there was insufficient information provided to address the use of variable bias, and FRO determination was questionable. Several commenters were concerned with the role assigned to the ERO, questioning how the ERO will use the FRM to determine the required BA Frequency Bias Setting and if the ERO was the correct entity to perform this action. Commenters also expressed concerns with performing an FRM analysis at the end of the year over the holiday period, suggesting the implementation time should be increased from one month to two months. Some commenters also expressed concern that CPS and L10 compliance may be adversely affected by the requirements proposed for calculating the Frequency Bias Setting.

In response to the comments received from industry, the SDT has revised Attachment A to clarify the calculation methodology; revised Requirement R2 to clarify how an entity implements the Frequency Bias Setting provided by the ERO; and also modified FRS Form 1 to allow for adjustments. Regarding FRO determination, the SDT is using a deterministic approach and also evaluating a probabilistic method. With respect to ERO actions, the SDT is evaluating whether modifications to the NERC Rules of Procedure are necessary to ensure the ERO provides the necessary support. The SDT also will develop a second draft standard attachment, Attachment B, to define the methodology for lowering the minimum Frequency Bias Setting required, including maintaining a safety margin.

R2. Each Balancing Authority not participating in Overlap Regulation Service shall implement the Frequency Bias Setting (fixed or variable) validated by the ERO into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effectively coordinated Tie Line Bias.

| Organization | Yes or No | Question 5 Comment |
| :--- | :---: | :--- |
| Santee Cooper | No | It is not clear what the methodology (should be method) is in Attachment A. Is the frequency bias setting the <br> BA's prior year FRM with a minimum value being a percentage of estimated yearly peak load or upcoming <br> year maximum generation? <br> What does "provided by the ERO" mean? Perhaps it should be verified or approved by the ERO (NERC). |

| Organization | Yes or No | Question 5 Comment |
| :--- | :---: | :---: |
| Response: Attachment A has been revised to clarify the calculation methodology. |  |  |
| Requirement R2 has been revised for clarity and now reads, "Each Balancing Authority not participating in Overlap Regulation Service shall implement the |  |  |
| Frequency Bias Setting (fixed or variable) validated by the ERO, into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure |  |  | Frequency Bias Setting (fixed or variable) validated by the ERO, into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effectively coordinated Tie Line Bias control."

| LG\&E and KU Energy | No | It is not clear what the methodology (should be method) is in Attachment A. Is the frequency bias setting the <br> BA's prior year FRM with a minimum value being a percentage of estimated yearly peak load or upcoming <br> year maximum generation? What does "provided by the ERO" mean? Perhaps it should be verified or <br> approved by the ERO (NERC). |
| :--- | :---: | :--- |

Response: Attachment A has been revised to clarify the calculation methodology.
Requirement R2 has been revised for clarity and now reads, "Each Balancing Authority not participating in Overlap Regulation Service shall implement the Frequency Bias Setting (fixed or variable) validated by the ERO, into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effectively coordinated Tie Line Bias control."

| SERC OC Standards Review <br> Group | No | It is not clear what the methodology (should be method) is in Attachment A. Is the frequency bias setting the <br> BA's prior year FRM with a minimum value being a percentage of estimated yearly peak load or upcoming <br> year maximum generation? What does "provided by the ERO" mean? Perhaps it should be verified or <br> approved by the ERO (NERC). |
| :--- | :---: | :--- |

Response: Attachment A has been revised to clarify the calculation methodology.
Requirement R2 has been revised for clarity and now reads, "Each Balancing Authority not participating in Overlap Regulation Service shall implement the Frequency Bias Setting (fixed or variable) validated by the ERO, into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effectively coordinated Tie Line Bias control."

| South Carolina Electric and Gas | No | It is not clear what the methodology (should be method) is in Attachment A. Is the frequency bias setting the <br> BA's prior year FRM with a minimum value being a percentage of estimated yearly peak load or upcoming <br> year maximum generation? What does "provided by the ERO" mean? Perhaps it should be verified or <br> approved by the ERO (NERC). <br> We suggest defining the date as by the end of the first business day following the deadline for Frequency Bias <br> Setting implementation. |
| :--- | :--- | :--- |

Response: Attachment A has been revised to clarify the calculation methodology.
Requirement R2 has been revised for clarity and now reads, "Each Balancing Authority not participating in Overlap Regulation Service shall implement the Frequency Bias Setting (fixed or variable) validated by the ERO, into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure

| Organization | Yes or No | Question 5 Comment |
| :--- | :---: | :--- |

effectively coordinated Tie Line Bias control."
The SDT does not believe the suggestion to define the date is necessary since there is language in the standard stating the ERO will allow sufficient time to implement the Frequency Bias Setting.

| MRO's NERC Standards Review | No | Flexibility established in the date is better than the existing currently defined date in the standards. It is better <br> Subcommittee <br> fo allow the ERO to specify the date to allow some flexibility in inplementation. It appears that the responsible <br> for identifying Frequency Bias Setting is being removed from the Balancing Authority. There is an implied <br> obligation that the ERO will determine the Frequency Bias Setting but it is not stated explicitly. Thus, we are <br> left wondering who has the responsibility for determining the Frequency Bias Setting. |
| :--- | :--- | :--- |
| Frequency Response of the interconnection is constantly changing. As a result, the Frequency Bias Setting <br> will never match the Frequency Response exactly. It is better to overbias than underbias to prevent <br> withdrawal of frequency response by AGC. Historically, the 1\% floor for frequency bias setting was chosen to <br> ensure that BAs are always over-biased. The standard needs to allow some margin in the frequency bias <br> setting to ensure that the bias setting is overbiased. |  |  |

Response: The SDT has modified the language in Requirement R2 to provide further clarity. The Requirement now reads "Each Balancing Authority not participating in Overlap Regulation Service shall implement the Frequency Bias Setting (fixed or variable) validated by the ERO, into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effectively coordinated Tie Line Bias control."
The SDT agrees that over-bias is better than under-bias and has added Attachment B to define the methodology to lower the minimum Frequency Bias Setting and provide a safety margin.
Midwest ISO Standards No

Collaborators

Flexibility established in the date is better than the existing currently defined date in the standards. It is better to allow the ERO to specify the date to allow some flexibility in implementation. It appears that the responsible for identifying Frequency Bias Setting is being removed from the Balancing Authority. There is an implied obligation that the ERO will determine the Frequency Bias Setting but it is not stated explicitly. Thus, we are left wondering who has the responsibility for determining the Frequency Bias Setting.

Frequency Response of the interconnection is constantly changing. As a result, the Frequency Bias Setting will never match the Frequency Response exactly. It is better to overbias than underbias to prevent withdrawal of frequency response by AGC. Historically, the $1 \%$ floor for frequency bias setting was chosen to ensure that BAs are always over-biased. The standard needs to allow some margin in the frequency bias setting to ensure that the bias setting is overbiased.

Response: The SDT has modified the language in Requirement R2 to provide further clarity. The Requirement now reads "Each Balancing Authority not participating in Overlap Regulation Service shall implement the Frequency Bias Setting (fixed or variable) validated by the ERO, into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effectively coordinated Tie Line Bias control."
The SDT agrees that over-bias is better than under-bias and has added Attachment B to define the methodology to lower the minimum Frequency Bias Setting

| and provide a safety margin. |  |  |
| We Energies | No | Flexibility established in the date is better than the existing currently defined date in the standards. It is better to allow the ERO to specify the date to allow some flexibility in implementation. It appears that the responsibility for identifying Frequency Bias Setting is being removed from the Balancing Authority. There is an implied obligation that the ERO will determine the Frequency Bias Setting but it is not stated explicitly. Thus, we are left wondering who has the responsibility for determining the Frequency Bias Setting. <br> Frequency Response of the interconnection is constantly changing. As a result, the Frequency Bias Setting will never match the Frequency Response exactly. It is better to over-bias than under-bias to prevent withdrawal of frequency response by AGC. Historically, the $1 \%$ floor for frequency bias setting was chosen to ensure that BAs are always over-biased. The standard needs to allow some margin in the frequency bias setting to ensure that the bias setting is over-biased. |
| Response: The SDT has modified the language in Requirement R2 to provide further clarity. The Requirement now reads "Each Balancing Authority not participating in Overlap Regulation Service shall implement the Frequency Bias Setting (fixed or variable) validated by the ERO, into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effectively coordinated Tie Line Bias control." <br> The SDT agrees that over-bias is better than under-bias and has added Attachment B to define the methodology to lower the minimum Frequency Bias Setting and provide a safety margin. |  |  |
| FirstEnergy | No | We cannot agree at this time since Attachment A of the materials posted do not include sufficient details regarding the calculations used. Furthermore, there is no obligation imposed on the ERO to provide neither a reasonable time frame for implementation of the Frequency Bias Setting nor a requirement for the ERO to follow the methodology detailed in Attachment A. The team should consider adding a requirement for the ERO or clarifying where this obligation is covered in NERC's Rules of Procedure. |
| Response: Attachment A has been revised to clarify the calculation methodology. <br> The SDT is evaluating if a modification to the NERC Rules of Procedure to obligate the ERO to perform the tasks identified in the standard is necessary. |  |  |
| Bonneville Power Administration | No | R2-BPA believes that the ERO should not be providing the BA the Frequency Bias Settings for the BA. <br> R2 points to Attachment A as having the calculation methodology, but there is no methodology spelled out in Attachment A, there are simply data requirements, delta frequency that will be included in surveys, tools to be used, etc. <br> The statement 'natural frequency response' is in Attachment A many times, but it is never spelled out. What is meant by this phrase. This differs dramatically depending on when the event occurs due to different generating patterns, different types of load (frequency responsive versus not frequency responsive), etc. |

| Organization | Yes or No | Question 5 Comment |
| :--- | :--- | :--- |
|  |  | The methodology needs to spell out how this will be taken into account when calculating the correct frequency <br> bias. <br> Secondly, how would this be done for variable bias? |

Response: Requirement R2 has been revised for clarity and now reads, "Each Balancing Authority not participating in Overlap Regulation Service shall implement the Frequency Bias Setting (fixed or variable) validated by the ERO, into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effectively coordinated Tie Line Bias control."
Attachment A has been revised to clarify the calculation methodology.
The SDT agrees that over-bias is better than under-bias and has added Attachment B to define the methodology to lower the minimum Frequency Bias Setting and provide a safety margin.
Variable frequency bias settings are determined by Balancing Authorities using a calculation based on present operating conditions. The SDT will provide additional and sufficient direction related to variable bias after review of this issue during the field trial.
The term "natural frequency response" is no longer in Attachment A but it is used in the new Background Document. The SDT believes that this term is describing the response for any individual event and if calculated the statistical summation of multiple events. This term is more a work of art and not science and therefore is not capitalized or defined.

| SPP Standards Development | No | We would suggest ending the sentence at the second ERO, deleting the phrase '...to ensure effective <br> coordinated secondary control, using the results from the calculation methodology detailed in Attachment A.' <br> This phrase is more of an explanation of why this is being done rather than a part of an actual requirement. |
| :--- | :---: | :--- |
| Response: The SDT believes this language provides additional clarity and should remain as is. The SDT has removed the reference to Attachment A. |  |  |

Response: The SDT is not suggesting that the ERO determine the Frequency Bias Settings. The SDT has modified the language in Requirement R2 to clarify the

| Organization | Yes or No | Question 5 Comment |
| :--- | :--- | :--- |

role of the ERO. The Requirement now reads "Each Balancing Authority not participating in Overlap Regulation Service shall implement the Frequency Bias Setting (fixed or variable) validated by the ERO, into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effectively coordinated Tie Line Bias control."

The SDT disagrees that the standard should independently address each Interconnection, and believes it is necessary to have a common methodology applicable to each Interconnection. An entity can request a variance and justify why deviation from the methodology adopted is necessary.
The SDT is evaluating if a modification to the NERC Rules of Procedure to obligate the ERO to perform the tasks identified in the standard is necessary and will also define implementation timing.
ERCOT

It is not clear how the ERO uses the FRM to determine the required Frequency Bias Settings. It should not be necessary for the ERO to do the determination for all the Interconnections. There are already in place methods for this by the existing ERCOT and WECC Interconnections. The SRC suggests that the ERO may not be the appropriate technical entity. The ERO may be the appropriate entity to serve as the receiver of the forms and analyze results for the Eastern Interconnection, but existing processes are already in place elsewhere. It should be sufficient that those processes continue and submit copies of Form 1 to the ERO. This may also be appropriate for Hydro Quebec.

In addition, whichever entity determines the Frequency Bias Setting must provide implementation time for the BAs to implement the settings. The proposed language says only that the BA shall implement it on the date specified, but it doesn't address the need for that date to include some implementation time.

Response: The SDT is not suggesting that the ERO determine the Frequency Bias Settings. The SDT has modified the language in Requirement R2 to clarify the role of the ERO. The Requirement now reads "Each Balancing Authority not participating in Overlap Regulation Service shall implement the Frequency Bias Setting (fixed or variable) validated by the ERO, into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effectively coordinated Tie Line Bias control."
The SDT disagrees that the standard should independently address each Interconnection, and believes it is necessary to have a common methodology applicable to each Interconnection. An entity can request a variance and justify why deviation from the methodology adopted is necessary.
The SDT is evaluating if a modification to the NERC Rules of Procedure to obligate the ERO to perform the tasks identified in the standard is necessary and will also define implementation timing.

| Kansas City Power \& Light | No | The Frequency Response Obligation determination for the interconnection as described in Attachment A is a <br> crude method and will result in obligations that will exceed the FRO that is intended. This will result in <br> additional cost to BA's that is unnecessary to achieve the purpose of maintaining sufficient generation online <br> to arrest frequency degradation events caused by loss of generating resources. <br> The current NERC method for calculating a BA's actual frequency response are inaccurate and provide <br> misleading guidance in the actual frequency response of a BA. These methods need considerable <br> improvement before any attempts to hold a BA to an expected level of frequency response as this proposal |

| :--- | :---: | :--- | :---: | :---: | :---: |
|  | Question 5 Comment |  |  |  |  |
| Response: The minimum level of response selected for the field trial uses a deterministic approach. The actual level of response specified in the final version of <br> the draft standard may be based on analysis of data obtained from the field trial. The SDT is also evaluating a probabilistic method to determine the FRO. <br> FRS Form 1 has been modified to correctly calculate Frequency Response. |  |  |  |  |  |
| Southern Company | No | Comments: Comment 2: BAL-003-1, Requirement R2. The requirement should be made less prescriptive by <br> removing references to the calculation methodology and Attachment A. The responsible entity should <br> understand the fundamental and basic requirement - to implement the Frequency Bias Setting into its Areas <br> Control Error calculation. Proposed language is as follows: Each Balancing Authority shall implement the <br> Frequency Bias Setting fixed or variable) provided by the ERO into its Area Control Error (ACE) calculation <br> beginning on the date specified by the ERO to ensure effective coordinated secondary control. <br> Comment 3: BAL-003-1, Requirement R2 and Section 1.4 Additional Compliance Information. The SDT |  |  |  |
| should consider whether or not the ERO has compliance obligations pursuant to the obligations mentioned in |  |  |  |  |  |
| the proposed Standard. Requirement R2, states that the ERO should provide the BA with the Frequency Bias |  |  |  |  |  |
| Setting and the specified date to begin the calculation. The R1 Supplemental Information section states that |  |  |  |  |  |
| the ERO is obligated to post the official list of events. The R2 Supplemental Information section states that |  |  |  |  |  |
| the ERO is obligated to validate the FRM and Frequency Bias Setting and disseminate the Frequency Bias |  |  |  |  |  |
| Settings Report along with the implementation date. These obligations should be confirmed and properly |  |  |  |  |  |
| incorporated into Standard if appropriate. |  |  |  |  |  |

Response: The SDT disagrees that the standard should independently address each Interconnection, and believes it is necessary to have a common methodology applicable to each Interconnection. An entity can request a variance and justify why deviation from the methodology adopted is necessary.
The SDT is evaluating if a modification to the NERC Rules of Procedure to obligate the ERO to perform the tasks identified in the standard is necessary and will also define implementation timing.

| Energy Mark, Inc. | No | Comment 13: I agree that the BA shall implement the Frequency Bias Setting provided by the ERO into it <br> Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effective <br> coordinated secondary control. <br> Comment 14: I do not agree that the results from the calculation methodology detailed in Attachment A will <br> provide the correct Frequency Bias Setting. My comments on the calculation methodology are included <br> elsewhere in my comments on Attachment A and FRS Form 1. |
| :--- | :--- | :--- |

Response: Comment 13 - The SDT thanks you for your affirmative comment. Note that based on comments from other stakeholders, the language in Requirement R2 was modified to state, "Each Balancing Authority not participating in Overlap Regulation Service shall implement the Frequency Bias Setting (fixed or variable) "validated" by the ERO, into its Area Control Error (ACE) calculation . . ."

| Organization | Yes or No | Question 5 Comment |
| :--- | :---: | :---: |
| Comment 14- Please see the SDT response to your Attachment A and FRS Form 1 comments. |  |  |
| EKPC | No | The method is not clear in Attachment A. |
| Response: Attachment A has been revised to clarify the calculation methodology. |  |  |
| Seattle City Light | No | Currently a Balancing Authority has only about one month over holiday periods(December 10 to January 10) <br> to assemble its data and calculate the Frequency Response Measure (FRM). Further, Attachment A requires <br> the ERO to use at least 25 events for the calculation of FRM. Seattle City Light (SCL) believes that one month <br> is insufficient time given the number of events required. So SCL recommends additional time, such as two <br> months or to reduce the number of events to be included in annual reviews. |

Response: The SDT recommends posting the selected events on a quarterly basis which should provide ample time for BAs to provide the information.

| American Electric Power | No | It appears this standard deviates from past practice for calculating frequency bias. It is unclear how this might <br> affect the CPS Bounds L10 calculation. |
| :--- | :---: | :--- |

Response: The Frequency Bias Setting calculation remains the same. The SDT is only modifying the "minimum Frequency Bias Setting" threshold. The SDT understands reducing the minimum Frequency Bias Setting will affect L10 and ACE values which is why the SDT proposes monitoring these parameters and undoing the modification if adverse results are realized.

| Duke Energy | No | Duke Energy believes that this needs to be restated. Will the ERO perform the calculations to determine each <br> BA's Bias? <br> Will the ERO provide ample time between publication of the settings and the date of implementation? <br> If effective coordinated secondary control is desired, other related operational parameters (e.g., L10) need to <br> be set at the same time. <br> Since measurement and reporting of operational performance is primarily on a monthly basis (e.g., <br> CPS1/CPS2), the implementation date should be on or near the first of a month, but during normal working <br> hours (so that adequate support personnel are available). |
| :--- | :--- | :--- |
|  |  |  |

Response: The SDT is not suggesting that the ERO determine the Frequency Bias Settings. The SDT has modified the language in Requirement R2 to clarify the role of the ERO. The Requirement now reads "Each Balancing Authority not participating in Overlap Regulation Service shall implement the Frequency Bias Setting (fixed or variable) validated by the ERO, into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effectively coordinated Tie Line Bias control."

The SDT is evaluating if a modification to the NERC Rules of Procedure to obligate the ERO to perform the tasks identified in the standard is necessary and will

| Organization | Yes or No | Question 5 Comment |
| :---: | :---: | :---: |
| also define implementation timing. |  |  |
| The SDT understands reducing the minimum Frequency Bias Setting will affect L10 and ACE values which is why the SDT proposes monitoring these parameters and undoing the modification if adverse results are realized. |  |  |
| The SDT is not proposing to change the methodology presently used to set the timing of the implementation of the Frequency Bias Setting. |  |  |
| Patterson Consulting, Inc. | No | The concept of requiring a Balancing Authority to implement its Frequency Bias Setting at a specific time and using a specific calculation is meaningful. This requirement is not clearly worded, however. If the intent of Requirement 2 is to identify "...when the Balancing Authority must implement its Frequency Bias Setting..." the requirement should stop after "...on the date specified by the ERO." The remaining portion of the requirement explains the need for the requirement and should be moved to supporting material. |
|  |  | Attachment A does not have a "calculation methodology" associated with the Frequency Bias Setting unless the language describing historical practice and the benefits of moving a Frequency Bias Setting closer to a Balancing Authority's natural Frequency Response are intended to constitute a "calculation methodology." FRS Form 1 has the "calculation methodology" of using the minimum (since the value is negative) of last year's FRM, next year's FRO, and percentage of next year's peak load or generation. Attachment A does not mention this methodology and the requirement does not mention FRS Form 1. The clause "..., using the results from the calculation methodology detailed in Attachment A." appears to place an obscure requirement on the ERO since the ERO is the entity providing the Frequency Bias Setting to be implemented by the Balancing Authority. If the ERO is intended to use the value from FRS Form 1, after verifying data and calculations, then state that expectation explicitly and clearly. Otherwise, the ERO could set Frequency Bias Settings in another manner after observing the Form 1 values. |
|  |  | The requirement for the ERO to provide a Frequency Bias Setting to each Balancing Authority begs the question of how variable bias will be implemented. Historically, the Balancing Authority implements its algorithm with oversight from NERC (Resources Subcommittee). The manner and expectation for providing data and algorithms related to variable bias are inadequate. |

Response: The SDT has modified the language in Requirement R2 to clarify the role of the ERO. The Requirement now reads "Each Balancing Authority not participating in Overlap Regulation Service shall implement the Frequency Bias Setting (fixed or variable) validated by the ERO, into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effectively coordinated Tie Line Bias control."
The SDT is evaluating if a modification to the NERC Rules of Procedure to obligate the ERO to perform the tasks identified in the standard is necessary and will also define implementation timing.
Attachment A has been revised to clarify the calculation methodology.
FRS Form 1 has been modified to correctly calculate Frequency Response and to allow for adjustments (not exclusions) to the load and generation.
Variable frequency bias settings are determined by Balancing Authorities using a calculation based on present operating conditions. The SDT will provide
Organization $\quad$ Yes or No $\quad$ Question 5 Comment
additional and sufficient direction related to variable bias after review of this issue during the field trial.

| Alberta Electric System Operator | Yes | The AESO suggests that the standard should provide a description on how the ERO would determine the <br> frequency bias setting and the relation to the FRO. |
| :--- | :--- | :--- |

Response: The SDT is not suggesting that the ERO determine the Frequency Bias Settings. The SDT has modified the language in Requirement R2 to clarify the role of the ERO. The Requirement now reads, "Each Balancing Authority not participating in Overlap Regulation Service shall implement the Frequency Bias Setting (fixed or variable) validated by the ERO, into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effectively coordinated Tie Line Bias control."

The SDT is evaluating if a modification to the NERC Rules of Procedure to obligate the ERO to perform the tasks identified in the standard is necessary and will also define implementation timing.
NIPSCO

Response: The SDT is not suggesting that the ERO determine the Frequency Bias Settings. The SDT has modified the language in Requirement R2 to clarify the role of the ERO. The Requirement now reads, "Each Balancing Authority not participating in Overlap Regulation Service shall implement the Frequency Bias Setting (fixed or variable) validated by the ERO, into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effectively coordinated Tie Line Bias control."

| Manitoba Hydro | Yes | The implementation schedule seems reasonable. |

6. Requirement 3 mandates that a Balancing Authority operate its Automatic Generation Control (AGC) on Tie Line Bias unless it becomes adverse to the integrity of its system.

## R3. Each Balancing Authority shall operate its Automatic Generation Control (AGC) on Tie Line Bias, unless such operation would have an Adverse Reliability Impact on the Balancing Authority's Area.

Do you agree that a Balancing Authority should operate its AGC on Tie Line Bias unless it becomes adverse to its system? If not, please explain in the comment area below.

Summary Consideration: Approximately half of the comments received agreed that a Balancing Authority should operate its AGC in Tie Line Bias unless an Adverse Reliability Impact occurs. Many of the dissenters were concerned with the apparent conflict with BAL-005.1b Requirement R6, efforts of the Balancing Authority Reliability-based Controls (BARC) SDT with modifying BAL-005, and concern that the draft standard should not dictate an AGC operating control mode. Other commenters indicated the language of Requirement R3 needed to be revised for clarity and that the requirement could place a reporting burden on the Balancing Authorities. It was also noted that a single BA Interconnection does not operate AGC using Tie Line Bias mode.

In response to industry comments received, the SDT has revised Requirement R3 by adding Overlap Regulation Service language and allowing the AGC operating mode to be changed for an Adverse Reliability Impact.

R3. Each Balancing Authority not receiving Overlap Regulation Service shall operate its Automatic Generation Control (AGC) in Tie Line Bias mode to ensure effectively coordinated control, unless such operation would have an Adverse Reliability Impact on the Balancing Authority's Area.

Impact on the Balancing Authority's Area."
This standard is scheduled to be completed and filed with FERC prior to the BARC standard being completed. The SDT anticipates that work on the BARC standard will take into account the work completed on this standard.

| Bonneville Power Administration | No | R3. BPA does not believe this standard should dictate the control mode for AGC. That is better suited to be <br> in BAL-001 and should not be repeated in this standard - the ACE used for reporting is spelled out in BAL-001 <br> R1 and is also discussed in BAL-005 R6. R3 should be removed from this standard, not modified to fit with <br> what is stated in BAL-001 or BAL-005. |
| :--- | :--- | :--- |

Response: This standard is proposed to go into effect prior to implementation of the BARC draft standard. A determination of which reliability standard should specify the AGC control mode used for system operations can be made once development of the BARC draft standard is completed.
Requirement R3 has been revised for clarity and now reads "Each Balancing Authority not receiving Overlap Regulation Service shall operate its Automatic Generation Control (AGC) in Tie Line Bias mode to ensure effectively coordinated control, unless such operation would have an Adverse Reliability Impact on the Balancing Authority's Area."

| IRC Standards Review <br> Committee | No | Single BA Interconnections do not operate on Tie Line Bias. The requirement should be modified to <br> accommodate this or regional variances should be written by the SDT to address existing differences. <br> In addition this requirement, as written, does not provide for momentary cessation of AGC for any reason, nor <br> for reasonable system maintenance, repair, or updates. As written, it seems to say that any duration of <br> operation off Tie Line Bias is unacceptable and, thus, would be a violation. |
| :--- | :---: | :--- |

Response: The SDT agrees that a single BA Interconnection does not operate using Tie Line Bias mode. The "Additional Compliance Information" section has been revised to clarify this situation.

The SDT disagrees that the Requirement does not allow for instances of not operating in Tie Line Bias mode. The revised Requirement states "Each Balancing Authority not receiving Overlap Regulation Service shall operate its Automatic Generation Control (AGC) in Tie Line Bias mode to ensure effectively coordinated control, unless such operation would have an Adverse Reliability Impact on the Balancing Authority's Area."

ISO New Engand Inc.
No

Single BA Interconnections do not operate on Tie Line Bias. The requirement should be modified to accommodate this or regional variances should be written by the SDT to address existing differences.
In addition this requirement, as written, does not provide for momentary cessation of AGC for any reason, nor for reasonable system maintenance, repair, or updates. As written, it seems to say that any duration of operation off Tie Line Bias is unacceptable and, thus, would be a violation.

Response: The SDT agrees that a single BA Interconnection does not operate using Tie Line Bias mode. The "Additional Compliance Information" section has been revised to clarify this situation.

Consideration of Comments: Project 2007-12 BAL-003-1-1 $1^{\text {st }}$ Draft

## Organization

The SDT disagrees that the Requirement does not allow for instances of not operating in Tie Line Bias mode. The revised Requirement states "Each Balancing Authority not receiving Overlap Regulation Service shall operate its Automatic Generation Control (AGC) in Tie Line Bias mode to ensure effectively coordinated control, unless such operation would have an Adverse Reliability Impact on the Balancing Authority's Area."

| ERCOT | No | Single BA Interconnections do not operate on Tie Line Bias. The requirement should be modified to <br> accommodate this or regional variances should be written by the SDT to address existing differences. <br> In addition this requirement, as written, does not provide for momentary cessation of AGC for any reason, nor <br> for reasonable system maintenance, repair, or updates. As written, it seems to say that any duration of <br> operation off Tie Line Bias is unacceptable and, thus, would be a violation. |
| :--- | :--- | :--- |

Response: The SDT agrees that a single BA Interconnection does not operate using Tie Line Bias mode. The "Additional Compliance Information" section has been revised to clarify this situation.
The SDT disagrees that the Requirement does not allow for instances of not operating in Tie Line Bias mode. The revised Requirement states "Each Balancing Authority not receiving Overlap Regulation Service shall operate its Automatic Generation Control (AGC) in Tie Line Bias mode to ensure effectively coordinated control, unless such operation would have an Adverse Reliability Impact on the Balancing Authority's Area."

| Kansas City Power \& Light | No | The impact of operating in an inappropriate AGC control mode is bigger than the BA's own balancing area. <br> The control of the area affects other BA's around a BA and if enough BA's are involved, can affect an <br> interconnection. Recommend the requirement be modified to consider the reliability impact on its own <br> balancing area, the balancing areas of adjacent BA's and the interconnection. |
| :--- | :---: | :--- |

Response: The SDT agrees and has modified Requirement R3 to read, "Each Balancing Authority not receiving Overlap Regulation Service shall operate its Automatic Generation Control (AGC) in Tie Line Bias mode to ensure effectively coordinated control, unless such operation would have an Adverse Reliability Impact on the Balancing Authority's Area."

| Southern Company | No | Comments: Agree only to the extent that an accurate frequency measurement is available to the BA. If not <br> frequency measurement is available, then that should be considered an adverse condition and thus TLB is <br> not appropriate. In other words, one small BA maintaining TLB may not cause the condition in the Glossary <br> definition of Adverse Reliability Impact but it is still not appropriate for them to stay on TLB. |
| :--- | :---: | :--- |

Response: Requirement R3 has been revised for clarity and now reads "Each Balancing Authority not receiving Overlap Regulation Service shall operate its Automatic Generation Control (AGC) in Tie Line Bias mode to ensure effectively coordinated control, unless such operation would have an Adverse Reliability Impact on the Balancing Authority's Area."
This standard is scheduled to be completed and filed with FERC prior to the BARC standard being completed. The SDT anticipates that work on the BARC standard will take into account the work completed on this standard.

| Organization | Yes or No | Question 6 Comment |
| :---: | :---: | :---: |
| NIPSCO | No | Yes, It was proposed that AGC be replaced by Automatic Resource Control (ARC) in the standards but did not pass. The SDT may want to monitor this related effort. |
| Response: The SDT is using approved definitions listed in the NERC Glossary of Terms. Changes to current NERC Glossary of Terms definition language not used in this standard would need to occur as a separate project. |  |  |
| Energy Mark, Inc. | No | Comment 15: Requirement 3 as written is unenforceable because it is too difficult to define "unless such operation would have an Adverse Reliability Impact on the Balancing Authority's Area." <br> Comment 16: What if operation out of Tie line Bias control does not have an Adverse Reliability Impact on the Balancing Authority's Area, but does have an Adverse Reliability Impact on another BA? <br> Comment 17: A document follows that provides an initial starting justification for the elimination of this Requirement. See following "Requirements for AGC Operation, January 25, 2011."Requirements for AGC Operation, January 25, 2011 <br> Introduction:As of the date of these comments there are two requirements in the NERC Standards that address the operation of AGC. <br> - The first is in BAL-003-0.1b - Frequency Response and Bias, Requirement R3.R3. Each Balancing Authority shall operate its Automatic Generation Control (AGC) on Tie Line Frequency Bias, unless such operation is adverse to system or Interconnection reliability. <br> - The second is in BAL-005-0.1b - Automatic Generation Control, Requirement R7.R7. The Balancing Authority shall operate AGC continuously unless such operation adversely impacts the reliability of the Interconnection. If AGC has become inoperative, the Balancing Authority shall use manual control to adjust generation to maintain the Net Scheduled Interchange. <br> These requirements are misdirected and, for compliance purposes, they are difficult to measure effectively. This paper provides the technical basis for replacing these requirements with new requirements that will not only achieve the intent of these requirements, but do so in a more effective and measurable manner. <br> Background: <br> Automatic Generation Control (AGC) is a computer control system contained in the Control Center EMS that performs a number of critical functions related to the balancing function necessary to maintain frequency and associated reliability. Among the functions it performs are: <br> 1) the collection of telemetered and local data useful for determining the appropriate control actions, <br> 2) the calculation of Area Control Error (ACE), <br> 3) determination of desired control actions that should be sent to those resources available for automatic dispatch, and |

| Organization | Yes or No | Question 6 Comment |
| :---: | :---: | :---: |
|  |  | 4) sending the actual control signals to implement that dispatch. <br> Most AGC Systems have three basic modes of operation, <br> 1) Tie-line Frequency Bias, <br> 2) Constant Net Interchange and <br> 3) Constant Frequency. <br> The ACE Equation is the basis for all three modes of operation. <br> - In the Tie-line Frequency Bias mode, all of the ACE Equation is used as an input to control action determination. <br> - In the Constant Net Interchange mode, only the Tie-line Error portion of the ACE Equation is used as an input to control action determination. The Constant Net Interchange mode would normally be used when there is no information available to indicate interconnection frequency. <br> - In the Constant Frequency mode, only the Frequency Bias portion of the ACE Equation is used as an input to control action determination. The Constant Frequency mode of operation would be used when the Tie-line Error is known to be misleading, inaccurate or unavailable. It is also used when there are no tie-lines in service as in the case of a single BA interconnection or during islanded operation.AGC Systems have been used in the industry since before the development of digital computers. <br> Initially AGC Systems did little more than send instructions to generators based on evaluation of the ACE Equation. They have become more sophisticated since their inception and implement greater complexity in their evaluations of appropriate dispatch actions to the point that they include forecasting, reliability and economics within their algorithms. Modern AGC Systems determine control actions based on the collection of much more data than is included in the ACE Equation. This additional data includes: short-term load forecasts and forecast error estimates as influenced by weather; individual non-conforming load forecasts and forecast error; forecast interchange transaction information; generating unit ramp and response rates; generating unit economic operating points including valve position; generating unit incremental economic costs including start-up and maintenance; Hydro unit river flow limits as related to the operation of other units on the same waterway; energy storage capabilities and available energy; Inadvertent Interchange energy account balances; time error; and current control performance scores. <br> As AGC Systems have evolved, the control mode in which they are operating, Tie-line Frequency Bias, Constant Net Interchange, or Constant Frequency, provides less and less information about the control actions that they implement. In a modern AGC System the control mode provides little information about how control actions are being determined and implemented. In fact, only someone experienced in AGC programming and implementation would have the knowledge necessary to determine whether or not an AGC System is providing reasonable control actions or control actions consistent with Tie-line Frequency Bias Control. Even someone with the necessary experience observing the operation of a modern AGC System for |

| Organization | Yes or No | Question 6 Comment |
| :---: | :---: | :---: |
|  |  | a short period of time will be incapable of determining whether or not that system is providing effective or adequate control. Therefore, neither of the two requirements is effectively enforceable from a practical point of view. <br> Perspective:A couple of examples are offered to add perspective to the problem. <br> Example 1:R3 includes the requirement, "Each Balancing Authority shall operate its Automatic Generation Control (AGC) on Tie Line Frequency Bias, unless such operation is adverse to system or Interconnection reliability." There are three conditions when operation on Tie-line Frequency Bias control may be adverse to the system or Interconnection reliability. <br> 1. The first is when the Tie-line Error data used in the ACE Equation is incorrect. The ACE Equation will be incorrect when there are errors in the Actual or Scheduled Tie-line flow values. This condition will occur when there is telemetry failure of one or more tie-lines, when there is an unidentified scheduling error, or when there is a separation that causes a tie-line metering point to be located on a separate island due to interconnection separation or islanding. Telemetry failure will be indicated by the quality bits associated with the Tie-line telemetry. If AGC is disabled to identify a scheduling error, there should be an operating log entry. If AGC is disabled because of a separation, there will also be a log entry. <br> 2. The second is when the actual frequency is determined to be incorrect. If measured frequency is incorrect, this condition should be indicated by an operating log entry and transfer to the redundant frequency device to provide measured frequency. When the actual frequency fails, this condition will be indicated by the quality bits associated with the measured frequency value and transfer to the redundant frequency device to provide measured frequency. <br> 3. The third is when operation of AGC would provide control different from the desired control to address some emergency condition in the BA or elsewhere on the interconnection. If the operation of AGC would be adverse to system or Interconnection reliability and is disabled for this reason, this condition should be indicated by an operating log entry.In all cases, there should be a record of the reason for the use of other than Tie-line Frequency Bias control and records indicating the reason for the use of other control modes. In all cases, other than the third indicated above, an error in the value of ACE is the reason for not using Tie-line Bias Control and the quality bits for ACE or ACE component data should provide a reasonable explanation for the condition. The third case occurs with such infrequency that there should be no need for a special rule to address this condition. <br> Example 2:R7 includes the requirement, "...If AGC has become inoperative, the Balancing Authority shall use manual control to adjust generation to maintain the Net Scheduled Interchange." Cases have been observed of an AGC System that does not perform as well as the manual dispatch used when the AGC System is inoperative. If a BA has a CPS1 score of $120 \%$ when using AGC and a CPS1 score of $125 \%$ when performing manual dispatch, should that BA be penalized for not having its AGC continuously operating? What is the goal? Is the goal to operate on AGC regardless of the result or is the goal to operate in a manner |

| Organization | Yes or No | Question 6 Comment |
| :---: | :---: | :---: |
|  |  | that provides the best measured control? <br> Alternatives:Since these requirements are not effectively measurable or enforceable, can a requirement or requirements be written to provide an equivalent to the intent of the old requirements addressing AGC operation?The industry has three alternatives to address this issue: <br> 1. Retain requirements that are directed at the AGC System understanding that they are effectively not measureable or enforceable. <br> 2. Eliminate requirements that are directed at the AGC System with the understanding that they were not contributing to reliability. <br> 3. Determine an alternative method to evaluate, measure and enforce a requirement that will achieve a goal similar to the goal originally intended by the implementation of the AGC System requirements. <br> Elimination of the requirement is an appropriate solution. However, if it is determined that a replacement measure is required, then the solution to this problem lies with the third alternative above. <br> Solution:There is already a requirement that effectively enforces the intent of the above requirements. Instead of requiring the BA to control in a particular manner, CPS1, BAAL and DCS require the BA to achieve specific results with their control actions. All three measures require the BA to calculate ACE using Tie-line Frequency Bias for determination of their Reporting ACE. The requirements specify that at least $50 \%$ of the data must be valid for the one-minute average data to be included in the measures. The requirements for redundant frequency measurement devices assure that the BA will have the actual frequency data available to perform the necessary calculations. The data retention requirements specify the data they must retain to demonstrate that their control achieved the stated goals. <br> Finally, this approach is consistent with the White House Executive Order on Improving Regulation and Regulatory Review in Section 1(b)(4) stating that regulatory agencies must: "to the extent feasible, specify performance objectives, rather than specifying the behavior or manner of compliance that the regulated entities must adopt;..." |
| Response: Comment 15 \& 16: Requirement R3 has been revised for clarity and now reads "Each Balancing Authority not receiving Overlap Regulation Service shall operate its Automatic Generation Control (AGC) in Tie Line Bias mode to ensure effectively coordinated control, unless such operation would have an Adverse Reliability Impact on the Balancing Authority's Area." |  |  |
| This standard is scheduled to be completed and filed with FERC prior to the BARC standard being completed. The SDT anticipates that work on the BARC standard will take into account the work completed on this standard. |  |  |
| Comment 17: The SDT recognizes that from a compliance perspective it can be difficult to ascertain if an Adverse Reliability Impact exists. Nonetheless, the SDT is very concerned with adversely affecting primary Frequency Response when operating without AGC. The SDT believes revised language using NERC glossary defined terms will support proper compliance enforcement. It is expected entities will provide an explanation each time AGC Tie Line Bias mode is not used for |  |  |

| Organization | Yes or No | Question 6 Comment |
| :--- | :---: | :--- |
| the compliance auditor to assess. | No | Tie line bias is calculated using (NAI-NSI) while frequency bias is -10B(FA-FS). |
| EKPC | Response: Requirement R3 has been revised for clarity and now reads "Each Balancing Authority not receiving Overlap Regulation Service shall operate its <br> Automatic Generation Control (AGC) in Tie Line Bias mode to ensure effectively coordinated control, unless such operation would have an Adverse Reliability <br> Impact on the Balancing Authority's Area." |  |

| Duke Energy | No | Duke Energy agrees to the simple statement posed in the question; however, the requirement goes beyond that by using a defined term, Adverse Reliability Impact, which has a relatively narrow focus on extreme conditions. If a single BA lost a significant amount of its tie-line telemetry or its frequency sources, cascading outages and/or grid separation would not necessarily be imminent but it would be imprudent to remain in Tie Line Bias mode. Go back to the original language for the requirement - "Each Balancing Authority shall operate its Automatic Generation Control (AGC) on Tie Line Frequency Bias, unless such operation is adverse to system or Interconnection reliability." |
| :---: | :---: | :---: |
| Response: The SDT has revised Requirement R3 language and believes the use of NERC glossary defined terms in the Requirement provides necessary clarity for compliance. |  |  |
| Patterson Consulting, Inc. | No | While this requirement is in the existing standard, it places a significant reporting burden on a Balancing Authority to demonstrate compliance during audits for little reliability gain. <br> In addition for single Balancing Authority interconnections, operating in this AGC mode is functionally equivalent to operating in flat frequency mode. This may cause some interconnections to seek a variance, just to avoid compliance complications. Perhaps this requirement could be replaced with a requirement for Balancing Authorities to contribute to frequency performance as well as balance commitments and resources, or to calculate the ACE it uses to report in other standards in a specific manner. As written, it could be interpreted to create a violation when AGC suspends or is offline. |

Response: The SDT has taken into consideration the reporting burden on the Balancing Authority to demonstrate compliance. It is expected that entities will provide an explanation each time AGC Tie Line Bias mode is not used for the compliance auditor to assess.
The SDT agrees that a single BA Interconnection does not operate using Tie Line Bias mode. The "Additional Compliance Information" section has been revised to clarify this situation.
Requirement R3 has been revised for clarity and now reads "Each Balancing Authority not receiving Overlap Regulation Service shall operate its Automatic Generation Control (AGC) in Tie Line Bias mode to ensure effectively coordinated control, unless such operation would have an Adverse Reliability Impact on the Balancing Authority's Area."
This standard is scheduled to be completed and filed with FERC prior to the BARC standard being completed. The SDT anticipates that work on the BARC

Consideration of Comments: Project 2007-12 BAL-003-1 - $1^{\text {st }}$ Draft

| standard will take into account the work completed on this standard. |  |  |
| FirstEnergy | Yes | Although we mostly agree with the requirement, we believe it can be improved. We suggest that the team add <br> wording in the requirement to allow for brief periods where meters or communication channels fail and trip the <br> AGC off Tie Line Bias. In most areas, if merely one BA trips off bias it would not have an adverse affect on <br> BES reliability and furthermore, the BA can take alternative measures for these periods such as manual AGC. <br> We suggest the team add wording similar to the second sentence of requirement R7 of BAL-005 which states: <br> "If AGC has become inoperative, the Balancing Authority shall use manual control to adjust generation to <br> maintain the Net Scheduled Interchange." |

Response: Requirement R3 has been revised for clarity and now reads "Each Balancing Authority not receiving Overlap Regulation Service shall operate its Automatic Generation Control (AGC) in Tie Line Bias mode to ensure effectively coordinated control, unless such operation would have an Adverse Reliability Impact on the Balancing Authority's Area."
This standard is scheduled to be completed and filed with FERC prior to the BARC standard being completed. The SDT anticipates that work on the BARC standard will take into account the work completed on this standard.

| Arizona Public Service Company | Yes | As long as Appendix 1 interpretation remains in effect for WECC Auto Time Error Payback. WECC BAs <br> operate in Tie-Line and Time. |

## NERC

## Organization

Response: Please refer to our response to Question 17.
7. Do you agree with the proposed Implementation Plan for this standard? If not, please explain in the comment area.

Summary Consideration: The majority of the comments received stated that they did not agree with the proposed implementation plan for this standard. The main concerns were that the implementation plan would take several years to fully implement, that adjustment to the Frequency Bias Setting could not occur without first modifying the existing BAL-003-0.1b standard, and a preference for aligning implementation plan effective dates with the regulatory approval date. Several commenters expressed concern regarding the accuracy and clarity of Attachment A and how field testing efforts integrated into the implementation plan. One commenter observed that it would be ideal for the standard to require the use of variable bias.
In response to industry comments the SDT has revised Attachment A for correctness and clarity; changed all references in the standard and associated documents for BAL-003 to read "BAL-003-0.1b"; and removed the table showing the annual reduction schedule for the minimum bias setting. The SDT has provided a revised plan for reducing the minimum Frequency Bias Setting - the ERO will monitor the results of the reductions and make necessary corrections. Details for the reduction plan have been provided as Attachment $B$ to the standard.

| Organization | Yes or No | Question 7 Comment |
| :---: | :---: | :---: |
| Santee Cooper | No | The implementation plan has specific dates for reducing the bias settings currently defined in Requirement 5 over several years. Perhaps these dates should not be specific but tied to months following regulatory approval. Attachment A should be modified to match what is in the proposed standard. <br> The values currently shown as percent "of peak/ 0.1 Hz " should be changed to percent of estimated yearly peak demand per 0.1 Hz change. For BAs that do not serve native load, percent "of upcoming years maximum generation/ 0.1 Hz should be changed to percent of its estimated maximum generation level in the coming year/ 0.1 Hz change. |
| Response: The SDT believes that the affect reducing the minimum bias setting will have on frequency, including unintended consequences, will not be observable for meaningful analysis over a short-time interval which is why the implementation plan specifies reducing the bias setting on an annual basis. <br> The SDT deleted the section of the Implementation Plan that referenced "of peak/ 0.1 Hz ". |  |  |
| LG\&E and KU Energy | No | The implementation plan has specific dates for reducing the bias settings currently defined in Requirement 5 over several years. Perhaps these dates should not be specific but tied to months following regulatory approval. Attachment A should be modified to match what is in the proposed standard. The values currently shown as percent "of peak/0.1 Hz" should be changed to percent of estimated yearly peak demand per 0.1 Hz change. For BAs that do not serve native load, percent "of upcoming years maximum generation/0.1 Hz should be changed to percent of its estimated maximum generation level in the coming year/ 0.1 Hz change |

| :--- | :--- | :--- |
|  |  | plan makes no mention of a field trial. It should. <br> Please change all BAL-003-0 to BAL-003-0.1b. |
| Response: The SDT has changed all references in the implementation plan for BAL-003-1 to read "BAL-003-0.1b." <br> The SDT has removed the table showing the reduction schedule for the minimum bias setting. |  |  |
| The SDT is proposing another method for reducing the minimum Frequency Bias Setting in which the ERO will monitor the results of the reduction and make <br> necessary corrections. Please refer to Attachment B for reduction plan details. |  |  |

| We Energies | No |
| :--- | :--- |

> We agree with the plan to phase out BAL-003-0.1b R5 over a period of years rather than abruptly terminate it because it will take several years to assess the impact. We recommend a wording change to the implementation plan. Please change 'BAL-003-0 Requirement 5 should be retired as outlined in the following table," to "BAL-003-0.1b Requirement 5 should be phased out by reducing the minimum frequency bias setting per the table."It is not clear if the minimum frequency bias setting can be modified without modifying the existing BAL-003-0.1b standard. Is this being accomplished through the field trial? The implementation plan makes no mention of a field trial. It should.Please change all BAL-003-0 to BAL-003-0.1b

Response: The SDT has changed all references in the implementation plan for BAL-003-1 to read "BAL-003-0.1b."
The SDT has removed the table showing the reduction schedule for the minimum bias setting.
The SDT is proposing another method for reducing the minimum Frequency Bias Setting in which the ERO will monitor the results of the reduction and make necessary corrections. Please refer to Attachment B for reduction plan details.

| FirstEnergy | No | We believe that the implementation plan should include information regarding the field trial and how it fits in <br> with the phase-in implementation. It appears as though the field trial is being conducted based on 2010 data <br> and will be concluded upon completion of the development of the standard but we think this could be clarified. <br> Furthermore, as stated in the process manual, a field test "should include at a minimum the data collection <br> and analysis or field test plan, the implementation schedule, and an expectation for periodic updates of the <br> results." The field test information posted is not clear on the implementation schedule of the field test as well <br> as when and how periodic updates will be available. |
| :--- | :--- | :--- |

Response: The SDT has revised the plan for reducing the minimum Frequency Bias Setting. The plan is no longer tied to the Field Trial. The SDT has removed the table showing the reduction schedule for the minimum bias setting. The SDT is proposing another method for reducing the minimum Frequency Bias Setting in which the ERO will monitor the results of the reduction and make necessary corrections. Please refer to Attachment B for reduction plan details.

| Bonneville Power Administration | No | From a compliance perspective, it is administratively very burdensome to have portions of two different <br> versions of a standard applicable at the same time, as specified in the Implementation Plan for BAL-003-1 |
| :--- | :--- | :--- |

| Organization | Yes or No | Question 7 Comment |
| :---: | :---: | :---: |
|  |  | This type of structure adds an additional layer of complexity to all parts of the compliance administration process, as necessary to distinguish between the separate versions of the standard. Rather than create and prolong this type of situation over a 4 year time period, BPA asks that BAL-003-0 be retired in its entirety and that the contents of BAL-003-1 be expanded to also include R5, as specified in BAL-003-0. This change resolves the identified issues while also ensuring that all requirements of BAL-005 are in effect, as originally intended. <br> The Implementation Plan for BAL-003-1 also includes a proposal to modify the specified limiting percentage of Native Load on a sliding scale over a 4 year time period. BAL-003-3 R5, as approved, explicitly specifies $1 \%$ as a minimum value for monthly average Frequency Bias Setting. As such, changing this value results in a change in the requirement itself. Instead of being done through an Implementation Plan, these types of changes should be made as specific modifications to the requirement in question. To resolve this issue, BPA asks that the sliding scale specified for percentage of peak load specified in the Implementation Plan be incorporated directly into BAL-003-1 as a part of the specified text of R5. This change meets the intended goal of applying a sliding scale to this value over time while assuring that the underlying change is implemented as a change to the requirement through the Standards Development Process. |

Response: The SDT has added the R5 Requirement back into the proposed standard. The SDT has revised the plan for reducing the minimum Frequency Bias Setting. The plan is no longer tied to the Field Trial. The SDT has removed the table showing the reduction schedule for the minimum bias setting. The SDT is proposing another method for reducing the minimum Frequency Bias Setting in which the ERO will monitor the results of the reduction and make necessary correction. Please refer to Attachment B for reduction plan details.

| IRC Standards Review | No | the |
| :--- | :--- | :--- |
| Committee |  |  |

What is the technical basis for the phase-out schedule? Making the standard requirements effective earlier than the schedule shown could result in the unintended consequence of non-compliance enforcement for performance that is caused by the change rather than by the non-performance of the functional entity
.Also, the effective dates given in the Implementation differ from those in the draft standard. Different requirement numbers are expressed in each.
Some of the implementation steps (retiring R5 of BAL-003-0) presented in the implementation plan start as early as May 2011. We do not believe that the BAL-003-1 standard will be approved by the industry or the NERC BoT at that time and that does not even take into account regulatory approval (or 12 months after BoT adoption in those jurisdictions where no regulatory approval is required).

How can a standard begins to phase out while the successor standard is not anywhere near becoming effective?If the SDT wants to propose a gradual replacement of the current R5, we would suggest that the phase-out steps be tied to the date that the standard becomes effective.

Response: The SDT has removed the table showing the reduction schedule for the minimum bias setting.

| Organization | Yes or No | Question 7 Comment |

| If the SDT wants to propose a gradual replacement of the current R5, we would suggest that the phase-out |  |  |
| steps be tied to the date that the standard becomes effective. |  |  |

Response: The SDT has removed the table showing the reduction schedule for the minimum bias setting.
The SDT has corrected the mismatch between effective dates in the implementation plan and the standard.
The SDT has added the R5 Requirement back into the proposed standard. The SDT has revised the plan for reducing the minimum Frequency Bias Setting. The plan is no longer tied to the Field Trial.

The SDT believes that it is necessary to observe the affect each decrement to the present standard has during all four seasons to assure reliability is not adversely impacted.
The SDT is proposing another method for reducing the minimum Frequency Bias Setting in which the ERO will monitor the results of the reduction and make necessary corrections. Please refer to Attachment B for reduction plan details.

| Kansas City Power \& Light | No | How can hard dates for the phasing out of the current R5 be in the implementation plan for a standard under <br> development? The concept of phasing out R5 and phasing in R2 could be done, however, this would take <br> considerable thought as to how to implement that. This current proposed implementation plan should be <br> carefully reconsidered. |
| :--- | :---: | :--- |

| Organization | Yes or No | Question 7 Comment |
| :--- | :--- | :--- |

Response: Thank you for your comments. The SDT has revised the plan for reducing the minimum Frequency Bias Setting. The plan is no longer tied to the Field Trial. The SDT has removed the table showing the reduction schedule for the minimum bias setting.
The SDT believes that it is necessary to observe the affect each decrement to the present standard has during all four seasons to assure reliability is not adversely impacted.

The SDT is proposing another method for reducing the minimum Frequency Bias Setting in which the ERO will monitor the results of the reduction and make necessary corrections. Please refer to Attachment B for reduction plan details.

| Progress Energy | No | We agree with the graduated implementation for the FRO portion of the standard, but feel NERC needs to <br> loosen the minimum frequency bias requirement immediately so that it matches the newly required frequency <br> response. There are also other areas within the EMS the besides BA's frequency bias that should be <br> addressed such as secondary frequency response systems that should also be included in this standard. <br> Additionally, if the industry was truly concerned with matching bias values to actual response, they would <br> switch to variable frequency bias. Variable bias requires additional up front work along with general <br> maintenance, but it truly is the best way to accurately bias the ACE equation. |
| :--- | :---: | :--- |

Response: The SDT believes that gradually relaxing the present standard is the prudent way to proceed. The SDT believes that it is necessary to observe the affect each decrement to the present standard has during all four seasons to assure reliability is not adversely impacted.
The SDT has revised the plan for reducing the minimum Frequency Bias Setting and is proposing another method for reducing the minimum Frequency Bias Setting in which the ERO will monitor the results of the reduction and make necessary corrections. Please refer to Attachment B for reduction plan details.
The SDT agrees that use of a variable, non-linear bias setting is the best solution.
We also agree with you that variable, non-linear bias setting would be a superior way to go.

| NIPSCO | No | "Effective Date" section at the top of the Standard does not match the Implementation plan; I think there is an <br> R4 missing in the second part of 1.3 . In the implementation plan add RSG to "Compliance with the Standards" <br> 5 year phase-in on removing the 1\% is a good idea |
| :--- | :---: | :--- | :--- |
| Response: The SDT has corrected the errors noted. The SDT has revised the plan for reducing the minimum Frequency Bias Setting and is proposing another <br> method for reducing the minimum Frequency Bias Setting in which the ERO will monitor the results of the reduction and make necessary corrections. Please refer <br> to Attachment B for reduction plan details. |  |  |
| Energy Mark, Inc. | No | Comment 18: The Proposed Effective Date in the implementation plan is inconsistent with the Effective Data <br> in the Draft Standard. <br> Comment 19: The completion of the implementation plan does not occur until 2015. This lengthy plan stems <br> from a standard that only measures reliability annually and provides only an annual window for changing |

| Organization | Yes or No | Question 7 Comment |
| :--- | :---: | :--- |
|  |  | parameters such as Minimum Frequency Response. Alternative methods that measure reliability more <br> frequently could me implemented with a shorter implementation plan. |
| Response: The SDT has corrected the mismatch between effective dates in the implementation plan and the standard. <br> The SDT believes that gradually relaxing the present standard is the prudent way to proceed. The SDT believes that it is necessary to observe the affect each <br> decrement to the present standard has during all four seasons to assure reliability is not adversely impacted. TThe SDT has revised the plan for reducing the <br> minimum Frequency Bias Setting and is proposing another method for reducing the minimum Frequency Bias Setting in which the ERO will monitor the results of <br> the reduction and make necessary corrections. Please refer to Attachment B for reduction plan details. |  |  |
| Beacon Power Corporation | No | Why is it appropriate to delay implementation of this standard for over 12 months after applicable approval? <br> This seems an unnecessary delay considering the intent to operate under a field test. Similarly, delaying <br> implementation of R2 for over 2 years seems unnecessary. Based on the suggested schedule for measuring <br> FRM and implementing Frequency Bias Settings, there may be rationale to implement the standard on the <br> first calendar year following approval. However, delays beyond the beginning of the next calendar year should <br> require conclusive justification. |

Response: The SDT believes that the affect reducing the minimum bias setting will have on frequency, including unintended consequences, will not be observable for meaningful analysis over a short-time interval.

The SDT has added the R5 Requirement back into the proposed standard. The SDT has revised the plan for reducing the minimum Frequency Bias Setting. The plan is no longer tied to the Field Trial. The SDT has removed the table showing the reduction schedule for the minimum bias setting.
The SDT believes that it is necessary to observe the affect each decrement to the present standard has during all four seasons to assure reliability is not adversely impacted.

| Patterson Consulting, Inc. | No | The implementation plan should address implementing these requirements at the same time for all Balancing Authorities within an interconnection, regardless of regulatory approvals. The present implementation plan will require some Balancing Authorities within an interconnection to operate to the new standard while other Balancing Authorities operate to the old standard if multiple regulatory jurisdictions exist as they do within two interconnections. This could lead to uncoordinated and unreliable operation within an interconnection. |
| :---: | :---: | :---: |
| Response: The SDT does not believe that staggered implementation will lead to uncoordinated and unreliable operation within an interconnection because these changes affect secondary control. With regards to your comment concerning different "regulatory jurisdictions", this issue is outside the scope of the project approved SAR. |  |  |
| Independent Electricity System Operator | No | We have a difficulty understanding the basis for some of the dates in the implementation plan.Some of the implementation steps (retiring R5 of BAL-003-0) start as early as May 2011. We do not believe that the BAL-003-1 standard will be approved by the industry or the NERC BoT at that time and that does not even take into account regulatory approval (or 12 months after BoT adoption in those jurisdictions where no regulatory approval is required). Attachment A has been revised for clarity.
Arizona Public Service Company

## AZPS has a few questions:

1) has frequency performance been affected by the on-going RBC field trial,
2) what steps will be taken to isolate this field trial from the effects of the RBC field trial,
3) will the frequency bias reduction to $0.8 \%$ of peak load include a CPS2 grace-period for thos BAs not involved in the RBC field trial?

Response: 1) The Frequency Response SDT cannot respond on RBS field trial matters.
2) This standard is meant to addresses primary control and the settings of the bias which would have an impact on the measures of the RBS field trial. SDT has revised the plan for reducing the minimum Frequency Bias Setting. The plan is no longer tied to the Field Trial. The SDT has removed the table showing the reduction schedule for the minimum bias setting. The SDT believes that it is necessary to observe the affect each decrement to the present standard has during all four seasons to assure reliability is not adversely impacted. The SDT is proposing another method for reducing the minimum Frequency Bias Setting in which the ERO will monitor the results of the reduction and make necessary corrections. Please refer to Attachment B for reduction plan details. The SDT believes the revised plan is doable and prudent.
3) The Frequency Response SDT anticipates the RBC field trial will be concluded when this standard takes effect. The SDT is proposing that standards requirements take effect for all entities within a regulatory jurisdiction at the same time.

| Northeast Power Coordinating <br> Council |  | Refer to the response to Question 17. |
| :--- | :--- | :--- |

Response: Please refer to the SDT response to Question 17.

## 8. This standard proposes to eliminate the 1\% minimum Frequency Bias over a period of 4 years as outlined in the Implementation Plan. Do you agree that the elimination of the 1\% minimum will bring Frequency Bias closer or equal to natural Frequency Response? If not, please explain in the comment area.

Summary Consideration: Comments received indicate commenters are divided over whether elimination of the $1 \%$ minimum will bring Frequency Bias closer or equal to the natural Frequency Response. Many commenters indicated that the Frequency Bias Setting will never match the Frequency Response and that it is far better for reliability to over bias than under bias. Commenters also expressed concern with how the Frequency Response Obligation (FRO) will be calculated; the rationale for the phase out schedule; and the impact this proposal will have on secondary control.

The FR SDT refined language to indicate it is better to have a somewhat over bias condition, provided additional details on how the FRO is calculated, explained the rationale for the phase out schedule proposed; including developing a reasonable, practical and accurate measurement for natural Frequency Response.

| :--- | :---: | :--- |
| MRO's NERC Standards Review <br> Subcommittee | No | We do note that the question asks if we disagree with eliminating Frequency Bias over a four year period. <br> The requirement actually applies to Frequency Bias Setting. This is important because there has been <br> confusion in some regulatory filings over the Frequency Response versus Frequency Bias Setting. Our <br> comments below assume that Frequency Bias Setting was intended to be used in the question since it is what <br> is in the BAL-003-0.1b R5. |
| We do not question the plan to change the minimum Frequency Bias Setting over a period of 4 years per se |  |  |
| in attempt to optimize AGC response by matching the Frequency Response of the system. However, |  |  |
| Frequency Response of the interconnection is constantly changing. As a result, the Frequency Bias Setting |  |  |
| will never match the Frequency Response exactly. It is better to overbias that underbias to prevent |  |  |
| withdrawal of frequency response by AGC. Historically, the 1\% floor for Frequency Bias Setting was chosen |  |  |
| to ensure that BAs are always over-biased. The standard needs to allow some margin in the Frequency Bias |  |  |
| Setting to ensure that the bias setting is overbiased. |  |  |

Response: The SDT agrees with your clarification that the $1 \%$ minimum applies to the Frequency Bias Setting. We also agree to evaluate the need to be somewhat (as opposed to extremely) over-biased. For example, if a Balancing Authority's observed Frequency Response was . $4 \%$ of its annual forecasted peak load then, at a minimum, a value such as $.1 \%$ would be added to the Frequency Bias setting to make it less likely that the Frequency Response will be counteracted by AGC actions.

| Bonneville Power Administration | No | Until the calculations used for FRO are spelled out and how natural Frequency Response is to be measured, <br> BPA cannot agree that elimination of the 1\% minimum will bring Frequecy Bias closer or equal to natural <br> Frequency Response. |
| :--- | :---: | :--- |
| Response: The SDT has provided clarification in Attachment A, Attachment B and the Background Documents. |  |  |
| IRC Standards Review | No | Please provide the technical basis for the 4-year phase-out schedule. |

| Organization | Yes or No |  |
| :--- | :--- | :--- |
| Committee |  | The SRC suggests that incremental changes should be made and evaluated to determine whether they are <br> indeed beneficial before additional changes are made. Until a standard is defined, it is not appropriate to set <br> an implementation date on the transition. |
| Also, please clarify that the process is to gather data, analyze that data to determine what has been the actual |  |  |
| frequency response, and then to determine the Frequency Bias Settings to be closer to or equal to the natural |  |  |
| frequency response, and is not saying that the next actual frequency response must equal the Frequency |  |  |
| Bias Setting that the ERO has assigned. There is a subtle difference here that must be clarified in order to |  |  |
| avoid the unintended consequence of "punishing" an entity for not providing a response equal to the |  |  |
| Frequency Bias Setting. |  |  |

Response: The technical basis for the phase out schedule is to allow time to evaluate how each Frequency Bias Setting change impacts both reliability and control criteria CPS1 and CPS2 performance.
The intent of the Implementation Plan proposed was to evaluate the effectiveness of each setting change before additional refinement to the Frequency Bias Setting is made and incorporated into the AGC algorithm. This has been removed from the Implementation Plan. The SDT has chosen an alternate method for reducing the minimum Frequency Bias Setting.

Standard language is not intended to penalize entities for not providing a response equal to its Frequency Bias Setting. The intent of the standard is to establish a Frequency Response Obligation (FRO) representing the minimum response required for reliable interconnected operations. The Frequency Bias Setting can differ from the determined FRO value as appropriate for reliability for which compliance will only evaluate if the Frequency Bias Setting is refined correctly and implemented in a timely manner.

| ERCOT | No | Please provide the technical basis for the 4-year phase-out schedule. | reducing the minimum Frequency Bias Setting. <br> Standard language is not intended to penalize entities for not providing a response equal to its Frequency Bias Setting. The intent of the standard is to establish a <br> Frequency Response Obligation (FRO) representing the minimum response required for reliable interconnected operations. The Frequency Bias Setting can differ <br> from the determined FRO value as appropriate for reliability for which compliance will only evaluate if the Frequency Bias Setting is refined correctly and <br> implemented in a timely manner. |  |  |
| Kansas City Power \& Light | No | Simply eliminating the minimum frequency response and establishing an FRO obligation for each BA will not <br> result in a knowledge that a BA has moved closer to its natural frequency response. First, there is an <br> underlying assumption that the FRO dictated for the BA will be "matched" by a BA's resources to achieve a <br> natural response close the FRO and until improved methods of calculating a BA's actual frequency response <br> are developed, there will be no accurate way of determining if a natural response is close to the FRO <br> obligation. |

Response: The intent of the first sentence in the comment above is not clear. There is no underlying assumption that natural response will match the frequency response obligation. However, the compliance process will provide a stimulus to the BA to achieve at least that level of frequency response.
The FR SDT is expending considerable effort to develop a reasonably accurate measurement of natural response, and is in the process of choosing among several promising metrics.

| NorthWestern Energy | No | Page 2 implies that there is currently too much frequency response based on the 1\% of peak demand method <br> of establishing frequency bias. Even though NWE does not use the 1\% method, NWE feels that the 1\% <br> minimum has been a tried and true method of providing frequency response in the Western Interconnection. |
| :--- | :--- | :--- |
| Without the 1\% minimum (and BA's using a natural response less than the 1\%), the total interconnection <br> frequency response would decrease according to research. This would lead to decreased interconnection <br> bias, causing other operational issues, such as lower L10 values and possible CPS2 compliance factors. |  |  |

Response: The opening sentence of this comment appears to be a misstatement. The FR SDT believes a gap exists between the natural Frequency Response and the Frequency Bias Settings calculated based on the $1 \%$ of peak demand criteria, resulting in excessive and unnecessary regulation occurring that is related to high frequency conditions following DCS events and other circumstances. The FR SDT agrees that a reduction in the $1 \%$ of peak demand criteria for the Frequency Bias Setting can adversely affect the overall Interconnection Frequency Bias Setting, L10 values, and possibly CPS 2 compliance also.

| Westar Energy | No | The 1\% requirement should be phased out with the implementation of this standard. |
| :--- | :---: | :--- |
| Response: <br> control criteria CPS1 and CPS2 performance. |  |  |
| FMPP | No | There still needs to a floor value; $1 \%$ may not be the correct value, but zero is not the correct floor. |

| Organization | Yes or No | Question 8 Comment |
| :--- | :---: | :--- | :--- |
| Response: The floor will not be zero. Each Balancing Authority will have a required FRO contribution reflective of the natural Frequency Response in its <br> Frequency Bias Setting. |  |  |
| American Electric Power | No | Please see response to question 7. |

Response: Please see our response to Question 7.

| Duke Energy | No | Duke Energy agrees that a gradual reduction (in magnitude) of the minimum as part of the field test is needed to determine what is the "right" amount of response needed, but the changes cannot be done in a vacuum. <br> Duke Energy continues to be concerned with the impact that the changes to the Frequency Bias Setting ("FBS") will have on the bounds guiding secondary control (CPS1, CPS2 and the draft Balancing Authority ACE Limit or "BAAL" currently under a Field Trial under NERC Project 2010-14). Eastern Interconnection Frequency Response: For those not familiar with the work of the FRRSDT or the NERC Resources Subcommittee around Frequency Response, the estimated response for the Eastern Interconnection on average appears to be less than half of the Interconnection's total FBS in magnitude today. If the decision was made to hold Frequency Response at its current level, this standard could result in the FBS being reduced for many, if not most, Balancing Authorities to about half of what it is today. The FRO allocation would eventually drive what the minimum FBS needs to be, with the FBS needing to be greater than or equal to the FRO, or perhaps FRM, in magnitude at a minimum. <br> Estimating the impact: To look further into the secondary control performance implications of BAs using a reduced FBS, Duke Energy took four sample months of clock-minute data for twelve BAs, cut the Interconnection total and each BA's FBS in half, recalculated each BA's clock-minute ACE taking out half of the bias component, and then calculated CPS1, CPS2 and BAAL estimated performance based upon those changes. Recognizing that the secondary control and resulting ACE of the BAs would be different and dependent upon the standards to be met, the results were not intended to estimate what the performance of the BAs would be, but were intended to help indicate where the problem areas existed based upon today's operation measured to a tighter control criteria. Impact on CPS1 and BAAL: The two bounds that are frequency-dependent, CPS1 and the draft BAAL, are cut in half for any given frequency by cutting the FBS in half. For CPS1 the impact of reducing the FBS looked reasonable with the results leaning toward overall improvement in CPS1 for almost half or better of the BAs (5 of 12, 8 of 12, 6 of 12, and 12 of 12) for the given months even with the tighter bounds, but more analysis may be needed. Though CPS1 looks manageable, the sample set did not include small BAs, and some BAs already in the 100-120\% range appeared more at risk. For BAAL the longest duration of ACE exceeding the low or high BAAL stayed the same or got worse in all cases. As with today where the BAAL bounds get wider as frequency gets closer to 60 Hz where the majority of operation occurs, the additional flexibility of operation is offset by the BAAL bounds getting tighter than the CPS2 limits as frequency deviates farther from 60 Hz . With BAAL cut in half for this scenario, compliance will be more challenging and costly to manage to not exceed 30 minutes for any event. One of the |
| :---: | :---: | :---: |

| Organization | Yes or No | Question 8 Comment |
| :---: | :---: | :---: |
|  |  | unknowns is whether the Frequency Trigger Limit for the BAAL calculation will stay where it's at or be lowered, as the current value was based upon UFLS at 59.82 Hz , rather than today's UFLS of 59.7 Hz . The BARCSDT under NERC Project 2010-14 has more work ahead before any changes can be proposed.Impact on CPS2: Though the industry is not seeing a reliability need to tighten secondary control in normal operation, the industry can't avoid such "tightening" with CPS2 limits directly dependent upon the FBS of the Balancing Authority and total FBS of the Interconnection. For the four months reviewed where CPS2 limits were cut in half, if one looked at the results individually the drop in CPS2 performance across the twelve BAs ranged from $2.6 \%$ to $33.8 \%, 4 \%$ to $33.5 \%, 3.8 \%$ to $37.8 \%$, and $3.1 \%$ to $35.1 \%$, with a median of $19.4 \%, 18.4 \%, 20.3 \%$ and $18.9 \%$ for the four months. Noting that CPS2 performance must be $90 \%$ or greater on a monthly basis, improving CPS2 performance by even $10 \%$ translates to over 70 hours of operation in a month where additional secondary generation control and other actions may be required. Duke Energy notes also that with less error in the ACE, the results indicate that the distribution of ten-minute events exceeding L10 would move closer toward the 50-50 chance that CPS2 will be forcing control action even though the ACE is in support of the Interconnection frequency (results showing the average moving from $27-34 \%$ to $39-43 \%$ of the ten-minute periods exceeded when in support of Interconnection frequency).Conclusion: Duke Energy does not believe there is a reliability need pushing the industry to tighten secondary control to the degree discussed above simply as a result of reducing the Frequency Bias Setting. If the calculated Frequency Response of the Interconnection stayed at its current level, what would be the justification for tightening the secondary control requirements of CPS1, CPS2 and the proposed BAAL? Duke Energy supports taking more of the error out of the ACE equation by having the FBS closer to the estimated Frequency Response of the Balancing Authority, however, Duke Energy does not believe the result should be a significant increase in secondary control costs to meet the CPS1, CPS2, or draft BAAL requirements. |

Response: The SDT appreciates receiving this analysis of the impact Frequency Bias setting can have on secondary control. Please continue to analyze and share this technical data to the extent possible with the SDT. The SDT will perform comparable analyses during the field trial for determining the proper balance between having less "over control" than is perceived with respect to possibly increasing the secondary control cost incurred by individual Balancing Authorities because a smaller Frequency Bias Setting is utilized.

| Alberta Electric System Operator | No | The standard seems to propose to replace the $1 \%$ minimum frequency bias with the new proposed FRO. The <br> AESO finds it difficult to comment on if it is not clear on how the FRO is determined. |
| :--- | :---: | :--- |

Response: The Frequency Response Obligation is used for determining if there is sufficient primary Frequency Response for reliability. The minimum Frequency Bias Setting to be used in AGC will have a floor value needed to assure reliable control, and can be different than the Frequency Response Obligation.
The SDT has modified Attachment A to provide additional clarity regarding the calculation methodologies.

| Independent Electricity System <br> Operator | Yes | We do not have an opinion on the proposed elimination but do have a difficulty understanding the phase-out <br> plan. Please see our comments under Q7, above. |
| :--- | :---: | :--- |

| Organization | Yes or No | Question 8 Comment |
| :--- | :--- | :--- |

Response: The FR SDT has created Attachment B to provide clarifying language for the phase-out plan.
Please refer to the SDT response to question \#7.

| SPP Standards Development | Yes | While we agree that we think such a change will move the industry in the right direction, we have nothing <br> upon which to base that opinion. On the other hand, the $1 \%$ minimum does provide a safety net for the <br> interconnection. Moving away from the minimum requirement over a 4-year period should give us the <br> necessary operating experience to become more confident in our numbers. |
| :--- | :---: | :--- |

Response: The goal of the phase-out plan is to determine the best Frequency Bias Setting floor value to use for reliability that is based on a measured and cautionary approach.

| Southern Company | Yes | Comments: Agree only to the extent that the natural Frequency response can be accurately determined. |
| :--- | :---: | :--- |

Response: The FR SDT is investing considerable effort on behalf of industry to develop a reasonable, practical and accurate measurement of natural frequency response and also a process for choosing the best of several promising metrics.

| Progress Energy | Yes | We have seen actual system operations harmed by the current, excessive biasing requirement on several <br> occasions. |  |
| :--- | :---: | :--- | :--- |
| Response: The SDT thanks you for your affirmative response and clarifying comment. |  |  |  |
| NIPSCO | Yes | Obviously it will bring it closer. The 4 year phase-in is a great idea. |  |
| Response: The SDT thanks you for your affirmative response and clarifying comment.. |  |  |  |
| Manitoba Hydro | Yes | Yes, the removal of the $1 \%$ of projected peak load which has a large window of probability for error should <br> improve BIAS calculations. |  |
| Response: The SDT thanks you for your affirmative response and clarifying comment. |  |  |  |
| Patterson Consulting, Inc. | Yes | Moving Frequency Bias Settings closer to natural Frequency Response is critical to improving observation, <br> reporting, and control. |  |
| Response: The SDT thanks you for your affirmative response and clarifying comment. |  |  |  |

| Response: Please refer to the SDT response to Question 17. |  |  |

## 9. Do you agree with the drafting team that this standard should be field tested? If not, please explain in the comment area.

Summary Consideration: The majority of the commenters agreed that this standard should be field tested. Most commenters indicated that the implementation plan should include information regarding the field trial and also be coordinated with the field trial schedule. Individual commenters suggested that the field trial is not required if detailed calculations and definitions were provided to entities for implementations and the field trial should not serve as a pre-established standard.
In response to industry feedback received, the SDT is presently field testing the methodologies for calculating FRM and FRO. The reduction of the Frequency Bias Setting is no longer part of the field trial. The SDT has defined a process for the ERO to follow to reduce the minimum Frequency Bias Setting once this proposed standard has been approved.

| Organization | Yes or No | Question 9 Comment |
| :--- | :---: | :--- |
| FirstEnergy | No | We believe that the implementation plan should include information regarding the field trial and how it fits in <br> with the phase-in implementation. It appears as though the field trial is being conducted based on 2010 data <br> and will be concluded upon completion of the development of the standard but we think this could be clarified. <br> Furthermore, as stated in the process manual, a field test "should include at a minimum the data collection <br> and analysis or field test tplan, the implementation schedule, and an expectation for periodic updates of the <br> results." The field test information posted is not clear on the implementation schedule of the field test as well <br> as when and how periodic updates will be available. |

Response: Requirement R5 has been inserted back into the proposed standard. SDT has revised the plan for reducing the minimum Frequency Bias Setting. The plan is no longer tied to the Field Trial. The SDT has removed the table showing the reduction schedule for the minimum bias setting. The SDT is proposing another method for reducing the minimum Frequency Bias Setting in which the ERO will monitor the results of the reduction and make necessary corrections. Please refer to Attachment $B$ for reduction plan details.

| Bonneville Power Administration |
| :--- |
| No | | BPA believes that this standard as written should not be field tested. The calculations to be used to set |
| :--- |
| frequency bias must be spelled out in detail and the definition of natural Frequency Response under multiple |
| loading conditions must also be detailed. Once these conditions have been adequately met, there will not be |
| a need for a field trial. |

10. Attachment $A$ of the proposed standard describes the criteria for selecting events to be analyzed. Do you agree with the criteria as described in Attached A? If not, please explain in the comment area.

Summary Consideration: Comments received indicate the majority of commenters agree with having criteria for selecting events to be analyzed and requested clarification on the rationale for the criteria proposed. Research performed by the FRR SDT indicates analysis using 25 events and mean frequency data values will result in stable, consistent results.
Many commenters also expressed concern that the selection criteria was too stringent; that criteria language would omit selection of events worth reviewing; that Balancing Authorities should have flexibility in choosing which event data is selected and also have ability to modify submitted data for ensuring accuracy; and that using event data from the prior year could create double jeopardy. The intent for frequency values selected is to ensure most generators responsive to the interconnection will experience a governor response. The FRR SDT also agrees that interconnection subject matter experts and Balancing Authorities require the flexibility to select noteworthy events of interest, flexibility to identify which events to include or exclude for analysis, and allowance for modifying data for quality and other relevant concerns. The FRR SDT also believes that in those years where 25 acceptable events do not exist, stability and consistency concerns outweigh any adverse impacts from utilizing a few events from the previous year for analysis and that actual impact on current year results will be negligible.
After reviewing comments, the FRR SDT has revised Attachment A language for clarity. The team separated the rationale into a separate document and also revised Form-1.

| Organization | Yes or No |  |
| :--- | :--- | :--- |
| Santee Cooper | No | In Attachment A, item 2.b. states that "The time from the start of the rapid change in frequency until the point <br> at which Frequency has largely stabilized should be less than 18 seconds." It appears that this statement <br> was to ensure that frequency is rapidly decaying; however, frequency could continue to decay beyond 18 <br> seconds and should still be considered an event. <br> Item 3 states that point A is calculated as "an average" is this considered to be an average of all samples or <br> selected samples. <br> Also, we would like to know how the different thresholds for the interconnections were determined. <br> We are also concerned with how the threshold would affect compliance to the standard if it was ever required <br> to be measured on an event basis, particularly those events close to the threshold dead-band settings. Words <br> such as "assumed" should be avoided. <br> Please explain how the number of 25 events was determined for the list of frequency events and explain how <br> those events will be distributed throughout the year (i.e., on and off-peak, and seasonal). |

| Organization | Yes or No | Question 10 Comment |
| :--- | :--- | :--- |
|  |  | Events that meet the selection criteria should be posted by the ERO on a monthly basis. This will allow BAs <br> to evaluate their performance throughout the year. |

Response: The intent for using the words "largely stabilized" in the sentence provides desired flexibility for selecting events for analysis. For example, if frequency drops from 60 Hz to 59.94 Hz in 6 seconds and then continues to decay to 59.935 Hz over the next 20 seconds; then this event would be selected for analysis.
With respect to point $A$, all available samples for the time window specified are averaged. The number of samples obtained for averaging will be determined by the Balancing Authority's EMS scan rate.
Each Interconnection threshold will be determined by subject matter experts who have knowledge of the historical events being analyzed, CERTS research and field trial results. It is not the intent of this standard to seek compliance on a per event basis especially since data quality issues make this type of analysis difficult to validate.
Analysis of metrics being considered by the SDT shows the median or mean frequency data analyzed will converge to a stable state using only 20 event samples obtained for the year being reviewed. The SDT expects the sample set to include seasonal, on-peak, and off-peak events that satisfy the selection criteria specified.
The SDT proposes posting event data on a quarterly basis so Balancing Authorities can periodically analyze data during the year.
Attachment A has been divided into two separate documents; a revised Attachment A containing the calculation methodology and a Background Document explaining the development rationale for the standard's requirements and measures.

| Bonneville Power Administration | No | BPA does not agree with the criteria described in the attachment. 36 mHz is not a large enough deviation to <br> adequately measure frequency response. There is no need to go to that small of a deviation in order to <br> insure that 25 events are found over the course of a year. |
| :--- | :--- | :--- |

Response: The FR SDT will consult with WECC subject matter experts to refine the frequency deviation selection criteria for the western interconnection. Keep in mind the selection threshold will be adjusted over time, as supported by evidence, to ensure reasonable selection criteria is utilized.

| SPP Standards Development | No | While Criteria 5 allows for the ERO to exclude 'non-conforming' SEFRD points there isn't a mechanism <br> provided that instructs us on how to exclude those points in FRS Form 1. <br> Would we be required to reach out for an additional point to get us back to 25 if a point is excluded? Who <br> excludes the point in question? Is it the BA or is it the ERO? Will the ERO have sufficient knowledge to <br> exclude the point in question? <br> In Critieria 2.a. the first sentence should read "The frequency deviation (Point A minus Point C) must <br> exceed...". Also, 36 MHz should be 36 mHz. |
| :--- | :--- | :--- | :--- | :--- |
| Response: The SDT has developed a new version of FRS Form 1, and it clarifies the process of how a Balancing Authority excludes an event. The ERO will not |  |  |

Consideration of Comments: Project 2007-12 BAL-003-1 - $1^{\text {st }}$ Draft

| Organization | Yes or No | Question 10 Comment |
| :--- | :---: | :--- |
| exclude events. <br> The Balancing Authority would not be required to replace an excluded event with another event since analysis of metrics being considered by the SDT shows the <br> median or mean frequency data analyzed will converge to a stable state using only 20 event samples obtained for the year being reviewed. Analysis also shows <br> that the median value is more consistent than the mean value when the sample set includes data for an event that otherwise should have been excluded from the <br> analysis. <br> The SDT thanks you for catching the typographical error referencing 36 mHz . The SDT has revised Attachment A and this value is no longer referenced. |  |  |
| IRC Standards Review <br> Committee | No | The criteria for events selection are acceptable, but the criteria stated in Attachment A for performance <br> required by the FRO is too stringent. Criteria requiring avoidance of Point C encroachment on step 1 of the <br> UFLS program is more stringent than proven performance that now exists. To make this change will be very <br> costly and will not provide for a commensurate increase in reliability. |
| Response: FRO values have not yet been selected. The intent is to choose FRO values that are necessary for the reliability of each interconnection. |  |  |

Response: The intent is to choose among the largest frequency deviation events to obtain a meaningful sample set for analysis accuracy. The FR SDT is open to suggestions to refine the selection criteria for each interconnection. A balance needs to be established between having an inadequate sample resulting in less computational accuracy versus having a sample that is not representative of actual response occurring for the larger frequency deviation events of concern.

| Progress Energy | No | It should be explicitly stated that point C must be outside the standard frequency deviation deadband <br> referenced from 60.0 Hz , not a deviation of more than the frequency deviation deadband from the pre- <br> disturbance frequency. Most of the new electronic govenors operate with a 60 Hz center instead of changes <br> in frequency relative to the current value. |
| :--- | :---: | :--- |

| Organization | Yes or No |  |
| :--- | :--- | :--- |
|  |  | Additionally, the first limit under number 2 should be 36 mHz, not 36 MHz as they are a factor of $10 \wedge 9$ <br> different. <br> Lastly, the event selection criteria listed in Attachment A uses the frequency as measured at Point $C$ to qualify <br> an event, in an effort to ensure that the deviation exceeds the governor deadband. However, Point $C$ is an <br> instantaneous point which will differ in value within the interconnect based on how close the loss of generation <br> is to the measuring point due to the elasticity of frequency across the interconnect during the inertial <br> response. Therefore, local readings by the BA should be allowed to exempt a specific event if the local <br> frequency did not exceed 36 mHz. |

Response: It is expected that the selection criteria will yield events with Point C that clearly exceed the generator governor deadband and result in a response action. While the distance between the measuring point and the loss of generation location will cause different Point C (and other) frequency values being measured at different system locations, the variation in Point C frequency values among the different locations will not be significant for most events or most Balancing Authorities. Keep in mind each Balancing Authority will use its EMS local frequency data for determining sample points A and B. The FR SDT anticipates selecting events that will not require the Balancing Authority to exclude events because of local frequency values measured. The FR SDT will consider high local frequency as a possible selection criteria exclusion factor in the next revision of Form 1.

| NorthWestern Energy | No | Should state "The Point C value is the minimum of frequency samples and should be within 8 seconds after <br> the start of the rapid change". NWE feels some instances could be more than 8 seconds and "should" would <br> allow for this if it occurred. |
| :--- | :---: | :--- |
| Response: <br> information. <br> changing "shall" language to give subject matter experts more flexibility with selecting events. |  |  |
| Hydro-Quebec TransEnergie | No | The criteria to determine what should be considered as a frequency event should be defined by <br> Interconnection. For example, HQT has no dead band on governors; therefore the 36 mHz is not applicable. <br> If more than 25 events occurred within a year, will they all be selected or only a set of 25 will be? Who will <br> perform this selection and base on what criteria. |
| Response |  |  |
| events will be chosen by subject matter experts for that interconnection. |  |  |

Consideration of Comments: Project 2007-12 BAL-003-1 - $1^{\text {st }}$ Draft

| Organization | Yes or No | Question 10 Comment |
| :--- | :--- | :--- |
|  |  | year then those second half of the year events are used in the next year, it could cause an inappropriate <br> violation. <br> BA's need the ability to exclude some events based on measure issues with specific events including scan <br> rates, unusual intermittent resource changes, non-conforming load, unusual ramping of load or interchange <br> during the event. |

Response: Based on comments received from industry, the SDT proposes posting event data on a quarterly basis so Balancing Authorities can periodically analyze data during the year.
Generally, each Balancing Authority will have 25 acceptable events occur each calendar year. Using a few events from the preceding year is not expected to adversely affect accuracy of analysis results. The SDT is re-evaluating exclusionary criteria and is also developing a process to permit reasonable adjustments to an event for atypical circumstances.

| FMPP | No | Attachment A states that if a year occurs in which there are not 25 events that meet the remaining criteria <br> below, then the most recent 25 events (as defined below) will be used for determination of an entity's <br> compliance with the FRM requirement and storage of SEFRD. <br> Problem - by using events from last year to determine an entity's compliance with a Requirement for this year <br> puts the entity in double jeopardy for last year's events, which were already used for compliance for last year. <br> Attachment A states that events occurring during periods in which either significant interchange schedule <br> ramping or load ramping is likely, should be excluded if other events are available for measurement purposes. <br> Questions - What is significant?How can the ERO determine significant interchange schedule ramping is <br> likely?Likely for how many BAs?It would be better to define significant and let the BA exclude any events that <br> meet this definition, since each BA will be ramping differently. Since SEFRD is defined as the individual <br> sample of event data from a Balancing Authority which represents the change in Net Actual Interchange <br> (NIA), divided by the change in frequency, expressed in MW/O.1Hz, whenever a BA includes an event with a <br> "significant" change in NIA due to a large interchange schedule ramp, the FRM is totally skewed, and should <br> not be included. If other events are available means that if other events are not available then an entity's <br> compliance is going to be based on an event or events that has been skewed for the BA by significant <br> interchange schedule ramp. |
| :--- | :--- | :--- | :--- | :--- |

| Organization | Yes or No | Question 10 Comment |
| :--- | :---: | :--- |
| American Electric Power | No | Attachment A only appears to be attempting to address the frequency bias setting for AGC portion of overall <br> frequency response without addressing the governor response portion issue. Attachment A still tries to <br>  <br> Generator Operator levels. <br> WECC has stated through previously submitted comments from its three extensive validation result tests on |
| frequency response with respect to 5\% droop for a 0.1 Hz frequency deviation that actual response would be |  |  |
| 2.5 times greater if the proper governor response actually occurred. The studies also showed only 40\% of the |  |  |
| governors effectively responded. Extensive test result studies such as WECC's should not be ignored. |  |  |
| Attachment A criteria does not address the lack of frequency response from contributing factors associated |  |  |
| with actual governor response, impact of droop setting, amount of BA generation actually on-line at time of |  |  |
| event, maximum loading of generation and amount of BA imported interchange to meet load. |  |  |

| Organization | Yes or No | Question 10 Comment |
| :--- | :--- | :--- |
|  |  | previous statement is a typical schedule, then the statement "The ERO will use the following criteria for the <br> selection of events to be analyzed." could be interpreted as merely the typical process to be used, but not a <br> binding one. In short, the purpose and intention of Attachment A is not communicated unambiguously. |

Response: Item 3 was intended as guidance to give subject matter experts flexibility in choosing the best possible events for analysis. The SDT recognizes that in some years valid but less than ideal events from a selection criteria perspective may be chosen for analysis. The SDT will improve document clarity and also consider if it is prudent to make selection criteria hard or soft requirements.

Attachment A has been divided into two separate documents; a revised Attachment A containing calculation methodology and a Background document explaining the development rationale for the standard requirements and measures.

| Xcel Energy | No | 1) Using 25 events is likely excessive in the Western Interconnection. Several of the past few years have had <br> less than 10 events. Given the extent to which generation is built and resource profiles change, projecting 25 <br> events will include events in the bias calculation that are less reflective of the current generation profile and <br> skew our bias results. |
| :--- | :--- | :--- |
| 2) Calculating point A as "...an average over the period from -16 second to 0 seconds" for any event that |  |  |
| meets the criteria set in Attachment A means that Point A will likely be within 1-2 mHz of 60 Hz, regardless of |  |  |
| starting system conditions. This can cause data to be skewed, as the response will appear to be less if the |  |  |
| frequency immediately before the event is further from 60 Hz than the average. Further, it requires additional |  |  |
| data. If there is some corrupted data in the 16 seconds prior to the event, it may be required to throw out |  |  |
| event data. The 16 seconds prior to the event is not useful data. |  |  |
| 3) Point 5 addresses excluding events "...in which significant interchange schedule ramping or load ramping is |  |  |
| likely..." Not only are the FRO and FRM definitions too vague, they require analysis of real time generation |  |  |
| and load ramping that may not be realistic. Attachment A should likely include specific criteria for removing |  |  |
| events, including lack of reasonable data and, as described here, significant schedule or load ramping, where |  |  |
| "significant" is defined. |  |  |

| Organization | Yes or No | Question 10 Comment |
| :--- | :---: | :--- |
|  |  | distributed throughout the year (i.e., on and off-peak, and seasonal).The criteria in Attachment A should <br> include how and where the arresting frequency is measured |
| Response: The SDT thanks you for your affirmative response and clarifying comments. <br> The magnitude of the frequency change and the initial frequency values identified were selected to ensure that most generators responsive to the interconnection <br> will exceed the governor frequency dead band limits. <br> It is not the intent of this standard to seek compliance on a per event basis especially since data quality issues make this type of analysis difficult to validate. <br> Analysis of metrics being considered by the SDT shows the median or mean frequency data analyzed will converge to a stable state using only 20 event samples <br> obtained for the year being reviewed. The SDT expects the sample set to include seasonal, on-peak, and off-peak events that satisfy the selection criteria <br> specified. <br> Generally, subject matter experts will use high speed frequency recorder data to select events for analysis. Technology is now available that allows cross- <br> checking data at multiple locations for the same event. |  |  |
| SERC Oc Standards Review <br> Group | Yes | While we agree with the basic process, we would like to know how the different thresholds for the <br> interconnections were determined. The review team is also concerned with how the threshold would affect <br> compliance to the standard if it was ever required to be measured on an event basis, particularly those events <br> close to the threshold dead-band settings. Words such as "assumed" should be avoided. Please explain how <br> the number of 25 events was determined for the list of frequency events and explain how those events will be <br> distributed throughout the year (i.e., on and off-peak, and seasonal). |

## Response: The SDT thanks you for your affirmative response and clarifying comment.

The magnitude of the frequency change and the initial frequency values identified were selected to ensure that most generators responsive to the interconnection will exceed the governor frequency dead band limits.
It is not the intent of this standard to seek compliance on a per event basis especially since data quality issues make this type of analysis difficult to validate.
Analysis of metrics being considered by the FR SDT shows the median or mean frequency data analyzed will converge to a stable state using only 20 event samples obtained for the year being reviewed. The FR SDT expects the sample set to include seasonal, on-peak, and off-peak events that satisfy the selection criteria specified.

| FirstEnergy | Yes |  |
| MRO's NERC Standards Review <br> Subcommittee | Yes |  |
| Alberta Electric System Operator |  | AESO suggests that the criteria should also consider including some frequency events where the BA has <br> controlled separation from a region. In the case of Alberta, the frequency deviation is larger than most <br> regional frequency deviations and provides a better measure on Frequency Response. Would the proposed <br> standard permit for BA's to choose these events for inclusion in the determination of the frequency response? |

Response: This is not a common occurrence. Very few Balancing Authorities operate in this manner. The expectation is events will be selected by the Balancing Authorities. The Balancing Authority may exclude events from consideration for specific conditions such as data quality issues.

## Northeast Power Coordinating <br> Council

Refer to the response to Question 17.

Response: Please refer to the SDT response to Question 17.

## 11. The proposed standard has a document attached to it that describes the SDT's reasoning for the Requirements (Attachment A - Frequency Response Background Document). Do you agree with the SDT that this document is useful and provides a clear understanding of the Requirements? If not, please explain in the comment area.

Summary Consideration: Several of the commenters did not agree that the Attachment A - Frequency Response Background document in its current form was useful and provided a clear understanding of the Requirements. In general most commenters indicated that Attachment A required correction, greater clarity and did not adequately explain the calculation methodology. The SDT has split Attachment A into two separate documents, revised Attachment A to better explain the calculation methodology, and improved the document's clarity. The SDT also revised FRS Form 1 and the background document for clarity. Several commenters stated Requirement R2 needed additional explanation so the SDT revised Requirement R2. Several commenters also expressed concern the standard was not well defined as drafted so Requirement R5 was inserted back into the draft standard to resolve this concern. Another concern identified that language appeared to give the ERO a blank check to make changes to the standard without an industry vote. Other commenters requested a better explanation for how FRO is determined and why the median value is considered a reliable statistical measure for calculating FRM.

R2. Each Balancing Authority not participating in Overlap Regulation Service shall implement the Frequency Bias Setting (fixed or variable) validated by the ERO into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effectively coordinated Tie Line Bias control.

R5. In order to ensure adequate control response, each Balancing Authority shall use a monthly average Frequency Bias Setting whose absolute value is at least equal to one of the following:

- The maximum percentage of the Balancing Authority Area's estimated yearly Peak Demand within its metered boundary per 0.1 Hz change as specified by the ERO in accordance with Attachment B.
- The minimum percentage of the Balancing Authority Area's estimated yearly peak generation for a generation-only Balancing Authority per 0.1 Hz change as specified by the ERO in accordance with Attachment B.

| :--- | :---: | :--- |
| MRO's NERC Standards Review <br> Subcommittee | No | Overall, we agree that the document is helpful. However, we do believe additional explanation is necessary <br> for Requirement 2. It appears that the eresponsibility for identifying Frequency Bias Setting is being removed <br> from the Balancing Authority. There is an implied obligation that the ERO will determine the Frequency Bias |

| Organization | Yes or No | Question 11 Comment |
| :---: | :---: | :---: |
|  |  | Setting but it is not stated explicitly. Thus, we are left wondering who has the responsibility for determining the Frequency Bias Setting. <br> On page 3 in the last paragraph of the Frequency Response Obligation and Allocation section, we suggest expanding the explanation of why Frequency Response Obligation is based on (peak generation + peak load)/2. This will result in less responsibility of Frequency Response today for a generator only control area than there currently is. Since load does respond to frequency, we are not suggesting this is wrong. We think it simply needs to be expanded upon in the explanation. <br> Does load contribute the same amount as generation? If not, perhaps the ratio of gen and load response to total response should be reflected in the calculation. |
| Response: The SDT is not suggesting that the ERO determine the Frequency Bias Settings. The SDT has modified the language in Requirement R2 to provide further clarity as to the role of the ERO. The Requirement now reads "Each Balancing Authority not participating in Overlap Regulation Service shall implement the Frequency Bias Setting (fixed or variable) validated by the ERO, into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effectively coordinated Tie Line Bias control." |  |  |
| The SDT believes that there is presently no obligation on the generator only BA and that the proposed FRO will place an obligation on the generator only BA. The SDT has modified Attachment A to provide additional clarity concerning the calculation methodology. |  |  |
| The SDT believes that this is a methodology that is technologically neutral and provides an FRO allocation across all geographic areas. |  |  |
| Midwest ISO Standards Collaborators | No | Overall, we agree that the document is helpful. However, we do believe additional explanation is necessary for Requirement 2. It appears that the responsibility for identifying Frequency Bias Setting is being removed from the Balancing Authority. There is an implied obligation that the ERO will determine the Frequency Bias Setting but it is not stated explicitly. Thus, we are left wondering who has the responsibility for determining the Frequency Bias Setting. On page 3 in the last paragraph of the Frequency Response Obligation and Allocation section, we suggest expanding the explanation of why Frequency Response Obligation is based on (peak generation + peak load)/2. This will result in less responsibility of Frequency Response today for a generator only control area than there currently is. Since load does respond to frequency, we are not suggesting this is wrong. We think it simply needs to be expanded upon in the explanation. Does load contribute the same amount as generation? If not, perhaps the ratio of gen and load response to total response should be reflected in the calculation. |

Response: The SDT is not suggesting that the ERO determine the Frequency Bias Settings. The SDT has modified the language in Requirement R2 to provide further clarity as to the role of the ERO. The Requirement now reads "Each Balancing Authority not participating in Overlap Regulation Service shall implement the Frequency Bias Setting (fixed or variable) validated by the ERO, into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effectively coordinated Tie Line Bias control."

The SDT believes that there is presently no obligation on the generator only BA and that the proposed FRO will place an obligation on the generator only BA. The

Organization
Yes or No
SDT has modified Attachment A to provide additional clarity concerning the calculation methodology.
The SDT believes that this is a methodology that is technologically neutral and provides an FRO allocation across all geographic areas.

| We Energies | No | Overall, we agree that the document is helpful. However, we do believe additional explanation is necessary <br> for Requirement 2. It appears that the responsibility for identifying Frequency Bias Setting is being removed <br> from the Balancing Authority. There is an implied obligation that the ERO will determine the Frequency Bias <br> Setting but it is not stated explicitly. Thus, we are left wondering who has the responsibility for determining <br> the Frequency Bias Setting. |
| :--- | :--- | :--- |

Response: The SDT is not suggesting that the ERO determine the Frequency Bias Settings. The SDT has modified the language in Requirement R2 to provide further clarity as to the role of the ERO. The Requirement now reads "Each Balancing Authority not participating in Overlap Regulation Service shall implement the Frequency Bias Setting (fixed or variable) validated by the ERO, into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effectively coordinated Tie Line Bias control."

| FirstEnergy | No | We believe that more work is needed on this document and the requirements to provide for more clarity. |
| :---: | :---: | :---: |
| Response: The SDT has modified the Background Document to provide additional clarity concerning the reasoning behind the proposed requirements. |  |  |
| Bonneville Power Administration | No | Overall comment: Attachment A does not adequately spell out the methodology that is to be used to determine the correct frequency bias for a Balancing Authority. In order for this standard to go forward, the methodology must be explicitly spelled out and moved into the standard, not attached as a background document that can be changed without vote. <br> o Frequency Bias Setting vs. Frequency Response <br> o RAS events should not be excluded. <br> These events are designed to not have response on the system, even though there may be some primary response. <br> o Paragraph 1 - "each BA has one month" conflicts with the standard that says prior to January 10th or 45 days (1.4 Additional Compliance Information). <br> o 2.a - BPA is assuming the Drafting Team meant 36 mHz .36 mHz is very small and can be achieve during normal frequency deviations. <br> Point C "within 8 seconds" must be moved to 10 to 12 second range in order to work in WECC. <br> o 2.b - Why so far back on the - 16 seconds? <br> o Third from the last paragraph - BPA cannot support a standard that isn't well defined, doesn't adequately spell out the methodology behind the requirements and essentially gives the ERO a blank check to make |

| Organization | Yes or No | Question 11 Comment |
| :---: | :---: | :---: |
|  |  | changes to the standard without a vote. <br> o Second to last paragraph -If you have a poor responding BA control less than they are currently the better responding BA will respond more due to the lower interconnection frequency. This will punish the BAs that have good response and reward those that have poor response, depending on the methodology used to calculate correct frequency bias terms. <br> o Frequency Bias Setting Floor - BPA cannot support a standard that isn't well defined and essentially gives the ERO a blank check to make changes to the standard without a vote. <br> o Frequency Response Obligation and Allocation - BPA cannot support a standard that isn't well defined and essentially gives the ERO a blank check for assigning an FRO to each BA. If this is the method for defining FRO, then it should be included in the requirements section of the standard. However, this section does not spell out how the FRO will be calculated other than that it will be based on the (peak generation + peak load)/2. The full methodology for calculating the FRO must be detailed and put in the standard. |
| Response: The SDT has modified Attachment A and the Background Document to provide additional clarity concerning the calculation methodology and the reasoning behind the proposed requirements. The SDT has been advised by NERC Legal that an attachment explicitly referenced in a Reliability Standard Requirement is enforceable as part of that Requirement. |  |  |
| The SDT has modified the FRS Form 1 to allow for adjustments. Any adjustment will have to be justified. |  |  |
| You are correct concerning the 36 mHZ and this has been corrected. The SDT is only using this to provide a minimum value for selection of events. |  |  |
| The SDT has analyzed several different time periods for the Point A , Point B and Point C values. The SDT has chosen the time periods based on this analysis as detailed in Attachment A and FRS Form 1. |  |  |
| The SDT is proposing to use -16 seconds in order to account for varying AGC scan rates to obtain an average. |  |  |
| The SDT does not believe that there is any requirement presently in place that identifies good or poor responding BAs. The SDT further believes that a BA that is providing proper Frequency Response recognizes the importance and will continue to provide the necessary Frequency Response. Those BAs that are not providing adequate and sustained Frequency Response will be identified through the measure. |  |  |
| The SDT disagrees with your comment that this proposed standard gives the ERO a "blank check" to modify the standard. The proposed standard is attempting to bring the Frequency Bias Setting and the natural Frequency Response closer together and not attempting to set a floor. |  |  |
| The SDT has modified Attachment A to provide additional clarity concerning the calculation methodologies. The SDT has been advised by NERC Legal that an attachment explicitly referenced in a Reliability Standard Requirement is enforceable as part of that Requirement. |  |  |
| SPP Standards Development | No | While we agree that Attachment A is useful, it hasn't quite got to the point where it clearly helps us understand the requirements as well as the calculations and other determinations that must accompany the standard. |

| Organization | Yes or No | Question 11 Comment |
| :--- | :--- | :--- |

Response: The SDT recognizes this and has responded by revising FRS Form 1 and splitting Attachment A into two documents to better clarify the calculation methodology and the reasoning for the requirements.

| IRC Standards Review <br> Committee | No | Attachment A is useful, but it does not provide a clear understanding of all topics and issues. This is <br> evidenced by the questions and comments the SRC is submitting. |
| :--- | :---: | :--- |

Response: The SDT recognizes this and have responded by revising FRS Form 1 and splitting Attachment A into two documents to better clarify the calculation methodology and the reasoning for the requirements.

| ERCOT | No | Attachment A is useful, but it does not provide a clear understanding of all topics and issues. This is <br> evidenced by the questions and comments the SRC is submitting. |
| :--- | :---: | :--- |
| Response: The SDT recognizes this and have responded by revising FRS Form 1 and splitting Attachment A into two documents to better clarify the calculation <br> methodology and the reasoning for the requirements. |  |  |
| Southern Company | No | We did not want to vote on question 11 - clicked 'NO' in error Comments: <br> Attachment A <br> Comment 1: The initial draft of BAL-003 - Attachment A provides a range of valuable background details and <br> historical information about Frequency Response. However, all of this information is not pertinent to the BAs <br> ability to understand and comply with the Standard. The SDT should consider utilizing the Standards <br> Processes Manual (page 39) which provides a detailed description of various alternatives to an attached <br> supporting document. Document types include References, Guidance, Supplements, Training Material, <br> Procedures, and White Papers. <br> Comment 2: The Standards Processes Manual (page 39) makes clear that supporting "documents may <br> explain or facilitate implementation of the standards but do not themselves contain mandatory requirements <br> subject to compliance review." Draft BAL-003 - Attachment A may be in contradiction to the Manual because <br> it suggests mandatory requirements for the BA. Refer to page one where a statement provides that the BA <br> must, within one month after receiving a listing of official events, assemble its data and calculate a Frequency <br> Response Measure. This obligation is not stated in BAL-003 or the proposed BAL-o03-1. The Manual <br> explains that any mandatory requirements must be incorporated into the standardin the standards <br> development process. The SDT should first evaluate whether or not this is a requirement and second, if <br> alternative language may alleviate confusion. |

Response: Attachment A has been split in to two documents. Attachment A now provides the calculation methodology to be used for the standard and a new document titled, "Frequency Response Standard Background Document", that explains the reasoning for the requirements.
The SDT has been advised by NERC Legal that an attachment explicitly referenced in a Reliability Standard Requirement is enforceable as part of that

Consideration of Comments: Project 2007-12 BAL-003-1 - $1^{\text {st }}$ Draft

| Organization | Yes or No | Question 11 Comment |
| :---: | :---: | :---: |
| Requirement. |  |  |
| Progress Energy | No | While the attachment provided insite into the distribution of the FRO for each BA, it lacks clarity on whether the interconnection FRO is based on the largest category C event that occurred, or if this event is based on a study. <br> Additionally, if the event is from actual data, what happens if the interconnection is shown to need less response than it currently has due to the response of frequency dependent loads. <br> What happens to BAs that "have only load with no native generation" if they do not meet their FRO? Are they going to be required to meet their FRO through load managmenet schemes? |
| Response: Attachment A has been split in to two documents. Attachment A now provides the calculation methodology to be used for the standard and a new document titled, "Frequency Response Standard Background Document", that explains the reasoning for the requirements. These documents have also been revised for clarity. |  |  |
| The SDT believes that a BA that is providing proper Frequency Response recognizes the importance and will continue to provide the necessary Frequency Response. Those BAs that are not providing adequate and sustained Frequency Response will be identified through the measure. The FRO is and will be determined based on the methodology detailed in Attachment A. |  |  |
| If $A$ BA does not meet the Requirements then it will be found noncompliant. The proposed standard is setting a minimum Frequency Response but not prescribing a method to meet the requirements. However, the SDT has identified methods of obtaining Frequency Response in the standard. |  |  |
| NorthWestern Energy | No | A Balancing Authority's frequency response is based upon a "median" value calculated from analyzing multiple events. Frequency response during some of these events is better than others, depending on the system conditions at the time and the amount system loading and unloaded generation online at the time of the event. Given these circumstances a BA's actual response could vary by event (better or worse than median), thus compliance measurement per event to a frequency response obligation based on the median response (over multiple events) could put BA's in non-compliant situations unjustly. |
| Response: The SDT, in consultation with the NERC Frequency Response Initiative, has performed empirical studies that demonstrate the median is more resilient to data quality problems and statistical outliers. |  |  |
| Energy Mark, Inc. | No | Comment 20: The document is useful, but it needs a number of modifications to provide a clear understanding of the Requirements.Frequency Bias Setting vs. Frequency Response Section: <br> Comment 21: In bullet 1 the use of the word "storage" is unclear. <br> Comment 22: In bullet 3, The two boxes indicating that the Point $A$ and Point $B$ values are averages should also indicate that the averaging periods for these calculations vary with the scan rate used to collect the data. The correct averaging periods were presented in a table from the NERC Reference Document Understand |

| Organization | Yes or No | Question 11 Comment |
| :---: | :---: | :---: |
|  |  | and Calculating Frequency Response developed by Frequency Response Standard Drafting Team. These scan values used for averaging should be included in the instructions.Frequency Response Obligation and Allocation Section: <br> Comment 23: In the second paragraph of this section there is no supporting analysis that indicates the level of reliability that the selection of "the largest category C event ( $\mathrm{N}-2$ )." Without such analysis, there is no way to determine the level of reliability that will be supported by this "target contingency protection criteria." A reliability criterion that supports an unknown level of reliability is no reliability criteria at all. <br> Comment 24: In paragraph four of this section, determination of the "administrative procedure to assign an FRO to each BA for the upcoming year" is removed from the stakeholders and given to the ERO and the NERC RS to determine. This is unacceptable in a stakeholder driven process without more information about how this determination will be made. <br> Comment 25: In paragraph five of this section, an initial method is offered to determine the proportion of total Frequency Response that each BA will use as their FRO. This method is not influenced by the need for Frequency Response in any manner. It therefore, creates perverse incentives for BAs attempting to make decisions concerning Frequency Response and fails to meet the requirement that "A reliability standard shall neither mandate nor prohibit any specific market structure." This is explained in greater detail later in my comments in response to Questions 16 and 17.Methods of Obtaining Response Section: <br> Comment 26: In the first paragraph, it is suggested that the Frequency Response Obligation could be fulfilled by participating in Reserve Sharing Group (RSG). RSGs were created because of the "non-coincident" nature of the need for Contingency Reserve among BAs. In creating RSGs, all of the BAs in the RSG could reduce the amount of Contingency Reserve that they individually held while still meeting the reliability requirements associated with recovering from disturbances. The savings achieved by reducing individual reserve and sharing reserves provided strong economic incentives to support the infrastructure to create, manage and operate these RSGs. Unlike Contingency Reserves, Frequency Responsive Reserves are always needed on a "coincident" basis because the frequency is the same throughout the interconnection. The strong economic incentives associated with the supply of Contingency Reserves by RSGs do not exist when considering the "coincident" need for Frequency Responsive Reserves. At best, there is only a small reduction in need for reserves on an event by event basis and that small effect is significantly reduced when the averaging period for event measurement is extended over time as the draft standard suggests, one year average measurement period for Frequency Response. <br> Comment 27: In the second paragraph, it is suggested that the problem of obtaining Frequency Response be passed to the RSGs rather than addressing it directly in this standard or in other standards under development. In the distant past, the term "spinning reserve" was weakly related to the amount of Frequency Responsive reserve available. However, in current NERC standards there is no defined relationship between "spinning reserve" and Frequency Responsive Reserve. Therefore, there is no reason to pass this problem to RSGs. However, if an RSG, after investigating the provision of Frequency Response chose to address the problem, there should be no objection to an RSG taking responsibility of its members' Frequency Response |

| Organization | Yes or No |  |
| :--- | :--- | :--- |
|  |  | Question 11 Comment |
|  | Obligations in a manner similar to a single BA. <br> Comment 28: In the third paragraph, it is suggested that "as long as all BAs within the RSG use the same <br> events for calculating FRM, BAs within the RSG may allocate a portion of their FRM to another RSG <br> participant." When one considers that there are expected to be over 25 events in the annual calculation, the <br> probability that all BAs in a RSG will have the data available for the same 25 events should be expected to be <br> small, especilly for large RSGs. Does selection of events for the RSG members in a manner to insure the <br> same 25 events offer an opportunity to bias the sample? |  |

Response: Comment 20 - Attachment A has been split into two documents. Attachment A now provides the calculation methodology to be used for the standard and a new document titled, "Frequency Response Standard Background Document", that explains the reasoning behind the requirements. These documents have also been revised to provide clarity.
Comment 21 - The SDT has removed the reference to "storage" from the documents.
Comment 22 - The SDT agrees and has included averaging periods based on AGC scan rates.
Comment 23 - The SDT agrees that further development is needed in this area, and will review this issue during the field trial and provide more definitive analyses.
Comment 24 - The SDT has revised Attachment A to clarify the calculation methodology.
Comment 25 - The NERC Reliability Standards do not necessarily dictate "how" Requirements are satisfied. A market can be created by a region, sub-region, ISO, RTO or other entities as appropriate to facilitate compliance however the NERC Reliability Standards do not establish markets.
Comments $26 \& 27 \& 28$ - The SDT appreciates these observations and has taken these comments under consideration including modifying the standard regarding RSGs.

| FMPP | No | It is useful, but Attachment A is not clear. |
| :--- | :---: | :--- |

Response: Attachment A has been split into two documents. Attachment A now provides the calculation methodology to be used for the standard and a new document titled, "Frequency Response Standard Background Document", that explains the reasoning for the requirements. These documents have also been revised for clarity.

| American Electric Power | No | As stated earlier, attempting to follow requirement(s) within multiple versions of the same standard would be <br> very difficult. In addition, more examples should be provided. |
| :--- | :---: | :--- |

Response: Requirement R5 has been inserted back into this version of the draft standard and should eliminate the concern of trying to operate using multiple versions of the same standard. This standard will replace all versions of BAL-003 currently in effect.
The SDT has also revised Attachment A and FRS Form 1 to provide clarity.

Consideration of Comments: Project 2007-12 BAL-003-1 - $1^{\text {st }}$ Draft

| Organization | Yes or No |  |
| :--- | :---: | :--- |
| Duke Energy | No | Question 11 Comment |
|  |  | Attachment A is useful, however R2 of the standard references a "calculation methodology detailed in <br> Attachment A" and it isn't clear to us what part of Attachment A is the methodology. <br> Also, in Attachment A the term "Interconnection Frequency Response Obligation" is used, but the definition of <br> FRO says it's a BA value, so that's inconsistent. <br> Overall, we agree that the document is helpful; however, we do believe additional explanation is necessary for <br> Requirement 2. It appears that the responsibility for identifying Frequency Bias Setting is being removed from <br> the Balancing Authority. <br> There is an implied obligation that the ERO will determine the Frequency Bias Setting but it is not stated <br> explicitly. Under the proposed standard, who has the responsibility for determining the Frequency Bias <br> Setting? |

Response: The SDT has also revised Attachment A and FRS Form 1 to provide clarity.
The SDT is not suggesting that the ERO determine the Frequency Bias Settings. The SDT has modified the language in Requirement R2 to provide further clarity as to the role of the ERO. The Requirement now reads "Each Balancing Authority not participating in Overlap Regulation Service shall implement the Frequency Bias Setting (fixed or variable) validated by the ERO, into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effectively coordinated Tie Line Bias control."

Patterson Consulting, Inc.
No

The historical, contextual, and instruction information is valuable and needs to be associated with this standard. This material should not be included in Attacment A, though, as described in previous responses. In addition, there are inconsistent use of definitions and terms in the document that should be corrected.

Response: Attachment A has been split into two documents. Attachment A now provides the calculation methodology to be used for the standard and a new document titled, Frequency Response Standard Background Document", that explains the reasoning for the requirements. These documents have also been revised to provide clarity.

| South Carolina Electric and Gas | Yes | It would be helpful to have a heading to transition from the criteria section to the reasoning section. <br> Also, the title of attachment A should include "Frequency Response" before "Background Document." |
| :--- | :--- | :--- |

Response: The SDT thanks you for your affirmative response and clarifying comment.
Attachment A has been split into two documents. Attachment A now provides the calculation methodology to be used for the standard and a new document, titled, "Frequency Response Standard Background Document", that explains the reasoning for the requirements. | Response: Please refer to our response to Question 17. |  |  |

#### Abstract

12. The proposed standard requires the use of FRS Form 1 for calculating a Balancing Authority's FRM. Do you agree with the SDT that this is the proper method to calculate its FRM? If not, please explain in the comment area and if possible provide an alternate method to calculate FRM.

Summary Consideration: Several of the commenters agreed that the calculation in FRS Form 1 is the proper method for calculating the FRM. Many commenters expressed concern that the FRM calculation method was simplistic, did not capture all contributing factors, and that use of the median value may result in a determination of noncompliance for otherwise compliant conditions. Regarding FRS Form 1, many calculation errors were identified and several commenters indicated that the information provided was neither clear nor complete. There was general consensus for conducting a field trial during which consideration of other statistical methods will be evaluated by the SDT. A few commenters believe that the $1 \%$ of peak formula currently in use should be maintained. Another comment indicated that certain events including contingent Balancing Authority events should not be used for the calculation. One commenter indicated more study is needed to determine how to account for energy flowing across a Balancing Authority's Area since this flow could affect frequency response. Concern was also expressed indicating there is not a reliability basis or replacement for addressing the AGC Frequency Response phase out approach for Requirement R5.
In response to industry comments the SDT has revised FRS Form 1 (including calculations) to allow for adjustments to the calculations. The SDT affirms that the median is the preferred measure for eliminating statistical outliers which have a tendency to skew analysis results. Other statistical methods will be considered by the SDT during the field trial. The SDT agrees there needs to be a floor Frequency Response Setting threshold however the current 1\% of peak of peak load/generation threshold is causing many Balancing Authorities to over bias, causing unnecessary ACE and frequency undulations. The drafting team is proposing a phased approach for reducing the Frequency Bias Setting value to less than 1\% of peak load/generation for Balancing Authorities with actual Frequency Response is currently less than this value. This approach is detailed in Attachment B.

| Organization | Yes or No |  |
| :--- | :---: | :--- |
| Bonneville Power Administration | No | RAS events and Contingent BA events shouldn't be used in the calculation. The FRS Form 1 has a basic <br> flaw that needs correction. For Balancing Authorities that have frequency response wheeled across them by <br> other BAs for foxample, with BPA, any contingency that occurs in the south will have frequency response <br> from BCHydro wheeled across it) and the associated losses will show as less frequency response by the BA <br> that is being wheeled across. BPA recommends that the generation and load be measured, primarily <br> generation, in order to find the frequency response of the BA. Since few, if any, BAs directly measure their <br> total load, the calculated load will have the same issue due to the responses wheeling across the BA (load is <br> generally calculated as total generation minus total interchange). Therefore, more study needs to be done to <br> determine how to account for the energy flowing across a BA. |

Response: The drafting team has taken the suggestion to exclude RAS events for frequency response analysis and will study this further should there be a need to incorporate more events to perform frequency response analysis.
Organization Yes or No $\quad$ Question 12 Comment

The method of analyzing a BA response is formed on a net metered basis to obtain the BA response. The response is not summed across intermediate BAs for loss consideration and ultimate delivery of energy. In the case of Bias the deviation from present metering is an indication of response and load change within the $B A$ as noted in the response. Frequency response could be calculated by measuring each generator and load bus change but then there are distribution losses reflected in the numbers. The generally accepted method presently assumes that change in loss for the frequency response MW delivery is not significant when delivered by many sources.

SPP Standards Development $\quad$ No $\quad$ We do not necessarily agree that it does. Please see our response to Question 1.For the 2010 survey NERC provided the Points A and Points B for the listed events in the provided spreadsheet. FRS Form 1 does not contain that information, only the delta frequency. Please include the Point $A$ and Point $B$ frequencies for the SEFRD events in FRS Form 1.

Response: Please refer to our response for Question 1. The drafting team has revised FRS Form 1 and Points A and B values are calculated in FRS Form 2 and shown in FRS Form 1. These values will differ for each BA based on readings at the BAs location rather than a specific location in the interconnection.

| IRC Standards Review <br> Committee | No | It is one method, but not necessarily the only proper method. Not all existing methods need to be replaced. <br> The SRC suggests scan data could be used so that different metrics can be evaluated. |
| :--- | :---: | :--- |

Response: The drafting team agrees with the IRC Standards Review committee conclusion that the field trial evaluation will support the proper selection of the metric utilized. The SDT believes there is a need for a common methodology for evaluating Frequency Response.

| ERCOT | No | It is one method, but not necessarily the only proper method. Not all existing methods need to be replaced. <br> The SRC suggests scan data could be used so that different metrics can be evaluated. |
| :--- | :---: | :--- |

Response: The drafting team agrees with the IRC Standards Review committee conclusion that the field trial evaluation will support the proper selection of the metric utilized. The SDT believes there is a need for a common methodology for evaluating Frequency Response.

| ISO New Engand Inc. | No | It is one method, but not necessarily the only proper method. |
| :--- | :---: | :--- |
| Response: The drafting team agrees with the IRC Standards Review committee conclusion that the field trial evaluation will support the proper selection of the <br> metric utilized. The SDT believes there is a need for a common methodology for evaluating Frequency Response. |  |  |
| Kansas City Power \& Light | No | This method is too simplistic and does not take into account normal statistical variations in metering accuracy <br> and resolution for generation and tie-lines, does not take into account the natural variations of generation due <br> to mechanical variations, and does not take into account the impact of load control actions on generation. <br> Without taking these variations into account, the outcome is the wild calculation results that have been seen <br> in the current submiscions by BA's that should be an indication that the method needs considerable work to <br> be considered useful. |

| Organization | Yes or No | Question 12 Comment |
| :--- | :---: | :---: |
| Response: The drafting team disagrees that the method needs to address SCADA support concerns cited. There should be a documented reason for each error |  |  | which can be excluded. The field trial evaluation will identify errant calculations and any need for further revision.

| Progress Energy |
| :--- |

Response: The drafting team agrees that calculated frequency response varies from event to event. This is because there are multiple Balancing Authorities interconnected and each BA has a small frequency response contribution compared to the variation in its load and generation experienced at any given moment. This is why the drafting team is proposing to use the median value of events selected during the year as a measure of "average" response. The median is the preferred measure to eliminate population statistical outliers which have tendency to skew results.
The SDT agrees the Interconnections possess sufficient frequency response.
The drafting team is proposing testing using a bias setting value of less than $1 \%$ for BAs with frequency response that is less than the $1 \%$ value currently calculated in order to better match the natural response. The drafting team agrees there needs to be a floor threshold however the current $1 \%$ threshold is causing many BAs to over-bias, resulting in ACE and frequency undulations.
Please identify the research indicating control problems would occur using a minimum bias setting that is less than $1 \%$.

| Organization | Yes or No | $\quad$ Question 12 Comment |
| :--- | :--- | :--- |
| The SDT agrees bias setting changes may impact CPS compliance calculation which is why the drafting team is proposing field testing using small, incremental <br> changes to the bias setting. <br> fesearch by Nathan Cohn (Control of Generation and Power Flow on Interconnected Systems) indicates improved AGC and |  |  |
| frequency performance can be realized by better matching bias setting to frequency response; which should improve CPS compliance. |  |  |

| Organization | Yes or No | Question 12 Comment |
| :--- | :--- | :--- |

Response: Comments 29,31, 32, 33, 34 and 35 - FRS Form 1 has been revised and corrected
Comments 30 - FRS Form 1 has been extensively revised and instructions for its use have be clarified.
Comment 36 - The SDT is evaluating several calculation methodologies. The SDT will propose the most suitable method in its final draft of this standard.

| American Electric Power | No | The FRS Form 1 is actually calculating prior performance results from identified events to determine future measure. The calculation method to determine a BA's FRM still is not capturing all contributing factors that occur in real time and have an impact at time of event occurrence to determine frequency response performance to be measured. The calculation method and FRM needs to be more complete to include all of these contributing factors such as magnitude of actual generation on line at time of occurrence that is capable of governor \& AGC response, actual generator loading, scheduled interchange imports to balance or meet load demand, etc. The calculation method and FRM also needs to be more dynamic to allow inclusion of these variable contributing factors to be able set proper measure and identify lack of performance to actually address the issue, if there truly is one. There needs to be some form of measure at the actual generator level. Measuring a BA's aggregate response will not address contributing generators having negative governor or AGC frequency response, and puts the entire burden on the BA when the performance issue to be resolved is more at generator level. <br> There appears to be no reliability basis or replacement for addressing the AGC frequency response phase out approach for R5 implementation plan. Without a reliability results based study to support this approach, it appears on the surface that there is the potential to lose some of the AGC part of response. <br> Variable energy resources that are non-responsive must also be addressed in the overall calculation and measure. Because the electric industry has evolved with unbundling of generation/transmission and implementation of energy markets, there needs to be an ancillary service component for frequency response to address the factor of independent players that impact the lack of or negative frequency response issue. When impacting entities have financial factors that conflict with reliability intent, the reliability performance process can be compromised and made more difficult to achieve. |
| :---: | :---: | :---: |

## Response: FRS Form 1 has been revised.

The dynamic measure as suggested implies the BA should have a dynamic response incorporated into its frequency bias setting as a variable component.
The SDT believes that the current $1 \%$ of peak of peak load/generation threshold is causing many Balancing Authorities to over bias, causing unnecessary ACE and frequency undulations. The drafting team is proposing a phased approach for reducing the Frequency Bias Setting value to less than $1 \%$ of peak load/generation for Balancing Authorities with actual Frequency Response that is currently less than this value. This approach is detailed in Attachment B.

The drafting team welcomes the initiative of companies to offer a NAESB solution for ancillary services which is beyond the scope of this SAR.

| FMPP | Yes |  |
| Arizona Public Service Company | Yes |  |
| Midwest ISO Standards <br> Collaborators | Yes |  |
| Independent Electricity System <br> Operator | Yes |  |
| MRO's NERC Standards Review <br> Subcommittee | Yes |  |
| Alberta Electric System Operator |  | The standard uses median of multiple SEFRD for the calculation of FRM, which is a reasonable method. The <br> AESO suggests NERC considers the alternative "zero-cross linear regression" method for the FRM <br> calculation. The key difference of "zero-cross linear regression" is that it puts more weight on events with <br> bigger frequency deviation. As the standard is to address the concerns related with large frequency error that <br> could cause UFLS, the more weight put on larger events seems more reasonable. |

#### Abstract

13. The proposed standard requires the use of FRS Form 1 for calculating a Balancing Authority's Frequency Bias Setting. Do you agree with the SDT that this is the proper method to calculate its Frequency Bias Setting? If not, please explain in the comment area and if possible provide an alternate method to calculate Frequency Bias Setting.

Summary Consideration: Many of the commenters agreed with requiring the use of FRS Form 1 for calculating a Balancing Authority's Frequency Bias Setting. Most commenters agreed with the concept but expressed concern that FRS Form 1 had errors, incorrect calculations, did not provide consideration for variable bias, and instructions were vague. Some commenters indicated that the methodology was too simplistic and use of the median value is not an adequate approach. Comments were also received suggesting the current 1\% of peak methodology is a proven method that should be maintained and each Balancing Authority should be allowed to determine its Frequency Bias Setting. One commenter suggested the FRO value should not be considered when determining the Frequency Bias Setting. Another commenter suggested gradually lowering the Frequency Bias Setting floor threshold over several years to assess the associated reliability impacts. The SDT agrees and implemented this approach. Initially the FRM will be computed to $0.8 \%$ of the Balancing Authority's forecasted peak load or generation. A recommendation was provided to estimate the Frequency Bias Setting using a linear slope approach with a least square fit method. The SDT will assess this method as part of the field trial. Observations provided include field testing must validate the methodology and that the methodology should include two measures (AGC and interchange) for identifying lack of frequency response.
In response to industry comments the SDT has revised FRS Form 1 to allow adjustments for known variables that will impact the measure. One commenter noted that Requirement R2 states that the ERO will provide the Frequency Bias Setting for each Balancing Authority whereas FRS Form 1 specifies a calculation to obtain a value which the ERO is not required to review or use. The SDT has modified the requirement to address this process reporting and implementation concern.

| Organization | Yes or No |  |
| :--- | :---: | :--- |
| Bonneville Power Administration | No | BPA thinks that the Form can be used as a tool, but the results shouldn't be the required Frequency Bias <br> setting. Each individual BA should be allowed to set their own. Also, this shows no consideration for variable <br> bias. Variable bias changes greatly during a contingency and this should be considered. Please see <br> comments to number 12. |
| Response: The SDT agrees that measurement of individual generator's performance would produce a more accurate measure of Primary Frequency Control and <br> that the SDT had not considered losses within a BA's system due to frequency response of other BA's frequency response flowing through their system. This |  |  |
| could indeed have some effect on the accuracy of the measure when using Interchange Actual for the measure. The SDT agrees that variable bias, based on real |  |  |
| time conditions (up and down headroom) of on line generators and other frequency responsive devices, will produce the most accurate value for the bias setting |  |  |
| if the BA implements a program that will accurately estimate Primary Frequency Control from each of its generators or other frequency responsive devices and |  |  |
| account for load dampening. Form 1 could still be used as a confirmation of general performance and to consistently measure every BA to the same events for |  |  |
| comparison to the Interconnection's performance as a whole. If the BA were willing to measure performance of each generator and other frequency responsive |  |  |
| devices to the same list of events as an additional measure, this could be used in the field trial to determine the magnitude of the measurement error of Form 1. |  |  |

| Organization | Yes or No | Question 13 Comment |
| :--- | :---: | :---: |
| The SDT would like to move the industry to accept the use of variable bias as the superior method for setting the Bias in the ACE equation as long as the BA <br> meets its minimum FRO and that the variable bias result matches actual Primary Frequency Control performance within some tolerance. A BA should not be |  |  | meets its minimum FRO and that the variable bias result matches actual Primary Frequency Control performance within some tolerance. A BA should not be allowed to use a variable bias just to inflate their L10 values for CPS2 compliance.

| SPP Standards Development | No | We do not necessarily agree that it does. Please see our response to Question 1.Given the disclaimers on <br> page 7 of the FRS Form 1 instructions under Data Values, do the BAs have the discretion to change data in <br> Form 1 if it doesn't match the data they recorded on their system? |
| :--- | :--- | :--- |

Response: FRS Form 1 has been revised to allow adjustments for known variables that will impact the measure. The field trial will validate the accuracy of the measure and identify problems using Interchange Actual. The BA can adjust the $t(0)$ event time to align with their frequency data but they should not change their data. Adjustments should be made in the columns provided in the revised FRS Form 1.

| IRC Standards Review <br> Committee | No | It appears to be one acceptable method, but not all the calculations done through the use of the form are <br> clearly described. Further, it says that the Frequency Bias Setting will be based upon the FRM, but it doesn't <br> say how that will be done. |
| :--- | :---: | :--- |

Response: FRS Form 1 has been revised to be clearer. Initially the FRM will be compared to $0.8 \%$ of the BA's forecasted peak load or generation. The Bias setting will be based on the larger value. BA's will continue to be able to use a variable bias.

| ERCOT | No | It appears to be one acceptable method, but not all the calculations done through the use of the form are <br> clearly described. Further, it says that the Frequency Bias Setting will be based upon the FRM, but it doesn't <br> say how that will be done. |
| :--- | :---: | :--- |

Response: FRS Form 1 has been revised to be clearer. Initially the FRM will be compared to $0.8 \%$ of the BA's forecasted peak load or generation. The Bias setting will be based on the larger value. BA's will continue to be able to use a variable bias.

| Kansas City Power \& Light | No | This method is too simplistic and does not take into account normal statistical variations in metering accuracy <br> and resolution for generation and tie-lines, does not take into account the natural variations of generation due <br> to mechanical variations, and does not take into account the impact of load control actions on generation. <br> Without taking these variations into account, the outcome is the wild calculation results that have been seen <br> in the current submissions by BA's that should be an indication that the method needs considerable work to <br> be considered useful. |
| :--- | :---: | :--- |

Response: When the BA's bias setting closely matches natural Primary Frequency Control, L10 and CPS1 and CPS2 will more accurately measure the BA's ACE impact on the Interconnection's frequency. This may also cause greater difficulty maintaining CPS1 and CPS2 compliance. The sample size of identified events is intended to address BA performance variability concerns.
FRS Form 1 has been revised to account for known variables that will impact the measure. The SDT believes that when actual BA Primary Frequency Control

Consideration of Comments: Project 2007-12 BAL-003-1 - $1^{\text {st }}$ Draft

| Organization | Yes or No | Question 13 Comment |
| :--- | :---: | :---: | :---: |
| improves, the measure will be more consistent and useful. |  |  |
| Progress Energy | No | The FRO should not be part of the determination of the bias setting unless you are actually going to respond <br> by the FRO value. BAs should be trying to get their FRC $<=$ FRO, but not biasing by the FRO. The bias has <br> no effect on the FRC. Progress Energy also think the $\%$ of projected peak requirement should be removed <br> now. |

Response: The SDT agrees that the \% of projected peak requirement has been contributing to Secondary Frequency Control problems and has determined that a phased-in approach is the preferred method of eliminating this requirement. The FRO is not intended to be the BA's bias setting unless the BA's actual Primary Frequency Control is equal to the BA's FRO and meets the minimum of the $0.8 \%$ of the BA's forecasted Peak Load or Generation.

| NIPSCO | No | Not sure, It appears that the FR is about $1 / 2$ of the freq bias in the East Int. I think that the bias could be <br> brought down gradually over several years while monitoring system frequency for reliability. |
| :--- | :---: | :--- |

Response: The SDT agrees and the standard has been modified to reflect your concern.

| NorthWestern Energy | No | Page 2 implies that there is currently too much frequency response based on the 1\% of peak demand method <br> of establishing frequency bias. Even though NWE does not use the 1\% method, NWE feels that the $1 \%$ <br> minimum has been a tried and true method of providing frequency response in the Western |
| :--- | :--- | :--- |
| Interconnection. Without the 1\% minimum (and BA's using a natural response less than the 1\%), the total |  |  |
| interconnection frequency response would decrease according to research. This would lead to decreased |  |  |
| interconnection bias, causing other operational issues, such as lower L10 values and possible CPS2 |  |  |
| compliance factors. A Balancing Authority's frequency response is based upon a "median" value calculated |  |  |
| from analyzing multiple events. Frequency response during some of these events is better than others, |  |  |
| depending on the system conditions at the time and the amount system loading and unloaded generation |  |  |
| online at the time of the event. Given these circumstances a BA's actual response could vary by event (better |  |  |
| or worse than median), thus compliance measurement per event to a frequency response obligation based on |  |  |
| the median response (over multiple events) could put BA's in non-compliant situations unjustly. |  |  |

Response: The drafting team agrees that calculated frequency response varies from event to event. This is because there are multiple Balancing Authorities interconnected and each BA has a small frequency response contribution compared to the variation in its load and generation experienced at any given moment. This is why the drafting team is proposing to use the median value of events selected during the year as a measure of "average" response. The median is the preferred measure to eliminate population statistical outliers which have tendency to skew results.

The SDT agrees the Interconnections possess sufficient frequency response.
The drafting team is proposing testing using a bias setting value of less than $1 \%$ for BAs with frequency response that is less than the $1 \%$ value currently calculated in order to better match the natural response. The drafting team agrees there needs to be a floor threshold however the current $1 \%$ threshold is

| Organization | Yes or No | Question 13 Comment |
| :--- | :--- | :--- |

causing many BAs to over-bias, resulting in ACE and frequency undulations.
Please identify the research indicating control problems would occur using a minimum bias setting that is less than $1 \%$.
The SDT agrees bias setting changes may impact CPS compliance calculation which is why the drafting team is proposing field testing using small, incremental changes to the bias setting. Research by Nathan Cohn (Control of Generation and Power Flow on Interconnected Systems) indicates improved AGC and frequency performance can be realized by better matching bias setting to frequency response; which should improve CPS compliance.
The SDT agrees bias setting changes may impact CPS compliance calculation which is why the drafting team is proposing field testing using small, incremental changes to the bias setting. Research by Nathan Cohn (Control of Generation and Power Flow on Interconnected Systems) indicates improved AGC and frequency performance can be realized by better matching bias setting to frequency response; which should improve CPS compliance.
The SDT fails to see the implication that there is too much frequency response based on the $1 \%$ of peak demand method of establishing frequency bias. The bias setting will not increase or decrease Primary Frequency Control. It will only impact the measure of ACE and the resulting Secondary Control of the BA. The 1\% minimum requirement was appropriate in the past when BA's Primary Frequency Control was nearly equal to $1 \%$ of the forecasted peak load or peak generation. Form 1 and this revision to BAL-003 would still require that the Bias setting in the ACE equation be equal to or greater than the natural Primary Frequency Control of the BA with a minimum value of $0.8 \%$ of the BA's forecasted peak load or peak generation. When the BA's bias setting closely matches natural Primary Frequency Control, L10 and CPS1 and CPS2 will more accurately measure the BA's ACE impact on the Interconnection's frequency. This may also cause greater difficulty maintaining CPS1 and CPS2 compliance. The sample size of identified events is intended to address BA performance variability concerns. The field trial results should prove if this is a correct assumption.

Energy Mark, Inc.
No

Comment 37: My initial comments associated with calculation of the Frequency Bias Setting are included in my comments $3,4,5,6,30,31,32,33,34$ and 36.
Comment 38: The determination of the Frequency Bias Setting using a median or mean value provides an incorrect weighting of the individual SEFRD measurements to correctly determine the Frequency Bias Setting. The Frequency Bias Setting as used in the ACE Equation represents a linear function of Frequency Response to frequency error. The best estimate of the Frequency Bias Setting from this SEFRD data is the slope of the line through the origin using a least-squares fit. Any other method of determining the Frequency Bias Setting will improperly weight the individual data points contribution to the error thus providing a poorer estimate of the true value of Frequency Response.

Response: Comment 37 - Please refer to our response to the comments noted.
Comment 38 - Once events have been identified and data collected the SDT can and will use multiple methods of determining the best selection of a bias setting for BA's using a fixed bias. The SDT will include your recommended method as one that is considered.

| FMPP | No | It would be better to define significant and let the BA exclude any events that meet this definition, since each <br> BA will be ramping differently. Since SEFRD is defined as the individual sample of event data from a <br> Balancing Authority which represents the change in Net Actual Interchange (NIA), divided by the change in <br> frequency, expressed in MW/O.1Hz, whenever a BA includes an event with a "significant" change in NIA due |
| :--- | :--- | :--- |

Consideration of Comments: Project 2007-12 BAL-003-1 - $1^{\text {st }}$ Draft

| Organization | Yes or No | Question 13 Comment |
| :--- | :--- | :--- |
|  |  | to a large interchange schedule ramp, the FRM is totally skewed, and should not be included. If other events <br> are available means that if other events are not available then an entity's compliance is going to be based on <br> an event or events that has been skewed for the BA by significant interchange schedule ramp. |

Response: FRS Form 1 has been revised to account for known variables that will impact the measure. The SDT believes that when actual BA Primary Frequency Control improves, the measure will be more consistent and useful. Using identified events and measuring every BA's performance during these events will provide comparison of all BA's performance to the Interconnection's performance as a whole.

| American Electric Power | No | There should be two measures to identify lack of frequency response: A calculation and measure for the AGC <br> part of frequency response based on actual load and generation on line at time of occurrence that is variably <br> adjusted and measured, while also accounting for interchange imports to balance. Today's frequency bias <br> setting does not really address the governor response issue. There also needs to be some form of generator <br> governor response calculation and measure that starts with a base foundation of droop setting/relative |
| :--- | :--- | :--- |
| governor response and is adjusted accordingly. As WECC appears to have shown in its studies, there would |  |  |
| be excessive governor response based on current droop setting if governors responded as they are expected. |  |  |
| This could be an indicator that governor response measure should only be a percentage of this droop, which |  |  |
| protects the generator. Different types of generators and their characteristics must also be factored in.Since |  |  |
| there does not appear to be a performance issue with the Standards involving CPS, we do not believe the |  |  |
| CPS Bounds L10 values should be reduced. |  |  |

Response: FRS Form 1 has been revised to account for identified variables in measuring Primary Frequency Control. The SDT agrees that measuring generator governor response and Primary Frequency Control would be beneficial for determining proper delivery of frequency response. The SDT also agrees that generator governor and droop settings will impact Primary Frequency Control but this concern is outside the scope of this project and a separate SAR will be required to address governor settings. The SDT is not aware of any WECC studies indicating excessive governor response based on current droop settings if governors responded as they are expected. The industry nominal droop setting is $5 \%$ and this level of performance should limit transmission flows across specific elements unless the planning process does not account for this flow during contingencies. If Primary Frequency Control is not evenly distributed across the Interconnection or there is not participation in Primary Frequency Control by all generators with sufficient regulation margin, elements of the transmission system can become overloaded during a contingency. The SDT believes that when the Bias setting in the BA's ACE equation closely matches the Primary Frequency Control of the BA, then the ACE will accurately measure the BA's impact on Interconnection frequency through the CPS 1 and CPS 2 measures. If a BA has very low Primary Frequency Control and resulting lower Bias setting, the L10 value will change also.

| Duke Energy | No | Other factors need to be considered and incorporated in the calculation. See comments to 1 and 2 above. |

| Organization | Yes or No | Question 14 Comment |
| :---: | :---: | :---: |
| Response: The SDT has modified the FRS Form 1 and included instructions to provide clarity in using the form. |  |  |
| SERC OC Standards Review Group | No | We believe the FRS form 1 instructions should be improved by better defining the terms used and improving the overall layout of the form. Fiqure 1 in Section B of the FRS Form 1 Instructions document should be corrected so that it is viewable. |
| Response: The SDT has modified the FRS Form 1 and included instructions to provide clarity in using the form. |  |  |
| South Carolina Electric and Gas | No | We believe the FRS form 1 instructions should be improved by better defining the terms used and improving the overall layout of the form. The document provided should be corrected so that all figures are viewable. |
| Response: The SDT has modified the FRS Form 1 and included instructions to provide clarity in using the form. |  |  |
| Bonneville Power Administration | No | There is no explanation for variable bias. If the suggesting from tab 2 is that a monthly average should be used then this grossly misrepresents the amount of variable bias that is used during a contingency. For example: BPAs monthly average ranges from-150 to -160, but during a contingency it can be in the -400 to 500 range. <br> Figure 1 does not show up so it cannot be determined if BPA agrees with Points A, B and C. Averaging the pre and post data with 16 seconds and 34 seconds, respectively, will cause the calculations to be skewed with some generator response, some tertiary response, etc. We do agree, if Figure 1 appears, that this does spell out how to use the form, BPA just has issues with the data to be provided. |
| Response: Variable frequency bias settings are determined by Balancing Authorities using a calculation based on present operating conditions. The SDT is aware of the extraneous influences in Net Actual Interchange values, and intends to select a sampling interval and an aggregation technique to minimize these influences. <br> We apologize for the exclusion of Figure 1. The SDT has removed this figure from the revised instructions and has modified the FRS Form 1 and including instructions within the form to provide clarity in using the spreadsheet. |  |  |
| SPP Standards Development | No | This document provides valuable background information regarding frequency deviations but lacks the specific line-by-line Form 1 instructions as mentioned at the top of page 7 . We need those details, what goes in each column, how do we determine which values to use, etc. This would tend to minimize any confusion that currently exists regarding completing the form. One specific item we'd like to see provided in the instructions, as well as changed in Form 1, is carrying the Frequency Bias Setting value (Cell L32) out to two decimals. The current limitation of one decimal has caused confusion in past surveys. |

Response: The SDT has modified the FRS Form 1 and included instructions to provide clarity in using the form.

| Organization | Yes or No | Question 14 Comment |
| :---: | :---: | :---: |
| IRC Standards Review Committee | No | The document explains much of the FRS Form 1, but not all, as commented previously. |
| Response: The SDT has modified the FRS Form 1 and included instructions to provide clarity in using the form. |  |  |
| ERCOT | No | The document explains much of the FRS Form 1, but not all, as commented previously. |
| Response: The SDT has modified the FRS Form 1 and included instructions to provide clarity in using the form. |  |  |
| Progress Energy | No | The forms clarity can only truly be found by reverse engineering the formulas within each of the cells. |
| Response: The SDT has modified the FRS Form 1 and included instructions to provide clarity in using the form. |  |  |
| ENBALA Power Networks | No | The FRS Form 1 Instructions that was downloaded from the supporting website seemed to be missing information on page 5 . We found that the accompanying FRS Form 1 (excel document) was more useful than the actual instruction document in providing detail on the required calculation for the Bias Setting. |
| Response: The SDT has modified the FRS Form 1 and included instructions to provide clarity in using the form. |  |  |
| Energy Mark, Inc. | No | Comment 39: The following comments apply to Balancing Authority FRS Form 1 Background and Instructions.Section A: <br> Comment 40: The last sentence in the second paragraph should be modified to read, "Therefore, it is better to analyze response only when significant frequency deviations occur until better measurement methods can be developed to overcome these difficulties."Section A, Subsection 1, Frequency Response: <br> Comment 41: The words "continuous and inverse relationship" should be changed to "bidirectional, continuous and inverse relationship" in all three bullets. Frequency Response that is not provided bidirectionally will be rapidly depleted by oscillating frequency events. <br> Comment 42: If a BA has "non-bidirectional step-function Frequency Response" to frequency, it must also have sufficient continuous frequency response to restore frequency, frequency response, and frequency responsive reserves (margins) following the use of the "non-bidirectional step-function Frequency Response." Therefore, the Frequency Response of primary interest for this standard is a subset of the Frequency Response defined in the NERC Glossary. <br> Comment 43: Simulations and actual experience on the interconnections have demonstrated that step function Frequency Responses can result in frequency instability and oscillations when they are not effectively coordinated with bidirectional, continuous and inverse Frequency Response. Therefore, it is imperative that the standard differentiate this bidirectional, continuous and inverse Base Frequency Response from other |

| :---: | :---: | :---: |
|  |  | replacement power provided to the Contingent BA from the interconnection. The initial amount of replacement power supplied to the Contingent BA is unaffected by the Frequency Bias Settings. The Frequency Bias Settings will only affect how quickly the replacement power is withdrawn after the frequency is arrested and stabilizes. The risk is that the replacement power will be withdrawn before the Contingent BA or RSG can replace it. <br> Comment 49: The two boxes indicating that the Point $A$ and Point $B$ values are averages should also indicate that the averaging periods for these calculations vary with the scan rate used to collect the data. The correct averaging periods were presented in Definitions of Frequency Values for Frequency Response Calculation in NERC Reference Document - Understand and Calculating Frequency Response. |

Response: Comments 39 through 48: The SDT has removed the FRS Form 1 Background Document from this standard and therefore your comments concerning language within this document are not incorporated in this version.
Comment 49: The SDT created FRS Form 2 to address your comments. In addition, the SDT has extensively modified the instructions for the use of these forms to provide additional clarity.

| EKPC | No | The form should include clear instructions for use and clear definitions for terms. All figures within the <br> document should be viewable. More examples for various situations (non-conforming loads) should be <br> included. |
| :--- | :---: | :--- |

Response: The SDT has removed the FRS Form 1 Background Document from this standard and therefore your comments concerning figures within this document are not incorporated in this version.
The SDT has modified the FRS Form 1 and included detailed instructions within the form to provide clarity in using the form.

| American Electric Power | No | The FRO value and calculation formula assigned by the ERO is not totally clear. The survey form should <br> indicate the complete formula used by the ERO. It appears to be missing. |
| :--- | :---: | :--- | :--- |
| Response: The information you are referencing is now included in Attachment A. The SDT has also modified the FRS Form 1 and included detailed instructions <br> to provide clarity in using the form. |  |  |
| Duke Energy | No | The form does not recognize the impacts noted in the comment to 1 above. The form does show a column <br> that appears to allow for exclusion of contingent BA events, but it is not clear how that is accomplished, nor <br> how doing so matches the definitions currently proposed. Duke Energy agrees with the SERC OC comments <br> "We believe the FRS form 1 instructions should be improved by better defining the terms used and improving <br> the overall layout of the form. The document provided should be corrected so that all figures are viewable." <br> The form does not provide much in the way of instructions. |

## Organization

Response: The SDT has removed the FRS Form 1 Background Document from this standard and therefore your comments concerning figures within this document are not incorporated in this version.
The SDT has also modified the FRS Form 1 and included detailed instructions within the form to provide clarity in using the form.

| Santee Cooper | Yes | The instructions should include how to take into account changes in metered non-conforming loads. |
| :--- | :--- | :--- |

Response: The SDT thanks you for your affirmative response and clarifying comment. The SDT has modified FRS Form 1 to allow for adjustments such as nonconforming load.

The SDT has modified the FRS Form 1 and included instructions to provide clarity in using the form.

| NIPSCO | Yes | We didn't read it but the form looks good. |
| :--- | :--- | :--- |

Response: The SDT thanks you for your affirmative response and clarifying comment.
The SDT has modified the FRS Form 1 and included instructions to provide clarity in using the form.

| Patterson Consulting, Inc. | Yes | There are inaccuracies that should be corrected, but the document is useful and valuable. The desired <br> "averaging" of scan-cycle data included in FRS Form 1 Background and Instructions should be made <br> mandatory to |
| :--- | :--- | :--- | mandatory to achieve the standard's purpose of providing consistent measurement methods.

Response: The SDT thanks you for your affirmative response and clarifying comment.
The SDT created FRS Form 2 to address the averaging issue identified in your comment. In addition, the SDT has extensively modified the instructions for the use of these forms to provide additional clarity. The SDT has also modified the FRS Form 1, correcting errors in the calculations.

| Response: Please refer to our response to Question 17. |  |  |

15. The SDT is soliciting comments on methods of obtaining Frequency Response to meet the FERC Order 693 directive. If possible please provide any thoughts you may have on this subject.

Summary Consideration: Stakeholders provided the suggestions shown below as possible methods of obtaining Frequency Response to meet the FERC Order 693 directive:

1. Develop requirements applicable to the Generator Owner.
2. Address droop, dead band settings and governor operation.
3. Corroborate with manufacturers to address load demand response.
4. Use generator output as a primary input for calculating Frequency Response
5. Define ways Reserve Sharing Groups can assist Balancing Authorities in providing Frequency Response.
6. Write standard requirements based on performance needs.
7. Establish demand response as an ancillary service providing frequency response.
8. Do not apply the standard to entities that do not have generation resources.
9. Create a primary frequency market.
10. Keep the $1 \%$ method currently in use.
11. Ensure generators provide appropriate governor response and merchant generation contracts include a Frequency Response obligation.
12. Develop a specific continent wide Frequency Response definition.
13. Provide a customer compensated pre-emptive load shedding program.

In response to industry comments the SDT delivered to NERC staff the recommendation for collaboration between the ERO and manufacturers regarding load demand response. The SDT has specified in the latest draft standard other methods for a BA to obtain Frequency Response. The SDT will examine, during the field trial, the possibility of transferring Frequency Response between BAs.

| Organization | Yes or No | Question 15 Comment |
| :--- | :--- | :--- |
| Santee Cooper |  | The SDT should consider focusing and directing requirements at root causes. Specifically, the SDT should <br> develop requirements that apply to GOs and address droop requirements, deadband settings, governor <br> operation, etc., as well as specific response expectations which are measured and compared to reported |

| Organization | Yes or No |  |  |  |
| :--- | :--- | :--- | :---: | :---: |
|  |  | Qettings. Such requirements would likely include exemption criteria to address older existing systems as well <br> as current operating conditions. Newer systems should be developed, however, to meet specific <br> requirements that will ultimately improve or maintain Frequency Response at acceptable levels. Subsequent <br> efforts by the ERO should also consider collaboration with manufacturers to address demand responses <br> associated with loads. |  |  |
| Response: This issue has been discussed and the SDT understands your concern. However, governor droop requirements, dead-band settings and governor <br> operation are outside the scope of the project approved SAR. The SDT believes that the Generator Verification standards will help address these concerns. The <br> SDT will pass on your suggestion concerning further collaborations between the ERO and manufacturers. |  |  |  |  |
| Bonneville Power Administration | Primarily, frequency response comes from governor control at generators. In order to accurately measure <br> this, the output of generation should be used as one of the primary inputs to the calculation of frequency <br> response. Due to losses, as earlier explained, some BAs could be penalized due to losses associated with <br> other BA frequency response flowing over the BAs' transmission system. This needs to be taken into account <br> when calculating the frequency response of the BAs. |  |  |  |
| Response: The SDT does not have adequate information to address this suggestion. An impact study would be the best option for conducting an analysis. |  |  |  |  |

| Organization | Yes or No |  |
| :--- | :--- | :--- |
|  |  | services. <br> As indicated in our comments under Q2, there is a missing piece to maintaining system frequency and <br> arresting frequency deviation, and that is the generators' governor response. We suggest the SDT conduct an <br> industry discussion on this subject, and determine the entity(ies) responsible for governor actions/setting, the <br> mechanism to provide such a response, and the place for stipulating the necessary standard requirements to <br> enforce compliance for governor actions before further developing this BAL-003-1 standard. |

Response: Manual deployment is not quick enough for frequency response. Automatic deployment of other devices could be useful to provide the desired frequency response. The SDT has also specified in the latest draft standard version other methods for a BA to obtain Frequency Response.
Regarding governor response - this issue has been discussed and the SDT understands your concern However, generator droop requirements, dead-band settings and governor operation are outside the scope of the project approved SAR. The SDT believes that the Generator Verification standards will help address these concerns.

| ERCOT | Demand Response performing as an ancillary service in which the resources are paid to reduce load upon automatic or manual deployment can provide frequency response. Other devices are available, such as flywheels or storage arrangements, such as battery banks, that can provide fast and sustainable response, could also provide frequency response. The standard must be written around performance requirements and results rather than prescriptive requirements that may have the unintended consequence of stifling innovation and creativity in this area. <br> Within the ERCOT Interconnection and the ERCOT market construct, an ancillary service titled Load acting as a Resource (LaaR) may provide up to $50 \%$ of the responsive reserve requirement and provides automatic underfrequency relay activated response to frequency drops. Other market constructs provide for similar services. <br> As indicated in our comments under Q2, there is a missing piece to maintaining system frequency and arresting frequency deviation, and that is the generators' governor response. We suggest the SDT conduct an industry discussion on this subject, and determine the entity(ies) responsible for governor actions/setting, the mechanism to provide such a response, and the place for stipulating the necessary standard requirements to enforce compliance for governor actions before further developing this BAL-003-1 standard. |

| :--- | :--- | :--- |$|$| Kansas City Power \& Light |  | The determination of sufficient frequency response in the interconnection is complex and varies according to <br> the ratio of generation online and the load in the interconnection. The calculation of actual frequency <br> response is also extremely challenging considering metering accuracy \& resolution, SCADA sample rates, <br> statistical variations of load and generation. To accurately assess what is needed and the methods to <br> implement such a complex subject will take considerable thoughtfulness, time, testing and engineering <br> ingenuity. |
| :--- | :--- | :--- |
| Response: The SDT agrees with your comments and thanks you for your participation. |  |  |

| Organization | Yes or No | Question 15 Comment |
| :--- | :--- | :--- |
| Response: <br> RTO or other entities as appropriate to facilitate compliance however the NERC Reliability Standards do not establish markets. |  |  |
| NIPSCO |  | We reviewed the related NERC Training Document from 2003 and your proposed method seems like the best <br> approach. |

Response: The SDT thanks you for your support.

| NorthWestern Energy | A Balancing Authority's frequency response is based upon a "median" value calculated from analyzing <br> multiple events. Frequency response during some of these events is better than others, depending on the <br> system conditions at the time and the amount system loading and unloaded generation online at the time of <br> the event. Given these circumstances a BA's actual response could vary by event (better or worse than <br> median), thus compliance measurement per event to a frequency response obligation based on the median <br> response (over multiple events) could put BA's in non-compliant situations unjustly. Page 2 implies that there <br> is currently too much frequency response based on the 1\% of peak demand method of establishing frequency <br> bis. Even though NWE does not use the 1\% method, NWE feels that the 1\% minimum has been a tried and <br> true method of providing frequency response in the Western Interconnection. <br>  <br>  <br>  <br>  <br>  <br>  <br>  <br> Without the 1\% minimum (and BA's using a natural response less than the 1\%), the total interconnection <br> frequency response would decrease according to research. This would lead to decreased interconnection <br> bias, causing other operational issues, such as lower L10 values and possible CPS2 compliance factors. |
| :--- | :--- | :--- |

Response: The drafting team agrees that there is great variability in calculated frequency response event to event. This is because in a multi-BA Interconnection, a given BA's frequency response contribution is small compared to the variations in load and generation within the BA at any given moment. This is why the drafting team is proposing to use the median value of many events during the year as the measure of "average" response. The median is the preferred measure of by statisticians when dealing with data populations containing outliers.
The SDT agrees the Interconnections possess sufficient frequency response.
The drafting team is proposing a test allowing all BAs with frequency response less than the $1 \%$ of peak to use a Frequency Bias Setting set less than $1 \%$ of peak to better match the Frequency Bias setting to the natural response. The drafting team agrees a floor threshold needs to be maintained however the current $1 \%$ of peak requirement is causing many BAs to over-bias, causing undulations in ACE and frequency.
The SDT would appreciate it if you could identify the research indicating control problems would be realized if the minimum bias setting was set less than $1 \%$.
The SDT also agrees CPS compliance scoring may be affected which is why the drafting team proposes testing using incremental changes to the Frequency Bias Setting. Research by Nathan Cohn (Control of Generation and Power Flow on Interconnected Systems) implies that better matching of the Frequency Bias Setting to the system Frequency Response Characteristic will improve AGC and frequency performance, and also improve CPS compliance scoring.
The SDT does not agree that there is excessive frequency response because of the $1 \%$ of peak demand method for establishing the Frequency Bias Setting. The
Organization
bias setting does not increase or decrease Primary Frequency Control. The bias setting value will only impact the measure of ACE and resulting Secondary
Control. The 1\% of peak minimum threshold was appropriate in the past when BA Primary Frequency Control was nearly equal to $1 \%$ of the forecasted peak load
or peak generation. Keep in mind FRS Form 1 and the BAL-003 draft standard still require the ACE Frequency Bias Setting be set equal to or greater than the
Frequency Response Characteristic with an initial minimum value of $0.8 \%$ of the BA forecasted peak load or peak generation. When the BA Frequency Bias
Setting better matches the Frequency Response Characteristic, L10 and CPS1 and CPS2 will more accurately measure the BA's ACE impact on Interconnection
frequency. This may result in lower CPS1 and CPS2 compliance scoring than currently realized.
The sample size of selected events used for analysis in intended to minimize the concern about variability of performance observed on an event-to-event basis so
that the BA can realize a consistent reference measure when performing analysis.

Energy Mark, Inc.

> Comment 50: In those regions of North America where energy is supplied through markets, Frequency Response should be defined as an additional Ancillary Service and acquired through these Ancillary Service Markets. Attempts to acquire Frequency Response through methods external to the Ancillary Service markets will contribute to market inefficiencies since these external methods must affect the capacity available to the Ancillary Service markets. Use of out-of-market methods would oppose the very reasons that electric energy markets were created in the first place.
> Comment 51: BAs not participating in formal RTOs or ISOs could obtain Frequency Response by insuring that their owned generation is providing appropriate Governor Response to the BA and that contracts will merchant generation are modified to include the provision of Frequency Response in the merchant contracts. It may be appropriate to request guidance from regulatory agencies encouraging the renogiation efforts required to modify existing merchant generator contracts.
> Comment 52: Whether Frequency Response is obtained through Ancillary Service Markets, merchant generator contracts or owned generation, specific continent wide definitions for Frequency Response should be developed to provide guidance and consistency in these diverse circumstances. NERC should be taking the lead on developing the necessary continent wide definitions or policies for Frequency Response.

Response: Comments 50 \& 51: The NERC Reliability Standards do not necessarily dictate "how" Requirements are satisfied. A market can be created by a region, sub-region, ISO, RTO or other entities as appropriate to facilitate compliance however the NERC Reliability Standards do not establish markets.
Comment 52: The SDT will forward this comment to NERC staff.

| Beacon Power Corporation | Beacon Power is a manufacturer and merchant developer of an innovative advanced energy storage <br> technology that uses flywheels. Beacon Power's technology operates by using flywheels to rapidly recycle <br> energy from the grid in order to follow moment-by-moment changes in frequency nearly instantaneously. The <br> following characteristics of Beacon's technology support the use of this technology for frequency response on <br> the electric grid. ấ' Responds to local frequency change in less than 1 second; full response in less than 4 |
| :--- | :--- | :--- |
|  | seconds â' State of the art electronic control - accurate response. No dead-band required, but could be <br> incorporated if beneficial - Inherently modular - Can be distributed around the grid. With distributed local |

| Organization | Yes or No | Question 15 Comment |
| :---: | :---: | :---: |
|  |  | response to frequency, less likely to be limited by congestion, and ensures islanded portions of the grid maintain frequency response. The ability of Beacon Power's flywheels to quickly and precisely respond to frequency events on the grid makes this technology an ideal source of frequency response. The fast response provided can aid in arresting rapid frequency decline on the system, which can assist in preventing the frequency nadir from encroaching on the first step of Under Frequency Load Shedding. Because of its modular design, flywheels can be built and positioned throughout the grid to provide a diversified frequency response, ensuring adequate response during events that cause the grid to separate into islands. Any standards developed by NERC must allow energy storage and should be inclusive of all technologies able to provide frequency response. Storage resources that provide frequency response should be allowed to recover their costs as a wholesale transmission facility subject to FERC's jurisdiction. Storage facilities do not generate electricity and operate only to enhance the reliability of transmission service. Given that there is no open-market for frequency response, there are no concerns of cross-subsidization or competitive concerns. This will address the FERC Order 693 directive to develop a method of obtaining frequency response, and will improve the overall reliability of the interconnections. Beacon agrees with the approach of mandating Balancing Authority response. <br> However, the SDT should go further to define performance requirements for different tiers of frequency response, for example full response in 5 seconds maintained until 15 seconds, and full response in 15 seconds maintained until 90 seconds (numbers are for example only, the SDT would determine the appropriate values), so that Balancing Authorities can be confident when acquiring new sources that demonstrate those performance characteristics. <br> The use of Reserve Sharing Groups (as detailed in Attachment A) to provide a means of sharing Frequency Response seems unnecessary. Since Frequency Response is contributed to the entire interconnection, ignoring any propagation delays, any Balancing Authorities within an interconnection can share Frequency Response if a consistent method of measuring and allocating it can be determined. However, since all online sources of Frequency Response will contribute based on the change in frequency, this sharing of Frequency Response will not improve interconnection performance. It will only allow Balancing Authorities with too few sources to meet NERC requirements. Hence, sharing arrangements would only improve frequency performance if it results in more frequency responsive sources being online during an event. Additionally, due to the geographical differences of the Balancing Authorities within the Reserve Sharing Groups, their use is not conducive to a diversified interconnection frequency response. |

Response: Frequency Response required by the Standard fully satisfies the reliability needs of each Interconnection.
Since these are new Requirements, existing RSG agreements most likely do not address Frequency Response. The SDT is just offering this as a suggestion that needs to be vetted. The SDT has also specified in the latest draft standard version other methods for a BA to obtain Frequency Response.

| Westar Energy | RSG and Spinning Reserve today is SECONDARY response. How does FERC see the RSG (or RTO <br> markets) providing PRIMARY frequency response? Allowing the RSG option does not "address the 693 |

| Organization | Yes or No | Question 15 Comment |
| :--- | :--- | :--- |
|  |  | directive", only dumps it on the RSG with no direction. Using frequency responsive loads seems impractical <br> based on the small frequency deviation levels required. What customer would be ok with dropping load when <br> frequency drops to 59.964 or 59.92, etc. |

Response: Since these are new Requirements, existing RSG agreements most likely do not address Frequency Response. The SDT is just offering this as a suggestion that needs to be vetted. The SDT has also specified in the latest draft standard version other methods for a BA to obtain Frequency Response. Customers are not required to provide frequency responsive load for reliability however this is an options entities may wish to explore.

ISO New England Inc.
As indicated previously in our comments, there is missing piece to maintaining system frequency and arresting frequency deviation, and that is the generators' governor response. This standard appears to incorrectly assume that the BAs have the resources/ability to provide (primary) Frequency Response, and this is simply not the case. The BAs do not necessarily own facilities which can provide this service.

Response: The SDT is responding to a FERC directive to "...define methods of obtaining Frequency Response..." The SDT has also specified in the latest draft standard version other methods for a BA to obtain Frequency Response.
Regarding governor response - this issue has been discussed and the SDT understands your concern. However, governor droop requirements, dead-band settings and governor operation are outside the scope of the project approved SAR. The SDT believes that the Generator Verification standards will help address these concerns.

Independent Electricity System Operator

As indicated in our comments under Q2, there is missing piece to maintaining system frequency and arresting frequency deviation, and that is the generators' governor response. We suggest the SDT conduct an industry discussion on this piece, and determine the entity responsible for governor actions/setting, the mechanism to provide such a response, and the place for stipulating the necessary standard requirements to enforce compliance for governor actions before further developing this BAL-003-1 standard.

Response: The NERC Reliability Standards do not dictate how Requirements are satisfied.
The SDT believes each Interconnection possesses sufficient frequency response.
Regarding governor response - this issue has been discussed and the SDT understands your concern. However, governor droop requirements, dead-band settings and governor operation are outside the scope of the project approved SAR. The SDT believes that the Generator Verification standards will help address these concerns.

|  |  |

The efforts to develop the MOD-025/026 standards and the associated work to determine actual and predicted generator response will do much to identify the response available and provide ways to plan for and validate the response needed and supplied. ERCOT has demonstrated effective use of Load Acting as a Resource (LAAR - essentially customer compensated pre-emptive load shedding). Exploration of similar applications of this in other interconnections is warranted.

| Organization | Yes or No | Question 15 Comment |
| :---: | :---: | :---: |
| Response: The NERC Reliability Standards do not necessarily dictate "how" Requirements are satisfied. A market can be created by a region, sub-region, ISO, RTO or other entities as appropriate to facilitate compliance however the NERC Reliability Standards do not establish markets. |  |  |
| Patterson Consulting, Inc. |  | The SDT has taken the correct approach in mandating Balancing Authority response. Balancing Authorities should be able to acquire that response from various sources to create a suitable portfolio to meet the required performance. The industry may benefit if the SDT defined required performance characteristics for Frequency Response from a technical perspective, such as initial response in less than 2-8 seconds, maximum response in less than 2-40 seconds, continuous (or not) response, etc. (These values are examples and should be determined by the SDT.) Once the market and industry understand expectations, existing or new technologies with those characteristics become possible sources. Then, it is just a matter of adjusting tariffs (compensation) to incent implementation. If Frequency Response is allowed to be shared between Balancing Authorities, the SDT must create requirements to address such issues as deliverability, measurement, and suitable electrical diversity throughout the interconnection. |
| Response: The SDT agrees with your comment. However, keep in mind that the SDT is responding to a FERC directive to "...define methods of obtaining Frequency Response..." The SDT has also specified in the latest draft standard version other methods for a BA to obtain Frequency Response. <br> The SDT is evaluating several averaging time periods during the field trial. The SDT will select the averaging time period that provides the most accurate results. |  |  |
| Alberta Electric System Operator |  | Frequency Response has different aspects and time frames (inertia, governor and AGC response), the method of obtaining Frequency Response should respect these different aspects and time frames. |
| Response: The SDT is responding to a FERC directive to "...define methods of obtaining Frequency Response..." The SDT has also specified in the latest draft standard version other methods for a BA to obtain Frequency Response. |  |  |

#### Abstract

16. If you are aware of any conflicts between the proposed standard and any regulatory function, rule order, tariff, rate schedule, legislative requirement, or agreement please identify the conflict here.

Summary Consideration: Most of the commenters responding to this question provided a response but did not identify any conflicts. A couple of the commenters felt that there may be a conflict with both the FERC Order 693 and the FERC March 18, 2010 order. Another commenter felt that the requirements could impact CPS performance and that using events from the prior evaluation period could create the possibility of double jeopardy.
The SDT explained that the comment concerning the "..scheduled periodicity of Frequency Response surveys..." being the only issue needing to be addressed at this time was not correct. The SDT stated that in the December 16, 2010 FERC Order Accepting NERC's Compliance Filing the Commission states in par 12 "...NERC's proposed action plan demonstrates a commitment to develop requirements for minimum levels of frequency response needed for Reliable Operation consistent with the Commission's directives in Order No. 693." The SDT believes that this clearly states that the directives from FERC Order 693 are to be addressed.
Concerning the comment that the requirements could impact CPS performance the SDT explained that it believes that the large gap commonly found between natural frequency response and the frequency bias settings deployed based on $1 \%$ of peak load was resulting in excessive and unnecessary regulation and was related to high frequency following DCS events and in other circumstances as well. The SDT agreed that the reduction of the $1 \%$ of peak load floor for the frequency bias setting can affect the total interconnection frequency bias setting, L10 values, and possibly CPS 2 compliance as well. The SDT further explained that it put Requirement R5 back in the proposed standard with a process for reducing the minimum to provide for monitoring the system to ensure reliable operation.
With regards to the comment concerning the possibility for double jeopardy the SDT responded that the SDT expected each year to normally have enough frequency events to avoid double jeopardy, but there was a need to have a backup plan in case a year does not yield sufficient frequency events.

| Organization | Yes or No |  |
| :--- | :--- | :--- |
| FirstEnergy |  | We are not aware of any conflicts at this time. |
| Response: The SDT thanks you for your participation. |  |  |
| IRC Standards Review <br> Committee | This proposed Field Trial and standard MAY conflict with Order 693 and the March 18, 2010 Order that <br> state:Specifically, the Commission stated: As the Commission noted in the NOPR and in our response to <br> FirstEnergy, Requirement R2 of this Reliability Standard states that " [e]ach Balancing Authority shall establish <br> and maintain a Frequency Bias Setting that is as close as practical to, or greater than, the Balancing <br> Authority's Frequency Response." The Commission believes that the achievement of this Requirement is <br> fundamental to the tie line bias control schemes that have been in use to assist in balancing generation and <br> load in the Interconnections for many years. |  |

| Organization | Yes or No | Question 16 Comment |
| :---: | :---: | :---: |
|  |  | Further, in Order No. 693 the Commission concluded: We understand that the present Reliability Standard sets the required frequency response of the balancing authorities to be approximately one percent or greater by requiring that the frequency bias shall not be less than one percent and that the frequency bias be as close as practical to, or greater than, the actual frequency response. March 18 Order concludesAccordingly, to assure that NERC proceeds expeditiously, the Commission is setting a compliance deadline of six months from the date of issuance of this order for the development of modifications to Reliability Standard BAL-003-0 that comply with the Commission's directives as set forth in Order No. 693 to define the appropriate periodicity of frequency response surveys necessary to ensure that Requirement R2 and other requirements of the Reliability Standard are being met and the necessary amount of frequency response needed for reliable operation. May 13, 2010 Order for a Technical Conference statedThus, we direct that NERC submit, within 30 days after the technical conference, a proposed schedule that includes firm deadlines for completing studies, analyses needed to develop a frequency response requirement, and for submission of a modified Reliability Standard that is responsive to the Commission directives in Order No. 693 pertaining to Reliability Standard BAL-003-0. <br> In short the Orders only ask for the BAL-003 to be revised to provide a schedule for the Frequency Response surveys. We may question whether the subjective 25 events per year is the same as a scheduled periodicity, but the point here is that that is the only mandate that is needed immediately. <br> The only other requirement is that NERC file a schedule for completing its studies. Note that is not something that is for a standard it is something for a NERC filing. |
| Response: The SDT disagrees with your comment concerning the ".. scheduled periodicity of Frequency Response surveys..." being the only issue needing to be addressed at this time. In the December 16, 2010 FERC Order Accepting NERC's Compliance Filing the Commission states in par 12 "...NERC's proposed action plan demonstrates a commitment to develop requirements for minimum levels of frequency response needed for Reliable Operation consistent with the Commission's directives in Order No. 693." This clearly states that the directives from FERC Order 693 are to be addressed. |  |  |
| ERCOT |  | This proposed Field Trial and standard MAY conflict with Order 693 and the March 18, 2010 Order that state:Specifically, the Commission stated: As the Commission noted in the NOPR and in our response to FirstEnergy, Requirement R2 of this Reliability Standard states that "[e]ach Balancing Authority shall establish and maintain a Frequency Bias Setting that is as close as practical to, or greater than, the Balancing Authority's Frequency Response." The Commission believes that the achievement of this Requirement is fundamental to the tie line bias control schemes that have been in use to assist in balancing generation and load in the Interconnections for many years. Further, in Order No. 693 the Commission concluded: We understand that the present Reliability Standard sets the required frequency response of the balancing authorities to be approximately one percent or greater by requiring that the frequency bias shall not be less than one percent and that the frequency bias be as close as practical to, or greater than, the actual frequency response. March 18 Order concludesAccordingly, to assure that NERC proceeds expeditiously, the Commission is setting a compliance deadline of six months from the date of issuance of this order for the development of modifications to Reliability Standard BAL-003-0 that comply with the Commission's directives |

| Organization | Yes or No | Question 16 Comment |

|  |  | as set forth in Order No. 693 to define the appropriate periodicity of frequency response surveys necessary to ensure that Requirement R2 and other requirements of the Reliability Standard are being met and the necessary amount of frequency response needed for reliable operation. May 13, 2010 Order for a Technical Conference statedThus, we direct that NERC submit, within 30 days after the technical conference, a proposed schedule that includes firm deadlines for completing studies, analyses needed to develop a frequency response requirement, and for submission of a modified Reliability Standard that is responsive to the Commission directives in Order No. 693 pertaining to Reliability Standard BAL-003-0. In short the Orders only ask for the BAL-003 to be revised to provide a schedule for the Frequency Response surveys. We may question whether the subjective 25 events per year is the same as a scheduled periodicity, but the point here is that that is the only mandate that is needed immediately. The only other requirement is that NERC file a schedule for completing its studies. Note that is not something that is for a standard it is something for a NERC filing. |
| Response: The SDT disagrees with your comment concerning the ".. scheduled periodicity of Frequency Response surveys..." being the only issue needing to be addressed at this time. In the December 16, 2010 FERC Order Accepting NERC's Compliance Filing the Commission states in par 12 "...NERC's proposed action plan demonstrates a commitment to develop requirements for minimum levels of frequency response needed for Reliable Operation consistent with the Commission's directives in Order No. 693." This clearly states that the directives from FERC Order 693 are to be addressed. |  |  |
| Arizona Public Service Company |  | AZPS would like clarity if Interpretations of BAL-003-0 will be part of BAL-003-1. |
| Response: This standard will replace all existing BA-003's and incorporates any approved interpretation. |  |  |
| Energy Mark, Inc. |  | Comment 53: In Comment 25 I indicated that the suggested allocation method fails to meet the requirement that "A reliability standard shall neither mandate nor prohibit any specific market structure." My comments here support that contention. The allocation method is not influenced by demand for frequency response. As a consequence, only one side of a fair market is represented. Markets are effective because: <br> 1. Markets are voluntary allowing the demand side of the market to choose to not create the need to acquire a product or service. <br> 2. Markets select the lowest cost product or service from competing offers to supply the product or service demanded. When the allocation method is blind to the demand for the product or service it eliminates the most efficient market designs from consideration, and therefore, mandates a market design that only looks at the supply side of the market. <br> Comment 54: Selecting an allocation method for Frequency Response that considers both the supply and demand sides of the market for Frequency Response would enable the implementation of a much more efficient market design. Such an allocation method would allow demand side reductions in the need for Frequency Response to compete with supply side increases in the need for Frequency Response allowing for |

| Organization | Yes or No | Question 16 Comment |
| :---: | :---: | :---: |
|  |  | the creation of the most efficient markets in this Ancillary Service. |
| Response: The SDT acknowledges your concerns but your market-related suggestions are outside the scope of the industry approved SAR. |  |  |
| FMPP |  | NERC Relablity Standards Conflict - by using events from last year to determine an entity's compliance with a Requirement for this year puts the entity in double jeopardy for last year's events, which were already used for compliance for last year. |
| Response: The SDT agrees that a standard should not place an entity in double jeopardy. The SDT expects that each year will normally have enough frequency events to avoid double jeopardy, but it needs to have a backup plan in case a year does not yield sufficient frequency events. |  |  |
| American Electric Power |  | This Standard has the potential to affect Standards involving CPS performance with respect to the calculated CPS Bounds L10 if relative. |
| Response: The SDT believes that the large gap commonly found between natural frequency response and the frequency bias settings deployed based on $1 \%$ of peak load is resulting in excessive and unnecessary regulation and is related to high frequency following DCS events and in other circumstances as well. You are correct in asserting that the reduction of the $1 \%$ of peak load floor for the frequency bias setting can affect the total interconnection frequency bias setting, L10 values, and possibly CPS 2 compliance as well. <br> The SDT has put Requirement R5 back in the proposed standard. The SDT has modified the plan for reduction of the minimum Frequency Bias Setting. The plan is no longer tied to the Field Trial. The SDT has removed the table reflecting the reduction of the minimum bias setting. The SDT is proposing a method of reducing the minimum Frequency Bias Setting in which the ERO will monitor the results of the reductions and adjusting them accordingly in an effort to bring the Frequency Bias Setting closer to natural Frequency Response. Please refer to Attachment B for details of this reduction plan. |  |  |
|  |  |  |
| Northeast Power Coordinating Council |  | Refer to the response to Question 17. |

| Patterson Consulting, Inc. |  | None. |
| Kansas City Power \& Light |  | No other comments. |

## 17. Please provide any other comments (that you have not already provided in response to the questions above) that you

 have on the draft standard BAL-003-1.> Summary Consideration: Several commenters indicated that the supplemental compliance information and attachment sections created additional standard requirements. In response to this concern these documents have been revised. If a requirement states that the entity must perform in accordnace with Attachment $X$, then Attachment $X$ is an extension of that requirement and the performance identified in the attachment is mandatory and enforceable.
> Several commenters expressed concern that the Balancing Authority may not have the necessary means to effectively manage Frequency Response and recommended that the SDT consider establishing a standard for generators to support the Balancing Authorities achieve the necessary level of Frequency Response. The SDT explained that this standard will provide the metrics for Frequency Response while the market will define itself.
> Commenters also stated that insufficient detail has been provided for evaluating the appropriateness of the methodology used for determining FRO. They indicated that the standard needed more details on how the FRO is calculated and allocated among the Balancing Authorities. The SDT made significant modifications to Attachment A - Supporting Document which details the methodology used to determine the calculations.
> Commenters indicated that the plan to annually reduce the floor percentage for the Frequency Bias Settings may adversely impact reliability. In response to this concern the Implementation Plan no longer outlines the Frequency Bias Setting reduction plan initially proposed. Attachment B sets forth the procedure for reducing the Frequency Bias Setting floor threshold.
> Another commenter stated that emphasis should be placed on the Frequency Excursion Curve Point $C$ value and not other values because the Point C value is critical for reliability. A request was also received to correlate the frequency response for the Point B value timeframe window with the timeframe window for the Point C value. The SDT committed to reviewing this relationship during the field trial.

> One commenter asked how to attain or schedule Frequency Response from another Balancing Authority if it is a market resource. The SDT responded that the standard simply provides reliability metrics. Industry determines which markets and independent solutions could be developed.
> A comment was received requesting clarification of the NERC glossary term "native load" mentioned in the Implementation Plan. Instead of providing clarification, this term has been removed from the Implementation Plan.

> Twenty-five additional industry comments have been received regarding the draft BAL-003-1 standard as noted in the following table.

| Organization |  |
| :--- | :--- |
| Northeast Power Coordinating <br> Council | It is not clear from either Form 1 or its instructions whether the supplied frequency deviation for an event should be used <br> without modification, or if it should be overwritten with a value computed from the Balancing Authority's data source (or if |

| Organization | Question 17 Comment |
| :---: | :---: |
|  | there is an option, to use the lesser value, for example). Clearly express which frequency deviation value to use. <br> The load sensitivity calculation is an important Balancing Authority Area value to compute accurately for modeling purposes. As proposed, it would use the same computational technique as that used for frequency bias sampling calculations. To yield a useful result, load values would need to have "convergence characteristics" similar to that found in the actual net interchange values used for frequency bias sampling. While experience has shown that the average or median values of the frequency bias samples computed for most Balancing Authorities will converge with about 20 samples, a similar outcome for load sensitivity calculations might not occur. Frequency bias samples rely on the measured actual net interchange values that are sampled at the AGC scan rate, and the actual net interchange tends to be a rather stable value because AGC and operator actions usually keep the actual net interchange close to a scheduled value. The total net system load may have greater volatility and may be trending in a particular direction much more often than actual net interchange. Also, the load calculation typically relies on adding the sum of the generation within the Balancing Authority to the actual net interchange. The generation values may have a slower scan rate, longer data latency periods, and smaller generators might not be telemetered, with hourly scheduled values or manually entered values being used instead. These differences can contribute to a very different convergence characteristic than that found for actual net interchange. Simply put, the load sensitivity calculation needs validation. <br> The Form 1 instructions mention a generation only Balancing Authority form to be filled in. It is not shown on the spreadsheet provided, and it is not clear what data should be entered, though it seems like it would still be actual net interchange.Form 1 contains an entry form for a single Balancing Authority Interconnection, however, it is not referenced in the Form 1 instructions.Section A of the Form 1 instructions contains excellent background material that explains why this effort is important. However, section B needs a careful review so that the instructions are thorough and unambiguous. The information on variable bias calculations seems sparse, and the requirements for variable bias should be reviewed thoroughly with those Balancing Authorities that are familiar with the nuances and challenges of determining an appropriate variable bias.If BIAS is set equal to response, about $50 \%$ of the time, AGC will cancel out the primary response; the BIAS, therefore, should be slightly higher than the natural response but clearly $1 \%$ is too large. The game plan to continually reduce the floor percentage for frequency bias settings needs to be reconsidered. With . $4 \%$ peak load being a typical actual frequency response lately for Balancing Authorities, the $1 \%$ of peak load to $.8 \%$ of peak load transition seems prudent. Perhaps a further reduction to $.6 \%$ may be useful as well, but lesser floors may in effect result in AGC too often canceling out the primary frequency response being provided. While the 16 to 52 second sampling window for point B computations seem to be a reasonable initial guess for the metric, preliminary studies by the Frequency Responsive Reserve Standard Drafting Team (FRRSDT) indicate that AGC contributions from fast acting hydro generators will be included in the samples. As those same studies were not conclusive, perhaps the initial years of this standard could require the provision of scan rate data from 30 seconds before to 60 seconds after the start of the frequency decline for each event. While this significantly increases the volume of data to be provided, it would allow the FRRSDT to determine the best sampling intervals to be used. Perhaps a point B sampling interval of 15 to 30 seconds would filter out most of the fast acting AGC, but more data/analysis is needed to determine the best sampling interval to be sure that the primary response data is not being corrupted by this fast acting AGC response.To support Balancing Authorities in achieving the targeted level of frequency response, a standard for generators is needed as well, as they are historically the largest source of discretionary frequency response. The standard could give a Balancing Authority the right to waive these requirements should they pursue other sources of frequency |

|  | response, such as ERCOT's "load acting as a resource (LAAR)" efforts. |
|  | Point C values are the more important reliability metric. Since point C metrics are challenged with data quality issues on a |
|  | Balancing Authority and generator level, an effort should be made to correlate the required frequency response in the point B |
|  |  |
|  |  |
|  | While Attachment A mentions that N-2 category C events will be used to determine the frequency response obligation on an <br> interconnection level, there is insufficient detail provided at this time to evaluate the appropriateness of the obligations <br> selected. Efforts in this area for the frequency model developed by the Reliability-Based Control Standard Drafting Team <br> (and now the BARCSDT) for HQTE may shed some insight into this process. |

Response: The SDT agrees that clearer instructions are needed in Form 1. This has been addressed in the revised form. The SDT also agrees that there may be limited benefit from measuring the load response of a BA due to data fidelity and resolution. An attempt to measure a BA's load response was included for the field trial to determine its value and was not used in the BA's frequency response measure. It is believed that some BA's with generation data that is on a similar scan rate as their Interchange data may find that it accurately measures their load dampening. The field trial will determine if it is useful or not. The SDT agrees that the 16 to 52 second sampling window may include some fast acting AGC. The field trial will determine if this sampling period should be reduced. Form 1 has been revised to include a minimum data set that starts 30 seconds before the event and ends not earlier than 60 seconds after the event to help identify the overall best averaging periods. The SDT also agrees that the use of LaaRs in ERCOT is a great backup to Primary Frequency Control but would also like to point out that this response only responds in one direction and does not provide bidirectional frequency stability for the moment to moment changes in frequency. Once utilized, it takes hours to restore the service for the next contingency. During this time, the BA and Interconnection depends on Primary Frequency Control from other sources that are continuous and bidirectional as long as headroom is available. The SDT agrees that Point C Primary Frequency Control is critical for preventing UFLS and will use the field trial results to determine if the Point B measure of performance can be correlated to Point C performance. Thank you for your comments.
Regarding governor response - this issue concerning generators has been discussed by the SDT. The SDT understands your concern. However, governor droop requirements, dead-band settings, and governor operation is outside of the industry approved SAR. The SDT believes that the Generator Verification standards will help address these concerns.
The $\mathrm{N}-2$ criteria is being evaluated during the field trial.
ISO New Engand Inc.
It is not clear from either Form 1 or its instructions whether the supplied frequency deviation for an event should be used without modification, or if it should be overwritten with a value computed from the Balancing Authority's data source (or if there is an option, to use the lesser value, for example). Clearly express which frequency deviation value to use.
2. The load sensitivity calculation is an important Balancing Authority Area value to compute accurately for modeling purposes. As proposed, it would use the same computational technique as that used for frequency bias sampling calculations. To yield a useful result, load values would need to have "convergence characteristics" similar to that found in the actual net interchange values used for frequency bias sampling. While experience has shown that the average or median values of the frequency bias samples computed for most Balancing Authorities will converge with about 20 samples, a similar outcome for load sensitivity calculations might not occur. Frequency bias samples rely on the measured actual net
interchange values that are sampled at the AGC scan rate, and the actual net interchange tends to be a rather stable value because AGC and operator actions usually keep the actual net interchange close to a scheduled value. The total net system load may have greater volatility and may be trending in a particular direction much more often than actual net interchange. Also, the load calculation typically relies on adding the sum of the generation within the Balancing Authority to the actual net interchange. The generation values may have a slower scan rate, longer data latency periods, and smaller generators might not be telemetered, with hourly scheduled values or manually entered values being used instead. These differences can contribute to a very different convergence characteristic than that found for actual net interchange. Simply put, the load sensitivity calculation needs validation. The Form 1 instructions mention a generation only Balancing Authority form to be filled in. It is not shown on the spreadsheet provided, and it is not clear what data should be entered, though it seems like it would still be actual net interchange.Form 1 contains an entry form for a single Balancing Authority Interconnection, however, it is not referenced in the Form 1 instructions. Section A of the Form 1 instructions contains excellent background material that explains why this effort is important. However, section B needs a careful review so that the instructions are thorough and unambiguous. The information on variable bias calculations seems sparse, and the requirements for variable bias should be reviewed thoroughly with those Balancing Authorities that are familiar with the nuances and challenges of determining an appropriate variable bias.If BIAS is set equal to response, about $50 \%$ of the time, AGC will cancel out the primary response; the BIAS, therefore, should be slightly higher than the natural response but clearly $1 \%$ is too large. The game plan to continually reduce the floor percentage for frequency bias settings needs to be reconsidered. With $.4 \%$ peak load being a typical actual frequency response lately for Balancing Authorities, the 1\% of peak load to $.8 \%$ of peak load transition seems prudent. Perhaps a further reduction to $.6 \%$ may be useful as well, but lesser floors may in effect result in AGC too often canceling out the primary frequency response being provided.

While the 16 to 52 second sampling window for point $B$ computations seem to be a reasonable initial guess for the metric, preliminary studies by the Frequency Responsive Reserve Standard Drafting Team (FRRSDT) indicate that AGC contributions from fast acting hydro generators will be included in the samples. As those same studies were not conclusive, perhaps the initial years of this standard could require the provision of scan rate data from 30 seconds before to 60 seconds after the start of the frequency decline for each event. While this significantly increases the volume of data to be provided, it would allow the FRRSDT to determine the best sampling intervals to be used. Perhaps a point B sampling interval of 15 to 30 seconds would filter out most of the fast acting AGC, but more data/analysis is needed to determine the best sampling interval to be sure that the primary response data is not being corrupted by this fast acting AGC response.
To support Balancing Authorities in achieving the targeted level of frequency response, a standard for generators is needed as well, as they are historically the largest source of discretionary frequency response. The standard could give a Balancing Authority the right to waive these requirements should they pursue other sources of frequency response, such as ERCOT's "load acting as a resource (LAAR)" efforts.
Point $C$ values are the more important reliability metric. Since point $C$ metrics are challenged with data quality issues on a Balancing Authority and generator level, an effort should be made to correlate the required frequency response in the point B time window with that needed in the point C time window (perhaps using rules of thumb, such as $100 \%$ of load's frequency response and $30 \%$ of generator's frequency response occurs in time for point C). While Attachment A mentions that $\mathrm{n}-2$ category $C$ events will be used to determine the frequency response obligation on an interconnection level, there is insufficient detail provided at this time to evaluate the appropriateness of the obligations selected. Efforts in this area for the

|  | frequency model developed by the Reliability-Based Control Standard Drafting Team (and now the BARCSDT) for HQTE may shed some insight into this process. |
| Response: The SDT agrees that clearer instructions are needed in Form 1. This has been addressed in the revised form. The SDT also agrees that there may be limited benefit from measuring the load response of a BA due to data fidelity and resolution. An attempt to measure a BA's load response was included for the field trial to determine its value and was not used in the BA's frequency response measure. It is believed that some BA's with generation data that is on a similar scan rate as their Interchange data may find that it accurately measures their load dampening. The field trial will determine if it is useful or not. The SDT agrees that the 16 to 52 second sampling window may include some fast acting AGC. The field trial will determine if this sampling period should be reduced. Form 1 has been revised to include a minimum data set that starts 30 seconds before the event and ends not earlier than 60 seconds after the event to help identify the overall best averaging periods. The SDT also agrees that the use of LaaRs in ERCOT is a great backup to Primary Frequency Control but would also like to point out that this response only responds in one direction and does not provide bidirectional frequency stability for the moment to moment changes in frequency. Once utilized, it takes hours to restore the service for the next contingency. During this time, the BA and Interconnection depends on Primary Frequency Control from other sources that are continuous and bidirectional as long as headroom is available. The SDT agrees that Point C Primary Frequency Control is critical for preventing UFLS and will use the field trial results to determine if the Point B measure of performance can be correlated to Point C performance. Thank you for your comments. |  |
| Santee Cooper | Again, we believe that the SDT should consided or prior years' data. We are concerned with how the total frequency response obligation of an interconnection will be determined since this will ultimately determine each BA's FRO. We believe more detail should be presented on this issue. We appreciate the time and the work performed by the standard drafting team on this standard that we feel is a necessary component for reliable operation of the Interconnections. |
| Response: The SDT does not understand the intent of the first sentence in your comment.. The next posting will be more explicit in the method for determining the FRO. |  |
| MRO's NERC Standards Review Subcommittee | We feel the Reserve Sharing Group should be removed from the applicability section as it's not included in any requirement. |
| Response: The SDT has modified the proposed standard to better reflect the RSG responsibility in providing Frequency Response. |  |
| Xcel Energy | We feel Reserve Sharing Group should be removed from the applicability section since it is not included in any of the requirements. Additionally, the documents are not clear as to how there is a field trial included in the proposal. |

Organization Question 17 Comment

Response: The SDT has modified the proposed standard to better reflect the RSG responsibility in providing Frequency Response.

| LG\&E and KU Energy | We are concerned that, in attachment A, the generation/load split in determining FRO may not be the most equitable method <br> for allocation. In general, we feel that Attachment A needs additional clarity, i.e., is the split based on forecasted or prior <br> years' data.We are concerned with how the total frequency response obligation of an interconnection will be determined <br> since this will ultimately determine each BA's FRO. We believe more detail should be presented on this issue.Please make <br> sure enhanced frequency response from load is examined as an economical source of frequency response per FERC <br> requirements in Order 693 paragraphs 336 and 375. |
| :--- | :--- |
|  | The SDT has not addressed how the requirements of the proposed standard can be implemented without a market <br> mechanism.All frequency response available in an RTO/ISO ancillary services market should be offered in a non- <br> discriminatory way (possibly on an OASIS). |
|  | The standard needs more detail (not an attachment) on how the Interconnect FRO is allocated to BAs. We further suggest <br> the SDT consider providing detail in Attachment A that the Reliability Coordinator will need to be involved in allocation of the <br> FRO to specific regions or plants within the Reliability Coordinator Area. |
|  | There is a good chance that the proper geographic location of frequency responsive reserves will increase Transfer Path <br> capability when the Transfer Path capability is limited by a loss of generation. This may be the case in the west where loss of <br> two Palo Verde units establishes the California-Oregon Intertie SOL because frequency responsive reserves are carried in <br> the Pacific Northwest, not near Palo Verde. The BAL-OO3-1 standard does not consider this issue. |
|  | Please review the (pk gen+pk load)/2 method described in Attachment A, page 3. We appreciate the time and the work <br> performed by the standard drafting team on this standard that we feel is a necessary component for reliable operation of the <br> Interconnections. |

Response: The FRO is based on the forecasted values. The SDT had extensive discussions concerning the generation/load split for determining the BA FRO and believes that the proposed methodology is both reasonably equitable and non-discriminatory.
The SDT recognizes the need to convert Attachment A into two documents. The first document will remain part of the standard as Attachment A and provide greater detail for the calculation methodologies. The second document will explain the rationale for the requirements as supplemental standard information.
This standard provides metrics in which markets and independent solutions can be developed.
This standard provides a minimum requirement of a BA but does not prevent an RC from imposing further restrictions.
All of the methodologies proposed in this standard are being tested during the field trial.

SERC OC Standards Review
Group

The Standard Authorization Request Form references that BAL-003-0 originated as part of Project 2007-18, Reliability-based Control. Actually, it originated in Project 2007-05, Balancing Authority Control.
We are concerned that, in attachment A, the generation/load split in determining FRO may not be the most equitable method

|  | for allocation. In general, we feel that Attachment A needs additional clarity, i.e., is the split based on forecasted or prior <br> years' data. We are concerned with how the total frequency response obligation of an interconnection will be determined <br> since this will ultimately determine each BA's FRO. We believe more detail should be presented on this issue. <br> We appreciate the time and the work performed by the standard drafting team on this standard which we feel is a necessary <br> component for reliable operation of the Interconnections."The comments expressed herein represent a consensus of the <br> views of the above named members of the SERC OC Standards Review group only and should not be construed as the <br> position of SERC Reliability Corporation, its board or its officers." |
| Response: Revisions to BAL-003 were originally part of Project 2007-05, but Project 2007-05 was then merged on July 28, 2010 into Project 2007-18. <br> The SDT recognizes the need to convert Attachment A into two documents. The first document will remain part of the standard as Attachment A and provide <br> greater detail for the calculation methodologies. The second document will explain the rationale for the requirements as supplemental standard information. |  |
| The FRO is based on the forecasted values. |  |
| The methodologies proposed in this standard have been tested during the field trial. |  |

| Organization | Question 17 Comment |
| :---: | :---: |
| versions. |  |
| Bonneville Power Administration | o D1.4 R1 Supplemental Information (first paragraph) - Adds an additional requirement outside of the requirements section. <br> o D1.4 R2 Supplemental Information (first paragraph) - Adds an additional requirement outside of the requirement section. <br> o D1.4 R Supplemental Information (Second paragraph) - Adds an additional requirement outside of the requirements section. This number has nothing to do with frequency response during events. Also, has more to do with R1 than R2. |
| Response: The Additional Compliance Section has been completely revised and the issues you identified have been removed. |  |
| SPP Standards Development | The reporting requirement in Attachment A under R1 '...each BA has one month to assemble its data and calculate the FRM.' is not consistent with the reporting requirements in D. Compliance, 1.4 of the draft Standard. <br> R4 - We suggest replacing the word 'increase' with 'modify' or 'adjust'. <br> We also suggest deleting Balancing Authority Area and replacing it with combined areas at the end of the sentence. <br> Why is R4 in BAL-003-0 being retired? |
| Response: The SDT has correct <br> The SDT prefers to use the word suggesting could be interpreted to <br> BAL-003-01.b Requirement R4 is Frequency Bias Settings are calcu (\% of peak load/gen and FRO). T | the error in the wording. <br> crease" to provide clarity that the Frequency Bias Setting should go up when providing this service. Use of the terms you are low for adjustments up or down. <br> longer necessary. This Requirement addresses how to calculate Frequency Bias Settings. This is no longer needed since the ed in FRS Form 1 using Frequency Response associated with the "official" list of events and a couple of "floor or ceiling" limits entire calculation is built into the FRS Form 1 workbook. |
| IRC Standards Review Committee | The sections of "Additional Compliance Information" in the draft standard seem to create requirements as written. For example, revision of 1.4 for R1 Supplemental Information is suggested to be as follows: Each Balancing Authority or the Interconnection designated entity shall reports its previous year's Frequency Response Measure (FRM) to the ERO on Form 1 by January 10 each year. If the ERO posts the official list of events after December 10, Balancing Authorities or the Interconnection designated entity will be given 45 days from the date the ERO posts the official list of events to submit their FRS Form 1. <br> If aA Balancing Authority may elects to fulfill its Frequency Response Obligation by participating as a member of a Reserve Sharing Group (RSG). If a Balancing Authority elects to report as an RSG, the total of the participating Balancing Authorities' FRO will be compared to the total of the participating Balancing Authorities' FRM. <br> Further, revision of 1.4 for R2 Supplemental Information is suggested to be as follows: <br> Each Balancing Authority or the Interconnection designated entity shall reports its current year requested Frequency Bias |

However, this term is defined in the NERC Glossary of Terms. |  |
| ERCOT | The sections of "Additional Compliance Information" in the draft standard seem to create requirements as written. For example, revision of 1.4 for R1 Supplemental Information is suggested to be as follows: Each Balancing Authority or the Interconnection designated entity shall reports its previous year's Frequency Response Measure (FRM) to the ERO on Form |

Consideration of Comments: Project 2007-12 BAL-003-1 - $1^{\text {st }}$ Draft

1 by January 10 each year. If the ERO posts the official list of events after December 10, Balancing Authorities or the Interconnection designated entity will be given 45 days from the date the ERO posts the official list of events to submit their FRS Form 1. If aA Balancing Authority may elects to fulfill its Frequency Response Obligation by participating as a member of a Reserve Sharing Group (RSG). If a Balancing Authority elects to report as an RSG, the total of the participating Balancing Authorities' FRO will be compared to the total of the participating Balancing Authorities' FRM. Further, revision of 1.4 for R2 Supplemental Information is suggested to be as follows:Each Balancing Authority or the Interconnection designated entity shall reports its current year requested Frequency Bias Setting and Frequency Bias type (fixed or variable) to the ERO on FRS-Form 1 by January 10 each year. If the ERO posts the official list of events after December 10, Balancing Authorities will be given 45 days from the date the ERONERC posts the official list of events to submit their FRS Form 11. Once the FRM and Frequency Bias Settings have been validated by the ERO, the ERO will disseminate the Frequency Bias Settings Report for all Balancing Authorities in each Interconnection along with the implementation date.
Balancing Authorities with variable Frequency Bias Settings shall calculate monthly average Frequency Bias Settings. The previous year's monthly averages will be reported annually on FRS Form 1. Again, please clarify what qualifies as "variable" Frequency Bias Setting. Also please clarify how the "monthly average Frequency Bias Settings" are to be calculated. Is it a daily or weekly or hourly weighted average, or something else? In Attachment A: What is the "frequency deviation event threshold specified for the Interconnection"? Where is it specified? Please clarify.In Attachment A, 2.b.: Is this intended to be describing Point B? Please clarify.In Attachment A: While the ERO is deciding which events to use, does this mean that, throughout the year, the BA must collect and save all the relevant data for all events so as to have the data ready and available for when the ERO issues the list of events to be reported?In Attachment A, 4.: "Any indication or evidence of a secondary event occurrence after Point C should be reviewed for inclusion based on having sufficient information to perform a full analysis of the event". What meant by "should be reviewed"? Who is to be doing the review? What are the criteria for the review?In the Implementation Plan: "native load" is not defined in the ERCOT Interconnection. Please clarify.

Response: The Additional Compliance Section has been completely revised and the issues you identified have been removed.
The Requirement and Measure have been modified to include references to RSGs.
Variable frequency bias settings are determined by Balancing Authorities using a calculation based on present operating conditions.
The SDT recognizes the need to convert Attachment A into two documents in order to provide further clarity. The first document will remain part of the standard as Attachment A and provide greater detail for the calculation methodologies. The second document will explain the rationale for the requirements as supplemental standard information.
The current Reliability Standard BAL-005 cites the data required to be archived.
As envisioned, the ERO will post the events to be analyzed on a quarterly basis to allow a BA to review its performance throughout the year.
The Implementation Plan no longer references "Native Load". However, this term is defined in the NERC Glossary of Terms.
Progress Energy
We believe this standard insufficiently addresses the true nature of the problem; however it does accuratly address the fact

| Organization | $\quad$ Question 17 Comment |
| :--- | :--- |
|  | that the current BA minimum frequency bias setting is too large. <br> This standard should also exclude LSE's without generation capacity since this problem both exists and can be solved at the <br> generator level. |
| Response: The SDT agrees that the generator level can solve the issues. This standard is addressing directives from FERC Order 693. Any reference to a <br> generator requirement would be outside of the industry approved SAR. |  |
| The LSE is not cited as an applicable entity. |  |$|$| NIPSCO | We reviewed the number of BAs in the Eastern Interconnection and there are many. We're hoping that compliance to R1 <br> would be covered by the RSGs similar to DCS. |
| :--- | :--- |
| Response: The SDT added the RSG as a applicable entity to allow a BA an alternative method for complying with this standard. |  |

| Organization | Question 17 Comment |
| :---: | :---: |
|  | with respect to reliability and economics. <br> Comment 56: A series of four technical papers were written and offered to the Frequency Response Standard Drafting Team that describe a measurement method for Frequency Response that does not have the detrimental limitations that exist with the Peak Load / Peak Generation Ratio share method suggested in Attachment A. These four paper are:1. Illian, H. F., Frequency Response Risk Measure, Prepared for the Frequency Response Standard Drafting Team, Energy Mark, July 1, 2010 revised September 7, 2010.2. Illian, H. F., Understanding ACE and CPS1, Prepared for the Frequency Response Standard Drafting Team, Energy Mark, September 8, 2010.3. Illian, H. F., Frequency Response Reliability Measure for the Balancing Authority, Prepared for the Frequency Response Standard Drafting Team, Energy Mark, October 11, 2010.4. Illian, H. F., Description of Regressions for Frequency Response Analysis, Prepared for the Frequency Response Standard Drafting Team, Energy Mark, September 21, 2010.PDFs of these papers have been forwarded to supplement these comments and should be addended as part of my comments. |

Response: Comment 54 - The SDT understands your concerns and has taken them under consideration during the development of this standard. The SDT will provide technical justification for the methods it proposes within the standard.
Comment 55 - The SDT thanks you for your work in creating the aforementioned papers. The SDT has reviewed these papers and considered them during the development of this standard. Furthermore, the SDT will forward them on to the appropriate NERC personnel.

Hydro-Quebec TransEnergie
The proposed NERC standard (BAL-003) does not take into account the "point $C$ " issue. The proposed requirements are only related to "point B". The proposed NERC standard (BAL-003) validates that the Balancing Authority carries enough Synchronized Reserve and that this reserve is really Frequency Responsive, on average in the most common situations (based on the median). It is an "after-the-fact" evaluation of the performance of the Balancing Authority. However, there is no guaranty that the Balancing Authority will maintain the required Synchronized Reserve either when the load is very low or during peak load periods Real-time Monitoring of the frequency responsive reserve would be a good way to avoid this issue.

Response: The SDT is proposing a more conservative Point B result in order to protect for Point C UFLS.
We encourage real-time monitoring of Frequency Response as a good practice but mandating it is beyond industry approved SAR. Also, the SDT believes that this is being addressed in the development of the Balancing Authority Reliability-based Control standards in Project 2010-14.

## Westar Energy

Based on a Category C (N-2) event, what is the approximate Interconnection Frequency Response Obligation for each Interconnection? What is the First Step UFLS for each Interconnection?
Since there is no NERC Standard requirement for what first step UFLS is, what if it changes during the year?
Response: The SDT recognized the need to convert Attachment A into two documents. The first document will remain part of the standard as Attachment A and provide greater detail for the calculation methodologies, including FRO. The second document will explain the rationale for the requirements as supplemental standard information. Table 2 in revised Attachment A shows the FRO for each interconnection and the methodology used to determine this value. The UFLS set point used in the calculation is shown in Table 2 for each Interconnection. These values are intended to protect against frequency reaching the highest UFLS

Question 17 Comment
Organization Question 17 Comment
setting for credible contingencies.
The utilities have the ability to change the UFLS settings during the year. The entities FRO and Frequency Bias Setting would remain the same until it was reviewed by the ERO. Your comment does emphasize the need for the ERO to coordinate these changes across standards but this is outside the scope of this project..

| EKPC | EKPC would like to express the importance of considering large non-conforming loads and their effects on smaller BAs.We <br> appreciate the drafting team's effort and dedication to this standard. |
| :--- | :--- |
| Response: The SDT has modified FRS form 1 to allow for adjustments, including non-conforming load. |  |
| We Energies | The FRO and the standard in general focus on Frequency Response for an intact grid. Inadequate consideration is given to <br> unexpected events such as separation, islanding and partial or total BES failure. In these cases, the location of the FR <br> resources is important. For example, if a BA has a contract with an entity that controls load level to satisfy the required FRO, <br> that load may not be within the island created following a disruption to the BES. A complete BES failure may leave a black <br> start island with only load frequency response. Load frequency response is the ultimate dispersed source for this commodity, <br> but may be inadequate as the sole provider under abnormal grid conditions. For better grid security, other dispersed sources <br> of frequency response are desirable. <br> Comment on the NERC Resources Subcommittee Position Paper on Frequency Response (Discussion Draft):EOP-005-2 <br> does not contain requirements for the Balancing Authority in a restoration event involving the use of black start resources. <br> Only Transmission Operators, Generator Operators, Transmission Owners identified in the Transmission Operators <br> restoration plan, and Distribution Providers identified in the Transmission Operators restoration plan have roles in that <br> standard. How will the BA "bring more Frequency Responsive resources to bear" during black start if they have no defined <br> role? |

Response: This standard is not meant to be an emergency operations standard. However, this standard could assist an entity in identifying and solving the problem you have mentioned.

The NERC RS Position Paper on Frequency Response is not a product of this standard. It is an information paper requested by the NERC OC. The RS posted the document and received industry comments that were incorporated.

| American Electric Power | If a balancing authority loses generation, what happen to the neighboring balancing authority's AGC? <br> If an overall Reserve Sharing Group's performance can possibly be used to meet performance measures, why is the RSG <br> not included in the Standard applicability for such functional entity? |
| :--- | :--- |

Response: If the Frequency Bias Setting is close to natural Frequency Response, as this standard is proposing, the AGC impacts would be minimal or none. The RSG is listed in the Applicability Section of this standard. The SDT has further modified Requirement R1 to identify the RSG within the requirement.

| Organization | Question 17 Comment |
| :--- | :--- |
| Duke Energy | Below are just some of the points that Duke Energy believes need to be discussed further. <br> Relationship to other standards under development: Given the significant implications of this standard to the other balancing- <br> related standards, Duke Energy feels strongly that the Standards Committee should keep the work under Project 2010-14, <br> Balancing Authority Reliability-besed Control, high on the list of standards to be developed. CPS1 and the proposed BAAL <br> are measures that make sense in the long term, as they provide "support to maintain Interconnection Frequency within <br> predefined bounds" and aid in "supporting frequency until the frequency is restored to schedule" as desired in the purpose <br> statement of this standard. <br>  <br>  <br> Reserve Sharing Group: Duke Energy understands and supports the concept that Frequency Response could be aggregated <br> over a Reserve Sharing Group, however the details need to be addressed in the measures, and in the requirements, which in <br> the current draft only apply to the Balancing Authority. |
|  | Field test: Duke Energy found the implementation plan and field test confusing. The information didn't indicate when the field <br> test would start and end. The implementation plan proposes starting the gradual adjustment of BAL-003-0 R5 in May |
|  | what if the standard hasn't been approved by FERC by then? Shouldn't those dates be tied somehow to the effective date of |
| BAL-003-1 which is in turn tied to regulatory approval where required? Or is that gradual decrease actually part of the field |  |
| test? |  |

Organization

## Question 17 Comment

Under the proposed definition, the FRM calculation would only consider provision of response from resources external to the BA Area if the "interchange" came in the form of a Pseudo-tie adjustment to Actual Interchange - Dynamic Schedules would not be accounted for. As the use of Pseudo-ties changes load calculations and other data, even the use of them may not make sense compared perhaps to just having a mechanism to move the obligation to the area providing the response, and then determining if the provision of just Frequency Response must absolutely carry into increased secondary control requirements.

Separating primary response from secondary control:
Is it possible for resources in one BA to provide a measure of Frequency Response for another BA, but not result in a change to each BA's Frequency Bias Setting used in the secondary control requirements?

Response: The development of the Balancing Authority Reliability-based Control standards in Project 2010-14 are outside the scope of this SDT, however the need to coordinate development was raised with the Standards Committee and the standards in Project 2010-14 that address "reserves" have been advanced as high priority.
The SDT has modified Requirement R1 and the associated measure to identify the RSG.
In reference to your field trial comment the SDT has modified the Implementation Plan to no longer reference the field test or the reduction of the minimum Frequency Bias Setting. The SDT has developed a process by which the ERO will reduce the minimum Frequency Bias Setting. The procedure used to reduce the Frequency Bias Setting is detailed in Attachment B and is now tied to regulatory approval of this standard.

This standard will provide the metrics for Frequency Response while the market will define itself. The SDT encourages you to work with NAESB to define a market.
The SDT encourages you to open a discussion with the Interchange Subcommittee concerning Frequency Response as a market resource.
The SDT has included language that defines how the RSG is to perform and comply with this standard. The SDT agrees that a Reserve Sharing Group providing a "group frequency response" would not be interchange between the entities within that group. The SDT also agrees that the RSG would be evaluated as if it were a single $B A$.
The SDT has incorporated an improved FRS Form 1 with instructions for its use. The SDT thanks you for your comment concerning Pseudo-tie but, based on the information provided, the SDT is unsure of your question and cannot provide a further response.
With regards to your last comment, the SDT believes that it is possible as long as they are using a dynamic schedule.
Patterson Consulting, Inc.
Requirement 4 is worded incorrectly, although it is taken from the existing standard. Requirement 4 states "Each Balancing Authority that is performing Overlap Regulation Service shall [increase] its Frequency Bias Setting in its ACE calculation by combining the Frequency Bias Settings for the entire Baalancing Authority Area being controlled." (Bracketing added for emphasis.) Considering Frequency Bias Settings are negative numbers, this requirement should have Balancing Authorities "decrease" rather than "increase" their Frequency Bias Settings. For example, the requirement could state "Each Balancing Authority that is performing Overlap Regulation Service shall decrease..." or if "decrease" is undesirable then "Each Balancing Authority that is performing Overlap Regulation Service shall modify..."

Response: The SDT understands your concern with the use of the term "increase" and has replaced this word with "modify". The SDT revised Requirement R4 for additional clarity and it now reads:

Each Balancing Authority that is performing Overlap Regulation Service shall modify its Frequency Bias Setting in its ACE calculation to be equivalent to the sum of the Frequency Bias Settings of the participating Balancing Authorities as validated by the ERO or calculate the Frequency Bias Setting based on the entire area being combined and thereby represent the Frequency Response for the combined area being controlled.

## Associated Electric Cooperative,

 Inc.
## BAL-003-1 draft standard:

Apparent Intent and expectations:

1) I agree with this emerging standard's recognizing that the arbitrary 1\% of peak-load should be refined by being lowered to better reflect each BA's expected frequency response.
2) This emerging standard apparently attempts to address the divesture of generation from loads by utilizing the "(Load + Generation)/2" formula, which seems fair.
3) I'm still struggling with the concept of being able to share in the success of an RSG, but not its failures if your BA was individually successful. Something seems wrong with that approach. However if necessary, AECI will definitely use it to its advantage.
4) I really would have liked to see the Measures that are currently in draft.

Comment on Definitions:

1) SEFRD - I had to read this definition several times because "The individual sample of event data" is actually an internally calculated value derived from a set of event sample data, and not really a "sample" value at all. So, I believe the SEFRD definition needs further work.
2) FRM is defined by undefined terms "FRS" and "FRS Form 1".
3) FRO - fine
4) FRS - "Frequency Response Survey"

Requirements and Requirements Supplement Information1) R1 and R1 Supplemental Information, pp 2, 4
a) I believe these two sections should be combined into one requirement, specifying the basic BA requirement "or, if the BA was within an RSG and elects to report from within that RSG's performance," that RSG's performance requirement.
b) The time-frame for reporting should be another requirement, and with a companion Measurement. (Concerning the timing, the original response timeframe is 31 days, but the if NERC slips past the "normal" December 10 deadline, the

Organization

## Question 17 Comment

response time requirement is increased by $50 \%$, to 45 days? Did somebody make a mistake, or was this intentional?)
c) The problem with this requirement is that it relies on each BA to "read" its own frequency-performance, and does not provide a clear system of comparison between BAs for the same frequency event. In other words, the drafting team is trying to impose a nice bright-line objective standard, that is really resting on what is currently a very subjective calculation of SEFRD. . (See item 3, Rx-below)
2) R2 and R2 Supplemental Information pp $2 . .4$
a) See comment 1.b above, concerning reporting time-frame being another requirement
b) I believe every BA should report its monthly average frequency-bias setting, whether fixed-bias or variable-bias. In the case of reporting fixed-bias, the first two months will likely be different from the remaining ten months within the same calendar year.
3) $R x$ - I believe there is a hidden requirement, that the ERO monitor each interconnection's frequency for candidate events, then annually select and provide the top events for FRS Form 1 reporting. That same requirement should dictate that the ERO provide the corresponding $A, B$, and $C$ times for each FRS Form 1 reportable event, when the survey goes out. I believe this requirement should be spelled-out, in order to improve reporting consistency and make the FRS reporting process a bit more objective.

## Response: "Apparent Intent"

Comments 1) \& 2) - The SDT thanks you for your comment.
Comment 3) The SDT added the RSG as a applicable entity to allow a BA an alternative method for complying with this standard. The SDT has included language that defines how the RSG is to perform and comply with this standard.
Comment 4) The SDT purposely left the measures out of the first draft. This was to ensure the focus would be on the requirements themselves. The SDT also recognized that the requirements would probably need revision after receiving industry feedback.
Definitions:
Comment 1) The SDT agrees with your concern regarding the definition of SEFRD. The SDT has removed the definition from the standard.
Comment 2) The term FRS Form 1 is only identifying a form to be used when providing information to the ERO.
Comment 3) The SDT thanks you for your agreement with the definition.
Comment 4) Again, the term FRS is simply pointing to a particular for to be used when providing the information to the ERO.
Requirements:
Comment 1 a) The SDT has revised Requirement R1 to reference an RSG. The Requirement now reads "Each Balancing Authority (BA) or Reserve Sharing Group (RSG) shall achieve an annual Frequency Response Measure (FRM) (as detailed in Attachment A and calculated on FRS Form 1) that is equal to or more negative than its Frequency Response Obligation (FRO) to ensure that sufficient Frequency Response is provided by each BA or RSG to maintain an adequate level of
Organization Question 17 Comment

Frequency Response in the Interconnection."
Comment 1 b) The Additional Compliance Section has been completely revised and the issues you identified have been removed.
Comment 1 c) The revised standard changes the methodology from subjective to directed.
Comment 2 a) The Additional Compliance Section has been completely revised and the issues you identified have been removed. The SDT has corrected the timing issue you have referenced.
Comment 2 b) The SDT disagrees and believes that "fixed" should be reported on a annual basis while "variable" should be reported monthly due to the nature of the calculation.

Comment 3) The SDT believes that Point C is not needed for the methodology being recommended. The revised FRS Form 1 and the new Form 2 provide clarification concerning Point $A$ and Point $B$.

Alberta Electric System Operator
Is there any relation or coordination between the work of this standard and the effort on "NERC RS Position Paper on Frequency Response" ? The AESO believes these two projects should be coordinated. The AESO has also signed on to comments submitted by the SRC. We see the SRC comments as continent wide and these AESO comments as more Alberta specific.

Response: The NERC RS Position Paper on Frequency Response is not a product of this standard. It is an information paper requested by the NERC OC. The RS posted the document and received industry comments that were incorporated. In addition, some of the Frequency Response SDT membership are also members of the NERC RS.

Please refer to our comments to SRC.

| Kansas City Power \& Light |  | No other comments. |

## Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

## Development Steps Completed:

1. The Standards Committee approved the SAR for posting on January 13, 2005.
2. The SAR was posted for industry comment from January 17, 2005 through February 17, 2005.
3. Reply comments and a revised SAR were posted for a second industry comment period from April 4, 2006 through May 3, 2006.
4. Reply comments and a revised SAR were posted for a third industry comment period from February 8, 2007 through March 9, 2007.
5. Standards Committee approved moving the project into the standards development phase on July 12, 2007.
6. The Standards Committee appointed the Standard Drafting Team on August 13, 2007.
7. The draft standard was posted for a 30 day formal comment period from February 4, 2011 through March 7, 2011.

## Proposed Action Plan and Description of Current Draft:

This is the second posting of the proposed standard and its associated documents for a 45 day formal comment period and a successive 10 day ballot, from October 24, 2011through December 7, 2011.
Future Development Plan:

| Anticipated Actions | Anticipated Date |
| :---: | :---: |
| 1. Respond to comments submitted within the comment period <br> and with the successive ballot. | December, 2011 |
| 2. Conduct a recirculation ballot for ten days. | January, 2012 |
| 3. BOT adoption. | March, 2012 |

## Definitions of Terms used in the Standard

## Frequency Response Measure (FRM)

The median of all the Frequency Response observations reported annually on FRS Form 1.

## Frequency Response Obligation (FRO)

The Balancing Authority's share of the required Frequency Response needed for the reliable operation of an Interconnection.

## Frequency Bias Setting

A number, either fixed or variable, usually expressed in MW/0.1 Hz, included in a Balancing Authority's Area Control Error equation to account for the Balancing Authority's Frequency Response contribution to the Interconnection, and discourage response withdrawal through secondary control systems.

## A. Introduction

## Title: Frequency Response and Frequency Bias Setting

Number: BAL-003-1
Purpose: To require sufficient Frequency Response from the Balancing Authority to maintain Interconnection Frequency within predefined bounds by arresting frequency deviations and supporting frequency until the frequency is restored. To provide consistent methods for measuring Frequency Response and determining the Frequency Bias Setting.

Applicability:
1.1. Balancing Authority
1.2. Reserve Sharing Group (where applicable)

## Effective Date:

1.3. In those jurisdictions where regulatory approval is required, Requirements R2, R3 R4 and R5 of this standard shall become effective the first calendar day of the first calendar quarter 12 months after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, Requirements R2, R3, R4 and R5 of this standard shall become effective the first calendar day of the first calendar quarter 12 months after Board of Trustees adoption.
1.4. In those jurisdictions where regulatory approval is required, Requirements R1 of this standard shall become effective the first calendar day of the first calendar quarter 24 months after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, Requirements R1 of this standard shall become effective the first calendar day of the first calendar quarter 24 months after Board of Trustees adoption.

## B. Requirements

R1. Each Balancing Authority (BA) or Reserve Sharing Group (RSG) shall achieve an annual Frequency Response Measure (FRM) (as detailed in Attachment A and calculated on FRS Form 1) that is equal to or more negative than its Frequency Response Obligation (FRO) to ensure that sufficient Frequency Response is provided by each BA or RSG to maintain an adequate level of Frequency Response in the Interconnection. [Risk Factor: Medium ][Time Horizon: Operations Assessment]

R2. Each Balancing Authority not participating in Overlap Regulation Service shall implement the Frequency Bias Setting (fixed or variable) validated by the ERO, into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effectively coordinated Tie Line Bias control. [Risk Factor: Medium ][Time Horizon: Operations Planning]

R3. Each Balancing Authority not receiving Overlap Regulation Service shall operate its Automatic Generation Control (AGC) in Tie Line Bias mode to ensure effectively
coordinated control, unless such operation would have an Adverse Reliability Impact on the Balancing Authority’s Area. [Risk Factor: Medium ][Time Horizon: Real-time Operations]
R4. Each Balancing Authority that is performing Overlap Regulation Service shall modify its Frequency Bias Setting in its ACE calculation to be equivalent to the sum of the Frequency Bias Settings of the participating Balancing Authorities as validated by the ERO or calculate the Frequency Bias Setting based on the entire area being combined and thereby represent the Frequency Response for the combined area being controlled. [Risk Factor: Medium ][Time Horizon: Operations Planning]

R5. In order to ensure adequate control response, each Balancing Authority shall use a monthly average Frequency Bias Setting whose absolute value is at least equal to one of the following: [Risk Factor: Medium ][Time Horizon: Operations Planning]

- The minimum percentage of the Balancing Authority Area's estimated yearly Peak Demand within its metered boundary per 0.1 Hz change as specified by the ERO in accordance with Attachment B.
- The minimum percentage of the Balancing Authority Area’s estimated yearly peak generation for a generation-only Balancing Authority, per 0.1 Hz change as specified by the ERO in accordance with Attachment B.

## C. Measures

M1. The Balancing Authority or Reserve Sharing Group shall have FRS Form 1 with data to show that its FRM is equal to or more negative than FRO to demonstrate compliance with Requirement R1.

M2. The Balancing Authority shall have evidence such as a dated document in hard copy or electronic format showing the ERO validated Frequency Bias Setting was entered into its ACE calculation on the date specified or other evidence to demonstrate compliance with Requirement R2.
M3. The Balancing Authority shall have evidence such as a dated operating log, database or list in hard copy or electronic format or operator interviews supported by other evidence showing the AGC operating mode including explanation when operating in other than Tie Line Bias mode to demonstrate compliance with Requirement R3.

M4. The Balancing Authority shall have evidence such as a dated operating log, database or list in hard copy or electronic format showing when Overlap Regulation Service is provided including Frequency Bias Setting calculation to demonstrate compliance with Requirement R4.

M5. The Balancing Authority shall have evidence such as dated data plus documented formula to support the calculation retained in either hardcopy or electronic format showing the monthly average Frequency Bias Setting or other evidence to demonstrate compliance with Requirement R5.

## D. Compliance

## 1. Compliance Monitoring Process

### 1.1. Compliance Enforcement Authority

The Regional Entity is the Compliance Enforcement Authority except where the responsible entity works for the Regional Entity. Where the responsible entity works for the Regional Entity, the Regional Entity will establish an agreement with the ERO or another entity approved by the ERO and FERC (i.e. another Regional Entity), to be responsible for compliance enforcement.

### 1.2. Compliance Monitoring and Assessment Processes:

Compliance Audits
Self-Certifications
Spot Checking
Compliance Violation Investigations
Self-Reporting
Complaints
Periodic Data Submittals

### 1.3. Data Retention

The Balancing Authority shall retain data or evidence to show compliance with Requirements R1, R2, R3, R4 and R5, Measures M1, M2, M3, M4, and M5 for the current year plus three calendar years unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

The Reserve Sharing Group shall retain data or evidence to show compliance with Requirement R1 and Measure M1 for the current year plus three calendar years unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

If a Balancing Authority or Reserve Sharing Group is found non-compliant, it shall keep information related to the non-compliance until found compliant or for the time period specified above, whichever is longer.
The Compliance Enforcement Authority shall keep the last audit records and all subsequent requested and submitted records.

### 1.4. Additional Compliance Information

For Interconnections that are also Balancing Authorities, Tie Line Bias control and Flat Frequency control are equivalent and either is acceptable.

### 2.0 Violation Severity Levels

| R\# | Lower VSL | Medium VSL | High VSL | Severe VSL |
| :---: | :---: | :---: | :---: | :---: |

## Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

## Development Steps Completed:

1. The Standards Committee approved the SAR for posting on January 13, 2005.
2. The SAR was posted for industry comment from January 17, 2005 through February 17, 2005.
3. Reply comments and a revised SAR were posted for a second industry comment period from April 4, 2006 through May 3, 2006.
4. Reply comments and a revised SAR were posted for a third industry comment period from February 8, 2007 through March 9, 2007.
5. Standards Committee approved moving the project into the standards development phase on July 12, 2007.
6. The Standards Committee appointed the Standard Drafting Team on August 13, 2007.
7. The draft standard was posted for a 30 day formal comment period from February 4, 2011 through March 7, 2011.

## Proposed Action Plan and Description of Current Draft:

This is the second posting of the proposed standard and its associated documents for a 45 day formal comment period and a successive 10 day ballot, from October 2124, 2011through December 57, 2011.

## Future Development Plan:

| Anticipated Actions | Anticipated Date |
| :---: | :---: |
| 1. Respond to comments submitted within the comment period <br> and with the successive ballot. | December, 2011 |
| 2. Conduct a recirculation ballot for ten days. | January, 2012 |
| 3. BOT adoption. | March, 2012 |

# Definitions of Terms used in the Standard 

## Single Event Frequency Response Data (SEFRD)

The individual sample of event data from a Balancing Authority which represents the thange in Net Actual Interchange ( $\left(\mathrm{NH}_{\mathrm{A}}\right)$, divided by the change in frequency, expressed in MW/0.1Hz.

## Frequency Response Measure (FRM)

The median of all the Frequency Response Single Event Frequency Response Data observations reported annually on FRS Form 1.

## Frequency Response Obligation (FRO)

The Balancing Authority's share of the required Frequency Response contribution to the total aggregate Frequency Response needed for the reliable operation of an Interconnection-assigned by the ERO.

## Frequency Bias Setting

A numbervalue, (either a-fixed or variable-Frequency Bias), usually expressed in MW/0.1 Hz , included inset into a Balancing Authority's Area Control Error equation to account forthat allows the Balancing Authority's Frequency Response contribution to contribute its Frequency Response to the Interconnection, and discourage response withdrawal through secondary control systems.

## A. Introduction

## Title: Frequency Response and Frequency Bias Setting

Number: BAL-003-1
Purpose: To require sufficient Frequency Response from the Balancing Authority to maintain Interconnection Frequency within predefined bounds by arresting frequency deviations and supporting frequency until the frequency is restored. To schedule and provide consistent methods for measuring Frequency Response and determining the Frequency Bias Setting.

Applicability:
1.1. Balancing Authority
1.2. Reserve Sharing Group (where applicable)

## Effective Date:

1.3. In those jurisdictions where regulatory approval is required, Requirements R2, R3 and R4 and R5 of this standard shall become effective the first calendar day of the first calendar quarter 12 months after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, Requirements R2, and R3, R4 and R5 of this standard shall become effective the first calendar day of the first calendar quarter 12 months after Board of Trustees adoption.
1.4. In those jurisdictions where regulatory approval is required, Requirements R1_of this standard shall become effective the first calendar day of the first calendar quarter 24 months after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, Requirements R1 of this standard shall become effective the first calendar day of the first calendar quarter 24 months after Board of Trustees adoption.

## B. Requirements

R1. Each Balancing Authority (BA) or Reserve Sharing Group (RSG) shall achieve an annual Frequency Response Measure (FRM) (as detailed in Attachment A and calculated on FRS Form 1) that is equal to or more negative than its Frequency Response Obligation (FRO) to ensure that sufficient Frequency Response is provided by each BA or RSG to maintain an adequate level of Frequency Response in the Interconnection. [Risk Factor: Medium ][Time Horizon: Operations Assessment]

R1.R2. Each Balancing Authority not participating in Overlap Regulation
Service shall implement the Frequency Bias Setting (fixed or variable) validatedprovided by the $\mathrm{ERO}_{2}$ into its Area Control Error (ACE) calculation beginning on the date specified by the ERO to ensure effectively coordinated Tie Line Biassecondary control, using the results from the caleulation methodology detailed in Attachment A. [Risk Factor: Medium ][Time Horizon: Operations Planning]

R2.R3. Each Balancing Authority not receiving Overlap Regulation Service shall operate its Automatic Generation Control (AGC) inem Tie Line Bias mode to ensure effectively coordinated control, unless such operation would have an Adverse Reliability Impact on the Balancing Authority's Area. [Risk Factor: Medium ][Time Horizon: Real-time Operations]

R4. Each Balancing Authority that is performing Overlap Regulation Service shall modifyinerease its Frequency Bias Setting in its ACE calculation to be equivalent to the sum of by combining the Frequency Bias Settings of the participating Balancing Authorities as validated by the ERO or calculate the Frequency Bias Setting based on the entire area being combined and thereby represent the Frequency Response for the combinedentire area being controlled. [Risk Factor: Medium ][Time Horizon: Operations Planningl

R5. In order to ensure adequate control response, each Balancing Authority shall use a monthly average Frequency Bias Setting whose absolute value is at least equal to one of the following: [Risk Factor: Medium ][Time Horizon: Operations Planning]

- $\quad$ The minimum percentage of the Balancing Authority Area's estimated yearly Peak Demand within its metered boundary per 0.1 Hz change as specified by the ERO in accordance with Attachment B.
- $\quad$ The minimum percentage of the Balancing Authority Area's estimated yearly peak generation for a generation-only Balancing Authority, per 0.1 Hz change as specified by the ERO in accordance with Attachment B.

## C. Measures

Meastres for each Requirement will be provided in the second posting of the proposed standard.

M1. The Balancing Authority or Reserve Sharing Group shall have FRS Form 1 with data to show that its FRM is equal to or more negative than FRO to demonstrate compliance with Requirement R1.

M2. The Balancing Authority shall have evidence such as a dated document in hard copy or electronic format showing the ERO validated Frequency Bias Setting was entered into its ACE calculation on the date specified or other evidence to demonstrate compliance with Requirement R2.

M3. The Balancing Authority shall have evidence such as a dated operating log, database or list in hard copy or electronic format or operator interviews supported by other evidence showing the AGC operating mode including explanation when operating in other than Tie Line Bias mode to demonstrate compliance with Requirement R3.

M4. The Balancing Authority shall have evidence such as a dated operating log, database or list in hard copy or electronic format showing when Overlap Regulation Service is provided including Frequency Bias Setting calculation to demonstrate compliance with Requirement R4.

M1.M5. The Balancing Authority shall have evidence such as dated data plus documented formula to support the calculation retained in either hardcopy or electronic format showing the monthly average Frequency Bias Setting or other evidence to demonstrate compliance with Requirement R5.
D. Compliance

## 1. Compliance Monitoring Process

### 1.1. Compliance Enforcement Authority

The Regional Entity is the Compliance Enforcement Authority except where the responsible entity works for the Regional Entity. Where the responsible entity works for the Regional Entity, the Regional Entity will establish an agreement with the ERO or another entity approved by the ERO and FERC (i.e. another Regional Entity), to be responsible for compliance enforcement.Regional Entity shall serve as the Compliance Enforcement Authority.

### 1.2. Compliance Monitoring and Assessment Processes:

Compliance Audits
Self-Certifications
Spot Checking
Compliance Violation Investigations
Self-Reporting
Complaints
Periodic Data Submittals

### 1.3. Data Retention

The Balancing Authority shall retain data or evidence to show compliance with Requirements R1, R2, R3, R4 and R5, Measures M1, M2, M3, M4, and M5 for the current year plus three calendar years unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

The Reserve Sharing Group shall retain data or evidence to show compliance with Requirement R1 and Measure M1 for the current year plus three calendar years unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

If a Balancing Authority or Reserve Sharing Group is found non-compliant, it shall keep information related to the non-compliance until found compliant or for the time period specified above, whichever is longer.
The Compliance Enforcement Authority shall keep the last audit records and all subsequent requested and submitted records.

### 1.4. Additional Compliance Information

## R1 Supplemental Information

Each Balancing Authority shall report its previous year's Frequency Response Measure (FRM) to the ERO on Form 1 by January 10 each year. If the ERO posts the official list of events after December 10, Balancing Authorities will be given 45 days from the date the ERO posts the official list of events to submit their FRS Form 1.

A Balancing Authority may elect to fulfill its Frequency Response Obligation by participating as a member of a Reserve Sharing Group (RSG). If a Balancing Authority elects to report as an RSG, the total of the participating Balancing Authorities' FRO will be compared to the total of the participating Balaneing Authorities' FRM.

## R2 Supplemental Information.

Each Balancing Authority shall report its current year requested Frequency Bias Setting and Frequency Bias type (fixed or variable) to the ERO on FRS-Form 1 by Janmary 10 each year. If the ERO posts the official list of events after December 10, Balancing Authorities will be given 45 days from the date NERG pests the official list of events to submit their FRS Form 1. Once the FRM and Frequency Bias Settings have been validated by the ERO, the ERO will disseminate the Frequeney Bias Settings Report for all Balaneing Authorities in each Interconnection along with the implementation date.

Balancing Authorities with variable Frequency Bias Settings shall calculate monthly average Frequency Bias Settings. The previous year's monthly averages will be reported annually on FRS Form 1. For Interconnections that are also Balancing Authorities, Tie Line Bias control and Flat Frequency control are equivalent and either is acceptable.

## Attachment A

# BAL-003-1 Frequency Response \& Frequency Bias Setting Standard 

## Supporting Document

## Background

This document outlines the ERO process for supporting the Frequency Response Standard (FRS).

## Event Selection Criteria

The ERO will use the following criteria to select FRS frequency excursion events for analysis.

1. The evaluation period for performing the annual Frequency Bias Setting and the Frequency Response Measure (FRM) calculation is December 1 of the prior year through November 30 of the current year.
2. The ERO will identify at least 25 frequency excursion events in each Interconnection for calculating the Frequency Bias Setting and the FRM. If the ERO cannot identify in a given evaluation period 25 frequency excursion events satisfying the limits specified in criteria 3 below, then similar acceptable events from the previous evaluation period also satisfying listed criteria will be included with the data set by the ERO for determining FRS compliance.
3. The ERO will use two limits to determine if an acceptable frequency excursion event for determining FRM has occurred:
a. The change in frequency (delta F) and the arresting frequency (Point $C$ ) must exceed the excursion threshold values specified for the Interconnection in Table 1 below. Point $C$ is the arrested value of frequency observed within 8 seconds following the start of the excursion.

|  | Point C |  |  |
| :---: | :---: | :---: | :---: |
| Interconnection | Delta F | Under Frequency | Over Frequency |
| East | 0.04 Hz | $<59.97$ | $>60.03$ |
| West | 0.05 Hz | $<59.97$ | $>60.03$ |
| Texas | 0.15 Hz | $<59.90$ | $>60.10$ |
| HQ | 0.20 Hz | $<59.85$ | $>60.15$ |

Table 1: Interconnection Frequency Excursion Threshold Values
b. The time from the start of the rapid change in frequency until the point at which Frequency has stabilized within a narrow range should be less than 18 seconds.
4. Pre-disturbance frequency should be relatively steady and near 60.000 Hz . The A Value is computed as an average over the period from -16 seconds to 0 seconds before the frequency transient begins to decline.
5. Events that coincide with a second event that does not stabilize before the first scan used in the $B-V a l u e$ will not be considered.
6. Frequency excursion events occurring during periods when large interchange schedule ramping or load change is happening, and frequency excursion events occurring within 5 minutes of the top of the hour, should be excluded from consideration if other acceptable frequency excursion events can be used for analysis.
7. Select the cleanest 2 or 3 frequency excursion events occurring monthly that satisfy selection criteria. If there are not 2 frequency excursion events satisfying selection criteria occurring during the month, then other frequency excursion events from the same season of the year satisfying selection criteria should be considered for use if necessary.

To assist Balancing Authority preparation for complying with this standard, the ERO will provide quarterly posting of candidate frequency excursion events for the current year FRM calculation. The ERO will post the final list of frequency excursion events used for standard compliance by December 15 each year. Balancing Authorities are encouraged to develop scanning tools that identify candidate frequency excursion events so they are ready to access data files when needed.

NOTE: The ERO may use for analysis of Interconnection frequency performance, but not for Balancing Authority Frequency Response, additional frequency excursion events not satisfying the criteria specified.

## Frequency Response Obligation (FRO) for the Interconnection

Each Interconnection will establish target contingency protection criteria. The default target listed in Table 2 is based on the largest category C(N-2) event identified. However, this contingency protection criterion includes a safety margin to prevent Point C from encroaching on the interconnection's highest Under Frequency Load Shed (UFLS) step for credible contingencies.

|  | Eastern | Western | Texas | HQ |  |
| :--- | :---: | :---: | :---: | :---: | :--- |
| Starting Frequency | 60 | 60 | 60 | 60 | Hz |
| *Highest UFLS | 59.6 | 59.5 | 59.3 | 58.5 | Hz |
| Contingency Protection Criteria | 4500 | 2740 | 2750 | 1700 | MW |
| **Base Obligation | 1125 | 548 | 229 | 113 | $\mathrm{MW} / 0.1 \mathrm{~Hz}$ |
| With 25\% Safety Margin | 1406 | 685 | 286 | 141 | $\mathrm{MW} / 0.1 \mathrm{~Hz}$ |

Table 2: Interconnection Frequency Response Obligations
*The Eastern Interconnection set point listed is a compromise value for the highest UFLS step setting of 59.5 Hz used in the east and the special protection scheme's highest UFLS step setting of 59.7 Hz used in Florida. It is extremely unlikely that an event elsewhere in the Eastern Interconnection would cause the Florida UFLS special protection scheme to "false trip".
**In the Base Obligation measure for Texas, 1150 MW (Load Resources triggered by Under Frequency Relays at 59.70 Hz ) was reduced from its Contingency Protection Criteria level of 2750 MW to get 229 MW/0.1 Hz. This was reduced to accurately account for designed response from Load Resources within 30 cycles.

An Interconnection may propose alternate FRO protection criteria to the ERO. The ERO will confirm the proposed alternate FRO protection criteria.

## Balancing Authority Frequency Response Obligation (FRO) and Frequency Bias Setting

The ERO will manage the administrative procedure for annually assigning an FRO and Frequency Bias Setting to each Balancing Authority.

For a multiple Balancing Authority interconnection, the Interconnection Frequency Response Obligation is allocated based on either the Balancing Authority Peak Demand or peak generation. Initial FRO allocation will be based on the following method:
$\left[\begin{array}{c}\text { Projected BA Peak Load + BA installed capacity } \\ \text { Projected Interconnection Peak Load + Interco nnection installed ca pacity }\end{array}\right] x$ Interconnection FRO

Each Balancing Authority shall report its previous year's Frequency Response Measure (FRM), Frequency Bias Setting and Frequency Bias type (fixed or variable) to the ERO on FRS Form 1 by January 10 each year. If the ERO posts the official list of events after December 10, Balancing Authorities will be given 30 days from the date the ERO posts the official list of events to submit their FRS Form 1.

Once the ERO validates the data for all Balancing Authorities, the ERO will use FRS Form 1 data to post the following information for each Balancing Authority for the upcoming year:

- Frequency Bias Setting
- Frequency Response Obligation (FRO)

Frequency Bias Setting will be the greater of (in absolute terms) the FRM or the Interconnection minimum (as defined in Attachment B). FRS Form 1 will automatically calculate the Balancing Authority's Bias Settings. Balancing Authorities that provide Overlap Regulation will submit a FRS Form 1 that represents both the provider's and the recipient(s)' footprint. Once the data listed above is fully posted, the ERO will announce the implementation date for changing the Frequency Bias Setting.

## Attachment A

BAL-003-1 Frequency Response and Frequency Bias Setting
Supporting Document

## Frequency Response Measure (FRM)

The FRM will be computed from Single Event Frequency Response Data (SEFRD), defined as: "the data from an individual event from a Balancing Authority that is used to calculate its Frequency Response, expressed in MW/0.1Hz" as calculated on FRS Form 2. The SEFRD for a typical Balancing Authority in an Interconnection with more than one Balancing Authority is basically the change in its Net Actual Interchange on its tie lines with its adjacent Balancing Authorities divided by the change in Interconnection frequency. (Some Balancing Authorities may choose to apply corrections to their Net Actual Interchange values to account for factors such as nonconforming loads. FRS Form 1 shows the types of adjustments that are allowed.) The ERO will use a standardized sampling interval of 20 to 52 seconds in the computation of SEFRD values.

Assuming data entry is correct FRS Form 1 will automatically calculate the Balancing Authority's FRM for the past 12 months as the median of the SEFRD values. A Balancing Authority electing to report as an RSG or a provider of Overlap Regulation Service will provide an FRS Form 1 for the aggregate of its participants.

Interconnection frequency performance is improved the closer all Balancing Authorities' (BAs') natural Frequency Response is to Frequency Bias Setting (Cohn, 1966).

The BA calculates its natural Frequency Response based on the events in FRS Form 1. The BA will set its Frequency Bias Setting to the greater of (in absolute value):

- Natural Frequency Response
- Interconnection Minimum (initially 1\% of peak in BAL-003-0.1b).

For purposes of calculating the minimum Frequency Bias Setting, a Reserve Sharing Group or a Balancing Authority providing Overlap Regulation will report the projected peak demand and generation of its combined BAs' areas on FRS Form 1.

This attachment outlines the process the ERO is to use for modifying minimum Frequency Bias Settings to better meet reliability needs. The ERO may adjust the Frequency Bias Setting minimum in accordance with this Attachment B.

The ERO will post the minimum Frequency Bias Setting values on the ERO website along with other balancing standard limits.

The initial minimum Frequency Bias Settings are outlined in the following table.

| Interconnection | Minimum Frequency Bias Setting (in MW/0.1Hz) |
| :--- | :--- |
| Eastern | $0.8 \%$ of peak load or generation |
| Western | $0.8 \%$ of peak load or generation |
| Texas | $0.8 \%$ of peak load or generation |
| HQ | $0.8 \%$ of peak load or generation |

Table 1. Initial Frequency Bias Setting Minimums
The ERO will annually review Frequency Bias Setting data submitted by BAs. If an Interconnection's total minimum Frequency Bias Setting exceeds (in absolute value) the Interconnection's total natural Frequency Response by more (in absolute value) than 0.2 percentage points (of peak load expressed in $\mathrm{MW} / 0.1 \mathrm{~Hz}$ ), the ERO may reduce (in absolute value) the minimum Frequency Bias Setting for BAs within that Interconnection, by 0.1 percentage point to better match that Frequency Bias Setting and natural Frequency Response.

NORTH AMERICAN ELECTRIC
RELIABILITY CORPORATION

## I mplementation Plan for BAL-003-1 - Frequency Response \& Frequency Bias Setting Standard

## Prerequisite Approvals

There are no other reliability standards or Standard Authorization Requests (SARs), in progress or approved, that must be implemented before this standard can be implemented.

## Modified Standards

BAL-003-0.1b should be retired at midnight of the day immediately prior to the Effective Date of BAL-003-1 in the Jurisdiction in which the new standard is becoming effective.

## New or Modified Definitions

The following definitions shall become effective when BAL-003-1 Requirements R2, R3, R4 and R5 become effective:

Frequency Response Measure (FRM): The median of all the Frequency Response observations reported annually on FRS Form 1.

Frequency Response Obligation (FRO): The Balancing Authority's share of the required Frequency Response needed for the reliable operation of an Interconnection.

Frequency Bias Setting: A numbervalue, either fixed or variable, usually expressed in MW/0.1 Hz , included inset into a Balancing Authority's Area Control Error equation to account for algorithm that allows the Balancing Authority's Frequency Response contributionto contribute its frequency response to the Interconnection and discourage withdrawal through secondary control systems.

The existing definition of Frequency Bias Setting should be retired at midnight of the day immediately prior to the Effective Date of BAL-003-1 in the Jurisdiction in which the new standard is becoming effective.

The proposed revised definition for "Frequency Bias Setting" is incorporated in the following NERC approved standards:

- BAL-001-0.1a Real Power Balancing Control Performance
- BAL-004-0 Time Error Correction
- BAL-004-1 Time Error Correction
- BAL-005-0.1b Automatic Generation Control

## Compliance with Standards

Once this standard becomes effective, the responsible entities identified in the applicability section of the standard must comply with the requirements. These include:

- Balancing Authorities
- Reserve Sharing Groups

## Proposed Effective Date

Compliance with BAL-003-1 shall be implemented over a two-year period, as follows:

- In those jurisdictions where regulatory approval is required, Requirements R2, R3, R4 and R5 of this standard shall become effective the first calendar day of the first calendar quarter 12 months after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, Requirements R2, R3, R4 and R5 of this standard shall become effective the first calendar day of the first calendar quarter 12 months after Board of Trustees adoption.
- In those jurisdictions where regulatory approval is required, Requirements R1 of this standard shall become effective the first calendar day of the first calendar quarter 24 months after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, Requirements R1 of this standard shall become effective the first calendar day of the first calendar quarter 24 months after Board of Trustees adoption.

# Implementation Plan for BAL-003-1 - Frequency Response \& Frequency Bias Setting Standard 

## Prerequisite Approvals

There are no other reliability standards or Standard Authorization Requests (SARs), in progress or approved, that must be implemented before this standard can be implemented.

## Modified Standards

BAL-003-0.1b-Requirements R1, R2, R3, R4 and R6 should be retired midnight of the day immediately prior to the Effective Date of BAL-003-1 in the Jurisdiction in which the new standard is becoming becomes-effective.

BAL-003-0 Re1quirement R5 should be retired as outlined in the following table.
For those Balancing Authorities that serve native load:

- May 2011 through December $2011 \quad-0.8 \%$ of peak 0.1 Hz
- January 2012 through December $2012 \quad 0.6 \%$ of peak 10.1 Hz
- January 2013 through December $2013 \quad-0.4 \%$ of peak $/ 0.1 \mathrm{~Hz}$
- January 2014 through December $2014 \quad-0.2 \%$ of peak 10.1 Hz
- January 2015 through $0.0 \%$ of peak $/ 0.1 \mathrm{~Hz}$

For those Balancing Authorities that do not serve native load:

- May 2011 through December $2011 \quad-0.8 \%$ of upcoming years maximum generation/ 0.1 Hz
- January 2012 through December 2012 0.6\% of upcoming years maximum generation $/ 0.1 \mathrm{~Hz}$
- January 2013 through December 2013 -0.4\% of upcoming years maximum generation $/ 0.1 \mathrm{~Hz}$
- January 2014 through December $2014 \quad 0.2 \%$ of upcoming years maximum generation $/ 0.1 \mathrm{~Hz}$
- January 2015 through -0.0\% of upcoming years maximum generation/ 0.1 Hz

The FRR drafting team, NERC and the NERC Resources Subcommittee will observe the impact on frequency and will implement a reversion plan should frequency performance decline.

## New or Modified Definitions

The following definitions shall become effective when BAL-003-1 Requirements R2, R3, R4 and R5 become effective:

July 12, 2011
116-390 Village Boulevard, Princeton, New Jersey 08540-5721
Phone: 609.452.8060 • Fax: 609.452.9550 • www.nerc.com

Frequency Response Measure (FRM): The median of all the Frequency Response observations reported annually on FRS Form 1.

Frequency Response Obligation (FRO): The Balancing Authority's share of the required Frequency Response needed for the reliable operation of an Interconnection.

Frequency Bias Setting: A number, either a fixed or variable, usually expressed in MW/0.1 Hz, included in a Balancing Authority's Area Control Error equation to account for the Balancing Authority's Frequency Response contribution to the Interconnection, and discourage response withdrawal through secondary control systems.

The existing definition of Frequency Bias Setting should be retired midnight of the day immediately prior to the Effective Date of BAL-003-1 in the Jurisdiction in which the new standard is becoming effective.

The proposed revised definition for "Frequency Bias Setting" is incorporated in the following NERC approved standards:

- BAL-001-0.1a Real Power Balancing Control Performance
- BAL-004-0 Time Error Correction
- BAL-004-1 Time Error Correction
- BAL-005-0.1b Automatic Generation Control

## Compliance with Standards

Once this standard becomes effective, the responsible entities identified in the applicability section of the standard must comply with the requirements. These include:

- Balancing Authorities
- Reserve Sharing Groups

## Proposed Effective Date

Compliance with BAL-003-1 shall be implemented over a two-year period, as follows:

- In those jurisdictions where regulatory approval is required, Requirements R21, R3, R4 and R 54 of this standard shall become effective the first calendar day of the first calendar quarter 12 months after applicable regulatory approval. In those jurisdictions where no regulatory approval is required,
| Requirements R21, R3, R4 and R54 of this standard shall become effective the first calendar day of the first calendar quarter 12 months after Board of Trustees adoption.
- In those jurisdictions where regulatory approval is required, Requirements R1Z of this standard shall become effective the first calendar day of the first calendar quarter 24 months after applicable regulatory approval. In those jurisdictions where no regulatory approval is
| required, Requirements R $\underline{1 z}$ of this standard shall become effective the first calendar day of the first calendar quarter 24 months after Board of Trustees adoption.

## Introduction

This document provides background on the development, testing and implementation of BAL-003-1 - Frequency Response Standard (FRS). The intent is to explain the rationale and considerations for the Requirements and their associated compliance information. The document also provides good practices and tips for Balancing Authorities with regard to Frequency Response.

In Order No. 693, the FERC directed additional changes to BAL-003-0.1b. This document explains how those directives are met by BAL-003-1.

The original Standards Authorization Request (SAR), finalized on June 30, 2007, assumed ${ }_{2}$ assumed the Frequency Response currently available to be adequate in all the North American Interconnections. The goal of the SAR was to update the Standard to make the measurement process more objective and to provide this objective data to Planners and Operators for improved modeling. The improved models will improve understanding of the trends in Frequency Response to determine if reliability limits were being approached. The Standard would also lay the process groundwork for a transition to a performance-based Standard if reliability limits were approached.

This document will be periodically updated by the FRS Drafting Team until the Standard is approved (expected to occur during Springspring of 2012). Once approved, this document will then be maintained and updated by the ERO and the NERC Resources Subcommittee.

## Background and Rationale by Requirement

## Requirement 1

R1. Each Balancing Authority (BA) or Reserve Sharing Group (RSG) shall achieve an annual Frequency Response Measure (FRM) (as detailed in Attachment A and calculated on FRS Form 1) that is equal to or more negative than its Frequency Response Obligation (FRO) to ensure that sufficient Frequency Response is provided by each BA or RSG to maintain an adequate level of Frequency Response in the Interconnection.

## Background and Rationale

R1 is intended to meet the following primary objectives:

- Determine whether a Balancing Authority (BA) has sufficient Frequency Response for reliable operations.
- Provide the feeder information needed to calculate CPS limits and Frequency Bias Settings.
With regard to the first objective, FRS Form 1 and the process in Attachment A provide the method for determining the Interconnections' necessary amount of Frequency Response and allocating it to the Balancing Authorities. The field trial for BAL-003-1 is testing an allocation methodology based on the amount of load and generation in the BA. This is to accommodate the wide spectrum of BAs from generation-only all the way to load-only.

The basic Frequency Response Obligation is based on non-coincident peak load and generation data reported in FERC Form 714 for the previous full calendar year. The basic allocation formula used by NERC is:

$$
\mathrm{FRO}_{B A}=\mathrm{FRO}_{\operatorname{lnt}} \times \frac{\text { Peak Gen }_{B A}+\text { Peak Load }}{\text { Bea }}
$$

Where:

- Peak GenBA is the average of monthly "Output of Generating Plants", FERC Form 714, column f of Part II - Schedule 3.
- Peak LoadBA is the average of "Monthly Peak Demand (MW)", FERC Form 714, column j of Part II - Schedule 3.
- Peak GenInt is the sum of all BAs' in that interconnection reported average monthly peak generation.
- Peak LoadInt is the sum of all BAs in that interconnection reported average monthly peak demand.

Balancing Authorities can approximate their FRO by multiplying their Interconnection's FRO by their share of Interconnection bias.

Balancing Authorities that merge or that transfer load or generation need to notify the ERO of the change in footprint and corresponding changes in allocation such that the net obligation for the Interconnection remains the same.

Note: The methodology for determining the Interconnection's Frequency Response Obligation and allocating it to BAs may change on the basis of field trial results. The drafting team is evaluating a risk-based approach for basing the Interconnection Frequency Response Obligation on an historic probability density of frequency error, and for allocating the obligation on the basis of the Balancing Authority's average annual ACE share of frequency error.

Attachment A proposes the following Interconnection event criteria as a basis to determine an Interconnection's Frequency Response Obligation:

- Largest category C loss-of-resource (N-2) event
- Largest total generating plant with common voltage switchyard
- Largest loss of generation in the interconnection in the last 10 years

Given the fact that the Interconnections currently have sufficient Frequency Response, few BAs should encounter problems meeting R1, particularly with the options the Standard provides with regard to obtaining Frequency Response.

With regard to the second objective above (determining Frequency Bias Settings and CPS limits), Balancing Authorities have been asked to perform annual reviews of their Frequency Bias Settings by measuring their Frequency Response, dating back to Policy 1. This obligation
was carried forward into BAL-003-01.b. While the associated training document provided useful information, it left many of the details to the judgment of the person doing the analysis. The FRS Form 1 and FRS Form 2 provide a consistent, objective process for calculating Frequency Response to develop an annual measure, the FRM.

The FRM will be computed from Single Event Frequency Response Data (SEFRD), defined as: "the data from an individual event from a Balancing Authority that is used to calculate its Frequency Response, expressed in MW/0.1Hz". The SEFRD for a typical Balancing Authority in an Interconnection with more than one Balancing Authority is basically the change its Net Actual Interchange on its tie lines with its adjacent Balancing Authorities divided by the change in Interconnection frequency. (Some Balancing Authorities may choose to apply corrections to their Net Actual Interchange values to account for factors such as nonconforming loads. FRS Form 1 shows the types of adjustments that are allowed.)

A standardized sampling interval of 20 to 52 seconds will be used in the computation of SEFRD values. Microsoft Excel ${ }^{\circledR}$ spreadsheet interfaces for EMS scan rates of 2 through 6 seconds will be provided to support the computation. During the field trial, other sampling intervals will be evaluated as well to determine if another sampling interval is more appropriate.

In an attempt to balance the workload of Balancing Authorities with the need for accuracy in the FRM, the field trial will require at least 25 samples selected during the course of the year to compute the FRM. Research conducted by the Frequency Responsive Reserve Standard Drafting Team (FRSDT) indicated that a Balancing Authority's FRM will converge to a reasonably stable value with 20 to 25 samples. The FRSDT will re-evaluate the required number of samples during the field trial.

The FRSDT also evaluated different approaches for "averaging" individual event observations to compute a technically sound estimate of Frequency Response Measure (FRM). The MW contribution for a single BA in a multi-BA Interconnection is small compared to the minute to minute changes in load, interchange and generation. For example, a 3000 MW BA in the east may only be called on to contribute 10 MW for the loss of a 1000 MW . The 10 MW of governor and load response may easily be masked ay a coincident change in load. Because of this large "noise to signal" ratio, the mean did not prove to be an appropriate measure of true typical performance.

In general, statisticians use the median as the best measure of central tendency when a population has outliers. Two independent reviews by the FRSDT has shown the Median to be less influenced by noise in the measurement process and the team has chosen the median as the initial metric for calculating the BAs' Frequency Response Measure. In addition, The FRSDT is evaluating the linear regression as a means to estimate the BA's typical frequency response. This calculation is embedded in FRS Form 1 and will be evaluated during the field trial. Initial review implies that the linear regression tends to skew calculated FRM due to the influence of outliers. The outliers are being evaluated by the FRSDT as they may point to needed improvements in the measurement process or training issues for the BA in question.

In order to support field trial evaluations of sample size, sampling intervals, and aggregation techniques, the FRSDT will be retrieving scan rate data from the Balancing Authorities for each SEFRD. Additional frequency events may also be requested for research purposes, though they will not be included in the FRM computation.

FERC Order No. 693 directed the ERO to define the number of Frequency Response surveys that were conducted each year and to define a necessary amount of Frequency Response. R1 addresses both of these directives:

- There is a single annual survey of at least 25-30 events each year.
- The FRM calculated on FRS Form 1 is compared by the ERO against the FRO determined 12 months earlier (when the last FRS Form 1 was submitted) to verify the Balancing Authority provided its share of Interconnection Frequency Response.

FERC Order No. 693 also directed that the Standard should identify methods for Balancing Authorities to obtain Frequency Response. Requirement R1 allows Balancing Authorities to participate in Reserve Sharing Groups (RSGs) to provide or obtain Frequency Response. These may be the same RSGs that cooperate for BAL-002-0 or may be RSGs that form for the purposes of BAL-003-1.

If BAs participate as an RSG for BAL-003-1, compliance is based on the sum of the participants' performance.

Two other ways that BAs could obtain Frequency Response are through Supplemental Service or Overlap Regulation Service:

- No special action is needed if a BA provides or receives supplemental regulation. If the regulation occurs via Pseudo Tie, the transfer occurs automatically as part of Net Actual Interchange (NIA) and in response to information transferred from recipient to provider.
- If a BA provides overlap regulation, its FRS Form 1 will include the Frequency Bias setting as well as peak load and generation of the combined Balancing Authority Areas. The FRM event data will be calculated on the sum of the provider's and recipient's performance.

In the Violation Severity Levels for Requirement R1, the impact of a BA not having enough frequency response depends on two factors:

- Does the Interconnection have sufficient response?
- How short is the BA in providing its FRO?

The VSL takes these factors into account.

Requirement 2
R2. Each Balancing Authority not participating in Overlap Regulation Service shall implement the Frequency Bias Setting (fixed or variable) validated by the ERO, into its Area Control Error
(ACE) calculation beginning on the date specified by the ERO to ensure effectively coordinated Tie Line Bias control.

## Background and Rationale

Attachment A of the Standard discusses the process the ERO will follow to validate the BA's FRS Form 1 data and publish the official Frequency Bias Settings. Historically, it has taken multiple rounds of validation and outreach to confirm each BA's data due to transcription errors, misunderstanding of instructions, and other issues. While BAs historically submit Bias Setting data by January 1, it often takes one or more months to complete the process.

The target is to have BAs submit their data by January 10. The BAs are given 30 days to assemble their data since the BAs are dependent on the ERO to provide them withthem with FRS Form 1, and there may be process delays in distributing the forms since they rely on identification of frequency events through November 30 of the preceding year.

Frequency Bias Settings generally change little from year to year. Given the fact that BAs can encounter staffing or EMS change issues coincident with the date the ERO sets for new Frequency Bias Setting implementation, the standard provides a 24 hour window on each side of the target date.

To recap the annual process:

1. The ERO posts the official list of frequency events to be used for this Standard in early December. The FRS Form 1for each Interconnection will be posted shortly thereafter.
2. The Balancing Authority submits its revised annual Frequency Bias Setting value to NERC by January 10.
3. The ERO and the Resources Subcommittee validate Frequency Bias Setting values, perform error checking, and calculate, validate, and update CPS2 L10 values. This data collection and validation process can take as long as two months.
4. Once the L10 and Frequency Bias Setting values are validated, The ERO posts the values for the upcoming year and also informs the Balancing Authorities of the date on which to implement revised Frequency Bias Setting values. Implementation typically would be on or about March $1^{\text {st }}$ of each year.

Requirement 3
R3. Each Balancing Authority not receiving Overlap Regulation Service shall operate its Automatic Generation Control (AGC) in Tie Line Bias mode to ensure effectively coordinated control, unless such operation would have an Adverse Reliability Impact on the Balancing Authority's Area.

## Background and Rationale

This requirement serves several functions. The primary reason for operating in Tie Line Bias is so ACE is calculated properly for performance purposes. Even if a BA temporarily operated in manual mode, as long as CPS is properly calculated and the BA met CPS, it is operating reliably.

There are legitimate reasons for taking AGC out of Tie Line Bias or operating manually including:

- Telemetry problems that lead the operator to believe ACE is significantly in error.
- The frequency input to AGC is not reflective of the BA's true frequency (such as if the control center were operating a local generator and disconnected from the Interconnection).
- During restoration (where one BA might be controlling frequency while another to which it is connected is managing interchange between them).
- For training purposes.
- Many AGC systems will automatically switch to an alternate mode if the EMS determines Tie Line Bias control could lead to problems.
- For single BA Interconnections, Flat Frequency and Tie Line Bias are equivalent.

Because it is rare that temporary operation out of Tie Line Bias can lead to reliability problems, the VSLs for this requirement are structured accordingly.

Requirement 4
R4. Each Balancing Authority that is performing Overlap Regulation Service shall modify its Frequency Bias Setting in its ACE calculation to be equivalent to the sum of the Frequency Bias Settings of the participating Balancing Authorities as validated by the ERO or calculate the Frequency Bias Setting based on the entire area being combined and thereby represent the Frequency Response for the combined area being controlled.

## Background and Rationale

This requirement reflects the operating principles first established by NERC Policy 1 and is similar to Requirement R6 of the approved BAL-003-0.1b standard. Overlap Regulation Service is a method of providing regulation service in which the Balancing Authority providing the regulation service incorporates another Balancing Authority's actual interchange, frequency response, and schedules into the providing Balancing Authority's AGC/ACE equation.

As noted earlier, a BA that is providing Overlap Regulation will report the sum of the Bias Settings in its FRS Form 1. Balancing Authorities receiving Overlap Regulation Service have an ACE and Frequency Bias Setting equal to zero (0).

Requirement 5
R5. In order to ensure adequate control response each Balancing Authority shall use a monthly average Frequency Bias Setting whose absolute value is at least equal to one of the following:

- The minimum percentage of the Balancing Authority Area's estimated yearly Peak Demand within its metered boundary per 0.1 Hz change as specified by the ERO in accordance with Attachment B.
- The minimum percentage of the Balancing Authority Area's estimated yearly peak generation for a generation- only BA, per 0.1 Hz change as specified by the ERO in accordance with Attachment B.

## Background and Rationale

BAL-003-0.1b standard requires a minimum Frequency Bias Setting equal in absolute value to one percent of the Balancing Authority's estimated yearly peak demand (or maximum generation level if native load is not served). For most Balancing Authorities this calculated amount of Frequency Bias is significantly greater in absolute value than their actual Frequency Response characteristic (which represents an over-bias condition) resulting in over-control since a larger magnitude response is realized. This is especially true in the Eastern Interconnection where this condition requires excessive secondary frequency control response which degrades overall system performance and increases operating cost as compared to requiring an appropriate balance of primary and secondary frequency control response.

Balancing Authorities were given a minimum Frequency Bias Setting obligation because there had never been a mandatory Frequency Response Obligation. This historic "one percent of peak per 0.1 Hz " obligation, dating back to NERC's predecessor, NAPSIC, was intended to ensure all BAs provide some support to Interconnection frequency.

The ideal system control state exists when the Frequency Bias Setting of the Balancing Authority exactly matches the actual Frequency Response characteristic of the Balancing Authority. If this is not achievable, over-bias is significantly better from a control perspective than under-bias with the caveat that Frequency Bias is set relatively close in magnitude to the Balancing Authority actual Frequency Response characteristic. Setting the Frequency Bias to better approximate the Balancing Authority natural Frequency Response characteristic will improve the quality and accuracy of ACE control, CPS \& DCS and general AGC System control response. This is the technical basis for recommending an adjustment to the long standing " $1 \%$ of peak/0.1 Hz" Frequency Bias Setting. Attachment B is intended to bring the Balancing Authorities' Frequency Bias Setting closer to their natural Frequency Response. Attachment B balances the following objectives:

- Bring the Frequency Bias Setting and Frequency Response closer together.
- Ensure there is no negative impact on other Standards (CPS, BAAL and to a lesser extent DCS) by adjustments in the minimum Frequency Bias Setting, by accommodating only minor adjustments.
- Do not allow the Frequency Bias Setting minimum to drop below natural Frequency Response, because under-biasing could affect an Interconnection adversely.

Finally, for BAs using variable bias, FRS Form 1 has a data entry location for the previous year's average monthly bias. The Balancing Authority and the ERO can compare this value to the previous year's Frequency Bias Setting minimum to ensure R5 has been met.

# How this Standard Meets the FERC Order 693 Directives 

## FERC Directive

The following is the relevant paragraph of Order No. 693.
Accordingly, the Commission approves Reliability Standard BAL-003-0 as mandatory and enforceable. In addition, the Commission directs the ERO to develop a modification to BAL-003-0 through the Reliability Standards development process that: (1) includes Levels of Non-Compliance; (2) determines the appropriate periodicity of frequency response surveys necessary to ensure that Requirement R2 and other requirements of the Reliability Standard are being met, and to modify Measure M1 based on that determination and (3) defines the necessary amount of Frequency Response needed for Reliable Operation for each balancing authority with methods of obtaining and measuring that the frequency response is achieved.

1. Levels of Non-Compliance

VRFs and VSLs are an equally effective way of assigning compliance elements to the standard.
2. Determine the appropriate periodicity of frequency response surveys necessary to ensure that Requirement R2 and other Requirements of the Reliability Standard are met
BAL-003 V0 R2 (the basis of Order No. 693) deals with the calculation of Frequency Bias Setting such that it reflects natural Frequency Response.

The drafting team has determined that a sample size on the order of at least 25-30 events is necessary to have a high confidence in the estimate of a BA's Frequency Response. Selection of the frequency excursion events used for analysis will be done via a method outlined in Attachment A to the Standard.

On average, these events will represent the largest 2-3 "clean" frequency excursions occurring each month.

Since Frequency Bias Setting is an annual obligation, the survey of the at least 25-30 frequency excursion events will occur once each year.
3. Define the necessary amount of Frequency Response needed for Reliable Operation for each Balancing Authority with methods of obtaining and measuring that the frequency response is achieved

## Necessary Amount of Frequency Response

The drafting team has proposed the following approach to defining the necessary amount of frequency response. In general, the goal is to avoid triggering the first step of under-frequency load shedding (UFLS) in the given Interconnection for reasonable contingencies expected. The
methodology for determining each Interconnection's and Balancing Authority's obligation is outlined in Attachment A to the Standard.

It should be noted that the standard cannot guarantee that there will never be a triggering of UFLS as the magnitude of "point C" differs throughout an interconnection during a disturbance and there are local areas that see much wider swings in frequency.

The contingency protection criterion is the largest reasonably expected contingency in the Interconnection. This can be based on the largest observed credible contingency in the previous 10 years or the largest Category C event for the Interconnection.

The Safety Margin included addresses the difference between Points B and C and accounts for variables.

For multiple BA interconnections, the Frequency Response Obligation is allocated to BAs based on size. This allocation will be based on the following calculation:

$$
\mathrm{FRO}_{B A}=F R O_{\operatorname{lnt}} \times \frac{\text { Peak Gen }}{\text { PA }}+\text { Peak Load }{ }_{B A}
$$

## Methods of Obtaining Frequency Response

The drafting team believes the following are valid methods of obtaining Frequency Response:

- Supplemental regulation.
- Overlap regulation.
- Contractual service (The drafting team has developed an approach to obtain a contractual share of Frequency Response from Adjacent Balancing Authorities. See FRS Form 1). While the final rules with regard to contractual services are being defined, the current expectation is that the ERO and the associated Region(s) should be notified beforehand and that the service be at least 6 months in duration.
- Through a tariff (e.g. Frequency Response and regulation service).
- From generators through an interconnection agreement.
- Contract with an internal resource or loads (The drafting team encourages the development of a NAESB business practice for Frequency Response service for linear (droop) and stepped (e.g. LaaR in Texas) response).

## Measuring that the Frequency Response is Achieved

FRS Form 1 and the underlying data retained by the BA will be used for measuring whether Frequency Response was provided. FRS Form 1 will provide the guidance on how to account for and measure Frequency Response.

Going Beyond the Directive
Based on the combined operating experience of the SDT, the drafting team believes each Interconnection has sufficient Frequency Response. If margins decline, there may be a need for additional standards or tools. The drafting team and the Resources Subcommittee are working with the ERO on its Frequency Response Initiative to develop processes and good practices so the Interconnections are prepared. These good practices and tools are described in the following section.

The drafting team is also evaluating a risk-based approach for basing the Interconnection Frequency Response Obligation on an historic probability density of frequency error, and for allocating the obligation on the basis of the Balancing Authority's average annual ACE share of frequency error. This allocation method uses the inverse of the rationale for allocating the CPS1 epsilon requirement by Bias share.

## Good Practices

Knowing the quantity and depth of frequency responsive reserves in real time is a possible next step to being better prepared for the next event. The challenge in achieving this is having the knowledge of the capabilities of all sources of frequency response. Presently the primary source of frequency response remains with the generation resources in our fleets. Understanding how each of these sources performs to changes in system frequency and knowing their limitations would improve the BA's ability to measure frequency responsive reserves. Presently there are only guidelines, criteria and protocols in some regions of the industry that identify specific settings and performance expectations of primary frequency response of resources. One method of gaining better understanding of performance is to measure performance during actual events that occur on the system. This approach would only provide feedback for performance during that specific event and would not provide insight into depth of response or other limitations. Repeated measurements will increase confidence in expected performance. NERC modeling standards are in process to be revised that will improve the BA's insight into predicting available frequency responsive reserves. However, knowing how resources are operated, what modes of operation provide sustained primary frequency response and knowing the operating range of this response would give the BA the knowledge to accurately predict frequency response and the amount of frequency responsive reserves available in real time.

Some benefits on several interconnections have been realized by communicating to generation resources (GO) the importance of operating in modes that allow primary frequency response to be sustained by the control systems of the resource. Other improvements in implementation of primary frequency response have been achieved through improved settings on turbine governors through the elimination of "step" frequency response with the simultaneous reduction in governor dead-band settings. Improvements in the full AGC control loop of the
generating resource, which accounts for the expected primary frequency response, have improved the delivery of quality primary frequency response while minimizing secondary control actions of generators. Some of these actions can provide quick improvement in delivery of primary frequency response.

Once primary frequency response sources are known the BA could calculate available reserves that are frequency responsive. Planning for these reserves during normal and emergency operations could be developed and added to the normal planning process.

Tools
Single generating resource primary frequency response performance evaluation tools for steam turbine, combustion turbine (simple cycle or combined cycle) and for intermittent resources are available at the following link.
http://texasre.org/standards rules/standardsdev/rsc/sar003/Pages/Default.aspx.
These tools and the regional standard associated with them are in their final stages of development in the Texas region.

These tools will be posted on the NERC website.

## Field Trial

This section is a summary of the Field Trial activities that have been or will be conducted by the ERO, the Resources Subcommittee and the FRS Drafting Team.

1. The NERC BA recommendation (alert) and observations.V
2. The NERC governor recommendation (alert) and observations.V
3. The 2011 bias calculation $\vee$
4. Evaluate measurement methodologyv
5. Serve as initial training for BAsV
6. Evaluate median, mean, regression and possibly other measures $V$
7. Evaluate sample size (to address the directive of frequency of surveys) $\vee$
8. Evaluate impact of inclusion/exclusion of internal contingencies $\vee$
9. Improve FRS Form 1 V
10. Create supporting process for FRS Form 1 V
11. For Interconnection benchmarking (proving adequacy of frequency response)
12. Evaluating trend
13. Test process for developing candidate list for FRS Form 1
14. 2012 bias calculation
15. Further refinement of items in 2011 bias calculation
16. Test the FRO allocation methodology
17. Test approach for handling variable bias
18. Evaluate 12 month vs. 24 month rolling average approach to performance
19. Evaluate reduction in bias setting floor below $1 \%$ (initially $0.8 \%$ in 2012) to evaluate impact on frequency and calculated CPS and BAAL performance.
20. Evaluate effectiveness of administrative process to support the standard.
21. Evaluate a risk-based approach for basing the Interconnection Frequency Response Obligation on an historic probability density of frequency error, and for allocating the obligation on the basis of the Balancing Authority's average annual ACE share of frequency error.
Body content goes here. Body content goes here. Body content goes here. Body content goes here.

## A. Introduction

1. Title: Frequency Response and Bias
2. Number: BAL-003-0.1b
3. Purpose: This standard provides a consistent method for calculating the Frequency Bias component of ACE.
4. Applicability:
4.1. Balancing Authorities.
5. Effective Date: Immediately after approval of applicable regulatory authorities.

## B. Requirements

R1. Each Balancing Authority shall review its Frequency Bias Settings by January 1 of each year and recalculate its setting to reflect any change in the Frequency Response of the Balancing Authority Area.

R1.1. The Balancing Authority may change its Frequency Bias Setting, and the method used to determine the setting, whenever any of the factors used to determine the current bias value change.

R1.2. Each Balancing Authority shall report its Frequency Bias Setting, and method for determining that setting, to the NERC Operating Committee.

R2. Each Balancing Authority shall establish and maintain a Frequency Bias Setting that is as close as practical to, or greater than, the Balancing Authority's Frequency Response.
Frequency Bias may be calculated several ways:
R2.1. The Balancing Authority may use a fixed Frequency Bias value which is based on a fixed, straight-line function of Tie Line deviation versus Frequency Deviation. The Balancing Authority shall determine the fixed value by observing and averaging the Frequency Response for several Disturbances during on-peak hours.

R2.2. The Balancing Authority may use a variable (linear or non-linear) bias value, which is based on a variable function of Tie Line deviation to Frequency Deviation. The Balancing Authority shall determine the variable frequency bias value by analyzing Frequency Response as it varies with factors such as load, generation, governor characteristics, and frequency.

R3. Each Balancing Authority shall operate its Automatic Generation Control (AGC) on Tie Line Frequency Bias, unless such operation is adverse to system or Interconnection reliability.

R4. Balancing Authorities that use Dynamic Scheduling or Pseudo-ties for jointly owned units shall reflect their respective share of the unit governor droop response in their respective Frequency Bias Setting.

R4.1. Fixed schedules for Jointly Owned Units mandate that Balancing Authority (A) that contains the Jointly Owned Unit must incorporate the respective share of the unit governor droop response for any Balancing Authorities that have fixed schedules (B and C). See the diagram below.

R4.2. The Balancing Authorities that have a fixed schedule (B and C) but do not contain the Jointly Owned Unit shall not include their share of the governor droop response in their Frequency Bias Setting.

R5. Balancing Authorities that serve native load shall have a monthly average Frequency Bias Setting that is at least $1 \%$ of the Balancing Authority's estimated yearly peak demand per 0.1 Hz change.

R5.1. Balancing Authorities that do not serve native load shall have a monthly average Frequency Bias Setting that is at least $1 \%$ of its estimated maximum generation level in the coming year per 0.1 Hz change.

R6. A Balancing Authority that is performing Overlap Regulation Service shall increase its Frequency Bias Setting to match the frequency response of the entire area being controlled. A Balancing Authority shall not change its Frequency Bias Setting when performing Supplemental Regulation Service.

## C. Measures

M1. Each Balancing Authority shall perform Frequency Response surveys when called for by the Operating Committee to determine the Balancing Authority's response to Interconnection Frequency Deviations.
D. Compliance

Not Specified.

## E. Regional Differences

None identified.

## F. Associated Documents

1. Appendix 1 - Interpretation of Requirement R3 (October 23, 2007).
2. Appendix 2 - Interpretation of Requirements R2, R2.2, R5, and R5.1 (February 12, 2008).

## Appendix 1

## Interpretation of Requirement 3

Request: Does the WECC Automatic Time Error Control Procedure (WATEC) violate Requirement 3 of BAL-003-0?

## Interpretation:

Requirement 3 of BAL-003-0 - Frequency Response and Bias deals with Balancing Authorities using Tie-Line Frequency Bias as the normal mode of automatic generation control.

## BAL-003-0

R3. Each Balancing Authority shall operate its Automatic Generation Control (AGC) on Tie Line Frequency Bias, unless such operation is adverse to system or Interconnection reliability.

- Tie-Line Frequency Bias is one of the three foundational control modes available in a Balancing Authority's energy management system. (The other two are flat-tie and flat-frequency.) Many Balancing Authorities layer other control objectives on top of their basic control mode, such as automatic inadvertent payback, CPS optimization, time control (in single BA Interconnections).
- As long as Tie-Line Frequency Bias is the underlying control mode and CPS1 is measured and reported on the associated ACE equation, there is no violation of BAL-003-0 Requirement 3 :

$$
\mathrm{ACE}=\left(\mathrm{NI}_{\mathrm{A}}-\mathrm{NI}_{\mathrm{S}}\right)-10 \mathrm{~B}\left(\mathrm{~F}_{\mathrm{A}}-\mathrm{F}_{\mathrm{S}}\right)-\mathrm{I}_{\mathrm{ME}}
$$

## Appendix 2

## Interpretation of Requirements R2, R2.2, R5, R5.1

Request: ERCOT specifically requests clarification that a Balancing Authority is entitled to use a variable bias value as authorized by Requirement R2.2, even though Requirement 5 seems not to account for the possibility of variable bias settings.

## Interpretation:

The consensus of the Resources Subcommittee is that BAL-003-0 - Frequency Response and Bias Requirement R2 does not conflict with BAL-003-0 Requirement R5.

BAL-003-0 - Frequency Response and Bias Requirement 2 requires a Balancing Authority to analyze its response to frequency excursions as a first step in determining its frequency bias setting. The Balancing Authority may then choose a fixed bias (constant through the year) per Requirement 2.1, or a variable bias (varies with load, specific generators, etc.) per Requirement 2.2.

## BAL-003-0

R2. Each Balancing Authority shall establish and maintain a Frequency Bias Setting that is as close as practical to, or greater than, the Balancing Authority's Frequency Response. Frequency Bias may be calculated several ways:

R2.1. The Balancing Authority may use a fixed Frequency Bias value which is based on a fixed, straight-line function of Tie Line deviation versus Frequency Deviation. The Balancing Authority shall determine the fixed value by observing and averaging the Frequency Response for several Disturbances during on-peak hours.

R2.2. The Balancing Authority may use a variable (linear or non-linear) bias value, which is based on a variable function of Tie Line deviation to Frequency Deviation. The Balancing Authority shall determine the variable frequency bias value by analyzing Frequency Response as it varies with factors such as load, generation, governor characteristics, and frequency.

BAL-003-0 - Frequency Response and Bias Requirement 5 sets a minimum contribution for all Balancing Authorities toward stabilizing interconnection frequency. The $1 \%$ bias setting establishes a minimum level of automatic generation control action to help stabilize frequency following a disturbance. By setting a floor on bias, Requirement 5 also helps ensure a consistent measure of control performance among all Balancing Authorities within a multi-Balancing Authority interconnection. However, ERCOT is a single Balancing Authority interconnection. The bias settings ERCOT uses do produce, on average, the best level of automatic generation control action to meet control performance metrics. The bias value in a single Balancing Authority interconnection does not impact the measure of control performance.

## BAL-003-0

R5. Balancing Authorities that serve native load shall have a monthly average Frequency Bias Setting that is at least $1 \%$ of the Balancing Authority's estimated yearly peak demand per 0.1 Hz change.
R5.1. Balancing Authorities that do not serve native load shall have a monthly average Frequency Bias Setting that is at least $1 \%$ of its estimated maximum generation level in the coming year per 0.1 Hz change.

## Unofficial Comment Form <br> Frequency Response (Project 2007-12)

Please DO NOT use this form to submit comments. Please use the electronic comment form to submit comments on the first formal posting for Project 2007-12-Frequency Response. The electronic comment form must be completed by December 8, 2011.

## 2007-12 Project Page

If you have questions please contact Darrel Richardson at darrel.richardson@nerc.net or 609.613.1848.

## Background

Frequency Response, a measure of an Interconnection's ability to stabilize frequency immediately following the sudden loss of generation or load, is a critical component to the reliable operation of the bulk power system, particularly during disturbances and restoration. There is evidence of continuing decline in Frequency Response over the past 10 years, but no confirmed reason for the apparent decline. The proposed standard requires entities to provide data so that Frequency Response in each of the Interconnections can be analyzed, and the reasons for the decline in Frequency Response can be identified. The standard would set a minimum Frequency Response obligation for each Balancing Authority, provide a uniform calculation of Frequency Response and Frequency Bias Settings that transition to values closer to natural Frequency Response, and encourage coordinated AGC operation.
The Drafting Team would like to receive industry comments on this standard.

## You do not have to answer all questions. Enter all comments in Simple Text Format.

1. The SDT has made minor modifications to the proposed definitions to provide additional clarity. Do you agree that these modifications provide sufficient clarity? If not, please explain in the comment area.YesNo
Comments:
2. The SDT has made minor modifications to the Requirements R1 through R4 to provide additional clarity. Do you agree that these modifications provide sufficient clarity to comply with the standard? If not, please explain in the comment area.Yes
Comments:
3. The SDT has developed VRFs for the proposed Requirements within this standard. Do you agree that these VRFs are appropriately set? If not, please explain in the comment area.Yes
Comments:
4. The SDT has developed Measures for the proposed Requirements within this standard. Do you agree with the proposed Measures in this standard? If not, please explain in the comment area.

## Instructions

Step 1 Enter data in all green cells on the "Data Entry" worksheet.
Step 2 For identified events in column B of the "Data Entry" worksheet, collect data and complete one FRS Form 2 workbook for each event in the list.
Step 3 PasteSpecial/Values data from FRS Form 2 "Form 1 Summary Data" worksheet into "BA Form 2 Event Data" worksheet of this workbook. Do this for each event in the list.
Step 4 Save this workbook using the following file name format:NYISO_yyyy_FRS_Form1.xlsx and send a copy of this workbook and all FRS_Form 2 workbooks to NERC. (where NYISO is replaced with your Balancing Authority abbreviation)

Step 5 "Summary" worksheet contains each event's results for your Balancing Authority.
Balancing Authorities with variable Frequency Bias Settings shall calculate monthly average Frequency Bias Settings. The previous year's monthly averages will be reported annually on FRS Form 1.

```
Instructions
Step 1 Enter data in all green cells on this "Data Entry" worksheet.
Step 2 For identified events in column B, collect data and complete FRS Form 2 for each event in the list.
Step \(3 \quad \begin{aligned} & \text { Pastespecial/Values data from FRS Form } 2 \text { "Form } 1 \text { Summary Data" into "BA Form } 2 \text { Data" } \\ & \text { worksheet of this workbook. Do this for each event inter list }\end{aligned}\) Pastespecialavalues data from FRS Form 2 "Form 1 Summary
worksheet of this workbook. Do this for each event in the list.
Save this workbook using the following file name format:NYISO_yyyy_FRS_Form1.x|sx and send a copy of this workbook and all FRS Form 2 workbooks to NERC. (where NYISO is replaced with you SA name)

## Instructions

Step 1 Enter data in all green cells on the "Data Entry" worksheet.
Step 2 For identified events in column B of the "Data Entry" worksheet, collect data and complete one FRS Form 2 workbook for each event in the list.
Step 3 PasteSpecial/Values data from FRS Form 2 "Form 1 Summary Data" worksheet into "BA Form 2 Event Data" worksheet of this workbook. Do this for each event in the list
 Balancing Authority abbreviation)

Step 5 "Summary" worksheet contains each event's results for your Balancing Authority.

No
Balancing Authorities with variable Frequency Bias Settings shall calculate monthly average Frequency Bias Settings. The previous year's monthly averages will be reported annually on FRS Form 1.

Instructions

Step 2 For identified events in column B, collect data and complete FRS Form 2 for each event in the list.
Step 3 PasteSpecial/values data from FRS Form 2 "Form 1 Summary Data" into "BA Form 2 Data" worksheet of this workbook. Do this for each event in the list.

Step 4 Save this workbook using the following file name format:NYISO__yyy_FRS_Form1.x|sx and send a . 2 workhooks tore NERC . whiso is replaced with your BA name)

Only average periods are hidden.

## Notes:

1) Balancing Authorities making adjustments must retain evidence to verify

Adjustment values are determined from scan-cycle data using Value A and Value B averaging periods. Scan-cycle data must be available if adjustments are made. Adjustments are necessary to improve accuracy of calculations compared to using Net Actual Interchange (contingency size for single BA interconnections) solely. Said differently, unless an adjustment compensates for significant known error, it should not be made. However, as noted in the next item, once a decision to include an adjustment for one or more of the six types is made for one event, the entity must calculate adjustments for that (those) type(s) for all events.
Adjustments are included consistently for all events (e.g. if adjustments for nonconforming load are made for one event, the load must be included for all events, etc.).
2) Dynamic Schedules:

- Values use schedule sign convention.

Adjustments should include only dynamic schedules accounting for joint-owned units. Other dynamic schedules should be ignored.
3) Nonconforming Loads:

- Values must be entered as negative numbers.

4) Pumped Hydro:

- Values for pumping must be entered as negative values.

Values for generating must be entered as positive values.
5) Rampling Units:

Values are entered as positive values.
6) Transferred Frequency Response:

This value is the amount agreed upon between the entities expressed in MW/0.1 Hz. Form 2 will adjust this amount for the frequency deviation experienced (e.g. if an entity agrees to provide $20 \mathrm{MW} / 0.1 \mathrm{~Hz}$ to another entity and a frequency event with a deviation of 50 mHz occurs, the delivering entity should enter +20 in the data column of Form 2 and the receiving entity should enter -20 . The spreadsheet will adjust the SEFRD for each entity by the 10 for this event.)
Values for the entity receiving the response must be entered as a negative number.
Values for the entity delivering the response must be entered as a positive number.
Values between entities must sum to zero.
7) Contingent Balancing Authority Adjustment:

Value for Value A is the pre-contingency generation from the contingent unit(s).
Value for Value B is usually 0 MW , but may be the load that remains on the system that was "netted" out by the now offline generation.

Current Year's Actual Peak
nternal Generating Capacity
Next Year's Projected Peak

## Current year

2011 Frequency Response Obligation (FRO)

## Average Frequency Response (MW/0.1Hz)

Regression Estimate of Frequency Response (MW/0.1Hz)

## Next Year's

## 2012 Frequency Response Obligation (FRO)

2012 Frequency Bias Setting - (minimum of FRM, next year's FRO, or $0.8 \%$ of Projected Peak [Load + Gen]/2)

2011 FRM - Median Frequency Response (MW/0.1Hz)

## Instructions

Step 1 Enter data in all green cells on the "Data Entry" worksheet.
Step 2 For identified events in column B of the "Data Entry" worksheet, collect data and complete one FRS Form 2 workbook for each event in the list.
Step 3 PasteSpecial/Values data from FRS Form 2 "Form 1 Summary Data" worksheet into "BA Form 2 Event Data" worksheet of this workbook. Do this for each event in the list.
Step 4 Save this workbook using the following file name format:NYISO_yyyy_FRS_Form1.xlsx and send a copy of this workbook and all FRS_Form 2 workbooks to NERC. (where NYISO is replaced with your Balancing Authority abbreviation)

Step 5 "Summary" worksheet contains each event's results for your Balancing Authority.
Balancing Authorities with variable Frequency Bias Settings shall calculate monthly average Frequency Bias Settings. The previous year's monthly averages will be reported annually on FRS Form 1.

##  <br>  <br>  <br> 

| Month | Minimum <br> FBS* for month | Maximum <br> FBS* for month | Time weighted ${ }^{* *}$ average FBS* for month |  |
| :---: | :---: | :---: | :---: | :---: |
| January |  |  | -10.0 |  |
| Feburary |  |  | -7.0 |  |
| March |  |  | -12.0 |  |
| April |  |  | -8.0 |  |
| May |  |  | -27.0 |  |
| June |  |  | -8.7 |  |
| July |  |  | -8.0 |  |
| August |  |  | -8.0 |  |
| September |  |  | -8.2 |  |

## Instructions

Step 1 Enter data in all green cells on the "Data Entry" worksheet.
Step 2 For identified events in column B of the "Data Entry" worksheet, collect data and complete one FRS Form 2 workbook for each event in the list.
Step 3 PasteSpecial/Values data from FRS Form 2 "Form 1 Summary Data" worksheet into "BA Form 2 Event Data" worksheet of this workbook. Do this for each event in the list.
Step 4 Save this workbook using the following file name format:NYISO_yyyy_FRS_Form1.xlsx and send a copy of this workbook and all FRS_Form 2 workbooks to NERC. (where NYISO is replaced with your Balancing Authority abbreviation)

Step 5 "Summary" worksheet contains each event's results for your Balancing Authority.
Balancing Authorities with variable Frequency Bias Settings shall calculate monthly average Frequency Bias Settings. The previous year's monthly averages will be reported annually on FRS Form 1.

## Steps To be completed for each event evaluated.

1 Set-up Data collection in exact same order as the "Data" sheet of this work book. Data should be in this order:
Column A: Date and Time in this format, $\mathrm{mm} / \mathrm{dd} / \mathrm{yy} \mathrm{HH}: \mathrm{MM}: \mathrm{SS}$
Column B: Frequency Hz
Column C: Net Actual Interchange
Column D: Joint Owned Unit dynamic schedule
Column E: Non Conforming Load
Column F: Pumped Hydro
Column G: Ramping units
Column H: Transferred Frequency Response
Column I: Contingent BA Lost load or generatio
Column J: BA Bias Setting
Column K: BA Load
2 Note: Columns D, E, F, G and H are optional data. If you choose not to use these, leave the columns blank. Do not delete the columns. Use the sign ( $+/-$ ) convention defined in FRS Form 1 .
3 Note: Columns $\mathrm{D}, \mathrm{E}, \mathrm{F}, \mathrm{G}$ and H are optional data. If you choose not to use these, leave the columns blank. Do not der
4 Data must be at 2 second sample rate for the full 25 minute minimum collection period that starts a minimum of two (2) minutes before the event begins and includes a minimum of 15 minutes after the beginning of the event.
The spreadsheet will work with up to 60 minutes of data. Be sure "Data" worksheet is clear of any old data.
If using PI historian as your data source, use "PasteSpecial/Values" to enter data into the spreadsheet. Do not include historian data collection formulas in the data
5 Once data is in place in the "Data" worksheet, determine when the beginning of the event occurred. This is accomplished by knowing the UTC event time from the master event list.
Convert the UTC event time to your PI data time and then scroll through the Data worksheet column B data of frequency and observe when frequency moves from the normal, pre-event frequency.
This will usually be a single change in frequency of 0.008 to 0.010 Hz more or less. Note the row number in the worksheet that this change occurs. In this sample data spreadsheet this occurs in row 313 of the data.
6 Edit cell "C8" of the "Entry Data" worksheet, change the formula in the cell "C8" to reference the row number identified in step 5 above. In the sample data of this workbook this formula is: "=Data!A313"
If the correct row is selected, the "Graph 20 to 52 s " worksheet will indicate the first change in frequency of the event on the center vertical grid line of the graph (Red Trend).
7 Determine the end of the event to be evaluated. Use the same rules that are used for DCS only look at frequency instead of ACE. Scroll down the frequency data in column B of the "Data" worksheet until frequency reaches 60 Hz or the pre-disturbance value. Note the row number in the worksheet that this occurs. In this sample data spreadsheet this occurs in row 427
8 Edit cell "C11" of the "Evaluation" worksheet, change the formula in the cell "C11" to reference the row number identified in step 7 above. In the sample data of this workbook this formula is: "=Data! A427"
In cell "R41" of the "Evaluation" spreadsheet, enter the MW value of the unit(s) that tripped (from the Master Event List). This is only necessary for the "Interconnection" evaluation if you're interested. It is not necessary to do this for the BA evaluation but it will provide a comparison of the BA frequency response as compared to the Interconnection frequency response.
10 Use the "copy" button provided to copy the evaluation and event specific data for the "FRS Form 1" of this field trial. This data is summarized in the correct order on worksheet "Form 1 Summary Data" of this workbook. Use PasteSpecial/Values when pasting the data into FRS Form 1 on the appropriate event row.

## Steps To be completed once at the initial setup of the evaluation spreadsheet for your BA.

A Enter the Balancing Authority name as you want it to appear on the graphs in cell "B1" of the "Entry Data" worksheet. For example: "NYISO".
C Enter your Balancing Authorities Frequency Response Obligation in cell "B2" of the "Entry Data" worksheet. For example: - $80 \mathrm{MW} / 0.1 \mathrm{~Hz}$ (This value could change annually) The time constant is located in cell "L13" of the "Evaluation" spreadsheet and should be edited for the types of generators in your BA. Presently this time constant is set at 0.35
The higher the value of the time constant, the faster the delivery of frequency response is expected. Setting the TC to 1.0 effectively turns off the delay and instantaneous frequency response will be modeled. Do not set higher than 1.0 This time constant is only used in the "Sustained" evaluation and is not used for the Field Trial evaluation of performance to the FRO
A typical setting for this time constant is 0.08 to 0.15 for hydro units, 0.10 to 0.20 for large steam turbines and 0.20 to 0.40 for combustion turbines.
By observing the slope of your "Interchange Actual" on the "Sustained" Graph, adjust the time constant until the initial slope of the "Target" is similar.
When set appropriately, the "Target" trend on the "Sustained" graph will model what Interchange Actual should have done during the event recovery period based on your minimum FRO,
Note: For ease of use, only the necessary worksheets are displayed. If you are interested in viewing graphs and other hidden worksheets, select the "tab" at the bottom, right click, select unhide and select the worksheet you wish to unhide.

| Time (T) | Hz |  | Jou Dynamic Schedules $\operatorname{Imp}(-) \operatorname{Exp}(+)$ MW | NonConforming Load Load (-) MW | $\begin{aligned} & \text { Pumped } \\ & \text { Hydro } \\ & \text { Load (-) Gen (+) } \\ & \text { MW } \end{aligned}$ | $\begin{aligned} & \text { Ramping } \\ & \text { Units } \\ & \text { Gen (+) } \end{aligned}$ | Transferred <br> Frequency <br> Response <br> $\operatorname{Rec}(-) \operatorname{Del}(+)$ <br> MW/0.1 Hz | Contingent BA Lost Generation Load (-) Gen (+) MW | BA <br> Bias <br> Setting <br> MW/0.1 Hz | BA Load |

## tops be completed for each event evaluated

1 Set-up Data collection in exact same order as the "Data" sheet of this work book. Data should be in this order:
Column A: Date and Time in this format, $\mathrm{mm} / \mathrm{dd} / \mathrm{yy} \mathrm{HH}: \mathrm{MM}: \mathrm{SS}$
Column B: Frequency Hz
Column C: Net Actual Interchange
Column D: Joint Owned Unit dynamic schedule
Column E: Non Conforming Load
Column F: Pumped Hydro
Column G: Ramping units
Column H: Transferred Frequency Response
Column I: Contingent BA Lost load or generatio
Column J: BA Bias Setting
Column K: BA Load
2 Note: Columns D, E, F, G and H are optional data. If you choose not to use these, leave the columns blank. Do not delete the columns. Use the sign (+/-) convention defined in FRS Form 1
3 Data compression must be turned off for each data point. Quality data will give you quality results in the evaluation.
4 Data must be at 3 second sample rate for the full 25 minute minimum collection period that starts a minimum of two (2) minutes before the event begins and includes a minimum of 15 minutes after the beginning of the event.
The spreadsheet will work with up to 60 minutes of data. Be sure "Data" worksheet is clear of any old data.
If using PI historian as your data source, use "PasteSpecial/Values" to enter data into the spreadsheet. Do not include historian data collection formulas in the data. The data must be numbers not text.
5 Once data is in place in the "Data" worksheet, determine when the beginning of the event occurred.
This will usually be a single change in frequency of 0.008 to 0.010 Hz more or less. Note the row number in the worksheet that this change occurs. In this sample data spreadsheet this occurs in row 313 of the data.
6 Edit cell "C8" of the "Entry Data" worksheet, change the formula in the cell "C8" to reference the row number identified in step 5 above. In the sample data of this workbook this formula is: "=Data!A313" If the correct row is selected, the "Graph 20 to 52 s " worksheet will indicate the first change in frequency of the event on the center vertical grid line of the graph (Red Trend).
7 Determine the end of the event to be evaluated. Use the same rules that are used for DCS only look at frequency instead of ACE. Scroll down the frequency data in column B of the "Data" worksheet until frequency reaches 60 Hz or the pre-disturbance value. Note the row number in the worksheet that this occurs. In this sample data spreadsheet this occurs in row 427
8 Edit cell "C11" of the "Entry Data" worksheet, change the formula in the cell "C11" to reference the row number identified in step 7 above. In the sample data of this workbook this formula is: "=Data! A427"
In cell "R41" of the "Evaluation" spreadsheet, enter the MW value of the unit(s) that tripped (from the Master Event List). This is only necessary for the "Interconnection" evaluation if you're interested. It is not necessary to do this for the BA evaluation but it will provide a comparison of the BA frequency response as compared to the Interconnection frequency response.
10 Use the "copy" button provided to copy the evaluation and event specific data for the "FRS Form 1" of this field trial. This data is summarized in the correct order on worksheet "Form 1 Summary Data" of this workbook. Use PasteSpecial/Values when pasting the data into FRS Form 1 on the appropriate event row.

## Steps To be completed once at the initial setup of the evaluation spreadsheet for your BA.

A Enter the Balancing Authority name as you want it to appear on the graphs in cell "B1" of the "Entry Data" worksheet. For example: "NYISO".
Enter your Balancing Authorities Frequency Response Obligation in cell "B2" of the "Entry Data" worksheet. For example: - $80 \mathrm{MW} / 0.1 \mathrm{~Hz}$ (This value could change annually) The time constant is located in cell "L13" of the "Evaluation" spreadsheet and should be edited for the types of generators in your BA. Presently this time constant is set at 0.35 ,
The higher the value of the time constant, the faster the delivery of frequency response is expected. Setting the TC to 1.0 effectively turns off the delay and instantaneous frequency response will be modeled. Do not set higher than 1.0 this time constant is only used in the "Sustained" evaluation and is not used for the Field Trial evaluation of performance to the FRO
A typical setting for this time constant is 0.08 to 0.15 for hydro units, 0.10 to 0.20 for large steam turbines and 0.20 to 0.40 for combustion turbines.
By observing the slope of your "Interchange Actual" on the "Sustained" Graph, adjust the time constant until the initial slope of the "Target" is similar.
When set appropriately, the "Target" trend on the "Sustained" graph will model what Interchange Actual should have done during the event recovery period based on your minimum FRO.
Note: For ease of use, only the necessary worksheets are displayed. If you are interested in viewing graphs and other hidden worksheets, select the "tab" at the bottom, right click, select unhide and select the worksheet you wish to unhide.

## Note: See "Instruction" tab for more detailed instructions.

| Step 1. | Copy and Paste Event Data into the appropriate cells of the "Data" worksheet. Maintain date and time format of $\mathrm{mm} / \mathrm{dd} / \mathrm{yy} \mathrm{hh}: \mathrm{mm}: \mathrm{ss}$. |
| :---: | :---: |
| Step 2. | Determine Time of $\mathrm{T}(0)$ and edit formula in cell "C8" to reference the correct row of the "Data" worksheet. <br> $\mathrm{T}(0)$ is the first change in frequency of about $0.010 \mathrm{~Hz}(10 \mathrm{mHz})$ which should be the first scan of frequency data of the event. |
| Step 3. | Time of Frequency Recovery to 60 Hz or Pre-Perturbation Hz |
| Step 4. | Enter MW output of generator or load that caused event (+ for gen loss, - for load loss) (Value from NERC Event List. If multiple units, enter total MW loss.) If MW loss value is not known, enter a default 1000 MW. |
| Step 5. | Hit the big blue button to copy your data for pasting into FRS Form 1 "BA Event Data" worksheet. <br> Copy Form 2 Data for Pasting into Form 1 |
| Step 6. | Paste data into "FRS Form 1" in the appropriate row on the "BA Event Data" worksheet. |

Step 7. Save this workbook using the following file name format:MyBA_yymmdd_hhmm_FRS_Form2.xlsm
09/10/12 Date yymmdd
2:27 Time hh:ss of T(0)
Where "MyBA" = your BA mnemonic

Date Time of T(0)
Time of Frequency Recovery to 60 Hz or Pre-Perturbation Hz Value A Pre-Perturbation Average Frequency [ $\mathrm{T}(-2)$ to $\mathrm{T}(-16)$ ] Value B Post-Perturbation Average Frequency [ $\mathrm{T}(+20$ to $\mathrm{T}(+52)$

Pre to Post Perturbation Delta Frequency Actual
Value A Pre-Perturbation Average Interchange MW [T(-2) to T(-16)] Value B Post-Perturbation Average Interchange MW [ $\mathrm{T}+20$ to $\mathrm{T}(+52)]$ Pre to Post Perturbation Interchange Delta MW Actual

Initial Performance Ramp Magnitude Adjustment
